Online papers on consciousness

Compiled by David Chalmers

This is a directory of 1123 online papers on consciousness and related topics. Suggestions for addition are welcome. Most papers are by academic philosophers or scientists.

I have now divided this page into three separate pages, as follows:

- Part I: Philosophy of Consciousness [368 papers]
- Part II: Other Philosophy of Mind [433 papers]
- Part III: Science of Consciousness [322 papers]

TABLE OF CONTENTS

I. PHILOSOPHY OF CONSCIOUSNESS

- The concept of consciousness
- The explanatory gap
- Materialism and dualism
- The knowledge argument
- Materialism and modality
- Metaphysics of consciousness
- Panpsychism
- Zombies
- Qualia
- The contents of consciousness
- Representationalism
- Consciousness as higher-order thought
- Introspection, self-knowledge, and self-consciousness
- The unity of consciousness
- The function of consciousness
- Philosophy of consciousness (misc.)

II. OTHER PHILOSOPHY OF MIND

- Language and thought
- Propositional attitudes
- Theories of content
Online papers on consciousness

- Internalism and externalism
- Concepts
- Mental content (misc.)
- Folk psychology
- Metaphysics of mind
- The self and personal identity
- Free will
- Philosophy of mind (misc.)
- The Chinese Room
- Godel's theorem and AI
- The Turing test
- Philosophy of connectionism
- Philosophy of AI (misc.)

III. SCIENCE OF CONSCIOUSNESS

- Neuroscience of visual consciousness
- Consciousness and neuroscience
- Cognitive models of consciousness
- Unconscious perception
- Implicit memory
- Implicit learning
- Change blindness and inattentional blindness
- Visual consciousness (misc.)
- Consciousness and psychology (misc.)
- Consciousness in the history of psychology
- Animal consciousness
- Consciousness and artificial intelligence
- Consciousness and physics
- Phenomenology
- Miscellaneous

For other sources of online papers, and for bibliographies of around 2000 offline papers on consciousness, see:

- people with online papers in philosophy
- web resources related to consciousness, philosophy, and such
- directory of online philosophy papers (Joe Lau)
Papers on Consciousness (David Chalmers).

This page contains pointers to some papers on consciousness. The papers here should be accessible to people without a background in philosophy. Philosophers might be interested in the more technical papers under papers on mind, modality, and meaning. A separate page has information on my book The Conscious Mind. Most items are in HTML, with a Postscript version also available in some cases. The papers fall into a few distinct categories.

The Problems of Consciousness

Consciousness and its Place in Nature

This is a new overview paper on the the metaphysics of consciousness. It summarizes arguments against materialism, and uses these to give a detailed taxonomy of reductive and nonreductive views (three each). It covers some of the same ground as the first two papers below (although it's oriented more toward metaphysics than toward science), while also covering some of the more technical material in my book and some new things. It will appear in the forthcoming Blackwell Guide to Philosophy of Mind, edited by Stephen Stich and Fritz Warfield.

Facing Up to the Problem of Consciousness (PS)

This paper gives a nontechnical overview of the problems of consciousness and my approach to them. In it I distinguish between the easy problems and the hard problem of consciousness, and argue that the hard problem eludes conventional methods of explanation. I argue that we need a new form of nonreductive explanation, and make some moves toward a detailed nonreductive theory. This paper, based on a talk I gave at the 1994 Tucson conference on consciousness, appeared in a special issue of the Journal of Consciousness Studies in 1995, and also in the 1996 collection Toward a Science of Consciousness, edited by Hameroff, Kaszniak, and Scott (MIT Press, 1996).

Moving Forward on the Problem of Consciousness

After "Facing Up..." was published, about 25 articles commenting on it or on other aspects of the "hard problem" appeared in JCS (links to some of these papers are contained in the article). My (lengthy) reply, "Moving Forward...", appeared in JCS vol. 4, pp. 3-46, 1997. All the papers and my reply have been collected in the book, Explaining Consciousness: The Hard Problem (edited by Jonathan Shear), published by MIT Press in July 1997.

The Puzzle of Conscious Experience

This paper appeared in Scientific American in December 1995. It is essentially an even less technical
version of the first article above, with some pretty pictures. As with most Scientific American articles, much of this article was heavily revised by the editors, and there are a few passages that I cringe at. But it's not a bad introduction.

**Consciousness and Cognition (PS)**

This is an older paper on consciousness, written when I was a graduate student at Indiana. It talks about the odd fact that even if consciousness is not reductively explainable, our claims about consciousness should be, and discusses various ways in which this tension might be resolved, eventually proposing a proto-theory of consciousness based on the notions of pattern and information. I no longer agree with everything in this paper, and it gets a bit wild toward the end, but it covers some interesting issues. I've never tried to publish it, but for some reason it is still my favorite among the papers I've written on the subject.

**The Science of Consciousness**

**On the Search for the Neural Correlate of Consciousness**

This is a constructive analysis of the search for the "neural correlate of consciousness" (or the NCC, as it's sometimes called). I argue that because we don't have any way of detecting consciousness directly (i.e., we have no "consciousness meter"), the search is driven by pre-empirical bridging principles instead. I discuss some of these principles and draw some conclusions about the shape of the search. This paper is largely a transcript of my talk at the 1996 Tucson conference on consciousness, although some fun and games have been omitted (here are some visuals from the talk). It was published in Toward a Science of Consciousness II, edited by Hameroff, Kaszniak, and Scott (MIT Press, 1998).

**What is a Neural Correlate of Consciousness?**

This more recent and longer paper deals with some different aspects of the NCC issue, with reference to recent empirical work in the field (e.g. work in visual neuroscience by Logothetis, Milner and Goodale, and others). In particular it addresses what it means to be a neural correlate of consciousness, distinguishes different sorts of NCCs, and discusses the methodology of the search. It raises some questions about the conclusions that can be drawn from lesion studies. This paper was given at the 1998 ASSC conference on Neural Correlates of Consciousness, and appeared in Neural Correlates of Consciousness: Conceptual and Empirical Questions, edited by Thomas Metzinger (MIT Press, 2000).

**First-Person Methods in the Science of Consciousness**

In this short paper I argue that the task of a science of consciousness is to connect third-person data about brain and behavior to first-person data about conscious experience, and I discuss the difficult question of how we might investigate and represent first-person data. I also discuss some specific issues about
emotion. This paper was written for a Tucson online workshop on emotion and consciousness, and appeared in the Fall 1999 *Consciousness Bulletin* from the Center for Consciousness Studies.

**Commentaries and Reviews**

**Insentience, Indexicality, and Intensions**

This is a commentary on John Perry's book *Knowledge, Possibility, and Consciousness* (MIT Press, 2001), which defends a materialist view against a number of arguments (the zombie argument, the knowledge argument, the modal argument), and addresses the discussion in my book. The commentary will appear in a symposium on Perry's book in *Philosophy and Phenomenological Research*.

**Availability: The Cognitive Basis of Experience?**

Here I argue that the cognitive correlate of conscious experience is *direct availability for global control*, and use this to shed light on a few vexing questions. This was written as a commentary on Ned Block's paper "On A Confusion about a Function of Consciousness", and appeared in *Behavioral and Brain Sciences* and also in the collection *The Nature of Consciousness: Philosophical Debates* from MIT Press, edited by Block, Flanagan, and Guzeldere. This paper overlaps to some extent with "On the search for a neural correlate of consciousness".

**Self-Ascription Without Qualia: A Case-Study**

This is a commentary on Alvin Goldman's piece "The Psychology of Folk Psychology", in *Behavioral and Brain Sciences* (June 1993). The paper contains a zombie thought-experiment or two, for people who like that sort of thing.

**Review of Journal of Consciousness Studies**

This is a review of the first issue of the *Journal of Consciousness Studies*. It appeared in the *Times Literary Supplement* in November 1994.

**Miscellaneous**

**Absent Qualia, Fading Qualia, Dancing Qualia (PS)**

In this paper I use thought-experiments to argue that functional organization fully determines conscious experience. These thought-experiments involve the gradual replacement of neurons by silicon chips, and similar scenarios. I argue that if "absent qualia" or "inverted qualia" are possible, then phenomena I call "fading qualia" and "dancing qualia" will be possible; but I argue that it is very implausible that fading or
dancing qualia are possible. The resulting position is a sort of "nonreductive functionalism". This paper appears in the collection *Conscious Experience* from Ferdinand Schöningh (1995), edited by Thomas Metzinger. (There is also a German version entitled "Fehlende Qualia, schwindende Qualia, tanzende Qualia" (!), but it is not available on the net.)

**What is the Unity of Consciousness?**

This paper is co-authored with Tim Bayne. We distinguish a number of different senses in which it might be said that a subject's conscious experiences are unified, and isolate a central notion for which the claim that consciousness is necessarily unified is tenable without being trivial. We then discuss potential counterexamples to this unity thesis, and will consider the implications of the unity thesis for theories of consciousness more generally. This paper is coming out in *The Unity of Consciousness: Binding, Integration, Dissociation* from Oxford University Press, edited by Axel Cleeremans.

Papers on Mind, Modality, and Meaning (David Chalmers).

This page contains some papers around the borders of the philosophy of mind and language, metaphysics, and epistemology. These papers (except "The Extended Mind") mostly presuppose significant philosophical background (non-philosophers might prefer my page of less technical papers on consciousness). The papers mostly deal with interwoven issues concerning meaning and modality, sometimes against a background of issues in the philosophy of mind. There is some overlap between the papers, as related issues are approached from different angles. Much of this is being cannibalized for a book manuscript currently in progress (working title: On What Might Be).

On Sense and Intension

Over the last few years I have been working on an account of meaning and of possibility on which these notions are closely tied to reason and cognition. The central tool in doing this has been a two-dimensional semantic framework (invoked in many of the papers on this page). This paper serves as an introduction to those ideas, motivated by the defense of a Fregean conception of meaning. In the paper, I articulate some Fregean theses about sense, develop an intensional account of sense on which it is constitutively connected to epistemic possibility, and use this account to deal with various objections to Fregean views. Along the way, the two-dimensional framework as I understand it emerges.

The Nature of Epistemic Space

This unpublished paper takes a more foundational approach to some of these issues, grounding some of the key ideas in a notion of epistemic possibility, and an epistemic space made up of maximal epistemic possibilities, or "scenarios". I explore various ways of constructing the space of scenarios -- one tied to centered possible worlds, and one tied directly to epistemic notions. And I outline some applications of the framework from this perspective: e.g. to Fregean sense, narrow content, indicative conditionals, and hyperintensionality.

The Foundations of Two-Dimensional Semantics

This monster paper (written for the Barcelona conference on two-dimensionalism) is a sort of "compare-and-contrast" on the various versions of two-dimensional semantics. It starts by motivating this sort of framework, and then discusses in detail the two main sorts of available understandings of the framework: contextual and epistemic understandings. I argue that contextual understandings (e.g. that of Stalnaker) can't do the work that is required, but that an epistemic uderstanding can. I set out my own understanding in detail, and then locate existing versions of the framework in the conceptual space as set out.

The Components of Content
This paper tries to do for thought what first paper above does for language: give an account of the contents of thought on which content is closely tied to reason and cognition. I decompose content into epistemic and subjunctive content, both of which are truth-conditional. Epistemic content is generally internal to a cognitive system, and governs rational relations between thoughts, so it can play the role of "narrow" or "cognitive" content. I apply this framework to a number of puzzles (Frege's puzzle, Kripke's puzzle, the problem of the essential indexical, the mode-of-presentation problem, etc.) in the philosophy of mind and the philosophy of language. The unpublished 1995 version of this paper has been fairly widely cited. The new revised version is finally to be published in my anthology Philosophy of Mind: Classical and Contemporary Readings in 2002.

**Does Conceivability Entail Possibility?**

This paper addresses the epistemology of modality, and argues for a sort of modal rationalism (a priori access to modality). It distinguishes a number of sorts of conceivability, and with these distinctions in hand argues that certain sorts of conceivability plausibly entail sorts of possibility. The second half of the paper addresses potential gaps between the two, and gives a positive argument for modal rationalism. Lots of interesting issues come up along the way. This paper is forthcoming in Conceivability and Possibility, edited by Tamar Gendler and John Hawthorne (Oxford, 2002).

**Conceptual Analysis and Reductive Explanation**

This paper, co-authored with Frank Jackson, is a reply to Ned Block and Robert Stalnaker's paper "Conceptual Analysis, Dualism, and the Explanatory Gap". It doesn't presuppose knowledge of that paper. It defends from first principles the thesis that there is an a priori entailment from microphysical and phenomenal truths (plus or minus a bit) to macroscopic truths; it addresses Block and Stalnaker's objections to this thesis; and finally argues that a priori entailment is required for reductive explanation and for physicalism. The paper appears in Philosophical Review 110:315-61, 2001.

**Materialism and the Metaphysics of Modality**

This paper was my response in a symposium on my book The Conscious Mind in Philosophy and Phenomenological Research in June 1999 (the corresponding precis of the book is also online). The commentators were Sydney Shoemaker, Brian Loar, Chris Hill & Brian McLaughin, and Stephen Yablo, all of whom take a "type-B materialist" position on which there is an epistemic gap between physical and phenomenal, but no modal gap. This gets quickly into issues about the 2-D analysis of a posteriori necessity, and whether there are "strong necessities" that escape it. I argue that there are not, and argue for a sort of modal rationalism.

**Mind and Modality**
This material (in detailed outline form) corresponds to a series of three lectures I gave at Princeton University in October 1998. The second and third largely contain material since written up in the papers on this page on conceivability and on phenomenal belief. The first lecture contains some material not contained elsewhere.

**The Content and Epistemology of Phenomenal Belief**

This long paper has two halves. The first half gives an account of phenomenal concepts and phenomenal beliefs, on which their content is partly constituted by the quality of an experience. The second half applies this account to epistemological issues: e.g. arguing for a limited incorrigibility thesis, defending a sort of foundationalism about phenomenal knowledge, defending the phenomenal realist from certain epistemological problems, and addressing the "Myth of the Given". The paper is forthcoming in *Consciousness: New Philosophical Essays*, edited by Quentin Smith and Alexandr Jokic (Oxford, 2002).

**The Tyranny of the Subjunctive**

This is just an extended outline at the moment. I argue for a parallel between indicative and subjunctive conditionals, on the one hand, and the two dimensions of possibility in the 2-D framework. The standard contemporary analysis of possibility and necessity is grounded in subjunctive conditionals. I suggest that this is entirely arbitrary, and has had a distorting effect on many areas of philosophy.

**The Extended Mind**

This paper (jointly written with Andy Clark) argues that cognitive states are not necessarily "in the head", for reasons quite independent of the reference-based considerations of Putnam and Burge. Instead, we advocate an "active externalism", focusing on situations in which an organism is coupled with their environment into what is effectively a single cognitive system (as with a person who relies on a notebook as memory, for example). We argue in detail that mental states such as beliefs can be externally constituted in this way. This leads to a reconception of the relation between mind and world. (Reconciling the externalism of this paper with the internalism of "The Components of Content" is left as an exercise for the reader.) This paper was published in *Analysis* 58:10-23, 1998, and was reprinted in *The Philosopher's Annual*, 1998. Here is a [commentary](http://www.u.arizona.edu/~chalmers/mmm-papers.html).

**Is There Synonymy in Ockham's Mental Language?**

This is my sole venture into the history of philosophy so far. It was written when I was a graduate student in Paul Spade's medieval logic class at Indiana. William of Ockham held that we think in a "mental language", not unlike the language of thought that some contemporary philosophers believe in. The question arises whether the mental language can contain synonyms, or whether these are just artifacts of ordinary language. Most people have said no. Here I give some reasons to say yes. This paper is published in *The Cambridge Companion to Ockham*, edited by Spade, published by Cambridge.
The Extended Mind

1 Introduction

Where does the mind stop and the rest of the world begin? The question invites two standard replies. Some accept the demarcations of skin and skull, and say that what is outside the body is outside the mind. Others are impressed by arguments suggesting that the meaning of our words "just ain't in the head", and hold that this externalism about meaning carries over into an externalism about mind. We propose to pursue a third position. We advocate a very different sort of externalism: an active externalism, based on the active role of the environment in driving cognitive processes.

2 Extended Cognition

Consider three cases of human problem-solving:

(1) A person sits in front of a computer screen which displays images of various two-dimensional geometric shapes and is asked to answer questions concerning the potential fit of such shapes into depicted "sockets". To assess fit, the person must mentally rotate the shapes to align them with the sockets.

(2) A person sits in front of a similar computer screen, but this time can choose either to physically rotate the image on the screen, by pressing a rotate button, or to mentally rotate the image as before. We can also suppose, not unrealistically, that some speed advantage accrues to the physical rotation operation.
(3) Sometime in the cyberpunk future, a person sits in front of a similar computer screen. This agent, however, has the benefit of a neural implant which can perform the rotation operation as fast as the computer in the previous example. The agent must still choose which internal resource to use (the implant or the good old fashioned mental rotation), as each resource makes different demands on attention and other concurrent brain activity.

How much cognition is present in these cases? We suggest that all three cases are similar. Case (3) with the neural implant seems clearly to be on a par with case (1). And case (2) with the rotation button displays the same sort of computational structure as case (3), although it is distributed across agent and computer instead of internalized within the agent. If the rotation in case (3) is cognitive, by what right do we count case (2) as fundamentally different? We cannot simply point to the skin/skull boundary as justification, since the legitimacy of that boundary is precisely what is at issue. But nothing else seems different.

The kind of case just described is by no means as exotic as it may at first appear. It is not just the presence of advanced external computing resources which raises the issue, but rather the general tendency of human reasoners to lean heavily on environmental supports. Thus consider the use of pen and paper to perform long multiplication (McClelland et al 1986, Clark 1989), the use of physical re-arrangements of letter tiles to prompt word recall in Scrabble (Kirsh 1995), the use of instruments such as the nautical slide rule (Hutchins 1995), and the general paraphernalia of language, books, diagrams, and culture. In all these cases the individual brain performs some operations, while others are delegated to manipulations of external media. Had our brains been different, this distribution of tasks would doubtless have varied.

In fact, even the mental rotation cases described in scenarios (1) and (2) are real. The cases reflect options available to players of the computer game Tetris. In Tetris, falling geometric shapes must be rapidly directed into an appropriate slot in an emerging structure. A rotation button can be used. David Kirsh and Paul Maglio (1994) calculate that the physical rotation of a shape through 90 degrees takes about 100 milliseconds, plus about 200 milliseconds to select the button. To achieve the same result by mental rotation takes about 1000 milliseconds. Kirsh and Maglio go on to present compelling evidence that physical rotation is used not just to position a shape ready to fit a slot, but often to help determine whether the shape and the slot are compatible. The latter use constitutes a case of what Kirsh and Maglio call an `epistemic action'. Epistemic actions alter the world so as to aid and augment cognitive processes such as recognition and search. Merely pragmatic actions, by contrast, alter the world because some physical change is desirable for its own sake (e.g., putting cement into a hole in a dam).

Epistemic action, we suggest, demands spread of epistemic credit. If, as we confront some task, a part of the world functions as a process which, were it done in the head, we would have no hesitation in recognizing as part of the cognitive process, then that part of the world is (so we claim) part of the cognitive process. Cognitive processes ain't (all) in the head!
3 Active Externalism

In these cases, the human organism is linked with an external entity in a two-way interaction, creating a coupled system that can be seen as a cognitive system in its own right. All the components in the system play an active causal role, and they jointly govern behavior in the same sort of way that cognition usually does. If we remove the external component the system's behavioral competence will drop, just as it would if we removed part of its brain. Our thesis is that this sort of coupled process counts equally well as a cognitive process, whether or not it is wholly in the head.

This externalism differs greatly from standard variety advocated by Putnam (1975) and Burge (1979). When I believe that water is wet and my twin believes that twin water is wet, the external features responsible for the difference in our beliefs are distal and historical, at the other end of a lengthy causal chain. Features of the present are not relevant: if I happen to be surrounded by XYZ right now (maybe I have teleported to Twin Earth), my beliefs still concern standard water, because of my history. In these cases, the relevant external features are passive. Because of their distal nature, they play no role in driving the cognitive process in the here-and-now. This is reflected by the fact that the actions performed by me and my twin are physically indistinguishable, despite our external differences.

In the cases we describe, by contrast, the relevant external features are active, playing a crucial role in the here-and-now. Because they are coupled with the human organism, they have a direct impact on the organism and on its behavior. In these cases, the relevant parts of the world are in the loop, not dangling at the other end of a long causal chain. Concentrating on this sort of coupling leads us to an active externalism, as opposed to the passive externalism of Putnam and Burge.

Many have complained that even if Putnam and Burge are right about the externality of content, it is not clear that these external aspects play a causal or explanatory role in the generation of action. In counterfactual cases where internal structure is held constant but these external features are changed, behavior looks just the same; so internal structure seems to be doing the crucial work. We will not adjudicate that issue here, but we note that active externalism is not threatened by any such problem. The external features in a coupled system play an ineliminable role - if we retain internal structure but change the external features, behavior may change completely. The external features here are just as causally relevant as typical internal features of the brain.[*]

[*][Much of the appeal of externalism in the philosophy of mind may stem from the intuitive appeal of active externalism. Externalists often make analogies involving external features in coupled systems, and appeal to the arbitrariness of boundaries between brain and environment. But these intuitions sit uneasily with the letter of standard externalism. In most of the Putnam/Burge cases, the immediate environment is irrelevant; only the historical environment counts. Debate has focused on the question of whether mind must be in the head, but a more relevant question in assessing these examples might be: is mind in the present?]

By embracing an active externalism, we allow a more natural explanation of all sorts of actions. Once can explain my choice of words in Scrabble, for example, as the outcome of an extended cognitive process involving the rearrangement of tiles on my tray. Of course, one could always try to explain my
action in terms of internal processes and a long series of "inputs" and "actions", but this explanation would be needless complex. If an isomorphic process were going on in the head, we would feel no urge to characterize it in this cumbersome way.[*] In a very real sense, the re-arrangement of tiles on the tray is not part of action; it is part of thought.

[*][Herbert Simon (1981) once suggested that we view internal memory as, in effect, an external resource upon which "real" inner processes operate. "Search in memory," he comments, "is not very different from search of the external environment." Simon's view at least has the virtue of treating internal and external processing with the parity they deserve, but we suspect that on his view the mind will shrink too small for most people's tastes.]]

The view we advocate here is reflected by a growing body of research in cognitive science. In areas as diverse as the theory of situated cognition (Suchman 1987), studies of real-world-robotics (Beer 1989), dynamical approaches to child development (Thelen and Smith 1994), and research on the cognitive properties of collectives of agents (Hutchins 1995), cognition is often taken to be continuous with processes in the environment.[*] Thus, in seeing cognition as extended one is not merely making a terminological decision; it makes a significant difference to the methodology of scientific investigation. In effect, explanatory methods that might once have been thought appropriate only for the analysis of "inner" processes are now being adapted for the study of the outer, and there is promise that our understanding of cognition will become richer for it.

[*][Philosophical views of a similar spirit can be found in Haugeland 1995, McClamrock 1985, Varela et al 1991, and Wilson 1994.]]

Some find this sort of externalism unpalatable. One reason may be that many identify the cognitive with the conscious, and it seems far from plausible that consciousness extends outside the head in these cases. But not every cognitive process, at least on standard usage, is a conscious process. It is widely accepted that all sorts of processes beyond the borders of consciousness play a crucial role in cognitive processing: in the retrieval of memories, linguistic processes, and skill acquisition, for example. So the mere fact that external processes are external where consciousness is internal is no reason to deny that those processes are cognitive.

More interestingly, one might argue that what keeps real cognition processes in the head is the requirement that cognitive processes be portable. Here, we are moved by a vision of what might be called the Naked Mind: a package of resources and operations we can always bring to bear on a cognitive task, regardless of the local environment. On this view, the trouble with coupled systems is that they are too easily decoupled. The true cognitive processes are those that lie at the constant core of the system; anything else is an add-on extra.

There is something to this objection. The brain (or brain and body) comprises a package of basic, portable, cognitive resources that is of interest in its own right. These resources may incorporate bodily actions into cognitive processes, as when we use our fingers as working memory in a tricky calculation, but they will not encompass the more contingent aspects of our external environment, such as a pocket calculator. Still, mere contingency of coupling does not rule out cognitive status. In the distant future we
may be able to plug various modules into our brain to help us out: a module for extra short-term memory when we need it, for example. When a module is plugged in, the processes involving it are just as cognitive as if they had been there all along.[*]

[[Or consider the following passage from a recent science fiction novel (McHugh 1992, p. 213): "I am taken to the system’s department where I am attuned to the system. All I do is jack in and then a technician instructs the system to attune and it does. I jack out and query the time. 10:52. The information pops up. Always before I could only access information when I was jacked in, it gave me a sense that I knew what I thought and what the system told me, but now, how do I know what is system and what is Zhang?"]]}

Even if one were to make the portability criterion pivotal, active externalism would not be undermined. Counting on our fingers has already been let in the door, for example, and it is easy to push things further. Think of the old image of the engineer with a slide rule hanging from his belt wherever he goes. What if people always carried a pocket calculator, or had them implanted? The real moral of the portability intuition is that for coupled systems to be relevant to the core of cognition, reliable coupling is required. It happens that most reliable coupling takes place within the brain, but there can easily be reliable coupling with the environment as well. If the resources of my calculator or my Filofax are always there when I need them, then they are coupled with me as reliably as we need. In effect, they are part of the basic package of cognitive resources that I bring to bear on the everyday world. These systems cannot be impugned simply on the basis of the danger of discrete damage, loss, or malfunction, or because of any occasional decoupling: the biological brain is in similar danger, and occasionally loses capacities temporarily in episodes of sleep, intoxication, and emotion. If the relevant capacities are generally there when they are required, this is coupling enough.

Moreover, it may be that the biological brain has in fact evolved and matured in ways which factor in the reliable presence of a manipulable external environment. It certainly seems that evolution has favored on-board capacities which are especially geared to parasitizing the local environment so as to reduce memory load, and even to transform the nature of the computational problems themselves. Our visual systems have evolved to rely on their environment in various ways: they exploit contingent facts about the structure of natural scenes (e.g. Ullman and Richards 1984), for example, and they take advantage of the computational shortcuts afforded by bodily motion and locomotion (e.g. Blake and Yuille, 1992). Perhaps there are other cases where evolution has found it advantageous to exploit the possibility of the environment being in the cognitive loop. If so, then external coupling is part of the truly basic package of cognitive resources that we bring to bear on the world.

Language may be an example. Language appears to be a central means by which cognitive processes are extended into the world. Think of a group of people brainstorming around a table, or a philosopher who thinks best by writing, developing her ideas as she goes. It may be that language evolved, in part, to enable such extensions of our cognitive resources within actively coupled systems.

Within the lifetime of an organism, too, individual learning may have molded the brain in ways that rely on cognitive extensions that surrounded us as we learned. Language is again a central example here, as are the various physical and computational artifacts that are routinely used as cognitive extensions by
children in schools and by trainees in numerous professions. In such cases the brain develops in a way that complements the external structures, and learns to play its role within a unified, densely coupled system. Once we recognize that the crucial role of the environment in constraining the evolution and development of cognition, we see that extended cognition is a core cognitive process, not an add-on extra.

An analogy may be helpful. The extraordinary efficiency of the fish as a swimming device is partly due, it now seems, to an evolved capacity to couple its swimming behaviors to the pools of external kinetic energy found as swirls, eddies and vortices in its watery environment (see Triantafyllou and G. Triantafyllou 1995). These vortices include both naturally occurring ones (e.g., where water hits a rock) and self-induced ones (created by well-timed tail flaps). The fish swims by building these externally occurring processes into the very heart of its locomotion routines. The fish and surrounding vortices together constitute a reliable feature of the human environment, such as the sea of words. This linguistic surround envelopes us from birth. Under such conditions, the plastic human brain will surely come to treat such structures as a reliable resource to be factored into the shaping of on-board cognitive routines. Where the fish flaps its tail to set up the eddies and vortices it subsequently exploits, we intervene in multiple linguistic media, creating local structures and disturbances whose reliable presence drives our ongoing internal processes. Words and external symbols are thus paramount among the cognitive vortices which help constitute human thought.

4 From Cognition to Mind

So far we have spoken largely about "cognitive processing", and argued for its extension into the environment. Some might think that the conclusion has been bought too cheaply. Perhaps some processing takes place in the environment, but what of mind? Everything we have said so far is compatible with the view that truly mental states - experiences, beliefs, desires, emotions, and so on - are all determined by states of the brain. Perhaps what is truly mental is internal, after all?

We propose to take things a step further. While some mental states, such as experiences, may be determined internally, there are other cases in which external factors make a significant contribution. In particular, we will argue that beliefs can be constituted partly by features of the environment, when those features play the right sort of role in driving cognitive processes. If so, the mind extends into the world.

First, consider a normal case of belief embedded in memory. Inga hears from a friend that there is an exhibition at the Museum of Modern Art, and decides to go see it. She thinks for a moment and recalls that the museum is on 53rd Street, so she walks to 53rd Street and goes into the museum. It seems clear that Inga believes that the museum is on 53rd Street, and that she believed this even before she consulted her memory. It was not previously an occurrent belief, but then neither are most of our beliefs. The belief was sitting somewhere in memory, waiting to be accessed.

Now consider Otto. Otto suffers from Alzheimer's disease, and like many Alzheimer's patients, he relies on information in the environment to help structure his life. Otto carries a notebook around with him
everywhere he goes. When he learns new information, he writes it down. When he needs some old information, he looks it up. For Otto, his notebook plays the role usually played by a biological memory. Today, Otto hears about the exhibition at the Museum of Modern Art, and decides to go see it. He consults the notebook, which says that the museum is on 53rd Street, so he walks to 53rd Street and goes into the museum.

Clearly, Otto walked to 53rd Street because he wanted to go to the museum and he believed the museum was on 53rd Street. And just as Inga had her belief even before she consulted her memory, it seems reasonable to say that Otto believed the museum was on 53rd Street even before consulting his notebook. For in relevant respects the cases are entirely analogous: the notebook plays for Otto the same role that memory plays for Inga. The information in the notebook functions just like the information constituting an ordinary non-occurrence belief; it just happens that this information lies beyond the skin.

The alternative is to say that Otto has no belief about the matter until he consults his notebook; at best, he believes that the museum is located at the address in the notebook. But if we follow Otto around for a while, we will see how unnatural this way of speaking is. Otto is constantly using his notebook as a matter of course. It is central to his actions in all sorts of contexts, in the way that an ordinary memory is central in an ordinary life. The same information might come up again and again, perhaps being slightly modified on occasion, before retreating into the recesses of his artificial memory. To say that the beliefs disappear when the notebook is filed away seems to miss the big picture in just the same way as saying that Inga's beliefs disappear as soon as she is longer conscious of them. In both cases the information is reliably there when needed, available to consciousness and available to guide action, in just the way that we expect a belief to be.

Certainly, insofar as beliefs and desires are characterized by their explanatory roles, Otto's and Inga's cases seem to be on a par: the essential causal dynamics of the two cases mirror each other precisely. We are happy to explain Inga's action in terms of her occurrent desire to go to the museum and her standing belief that the museum is on 53rd street, and we should be happy to explain Otto's action in the same way. The alternative is to explain Otto's action in terms of his occurrent desire to go to the museum, his standing belief that the Museum is on the location written in the notebook, and the accessible fact that the notebook says the Museum is on 53rd Street; but this complicates the explanation unnecessarily. If we must resort to explaining Otto's action this way, then we must also do so for the countless other actions in which his notebook is involved; in each of the explanations, there will be an extra term involving the notebook. We submit that to explain things this way is to take one step too many. It is pointlessly complex, in the same way that it would be pointlessly complex to explain Inga's actions in terms of beliefs about her memory. The notebook is a constant for Otto, in the same way that memory is a constant for Inga; to point to it in every belief/desire explanation would be redundant. In an explanation, simplicity is power.

If this is right, we can even construct the case of Twin Otto, who is just like Otto except that a while ago he mistakenly wrote in his notebook that the Museum of Modern Art was on 51st Street. Today, Twin Otto is a physical duplicate of Otto from the skin in, but his notebook differs. Consequently, Twin Otto is best characterized as believing that the museum is on 51st Street, where Otto believes it is on 53rd.
these cases, a belief is simply not in the head.

This mirrors the conclusion of Putnam and Burge, but again there are important differences. In the Putnam/Burge cases, the external features constituting differences in belief are distal and historical, so that twins in these cases produce physically indistinguishable behavior. In the cases we are describing, the relevant external features play an active role in the here-and-now, and have a direct impact on behavior. Where Otto walks to 53rd Street, Twin Otto walks to 51st. There is no question of explanatory irrelevance for this sort of external belief content; it is introduced precisely because of the central explanatory role that it plays. Like the Putnam and Burge cases, these cases involve differences in reference and truth-conditions, but they also involve differences in the dynamics of cognition.[*]

*[[In the terminology of Chalmers' "The Components of Content" (forthcoming): the twins in the Putnam and Burge cases differ only in their relational content, but Otto and his twin can be seen to differ in their notional content, which is the sort of content that governs cognition. Notional content is generally internal to a cognitive system, but in this case the cognitive system is itself effectively extended to include the notebook.]]

The moral is that when it comes to belief, there is nothing sacred about skull and skin. What makes some information count as a belief is the role it plays, and there is no reason why the relevant role can be played only from inside the body.

Some will resist this conclusion. An opponent might put her foot down and insist that as she uses the term "belief", or perhaps even according to standard usage, Otto simply does not qualify as believing that the museum is on 53rd Street. We do not intend to debate what is standard usage; our broader point is that the notion of belief ought to be used so that Otto qualifies as having the belief in question. In all important respects, Otto's case is similar to a standard case of (non-occurrent) belief. The differences between Otto's case and Inga's are striking, but they are superficial. By using the "belief" notion in a wider way, it picks out something more akin to a natural kind. The notion becomes deeper and more unified, and is more useful in explanation.

To provide substantial resistance, an opponent has to show that Otto's and Inga's cases differ in some important and relevant respect. But in what deep respect are the cases different? To make the case solely on the grounds that information is in the head in one case but not in the other would be to beg the question. If this difference is relevant to a difference in belief, it is surely not primitively relevant. To justify the different treatment, we must find some more basic underlying difference between the two.

It might be suggested that the cases are relevantly different in that Inga has more reliable access to the information. After all, someone might take away Otto's notebook at any time, but Inga's memory is safer. It is not implausible that constancy is relevant: indeed, the fact that Otto always uses his notebook played some role in our justifying its cognitive status. If Otto were consulting a guidebook as a one-off, we would be much less likely to ascribe him a standing belief. But in the original case, Otto's access to the notebook is very reliable - not perfectly reliable, to be sure, but then neither is Inga's access to her memory. A surgeon might tamper with her brain, or more mundanely, she might have too much to drink. The mere possibility of such tampering is not enough to deny her the belief.
Perhaps the intuition that Otto's is not a true belief comes from a residual feeling that the only true beliefs are occurrent beliefs. If we take this feeling seriously, Inga's belief will be ruled out too, as will many beliefs that we attribute in everyday life. This would be an extreme view, but it may be the most consistent way to deny Otto's belief. Upon even a slightly less extreme view - the view that a belief must be available for consciousness, for example - Otto's notebook entry seems to qualify just as well as Inga's memory. Once dispositional beliefs are let in the door, it is difficult to resist the conclusion that Otto's notebook has all the relevant dispositions.

5 Beyond the Outer Limits

If the thesis is accepted, how far should we go? All sorts of puzzle cases spring to mind. What of the amnesic villagers in *100 Years of Solitude*, who forget the names for everything and so hang labels everywhere? Does the information in my Filofax count as part of my memory? If Otto's notebook has been tampered with, does he believe the newly-installed information? Do I believe the contents of the page in front of me before I read it? Is my cognitive state somehow spread across the Internet?

We do not think that there are categorical answers to all of these questions, and we will not give them. But to help understand what is involved in ascriptions of extended belief, we can at least examine the features of our central case that make the notion so clearly applicable there. First, the notebook is a constant in Otto's life - in cases where the information in the notebook would be relevant, he will rarely take action without consulting it. Second, the information in the notebook is directly available without difficulty. Third, upon retrieving information from the notebook he automatically endorses it. Fourth, the information in the notebook has been consciously endorsed at some point in the past, and indeed is there as a consequence of this endorsement.[*] The status of the fourth feature as a criterion for belief is arguable (perhaps one can acquire beliefs through subliminal perception, or through memory tampering?), but the first three features certainly play a crucial role.

[*][[The constancy and past-endorsement criteria may suggest that history is partly constitutive of belief. One might react to this by removing any historical component (giving a purely dispositional reading of the constancy criterion and eliminating the past-endorsement criterion, for example), or one might allow such a component as long as the main burden is carried by features of the present.]]

Insofar as increasingly exotic puzzle cases lack these features, the applicability of the notion of "belief" gradually falls of. If I rarely take relevant action without consulting my Filofax, for example, its status within my cognitive system will resemble that of the notebook in Otto's. But if I often act without consultation - for example, if I sometimes answer relevant questions with "I don't know" - then information in it counts less clearly as part of my belief system. The Internet is likely to fail on multiple counts, unless I am unusually computer-reliant, facile with the technology, and trusting, but information in certain files on my computer may qualify. In intermediate cases, the question of whether a belief is present may be indeterminate, or the answer may depend on the varying standards that are at play in various contexts in which the question might be asked. But any indeterminacy here does not mean that in the central cases, the answer is not clear.
One might worry that Otto's access to his notebook in fact comes and goes. He showers without the notebook, for example, and he cannot read it when it is dark. Surely his belief cannot come and go so easily? We could get around this problem by redescribing the situation, but in any case an occasional temporary disconnection does not threaten our claim. After all, when Inga is asleep, or when she is intoxicated, we do not say that her belief disappears. What really counts is that the information is easily available when the subject needs it, and this constraint is satisfied equally in the two cases. If Otto's notebook were often unavailable to him at times when the information in it would be useful, there might be a problem, as the information would not be able to play the action-guiding role that is central to belief; but if it is easily available in most relevant situations, the belief is not endangered.

Perhaps a difference is that Inga has better access to the information than Otto does? Inga's "central" processes and her memory probably have a relatively high-bandwidth link between them, compared to the low-grade connection between Otto and his notebook. But this alone does not make a difference between believing and not believing. Consider Inga's museum-going friend Lucy, whose biological memory has only a low-grade link to her central systems, due to nonstandard biology or past misadventures. Processing in Lucy's case might be less efficient, but as long as the relevant information is accessible, Lucy clearly believes that the museum is on 53rd Street. If the connection was too indirect - if Lucy had to struggle hard to retrieve the information with mixed results, or a psychotherapist's aid were needed - we might become more reluctant to ascribe the belief, but such cases are well beyond Otto's situation, in which the information is easily accessible.

Another suggestion could be that Otto has access to the relevant information only by perception, whereas Inga has more direct access -- by introspection, perhaps. In some ways, however, to put things this way is to beg the question. After all, we are in effect advocating a point of view on which Otto's internal processes and his notebook constitute a single cognitive system. From the standpoint of this system, the flow of information between notebook and brain is not perceptual at all; it does not involve the impact of something outside the system. It is more akin to information flow within the brain. The only deep way in which the access is perceptual is that in Otto's case, there is a distinctly perceptual phenomenology associated with the retrieval of the information, whereas in Inga's case there is not. But why should the nature of an associated phenomenology make a difference to the status of a belief? Inga's memory may have some associated phenomenology, but it is still a belief. The phenomenology is not visual, to be sure. But for visual phenomenology consider the Terminator, from the Arnold Schwarzenegger movie of the same name. When he recalls some information from memory, it is "displayed" before him in his visual field (presumably he is conscious of it, as there are frequent shots depicting his point of view). The fact that standing memories are recalled in this unusual way surely makes little difference to their status as standing beliefs.

These various small differences between Otto's and Inga's cases are all shallow differences. To focus on them would be to miss the way in which for Otto, notebook entries play just the sort of role that beliefs play in guiding most people's lives.
What about socially extended cognition? Could my mental states be partly constituted by the states of other thinkers? We see no reason why not, in principle. In an unusually interdependent couple, it is entirely possible that one partner's beliefs will play the same sort of role for the other as the notebook plays for Otto.[*] What is central is a high degree of trust, reliance, and accessibility. In other social relationships these criteria may not be so clearly fulfilled, but they might nevertheless be fulfilled in specific domains. For example, the waiter at my favorite restaurant might act as a repository of my beliefs about my favorite meals (this might even be construed as a case of extended desire). In other cases, one's beliefs might be embodied in one's secretary, one's accountant, or one's collaborator.[*]

[[From the New York Times, March 30, 1995, p.B7, in an article on former UCLA basketball coach John Wooden: "Wooden and his wife attended 36 straight Final Fours, and she invariably served as his memory bank. Nell Wooden rarely forgot a name - her husband rarely remembered one - and in the standing-room-only Final Four lobbies, she would recognize people for him."
]]

[[Might this sort of reasoning also allow something like Burge's extended "arthritis" beliefs? After all, I might always defer to my doctor in taking relevant actions concerning my disease. Perhaps so, but there are some clear differences. For example, any extended beliefs would be grounded in an existing active relationship with the doctor, rather than in a historical relationship to a language community. And on the current analysis, my deference to the doctor would tend to yield something like a true belief that I have some other disease in my thigh, rather than the false belief that I have arthritis there. On the other hand, if I used medical experts solely as terminological consultants, the results of Burge's analysis might be mirrored.]]

In each of these cases, the major burden of the coupling between agents is carried by language. Without language, we might be much more akin to discrete Cartesian "inner" minds, in which high-level cognition relies largely on internal resources. But the advent of language has allowed us to spread this burden into the world. Language, thus construed, is not a mirror of our inner states but a complement to them. It serves as a tool whose role is to extend cognition in ways that on-board devices cannot. Indeed, it may be that the intellectual explosion in recent evolutionary time is due as much to this linguistically-enabled extension of cognition as to any independent development in our inner cognitive resources.

What, finally, of the self? Does the extended mind imply an extended self? It seems so. Most of us already accept that the self outstrips the boundaries of consciousness; my dispositional beliefs, for example, constitute in some deep sense part of who I am. If so, then these boundaries may also fall beyond the skin. The information in Otto's notebook, for example, is a central part of his identity as a cognitive agent. What this comes to is that Otto himself is best regarded as an extended system, a coupling of biological organism and external resources. To consistently resist this conclusion, we would have to shrink the self into a mere bundle of occurrent states, severely threatening its deep psychological continuity. Far better to take the broader view, and see agents themselves as spread into the world.

As with any reconception of ourselves, this view will have significant consequences. There are obvious consequences for philosophical views of the mind and for the methodology of research in cognitive science, but there will also be effects in the moral and social domains. It may be, for example, that in some cases interfering with someone's environment will have the same moral significance as interfering
with their person. And if the view is taken seriously, certain forms of social activity might be reconceived as less akin to communication and action, and as more akin to thought. In any case, once the hegemony of skin and skull is usurped, we may be able to see ourselves more truly as creatures of the world.

Tucson, AZ 85721.

chalmers@arizona.edu

What is involved in the meaning of our expressions? Frege suggested that there is an aspect of an expression's meaning - the expression's *sense* - that is constitutively tied to the expression's role in reason and cognition. Many contemporary philosophers have argued that there is no such aspect of meaning. I think that Frege was closer to the truth: one can make good sense of an aspect of meaning with many, although not all, of the properties that Frege attributed to sense. One can naturally associate an expression with an *epistemic intension* - a function from epistemic possibilities to extensions - such that an expression's epistemic intension is deeply tied to its role in reason and cognition, and such that it has many of the properties attributed to Fregean sense. I will argue that the claim that expressions have associated intensions of this sort is undefeated by the major contemporary arguments against Fregean sense.

1 Introduction

The simplest aspect of an expression's meaning is its *extension*. We can stipulate that the extension of a sentence is its truth-value, and that the extension of a singular term is its referent. The extension of other expressions can be seen as associated entities that contributes to the truth-value of a sentence in a manner broadly analogous to the way in which the referent of a singular term contributes to the truth-value of a sentence. In many cases, the extension of an expression will be what we intuitively think of as its referent, although this need not hold in all cases, as the case of sentences illustrates. While Frege himself is often interpreted as holding that a sentence's truth-value is its referent, this claim is counterintuitive and widely disputed. We can avoid that issue in the present framework by using the technical term 'extension'; in this context, the claim that the extension of a sentence is its truth-value is a stipulation.

Different sorts of expressions have different sorts of extensions. By the stipulation above, the extension of a singular term is an individual: the extension of 'France' is a particular country (France), and the extension of 'Bill Clinton' is a particular person (Clinton). Analogously, the extension of a general term is plausibly seen as a class: the extension of 'cat' is a particular class of animals (the class of cats). The extension of a kind term can be seen as a kind: the extension of 'water' is a particular substance (water). The extension of a predicate can be seen as a property or perhaps as a class: the extension of 'hot' is a particular property (hotness) or a particular class (the class of hot things).
The extensions of expressions can at least often be used to determine the extensions of complex expressions of which they are parts. This applies most obviously to the truth-values of sentences. For example, 'Sydney is in Australia' is true, and it is true because the extension of 'Sydney' (a particular city) is located in the extension of 'Australia' (a particular country). 'Michael Jordan is short' is false, and it is false because the individual who is the extension of 'Michael Jordan' does not have the property that is the extension of 'short'. This also applies to complex expressions shorter than sentences: for example, it is not implausible that the complex singular term 'the greatest cricket player' has an extension (Don Bradman), and that this extension is determined by the extensions of its parts.

There are various complexities here, and there are corresponding choices to be made. For example, some terms (e.g. 'Santa Claus') appear to have no referent: in such a case, one might say that they lack extension, or one might say that they have a null extension. In some cases (e.g. 'greatest' above), it appears that the extension of an expression can depend on context: for this reason, we may wish to assign extensions to expression tokens, or to expression types in contexts, rather than to expression types alone. In general, the truth-value of a sentence will be determined by the extensions of its parts within a regimented logical form, along with corresponding principles for determining truth-value of a regimented sentence from its logical form and the extensions of its parts; and the regimented sentence may look quite different from the original sentence, with different basic constituents and a more complex structure. Different semantic theories may assign extensions to expressions and logical forms to sentences in different ways.

Many of these complexities will not concern us here. The discussion that follows should be general over many specific proposals concerning logical form, extensions of simple terms, and compositional determination. I will simply take it for granted that sentences have a logical form and contain simple terms that have an extension; that these simple terms compose complex terms, which compose the sentence; and that the extension of a complex expression (including a sentence) is at least in many cases determined by its logical form and the extensions of its parts.

To clarify terminology: On my usage, an 'expression' is any entity that has an extension (or which is a candidate for extension). For ease of discussion, I will say that when an expression is of the sort that is a candidate for an extension, but appears to lack extension, it has a null extension. A 'term' is any expression other than a sentence. Complex expressions are expressions (including sentences) that are composed of other expressions. Complex terms are terms that are composed of other terms. Simple terms are terms that are not composed of other terms.

2 Sense and extension

A simple and attractive view of meaning ties the meaning of an expression to its extension. On such a view, the meaning of a simple term is its extension, and the meaning of a complex expression is determined by the extensions of its parts. On the strongest version of this view, the meaning of a complex expression is its extension. On a slightly weaker version, the meaning of a complex expression is a complex structure involving the extensions of the simple terms that are parts of the expression. Either
way, all meaning is grounded in extension.

There are three traditional reasons for doubting this simple view of meaning. First: some simple terms (such as 'Santa Claus' and 'phlogiston') appear to lack extension. On the view above, these terms will lack meaning, or they will all have the same trivial meaning, corresponding to the null extension. But intuitively it seems clear that these terms have some meaning, and that their meanings differ from each others'. If so, then meaning is more than extension.

Second: in some sentences, the role of a word in determining the sentence's truth-value appears to go beyond its extension. This applies especially to sentences about beliefs and related matters. For example, it is plausible that 'John believes that Cary Grant is an actor' could be true, while 'John believes that Archie Leach is an actor' is false, even though 'Cary Grant' and 'Archie Leach' have the same extension. If so, then either the truth-value of the sentence is not determined by the meanings of the terms, or there is more to meaning than reference.

Third: there is often more than one term referring to the same thing. In such cases, the terms often seem intuitively to have different meanings. Witness 'Hesperus', the ancients' name for the evening star, and 'Phosphorus', their name for the morning star. Or take 'water' and 'H2O', both of which refer to the same substance. If 'water' and 'H2O' refer to the same thing, and if reference is all there is to meaning, then 'water' and 'H2O' refer to the same thing. But intuitively, 'water' and 'H2O' have different meanings. If that is so, then reference cannot be all there is to meaning.

In "Über Sinn und Bedeutung" (1891), Frege lays out the central issue roughly as follows. The sentence 'Hesperus is Hesperus' is trivial. It can be known a priori, or without any appeal to experience. The knowledge that Hesperus is Hesperus requires almost no cognitive work at all, and gives us no significant information about the world. But the sentence 'Hesperus is Phosphorus' is nontrivial. It can only be known a posteriori, by appeal to much empirical experience. The knowledge that Hesperus is Phosphorus requires much cognitive work, and gives us significant information about the world.

As Frege put it, 'Hesperus is Phosphorus' is cognitively significant whereas 'Hesperus is Hesperus' is not. And intuitively, this difference in cognitive significance reflects a difference in the meanings of 'Hesperus' and 'Phosphorus'. When a subject comes to know that 'Hesperus is Phosphorus', what she learns depends on what she means by 'Hesperus' and by 'Phosphorus'. And intuitively, the subject learns something different when she learns that Hesperus is Phosphorus than when she learns that Hesperus is Hesperus. If these two claims are correct, then 'Hesperus' and 'Phosphorus' have different meanings, and then meaning involves more than extension.

If meaning involves more than extension, then what is the further element? Frege held that in addition to extension (or reference), an expression also has a sense. 'Hesperus' and 'Phosphorus' have the same referent, but different senses. 'Water' and 'H2O' have the same referent, but different senses. 'Cary Grant' and 'Archie Leach' have the same referent, but different senses. For all such cases, the intuitive difference in cognitive significance among pairs of terms such as these is reflected in a difference in the terms' senses.
The notion of sense has a number of important features, which I discuss in what follows. The discussion is intended as a broad and informal outline of a Fregean view, rather than as a faithful and representation of every feature of Frege's own view. Later, I will give more precise versions of some of these claims.

(1) Every expression that has an extension has a sense.

In "Über Sinn und Bedeutung", Frege concentrated mostly on the senses of names, holding that all names have a sense. But the same considerations apply to any expression that has an extension. Two general terms can have the same extension and different cognitive significance; two predicates can have the same extension and different cognitive significance; two sentences can have the same extension and different cognitive significance. So general terms, predicates, and sentences all have senses as well as extensions. The same goes for any expression that has an extension, or is a candidate for extension.

(2) Sense reflects cognitive significance.

The central feature of sense is that it is tied constitutively to cognitive significance. In the case of singular terms, Frege set out this connection as follows: two referring expressions `a' and `b' have different senses if and only if an identity statement `a=b' is cognitively significant. So `Hesperus' and `Phosphorus' have different senses, since `Hesperus is Phosphorus' is cognitively significant. `Hesperus is Hesperus', by contrast, is cognitively insignificant, and two sides of the identity correspondingly have the same sense.

One can naturally generalize this test to other expressions: a pair of expressions of the same type have different senses when a statement of their coextensiveness is cognitively significant. In the case of kind terms, one can apply the same test as before: 'a' and 'b' have different senses if and only if an identity statement 'a=b' is cognitively significant. So 'water' and 'H2O' have different senses, since 'water is H2O' is cognitively significant. In other cases, the test will be slightly different. For general terms, one can say that 'a' and 'b' have different senses when 'All a's are b's and all b's are a's' is cognitively significant: so 'renate' and 'cordate' have different senses. For predicates, one can say that 'A' and 'B' have different senses when 'For all x, x is A iff x is B' is cognitively significant: so 'has a heart' and 'has a kidney' have different senses. For sentences, one can say that S and T have different senses when 'S iff T' is cognitively significant: so 'Hesperus is a planet' and 'Phosphorus is a planet' have different senses.

It is possible for two different expressions to have the same sense. When two words are intuitively synonymous - `lawyer' and `attorney', perhaps - an identity between them is cognitively insignificant. The truth of `lawyers are attorneys' is arguably trivial: it is knowable a priori, requires no cognitive work, and gives no significant information about the world. If so, then `lawyer' and `attorney' have the same sense. In a similar way, it is plausible that the sentences 'Vixens are rare' and 'Female foxes are rare' are trivially equivalent. If so, the two sentences have the same sense.

We can think of the sense of an expression as mirroring the expression's role in reason and cognition. When two expressions are trivially equivalent, they will play almost the same role in reason and
cognition, and will have the same sense. When two expressions are not trivially equivalent, they will play
different roles in reason and cognition, and will have different senses. In this way, we can think of an
expression's sense as capturing its cognitive significance, and as representing the "cognitive value" or
"cognitive content" if the expression.

*[[Here and throughout the paper, I follow the convention of using sentence symbols such as S, which usually refer to a
sentence, to substitute for the sentence in quotational contexts, indirect contexts, and other contexts in which it is clear that
S is being used, not mentioned.]]

(3) The sense of a complex expression depends on the senses of its parts.

We saw before that the extension of a sentence (such as `John is hot and Mary is cold') at least typically
depends on the extension of the expressions it contains and on its logical form. In a similar way, the sense
of a sentence at least typically depends on the senses of the expressions it contains and its logical form.
The same goes for complex terms, such as 'the greatest cricket player': insofar as its extension depends on
the extensions of its parts, its sense depends on the sense of its parts.

This dependence of sense on sense may proceed in much the same way as the dependence of extension on
extension. We first determine the logical form of a complex expresion, then determine the senses of the
basic terms involved, and then compose these senses in a way that depends on the logical form, to
determine the sense of the complex expression. Just how this composition works is not quite clear, but I
will say more about it in what follows.

(4) Sense determines extension.

Frege held that the extension of a word, a complex expression, or a sentence is determined in some way
by its sense. He was not entirely clear about just what sort of determination is involved here. One way of
understanding the idea is the following: if two expressions have the same sense, then they have the same
extension. The reverse need not be true: we have seen that it is possible two terms to have the same
extension, but different sense. So there is no path from extension to sense, in general. But if this claim is
right, then there is a path from sense to extension.

One question is whether sense determines extension on its own, or whether something else contributes to
determining the extension. If the former, then it seems that the extension must somehow be present at
least implicitly within the sense. But it is not easy to see how this could work, at least if sense is taken to
reflect cognitive significance. The two terms `the morning star' and `the evening star' have the same
extension, for example, but it is not clear how this sameness of extension is present within the term's
senses. Similarly, a statement such as `There are 90 chemical elements that occur in nature' may be true,
but it is not clear how the truth of the sentence is determined by its sense alone. So it is natural to think
that something else must contribute: namely, the world. Intuitively, the sentence above is true not just
because of its sense, but because of the way the world is. And a term such as `the morning star' refers to
the planet Venus not just because of its sense, but because of the way the world is.
If this is right, the determination thesis might be put as follows: a term's extension is determined by its sense in conjunction with the world. Formulating this thesis so that it is both plausible and nontrivial is not easy: after all, is not everything determined by the way the world is? But there is at least an intuitive idea to keep in mind here, which we can return to later.

Frege also held some further theses concerning sense. These are not quite as crucial to a broadly Fregean view as the theses above, but they will be relevant to our discussion.

(5) *In indirect contexts, expressions refer to their senses.*

As we saw before, there are cases in which the truth-value of a sentence seems not to be determined by the extensions of its parts. This happens especially with sentences involving belief, and related ascriptions of attitudes. If `John believes that Cary Grant is an actor' is true and `John believes that Archie Leach is an actor' is false, and if `Cary Grant' and `Archie Leach' have the same extension, then the truth value of these sentence cannot be determined by the extensions of their parts. The same goes for many other constructions involving indirect contexts, a context where words appear inside a "that"-clause (such as `that Cary Grant is an actor').

To deal with these cases, Frege suggested that in indirect contexts, the expressions inside the "that"-clause do not have their usual extension. They refer instead to their (usual) *senses*. So inside such a clause, `Cary Grant' does not refer to a person, but to the (usual) sense of `Cary Grant'. In this way, we can see that `Cary Grant' and `Archie Leach' have *different* extensions within these sentences, so the thesis that truth-value depends on extension is preserved.

(6) *The sense of a sentence has an absolute truth-value.*

For Frege, the sense of a sentence is a special sort of entity, a `thought'. A Fregean "thought" is not a mental entity: it is more like what many philosophers call a *proposition*, capturing the content that a sentence expresses, when stripped of the accidental clothing of a particular language. Just as a sentence can be true or false, a proposition can be true or false. Frege held that propositions (thoughts) are the primary bearers of truth, and that sentences are true or false derivatively: a sentence is true if and only if the proposition that it expresses is true. Further, Frege held that a proposition is true or false *absolutely*. On his view, it is not possible for the same proposition to be true or false, for example at different times. If two sentences, uttered by any subjects at any times, express the same proposition, they will have the same truth-value.

This has strong consequences for the notion of sense. Many sentences can be true when uttered on one occasion, and false when uttered on another. For example, `It is raining here now' will be false if I utter it now, but it would have been true if I had uttered it at this time yesterday. One might have been tempted to say that both of these utterances had the same sense. But if senses are propositions with absolute-truth value, they cannot. The two sentences must have different senses, and express different propositions.
The sense of an expression can vary between occasions of use and between subjects.

It is tempting to hold that the sense of an expression is a universal feature of that expression: that is, that every token of an expression has the same sense. If this were right, then the sense of an expression could be seen as built into the language of which the expression is a part. But on Frege's view, sense is not universal in this fashion. One reason for this is given above: on Frege's view, the sense of a sentence such as `It is raining here now' differs between different occasions of use. One can presumably trace this difference to differences in the sense of expressions such as `here' and `now' between occasions of use. Another quite different reason is tied to names. Frege says that two different users of a name such as `Aristotle' might associate a different sense with it. He says that this should not happen in a `perfect language', but it does happen in natural languages. For reasons like these two, Frege's view entails that one cannot attach sense to expression types in general. To handle cases like this, one has to attach sense to expression tokens.

To sum up: Frege held that expressions have senses that satisfy (1)-(7). In recent years, many philosophers have doubted this. It has been widely argued that expressions do not have Fregean senses, and there is no notion that can play the role that sense is intended to play. In particular it is widely believed that it is difficult to satisfy (2), and that it is impossible to simultaneously satisfy (1)-(4).

To flag my conclusions: I think there is a viable notion of sense such that expressions have senses that satisfy slightly modified versions of the core requirements (1)-(4). On this notion of sense, theses (5) and (6) are rejected, but (7) is accepted. I think that such a view can vindicate the spirit, if not the letter, of Frege's view.

3 What are senses?

What are senses? I have outlined a number of features that Frege attributed to senses, but this is not yet to say what a sense is. Frege's own discussion leaves the matter somewhat unclear. He says that they are not mental entities, such as the idea or image associated with an expression, for example; and he holds that they are some sort of abstract objects (inhabiting the `third realm'). But this still leaves their nature open.

One natural suggestion is that senses are descriptions. Frege sometimes uses descriptions to specify senses. In talking about the sense of `Aristotle', for example, Frege says `It might, for instance, be taken to be the following: the pupil of Plato and teacher of Alexander the great'. And one might well hold that the sense of `Hesperus' is something like `the brightest object visible in the evening sky', and that the sense of `Phosphorus' is something like `the brightest object visible in the morning sky'.

Descriptions, on a natural understanding of the term, are linguistic entities. `The pupil of Plato and teacher of Alexander the great' is a linguistic entity, a complex expression containing ten words. Senses obviously cannot be descriptions of this sort: descriptions have senses of their own, so we will be left either with descriptions that serve their own sense or endless chains or circles of descriptions. And more importantly, senses of this sort will not break out of the linguistic domain.
A more plausible suggestion is that the sense of an expression is the *sense* of an associated description. But even if this is true, it does nothing to tell us what senses *are*. It is also far from clear that associated descriptions of the right sort exist for all expressions. For example, 'knowledge' seems to be a paradigmatic term with a sense: some states qualify as knowledge but others do not, and one might think of the sense as encapsulating a criterion for knowledge. But there famously appears to be no description that captures such a criterion. Gettier showed that `justified true belief' is inadequate, and all attempts at complex descriptions have failed. But even if there is no linguistic description that captures what it takes to be knowledge, this does not show that `knowledge' has no sense.

To find a better understanding of sense, it is useful to think about the work that descriptions are doing here. The role of a description is plausibly to give us a *condition* for determining the extension of an expression, depending on how the world turns out. If the world turns out such that the brightest object in the evening sky is Venus, then `Hesperus' will turn out to refer to Venus. If the world turns out such that the brightest object in the evening sky is Rigel Delta, then `Hesperus' will turn out to refer to Rigel Delta. And so on. That is, the crucial property of a description is that it gives us a way of identifying an expression's extension, given full knowledge of how the world turns out.

We might then generalize by saying that a sense captures how an expression's extension depends on which world we turn out to live in. For all we know a priori, there are many ways the world could be. We might live in a world with planets visible in the sky, or we might not. We might live in a world where people play cricket, or we might not. We might live in a world where some objects travel faster than light, or we might not. We might live in a world where the liquid in the oceans is a basic atomic substance, or we might not. For all we know a priori, our world could be one of an uncountable number of different possible worlds.

This a priori ignorance about the nature of our world reflects a corresponding a priori ignorance about the extensions of our expressions. For a typical expression, such as `Hesperus', or `the greatest cricket player', or `water', we cannot know what the expression refers to without much observation of the world. For all we know a priori, it might be that Hesperus is Rigel Delta, or that the greatest cricket player is Dennis Lillee, or that water is a basic element. The extensions of our expressions depend on how our world turn out. We might say: they depend on which possible world is actual.

Once we know enough about the nature of our world, we are usually in a position to know what our expressions refer to. Once we do enough astronomical work investigating the nature of the objects in the evening sky, we know that `Hesperus' refers to Venus, not Rigel Delta. Once we know about the performances of cricket players throughout the history of the game, we know that `the greatest cricket player' refers to Don Bradman, not Dennis Lillee. Once we know about the chemical makeup of the various substances in our environment, we know that `water' refers to H2O, not to a basic element. In general: once we know which possible world we live in, we can know what our expressions refer to.

We can think of this as being part of what competence with an expression involves. If a subject uses an expression, then given sufficient information about the world, the subject will be in a position to know the
extension of the expression. Furthermore, something like this will be the case however the world turns out: for any world, given sufficient information about that world, the subject will be in a position to determine what the extension of the expression will be if that world is actual. Of course in some cases the extension may be indeterminate, as it sometimes is in the actual world; but in such a case, the subject will be in a position to determine that, too.

One could put forward a thesis holding that when a subject using an expression is given sufficient information about a world, the subject is in a position to know what the extension of the expression will be if that world is actual. A full and precise version of such a thesis would require careful attention that I will not give here. But it is worthwhile to say one or two things to clarify it.

First, what counts as "sufficient information"? If we allow too much, the thesis becomes trivial: given the information that Hesperus is Phosphorus, one can trivially know that Hesperus is Phosphorus. But it is clear that in this case, no such information is required; neutrally specified information suffices. It is plausible that at least in many cases, `qualitative' information about the distribution of physical properties, appearances, and mental states (perhaps including some indexical information) in the actual world suffices to determine an expression's extension. I will not give a precise account of the relevant information here (see Chalmers, `Conceptual Analysis and Reductive Explanation', for a more precise hypothesis). What matters is rather the general idea that there is some constrained sort of information such that information of this sort can suffice to determine an expression's extension, and usually in a nontrivial way.

When is a subject "in a position to know" an expression's extension? We can that this is the case when sufficient reasoning from information available to the subject will allow the subject to know the expression's extension. Here the reasoning is restricted to a priori reasoning (or to armchair reasoning, if one prefers), so further empirical observation is disallowed. And we idealize away from poor reasoning: it is not a subject's actual reasoning that matters, but rather what the subject could know given unimpaired reasoning. For example, a subject possessing the relevant information might judge that 47 plus 59 is 116, due to a miscalculation, or that Alpha Centauri is the nearest star, because they overlook the sun. But these mistakes can be corrected by better reasoning, so are no counterexample to the thesis.

If something like this is right, then a subject using an expression is in a position to know the expression's extension given relevant empirical information and sufficient reasoning. The second clause entails that there is a normative element here; but what matters is that the extension is within the reach of reason. This feature of language and thought is responsible for a deep link between meaning, possibility, and rationality.

4 Senses as intensions

All this suggests that an expression's sense might be seen as an intension: a function from possible worlds to extensions. This function takes any given possible world, and associates it with an extension within that world. The extension will be either an entity present in that world, or the null extension. We can say
that the intension is *evaluated* at a possible world, and *returns* an extension in that world.

For the Fregean, these worlds will be thought of as *epistemic* possibilities, in a broad sense: ways the world could be, for all we know a priori. And the intension of an expression can be thought of as an *epistemic* intension: it captures (very roughly) the way the extension of the expression depends on which epistemic possibility turns out to be actual. For a sentence S and a world W, for example, a useful heuristic is to ask: if W is actual, is it the case that S? Or to stress the epistemic nature of this conditional: if W *turns out* to be actual, will it turn out that S? If yes, then the intension of S is true at W.

Take an expression such as `the greatest cricket player'. Let world W1 be a world where Australians never play cricket, and where Phil Tufnell scores more runs and takes more wickets than any other cricket player. Let world A be the world as it actually is, where Don Bradman's batting average is 99.94, and where the second highest batting average is around 61. For all we know a priori, world W is our world. For all we know a priori, world A is our world. If world W is our world, then the greatest cricket player is Phil Tufnell. So when evaluated at world W, the intension of `the greatest cricket player' returns Phil Tufnell. If world A is our world (as it is!), then the greatest cricket player is Don Bradman. So when evaluated at A, the intension of `the greatest cricket player' returns Don Bradman.

What about a term such as `Hesperus'? Here one can tell a Fregean story in a similar way. Let world W2 be a world where the brightest object visible in the evening is Rigel Delta, and where the brightest object visible in the morning is Neptune. For all we know a priori, W2 is our world. If it turns out that W2 is our world, then it will turn out that Hesperus is Rigel Delta. So when evaluated at W2, the intension of `Hesperus' returns Rigel Delta. If it turns out that A is our world, then it will turn out that Hesperus is Venus. So when evaluated at A, the intension of `Hesperus' returns Venus.

The same applies to a term such as `water'. Let world W3 be a `Twin Earth' world, where the clear, drinkable liquid in the oceans and lakes is XYZ. For all we know a priori, W3 is our world. If it turns out that W3 is our world, then it will turn out that water is XYZ. So when evaluated at W3, the intension of `water' returns XYZ. If it turns out that A is our world, then it will turn out that water is H2O. So when evaluated at A, the intension of `water' returns H2O.

One can do the same sort of thing for a whole sentence. Just as the extension of a term depends on the way the world turns out, so does the truth-value of a sentence. So a sentence will also be associated with an intension: this time, a function from possible worlds to truth-values. This function takes a possible world, and returns a truth-value associated with that sentence in the world. This truth-value will be `true', `false', or perhaps neither.

Take a sentence such as `Hesperus is Phosphorus'. One can tell a Fregean story here in a similar way. If it turns out that world W2 above (with Rigel Delta in the evening and Neptune in the morning) is actual, then it will turn out that Hesperus is not Phosphorus. So when evaluated at world W2, the intension of `Hesperus is Phosphorus' returns `false'. When evaluated at the actual world A, on the other hand, the intension of `Hesperus is Phosphorus' returns true.
The intuitive characterization of epistemic intensions using the heuristics I have given here make it plausible that such entities exist, I think. Giving a truly precise definition of an epistemic intensions involves complexities that I cannot go into here. Nevertheless, it may be useful to say a few words about the foundations of the idea, and about how a more precise definition can be constructed.

The basis for epistemic intensions lies in our ability to describe and evaluate epistemic possibilities. Let us say that it is epistemically possible (in the broad sense) for a speaker that S when the speaker cannot know a priori that not-S. Then it is epistemically possible that water is not H2O. It is also epistemically possible that our world is the XYZ-world: that is, that the clear liquid in the oceans and lakes (and so on) is XYZ. And when we reflect on the second, specific epistemic possibility, it reveals itself to us as an instance of the first epistemic possibility. That is, the epistemically possible hypothesis that the XYZ-world is actual is a specific version of the epistemically possible hypothesis that water is not H2O.

We can see, then, that we use language to describe and evaluate epistemic possibilities in a distinctive way. Quite generally, given a specific epistemically possible hypothesis W and some more general epistemic possibility S: a speaker can say, on reflection, that the epistemic possibility that W is an instance of the epistemic possibility that S, or an instance of the epistemic possibility that not-S, or is neither. If it is the first, then the epistemic intension of S is true in W. If it is the second, then the epistemic intension of S is false in W. If it is neither, then the epistemic intension of S is indeterminate in W.

Of course any specific world must be described in order for a speaker to be able to evaluate it as an epistemic possibility. What the speaker really considers is whether the epistemic possibility that D is an instance of the epistemic possibility that S, where D is a description (in some sense) of W. This raises the issues of what it is to be a description of an epistemically possible world, and of whether different descriptions of the same world might give different results. I think that these questions can be answered fairly straightforwardly, and that there is a class of canonical descriptions of a world that give equivalent results, but the matter is too complex to go into here. (For this purpose, one can invoke either "epistemically complete" or "qualitatively complete" descriptions, as defined in "Does Conceivability Entail Possibility"). For our purposes, the intuitive characterization of what it is for the epistemic intension of S to be true in W should suffice.

The epistemic intension of S at W corresponds to a speaker's judgment about whether the epistemic possibility that W is an instance of the epistemic possibility that S, or to the speaker's judgment about whether S is true if W is actual. But it is not the speaker's snap judgment that matters, nor any actual judgment of the speaker. Rather, it is the speaker's (potential) rational judgment that matters. Here we idealize away from poor reasoning, and consider judgments on ideal rational reflection.

An idealization like this can be made in a number of ways. The most obvious way is to invoke the idealization inherent in the notion of apriority. S is a priori not if a speaker knows that S, nor even if a speaker would be able to know that S on reflection, but rather if it would be possible for the speaker to know that S, using the concepts involved in S, on ideal rational reflection. So we can say that the
epistemic intension of S is true in W if a priori reasoning by the speaker could reveal the epistemic possibility of W to be an instance of the epistemic possibility that S.

All this suggests a natural definition of the epistemic intension of S for a speaker. For a given world W, let D be any canonical description of W. Then the epistemic intension of S is true at W iff the material conditional `D->S' is a priori; it is false at W if `D->~S' is a priori; and it is indeterminate at W if neither is a priori. Other forms of definition are also possible; for example, if someone rejects the notion of apriority, then one can appeal to a different construal of the relevant epistemic status. For this to be a truly precise definition, one needs to say more about the relevant worlds, descriptions, and epistemic status; so this is not yet a truly precise definition. (But see "The Structure of Epistemic Possibility" for a more precise treatment.)

It should be noted that to evaluate the epistemic intension of S at W, a token of S need not be present within W. None of the heuristics or definitions that I have given here rely on such a token; rather, they rely on first order claims about epistemic possibility and apriority using an expression present in the actual world. And one can often evaluate expressions at worlds with no such tokens. For example, there are epistemically possible worlds in which no-one uses language. When one considers such an epistemic possibility W, it reveals itself as an instance of the epistemic possibility that no words exist, that there are no novels, and so on. So the epistemic intension of `words exist' is false at W, and so on. It is even arguably epistemically possible that no-one exists (as long as `I exist' is not a priori). One can consider and evaluate that epistemic possibility in various ways; for example, the epistemic intension of `Someone exists' will be false there. Of course some sentences may yield indeterminate results at these epistemic possibilities, but all that matters is that some sentences yield determinate results there.

All of this arises from the fact that when a speaker is given the right sort of information about the actual world and engages in the right sort of reflection, conclusions about extension are within reach of reason. And when a speaker is given the right sort of information about an epistemic possibility, and engages in appropriate reflection, conclusions about extension within that epistemic possibility are within reach of reason.

We can use this to articulate, in this framework, the Fregean notion of `grasping' a sense. We can say that a subject grasps an intension when the subject is in a position to evaluate that intension: that is, when sufficient reasoning will allow the subject to determine the value of the intension at any world. Again, this does not require that the subject will actually determine the correct extension when a relevant epistemic possibility is specified, but it does require that the extension is within the grasp of reason. If what I have said here is right, then whenever a subject uses an expression competently, the subject will grasp the expression's epistemic intension.

Occasionally, the epistemic intension of a term will be the same as that of an associated description. For example, the epistemic intension of 'Neptune' as used by Leverrier was arguably the same as that of 'the object causing the perturbation of the orbit of Uranus'; and the epistemic intension of 'bachelor' is arguably the same as that of 'unmarried man'. In these cases, there is a sense in which the epistemic intension can be "captured" by a description.
This does not hold in general. For many or most terms, there may be no description (and certainly no short description) with the same epistemic intension as the term. We saw this in the case of 'knowledge', and the same applies to most names. In these cases, the best one can hope for is a description whose epistemic intension approximates that of the original term: as with `justified true belief' for `knowledge', or `the clear drinkable liquid in the oceans and lakes' for water, and so on. These descriptions may give one a rough and ready sense of how a term's epistemic intension functions, but they do no more than that. Usually there will be at least a small subset of epistemic possibilities (such as the Gettier cases, in the case of `knowledge') in which the epistemic intension of the original term and of the description come apart.

So in general, there is no reason to think that an epistemic intension can be captured by a description. And more generally, there is no reason to think that grasping an epistemic intension requires any sort of descriptive articulation of a concept by a subject. The epistemic intension is a function, not a description. It is revealed in a subject's rational evaluation of specific epistemic possibilities, not in any sort of explicit definition. Even where such a definition exists, a subject need not be able to articulate it to grasp the epistemic intension. Indeed, we usually evaluate the plausibility of such definitions precisely by deploying our prior grasp of a term's epistemic intension, to see how whether the definition gives the right results in specific cases. (Witness the literature on the definition of `knowledge'). So epistemic intensions are more basic than descriptions, and should not be assimilated to them.

Epistemic intensions can be associated with any expression that is a candidate for extension. Given the general type of the expression (singular term, general term, etc), it will be constrained to have a certain sort of extension (individual, class, etc). The intension of such an expression will be a function from worlds to the appropriate sort of extension. So the intension of a singular term is a function from worlds to individuals; the intension of a general term is a function from worlds to classes; the intension of a sentence is a function from worlds to truth-values; and so on.

This thesis can be considered a basic postulate of the Fregean framework:

(1) Every expression has an intension, which returns at a world an extension of the type appropriate for the expression.

We can add to this two further postulates:

(3) If the extension of a complex expression E depends on the extensions of its parts, then at a world W, E's intension returns an extension that depends in the same way on the extensions returned by the intensions of its parts.

(4) At the actual world, the intension of E returns the (actual) extension of E.

The Fregean could simply take these theses) as basic postulates. But it is also possible to see how they fit
with our intuitive understanding of an epistemic intension. For (2): part of that understanding is that any expression can be evaluated at arbitrary epistemic possibility, yielding the same sort of extension that it yields in the actual world. For (3): the dependence of the extension of a whole on the extension of parts is presumably not an accident about the actual world, so will hold across arbitrary epistemic possibilities. For (4): given appropriate information about the actual world, a subject will be in a position to determine the expression's actual extension.

Given (1), (3), and (4), and the equation of senses with intensions, it is easy to see how the Fregean requirements (1), (3), and (4) follow. Requirement (1), that every expression has a sense, follows immediately from (1). Requirement (3), that the sense of a sentence depends on the sense of its parts, follows from (3) along with the thesis that the extension of a sentence depends on the extension of its parts. Note that even if there are some cases where the latter thesis fails (such as belief contexts), requirement (3) can still be satisfied as long as the extension of a sentence depends on the extensions and the intensions of its parts. For then it is plausible that the extension of a sentence at a world will depend on the extension of its parts at a world along with the intensions of the parts, so the intension of the sentence will depend on the intensions of the parts.

As for requirement (4), that sense determines extension: a version of this immediately follows from (4). The relevant version is the second version given earlier, holding that sense determines extension in combination with the world. To determine an expression's extension, one simply evaluates the expression's intension at the actual world. One can naturally think of the intension as supplying criteria for determination of extension: in combination with the actual world, these criteria will determine an extension.

What about the crucial requirement (2), that sense reflects cognitive significance? Here matters are complicated by the fact that we lack a precise definition of `cognitive significance'. There is a natural understanding of cognitive significance that fits well with the intensional framework, however. We can say that a sentence S is cognitively insignificant when S is knowable a priori, or with justification independent of experience. And S is cognitively significant when it is not knowable a priori. `Hesperus is Hesperus' is knowable a priori, so it is cognitively insignificant. `Hesperus is Phosphorus' is not knowable a priori, so it is cognitively significant.

This understanding of cognitive significance is not quite Frege's. On Frege's account, a priori knowledge can be cognitively significant: the knowledge that 59+46 is 115 is cognitively significant, for example, because this knowledge requires some cognitive work. It is very hard to articulate this notion precisely, however, and it is not clear that there is a useful precise notion nearby. In any case, the definition in terms of apriority is at least not too far from Frege's central notion, and it handles most of Frege's central cases, which involve a posteriori knowledge. So it is this understanding that I will use.

For senses to reflect cognitive significance in this sense, it was required (among other things) that an identity `a=b' is cognitively significant if and only if `a' and `b' have different senses, and that two sentences S and T have the same sense if and only if the material conditionals `If S then T' and `If T then S' are cognitively insignificant. Recasting these claims in terms of intensions and apriority, we require the
On Sense and Intension

following: An identity `a=b' is a priori if and only if `a' and `b' have the same intension; and two sentences S and T have the same intension if and only if the material biconditional `S iff T' is a priori.

Both of these claims are entailed by the following principle:

(2) S is a priori if and only if its intension is true at all worlds.

>From (2), it follows that `a=b' is a priori iff its intension is true at all worlds. By (3) and the extensional semantics of identity, the intension of `a=b' is true at a world iff the intensions of `a' and `b' return the same extension there. So `a=b' is a priori iff the intensions of `a' and `b' return the same extensions at all worlds; that is, iff `a' and `b' have the same intensions.

>From (2), it also follows that `S iff T' is a priori iff its intension is true at all worlds. By (3) and the semantics of material conditionals, the intensions of `S iff T' is true at a world iff the intensions of S and T return the same truth-value there. So `S iff T' is a priori iff the intensions of S and T return the same truth-values at all worlds; that is, iff S and T have the same intensions.

So from (1)-(4), versions of the crucial Fregean requirements (1)-(4) can be satisfied. The question then becomes: why believe that (1)-(4) can be satisfied? The crucial claim is clearly (1). So, why believe that expressions can be associated with intensions that satisfy (1)?

The central reason stems from the Fregean understanding of these intensions and of the associated worlds. As we saw above, the worlds represent epistemic possibilities: ways the world might be, for all we know a priori. And the intensions are epistemic intensions: they capture a subject's idealized judgments about how an expression applies to an epistemic possibility, under the hypothesis that it is actual. On this understanding, a strong connection between intensions and epistemic notions such as apriority is built into the framework.

So consider the left-to-right direction of (1): if a statement is a priori, its epistemic intension is true at all worlds. This direction is straightforwardly plausible. If S is a priori, then for any epistemic possibility W: if W turns out to be actual, it will turn out that S. We might say that for all W, the epistemic possibility that W is actual is an instance of the epistemic possibility that S. So the epistemic intension of S is true in all worlds.

This is brought out by cases such as `Hesperus is Hesperus (if it exists)', `All bachelor are unmarried men', and even `The meter stick in Paris in one meter long (if it exists)', assuming that these are a priori. In each of these cases, there is no epistemic possibility of falsehood. No matter how the world turns out, it cannot turn out that Hesperus is not Hesperus, or that the meter stick in Paris is longer or shorter than one meter. So in every epistemic possibility W, the epistemic intensions of these sentences are true.

Something similar applies in the right-to-left direction, which we can consider in the contrapositive form: if S is not a priori, then there is some world in which its epistemic intension is not true. This fits the
familiar cases. `Hesperus is Phosphorus' is a posteriori, and its epistemic intension, as we saw above, is false in a world W2 where the objects visible in the morning and evening sky differ. `Water is H2O' is a posteriori, and its epistemic intension is false in the `Twin Earth' world W3. And this is no accident: the aposteriority of these statements seems to be reflected in the existence of these worlds in which the epistemic intension is false.

If S is not a priori, it is clearly epistemically possible that not-S. So all we need for the right-to-left direction of (1) is the following claim: if it is epistemically possible that T, then there is an epistemically possible world W in which the epistemic intension of T is true. This claim is suggested very strongly by the above examples, but it is not completely trivial.

Someone might hold in response that there are counterexamples to the claim. They might hold that `God exists' (S1) is necessary but not a priori, for example; or they might hold that the Continuum Hypothesis (S2) is necessary but not a priori. And they might suggest that in these cases (unlike cases involving water, Hesperus, and so on) there is no world W such that if W is actual, S1 is false or S2 is false.

These claimed counterexamples would be highly controversial, and a Fregean could simply deny them as contrary to his or her principles, holding that the opponent is assuming a false view of the cases, and perhaps tacitly assuming a false view of some of the crucial notions: apriority, possibility, intensions. But it is useful to probe just why a Fregean would deny them. The Fregean could deny them in at least two ways, depending on the relevant conception of possibility.

There are two ways in which the Fregean might understand the worlds that are considered as epistemic possibilities and over which epistemic intensions are defined. First, they might be a space of worlds that is *independently characterized*, perhaps as the space of metaphysically possible worlds. In this case, it becomes a substantive thesis that when S is epistemically possible, there is a world in which the epistemic intension of S is false. The thesis is plausible for familiar cases (including `water' and `Hesperus' cases), but an opponent might hold that in some cases, it is false. This might happen for reasons such as those in the case above, where an opponent could hold that there are not enough metaphysically possible worlds to go around.

On this understanding, for the Fregean to hold onto principles such as (1), she will have to deny the opponent's analysis of the cases. She might hold that God's existence cannot be necessary, for example, or perhaps that it is a priori; and she might hold that the Continuum Hypothesis is either a priori or indeterminate. This will require substantive argument. And the postulated connection between the independently characterized space of worlds and epistemic possibility will be a substantive thesis; it will have implications for just what is metaphysically possible, for example. Of course the thesis may well be plausible for all this. A Fregean might even argue for it directly, perhaps by noting that there are no clear counterexamples, and by arguing that there are constitutive connections between notions of metaphysical and epistemic possibility.

On the second understanding, the worlds involved are not independently characterized, but are understood as epistemic possibilities from the start. The Fregean might postulate or construct a space of
On Sense and Intension

worlds understood as `maximal epistemic possibilities', for example. These might intuitively correspond
to maximally specific epistemically possible hypotheses about the way things are, hypotheses from which
a priori reasoning can settle everything there is to be settled. This space might be defined quite
independently of notions of `metaphysical possibility'.

On this understand, a Fregean is free to accept much of the opponent's analysis of the cases above. She is
free to accept that `God exists' is a posteriori but metaphysically necessary, for example. If she accepts
this, she will simply insist that there is an epistemically possible world in which the epistemic intension
of `God exists' is false. This will follow naturally from the definition of those worlds. Once epistemic
possibility is separated from metaphysical possibility, the opponent will have no obvious reason to deny
this. On this understanding, the truth of (1) does not involve commitment to the substantive theses about
metaphysical possibility above, and it will be well-protected from counterexamples.

(A third possibility is that the Fregean could accept both the opponent's analysis of the cases and an
independently characterized notion of possibility, and accept that (1) is not true across the board. It might
be held that there are certain special domains where it fails, but that it holds in the most domains, or in
certain constrained domains. This is not out of the question, but I will set it aside here.)

My view is that the Fregean can go in either of these two ways. I think that (1) is plausible even given an
independently constrained notion of metaphysical possibility, and that it can be argued for directly; but
this is a nontrivial matter. If someone doubts this, however, the second option is available. This has the
advantage of making fewer substantive commitments. Here, the main burden is making the case for the
relevant space of epistemically possible worlds. This is also nontrivial, but I think that it can be done in a
reasonably straightforward way. (See my `Materialism and the Metaphysics of Modality' for arguments
that cash out the first strategy, and `The Structure of Epistemic Possibility' for a construction that cashes
out the second.)

In any case, we can see that the Fregean is not being unreasonable in accepting (1). It appears to fit the
clear cases, and there are natural ways to respond to one who doubts it. So it seems that the claim that
there are intensions of some sort that satisfy (1)-(4) is well-motivated. If there are such intensions, then
they can function as senses that satisfy (1)-(4).

To clarify what I have and have not done: I have not here tried to precisely define epistemic intensions, in
the sense of giving a precise recipe for evaluating a a sentence S's intension at a world W. I have also not
tried to give a knockdown argument that (1)-(4) can be satisfied. Rather, I have simply outlined a certain
sort of Fregean view, and I have tried to make it plausible that intensions satisfying (1)-(4) exist.

If this is correct, a Fregean can hold that there is at least a prima facie case for a notion of sense that
satisfies (1)-(4). But of course there have been numerous arguments against Fregean sense in recent
years. So we now need to examine these arguments to see whether they have any force against the
conception just outlined. I will focus on four main arguments: what we might call the argument from
indexicality, the modal argument, the epistemological argument, and the argument from variability.
5 The argument from indexicality

The first objection is not so much an explicit argument as a set of considerations put forward by a number of philosophers, especially John Perry (1977). These considerations revolve around Frege's treatment of indexicals, such as `I', `here', and `now'.

Recall that Frege held that the sense of a sentence has an absolute truth-value. This entails that if two utterances of a sentence express the same sense, they must have the same truth-value. But it is clear that certain indexical sentences, such as `It is now Saturday' can be uttered truly at one time and falsely at another time. So on Frege's picture, these two sentences must have different senses.

If the sense of the sentence depends on the sense of its parts, then some part of the sentence must have a sense that differs between the two occasions of utterance. The obvious source of the difference is the indexical expression `now'. So Frege's view entails that such an indexical expression has different senses on different occasions of utterance. The same goes for many other indexicals: `I', `here', `today', `tomorrow', and so on.

It is very hard to see how this is supposed to work. One idea is that the sense of such an expression should build in its referent. If so, my utterance of `now' today has a sense that builds in a particular Saturday, and my utterance of `now' tomorrow has a sense that builds in a particular Sunday. Similarly, my utterances of `I' have a sense that builds in a particular individual, David Chalmers, while your utterances have a sense that builds in a different individual.

It seems that something like this is required to preserve Frege's claims, but this also seems quite contrary to the overall spirit of Frege's framework. Sense is usually quite distinct from reference, and it is not clear why this case should be different. When I use an expression such as `now' or `today', the referent does not seem to be reflected in the cognitive significance of the expression for me. I might have no idea what day today is; and the day might change without it making any special difference to my cognition. So there seems to be a strong tension between this sort of claim and the general spirit of (2).

How will the intensional framework deal with these matters? Let us consider a sentence such as `It is raining here now'. If such a sentence determines a function from worlds to referents, there is an immediate problem. I can utter the sentence truly today, and falsely yesterday. But both days, I inhabit the same world: at least, the same `objective' world A. So if the intension of a sentence is a function from (objective) worlds to truth-values, then as before, the two utterances must have different intensions. And as before, the two tokens of `now' must have different intensions.

It is once again quite unclear how this should work. One might suggest that `now' should pick out a particular time (time t, the specific time of utterance) in all worlds. But then a sentence such as `It is now time t' will have a necessary epistemic intension. But this sentence is clearly a posteriori (and cognitively significant), so it must have a contingent epistemic intension. So this will not do. And it seems that any other intension will have a similar problem.
I think there is only one natural way for the intensional framework to deal with this issue. A proponent of this framework should deny that intensions are functions from objective worlds to extensions. Rather, intensions must be seen as functions from centered worlds to extensions. Here, a centered world is a world marked with a `center', where the center consists of an individual and a time present in that world.

This idea can be motivated in a natural way. On the Fregean intensional framework, worlds are supposed to represent a sort of maximal epistemic possibility. But it is a familiar idea (this time from the work of Perry (1979), among others) that an objective description of the world leaves some matters epistemically open. When I lie awake in the middle of the night, then even if I had a full objective description of the world, I might still wonder `what time is it now?', and I might not be able to settle this matter from the information available. Or I might have a full objective description of the world, but not know which individual in that world is me. So an objective description of the world is not an epistemically complete description of the world. To make it epistemically complete, the description also needs locating information: a `you are here' marker, indicating which individual is me and what time is now. This sort of epistemic possibility is best represented by a centered world.

Once epistemic possibilities are represented as centered worlds, we can deal with the problem straightforwardly. We can say that the epistemic intension of `I' picks out the individual marked at the center of any given world, and that the epistemic intension of `now' picks out the time marked at the center. The epistemic intension of `today' will pick out the day containing the time marked at the center of any given world, and the epistemic intension of `tomorrow' will pick out the following day. These intensions will be common to all occasions of use of these expressions.

When a subject uses an expression, the actual extension of the expression will be given by evaluating the expression's intension at the centered world inhabited by that subject: a world corresponding to the actual world centered on that subject and on the time of use. When two different subjects use an indexical expression such as `I', they will inhabit two different centered worlds: one centered on the first subject, and one on the second. So the epistemic intension of `I' will pick out different actual extensions for each. For each subject, the intension will pick out himself or herself. Something similar applies to `now': when this expression is used at different times, the intension will be evaluated at different centered worlds, and will always return the time of use.

Something like this can also help with terms that are not obviously indexical, such as `water'. If I am given a full objective specification of an epistemic possibility, and am told that it contains a planet where the watery stuff is H2O and a planet where the watery stuff is XYZ, then I may not be in a position to know what the extension of `water' is. To know that, I need to know which planet I am on. But if I am also given locating information, in which the center of my world is marked (e.g. on the planet with H2O), then there is no problem. I am now in a position to know which environment is my environment, to know which substances I am causally related to, and so on. So as long as I can derive the relevant objective information (about appearance, behavior, distribution of various substances), I will have no problem determining that if this centered world is actual, then water is H2O. So the epistemic intension of `water' will return H2O at this world.
There are a couple of subtleties to the use of centered worlds. One is the following: it is arguably not a priori that I exist (I know this through experience), but the epistemic intension of `I exist' is true in all centered worlds as defined. To deal with this, one should make the marking of a subject and time optional: some centered worlds have no marked subject and time, or perhaps mark just one but not both. In a centered world without a marked subject, the epistemic intension of `I exist' will be false. The other side of this coin is that there may be expressions that require the marking of further entities at the center of a world: some demonstratives (`that object') may require marked experiences, for example, and some special cases (`this thought') might required marked thoughts. These cases are not crucial to the current discussion, however, so we can mostly stay with worlds in which at most a center and a time is marked.

The introduction of centered worlds to the Fregean framework has one major consequence. The sense of a sentence will no longer have an absolute truth-value. When I say `It is raining here now' yesterday and today, my utterance has the same epistemic intension both times, but it is false yesterday and true today. So the intension is not true absolutely, or false absolutely. It is true or false only relative to a subject and a time. So the Fregean requirement (6) fails.

It is not clear what Frege would have thought of this. The requirement that the sense of a sentence (a `thought') be an absolute bearer of truth was very important to him. Still, it is widely held that Frege's treatment of indexicals needs major repair. And it seems to me that giving up thesis (6) does not do any significant damage to a broadly Fregean framework, and it allows one to preserve the crucial connection with cognitive significance and the determination of reference. So it may be that giving up this thesis is the best way to preserve a framework that is in the broad spirit of Frege's.

This adjustment also entails that we must give up on Frege's thesis (5), that expressions in belief contexts refer to their senses. Consider a belief attribution such as `John believes that I am British'. Here the sense of `I' is the epistemic intension that picks out the individual at the center of a given world, and the sense of `I am British' is true only in worlds where the individual at the center has a certain national origin. If John were to entertain a belief with that sense, then he would attribute that national origin to himself. But it is clear that this is not what John does when he believes that I am British. So on the current understanding of sense, thesis (5) entails that the wrong sort of belief is attributed to John. So we must give up on thesis (5).

I do not think that this is a high cost to pay. It is widely held that thesis (5) must be rejected, for a number of different reasons. The thesis yields an attractively elegant analysis of belief attributions, but on a close analysis, it seems that belief attributions are more subtle than the thesis suggests. The analysis of belief attributions was only a subsidiary element of Frege's view, however, and it is clear that giving it up preserves the broad spirit of his view. Of course we still need a good analysis of belief attribution, but that is a subject that needs much discussion in its own right. (I think that epistemic intensions can still be exploited, but in a more indirect way. See "The Components of Content".)

6 The modal argument
Perhaps the best-known argument against a Fregean view of language is the modal argument of Kripke (1972). Kripke's argument is concerned mostly with names, and also with natural-kind terms. He is arguing against 'descriptive' views of reference in the first instance, on which names are semantically akin to descriptions, but the arguments are generally taken to have force against any Fregean view.

Kripke argues that names cannot be equivalent to descriptions as follows. Take any name, such as 'Aristotle', and any description, such as 'the last great philosopher of antiquity'. Then it might have been that Aristotle was not the last great philosopher of antiquity; he might have died while an infant, for example. Something similar applies to any other description D that seems a likely candidate to capture the sense of the name: for any such description D, we judge that it might have been that Aristotle was not D. So `Aristotle' is not semantically equivalent to the description D.

Something similar applies in the case of `Hesperus'. A Fregean might hold that `Hesperus' is semantically equivalent to `the brightest object visible in the evening sky', or some such. But Kripke argues that it might have been that Hesperus was not the brightest object visible in the evening; it might have been destroyed millenia ago, or it might have been struck by a comet and left the solar system. So again, it seems that a name is not semantically equivalent to a description.

Kripke uses this to argue that it is not necessary that Hesperus is the brightest object visible in the evening sky, since it might have been otherwise. Or as it is sometimes put: it is not metaphysically necessary that Hesperus is visible in the evening, and it is metaphysically possible that it is not. In a similar way, he argues that there are possible worlds in which the evening star is not Hesperus: in a world where Venus was knocked off course by a comet and in which another object is visible in the evening, the evening star is not Hesperus but some other object.

He argues in a similar way that there are no possible worlds in which Hesperus is not Phosphorus. If Venus had been visible only in the morning with something else visible in the evening, this would have been a scenario in which Hesperus was not visible in the evening, and not a scenario in which Hesperus was not Phosphorus. He argues that Hesperus and Phosphorus are the same object (the planet Venus) in all worlds in which they exist. So `Hesperus is Phosphorus (if they exist)' is necessary.

Kripke puts this by suggesting that names are rigid designators, picking out the same object in all possible worlds. Most descriptions, in contrast, are not rigid: they pick out different objects in different possible worlds. So names are quite unlike descriptions. Where names are concerned, Kripke's view is closer to the simple view than to the Fregean view: the meaning of a name is simply its referent, and not any associated description or sense.

Kripke gives related arguments concerning natural kind terms. Take the case of `water' (Kripke does not concentrate on this case, but it is useful to stick to the familiar case). It can be argued that water might have behaved and appeared quite differently from the way in which it actually behaves and appears: it might never have appeared in liquid form, for example (witness the possibility of ice in the actual world). More generally, for any description D of water's macroscopic properties, it can be argued that if H2O had
not been D, water would not have been D. So it is not necessary that water is D, and it seems that natural kind terms are not equivalent to descriptions.

In a similar way, it can be argued that something might have satisfied any such description D without being water. In Putnam's Twin Earth world, a different chemical substance XYZ has all the superficial properties of water. But Putnam argues that this substance is not water. That is, in a counterfactual scenario in which XYZ was watery, XYZ would not be water. Rather, water is necessarily H2O. If so, `water' is akin to a rigid designator: it picks out H2O in all worlds.

Do Kripke's arguments have any force against the intensional framework I have outlined here? Do they show, for example, that names or natural kind terms do not have epistemic intensions that satisfy (1)-(4)? One might think that they do. I have argued that Hesperus has an epistemic intension that picks out something like an object visible in the evening, in any given world. So in a world where Mars rather than Venus is prominent in the evening sky, the epistemic intension will pick out Mars. But Kripke argues that Hesperus picks out Venus in all worlds, and that it needs not pick out the evening star, or anything like it.

The conflict is only superficial, however. Kripke takes care to distinguish metaphysical possibility from epistemic possibility. And he allows that it is epistemically possible that Hesperus is not Venus; he simply denies that it is metaphysically possible. Kripke allows that it might turn out that Hesperus is not Phosphorus; and he can allow that if it turns out that Venus was never visible in the evening but that Mars was, then it may turn out that Hesperus is not Phosphorus but Mars. So his argument is entirely compatible with `Hesperus' having an epistemic intension that functions roughly as I have suggested. Much the same applies to `water', and to other relevant terms.

This response is not ad hoc. The sort of possibility that is most relevant to a Fregean view is clearly epistemic possibility. When one thinks about sense in intensional terms, one thinks of it as giving criteria for the extension of an expression depending on how the world turns out. If the world turns out one way, it will turn out that water is H2O; if the world turns out another way, it will turn out that water is XYZ. Nothing in Kripke's modal argument gives any reason to deny this. And the notion of sense was always tied to epistemic notions such as apriority, not to notions such as `metaphysical necessity'. These connections are entirely preserved, even in the light of Kripke's argument.

The other crucial property of sense was that it determines an expression's extension in the actual world. Again, Kripke's argument does nothing to suggest that this is not the case. The epistemic intension determines an expression's actual extension when evaluated at the actual world. For all Kripke has said, it also determines an expression's extension under all epistemically possible hypotheses about the actual world.

What an epistemic intension does not do, if Kripke's arguments are correct, is determine an expression's extension when evaluated in explicitly counterfactual scenarios. When we consider these scenarios, we are not considering them as epistemic possibilities: as ways things might be. Rather, we are acknowledging that the character of the actual world is fixed, and are considering these possibilities in the subjunctive mood: as ways things might have been. That is, rather than considering the possibilities as
actual (as with epistemic possibilities), we are considering them as counterfactual. If Kripke is right, then evaluation in this sort of explicitly counterfactual context works quite differently from the evaluation of epistemic possibilities. This point still needs explaining.

It is striking that all of Kripke's conclusions concerning modality are grounded in claims concerning what might have been the case, or what could have been the case, or what would have been the case had something else been the case. Kripke is explicit (1980, pp. 36-37) in tying his notion of necessity to these formulations, and almost all of his arguments for modal claims proceed via these claims. What all these formulations have in common is that they involve scenarios that are acknowledged not to be actual, and that are explicitly considered as counterfactual scenarios.

All these claims are subjunctive claims, not in the syntactic sense, but in the semantic sense: they involve hypothetical situations that are considered as counterfactual. The paradigm of such a claim is a subjunctive conditional: `if P had been the case, Q would have been the case'. We can say that all these claims involve a subjunctive context, where a subjunctive context is one that invokes counterfactual consideration. Such contexts include those created by "might have", "would have", "could have", or "should have" (on the non-epistemic readings of these phrases), subjunctive conditionals involving "if/were/would be" or "if/had/would have", and other phrases. In Kripke's sense of "possible" and "necessary", where it taken to be possible that P if it might have been the case that P, then modal contexts such as "It is possible that" and the like can be considered as subjunctive contexts, too.

Kripke's central point against the description theory was that names and descriptions function differently in modal contexts: for a name `N' and a description `D', it is necessary that D is D (if it exists), but it is not necessary that N is D. We can put this somewhat more precisely by saying that names and descriptions function differently in subjunctive contexts. And more generally, names and descriptions seem to behave differently under subjunctive evaluation of hypothetical possibilities. How can a Fregean view handle this phenomenon?

I have not argued that names are equivalent to descriptions. I do allow, however that a name and a description can have the same sense, at least approximately and in some cases, as the case of `Hesperus' suggests. If so, then if Kripke's point is accepted, we must explain the different truth-value of subjunctive sentences by appealing to something other than than a difference in sense. So the question is: why is `it might have been that Hesperus was not the evening star' true, while `it might have been that the evening star was not the evening star' is false, given that `Hesperus' and `the evening star' have (roughly) the same sense?

There are a number of ways in which one might try to explain this. First, one might appeal to a difference in underlying logical form between subjunctive sentences containing names and descriptions. One could hold that in subjunctive contexts, names always take wide scope, so that the sentence involving `Hesperus' above has the logical form of `Hesperus is such that it might not have been the evening star'. Or one could hold that names always involve an unarticulated `actual', so that the sentence has the logical form of `it might have been that the actual Hesperus was not the evening star'. Once this logical form is in place, then substituting `the evening star' for `Hesperus' yields the same truth-value. On such a view, the
difference in the original sentences was solely due to a difference in underlying logical form, not in semantic content.

These explanations merit considerable discussion, but I will set them aside here. The second sort of explanation appeals to a semantic difference between names and descriptions, in some aspect that goes beyond their sense, and that affects how they function in subjunctive contexts. On such a view, a name may have sense and extension, but sense and extension do not exhaust the meaning of a name.

The simplest addition to the Fregean framework would be a semantic feature that is part of the meaning of all names but not part of the meaning of descriptions. When present in the meaning of an expression, this feature would indicate that within counterfactual contexts, the expression contributes its actual extension. There will be a correspond semantics of counterfactual contexts, such that the presence or absence of the feature is relevant to the truth-value of counterfactual statements. (Recanati (1993) proposes a feature he calls `REF' that works something like this, though he conceives of it differently.) This will explain the difference between names and descriptions.

I favor a more general semantic explanation. On this account, every expression is associated with two intensions: one governing its application to epistemic possibilities, and one governing its application to explicitly counterfactual possibilities. The first of these is the epistemic intension. The second is a subjunctive intension. Like the epistemic intension, this is a function from worlds to extensions. But here the worlds in question are seen as counterfactual metaphysical possibilities, and expressions are evaluated in these worlds in the way in which we evaluate counterfactual scenarios.

Just as the epistemic intension mirrors the way that we describe and evaluate epistemic possibilities, the subjunctive intension captures the way that we describe and evaluate subjunctive counterfactual possibilities. To evaluate the subjunctive intension of a sentence S in a world W, one can ask questions such as: if W were the case, would S be the case? For example, if W is a world in which Venus was knocked off course by a comet and in which Mars was prominent in the evening, we can say the following. If W were the case, Hesperus would not be visible in the evening; if W were the case, Hesperus would still be Phosphorus, and would still be Venus; if W were the case, Hesperus would not be Mars. So the subjunctive intension of `Hesperus is Phosphorus' is true in W.

The same sort of thing applies to a natural kind term, such as `water'. If W is the Twin Earth world, we can say: if W were the case, water would still be H2O, not XYZ. So the subjunctive intension of `water' is false in that world, and the subjunctive intension of `water' picks out H2O in that world. One can tell a related story for a general term such as `cat', whose subjunctive intension will pick out a class of members of a particular biological species in all worlds, and for a property term such as `hot', which will arguably pick out a certain sort of molecular motion in all worlds. (Note that at least in the 'cat' case, the extension is a different class in each world, and is not always the actual extension. This can be handled straightforwardly by a subjunctive intension, but it is harder for the other accounts above to handle, as they rely wholly on projecting the actual extension.)
Something similar applies to an indexical such as `I'. The epistemic intension picks out the being at the center of a world, but the subjunctive intension does not. The subjunctive intension of my use of `I' picks out me (David Chalmers) in all worlds. I can say `if David Chalmers were in a coma, then I would be in a coma', and so on. In evaluating counterfactual scenarios, `I' always picks out David Chalmers (though of course, he need not be called that). So we do not need a center to evaluate the subjunctive intension of `I'; and more generally, the worlds in the domain of subjunctive intensions can be taken to be standard uncentered worlds, not centered worlds.

Just as every expression has an epistemic intension, every expression will have a subjunctive intension. This intension will be a function from worlds to extensions of the appropriate sort: individuals, truth-values, and so on. And as long as the extension of a sentence depends on the extensions of its parts, the subjunctive intension of a sentence will depend on the subjunctive intension of its parts.

A name and a description may have similar epistemic intensions and similar extension, but their subjunctive intensions will be very different. This can be seen by examining world W above. Here we can say that if W were the case, then Hesperus would still be Venus, but the evening star would be Mars. So the subjunctive intensions of `Hesperus' and `the evening star' are distinct. The former picks out Venus in all worlds, while the latter picks out something that is visible in the evening in all worlds. More generally, the subjunctive intension of a name picks out its actual extension in all worlds, while the subjunctive intension of a description picks out the object that satisfies the description in all worlds.

The subjunctive intension of a name depends directly on its actual extension. The extension of a name can usually not be known a priori, so the subjunctive intension cannot be known a priori, either. If we lack relevant empirical information about the actual world, we might be unable to evaluate an expression's subjunctive intension at a counterfactual world, even given a detailed specification of that world. For similar reasons, two names (such as `Hesperus' and `Phosphorus') may have the same subjunctive intension without the subject knowing that a priori. The same goes for natural kind terms and indexicals. So subjunctive intensions do not reflect the cognitive significance of the expressions involved. This contrasts with the subjunctive intensions of descriptions, which can often be evaluated a priori (at least if the descriptions contain no names, natural kind terms, or indexicals), and it contrasts with epistemic intensions, which can generally be evaluated a priori for any expression.

Subjunctive intensions are most directly relevant to the evaluation of subjunctive sentences. When an expression occurs in a subjunctive context (`it might have been that S'; `if S had been the case, T would have been the case'; `if A were B, C would have been D'; and so on), its subjunctive intension is used in evaluating the truth-value of the sentence. For example, `it might have been that S' (at least in the relevant sense of `might have been') will be true iff the subjunctive intension of S is true at some world. `If S had been the case, T would have been the case' is true roughly iff the nearest world that satisfies S's subjunctive intension satisfies T's subjunctive intension. And so on.

Subjunctive intensions are also relevant to the evaluation of modal contexts, at least when these are interpreted the Kripkean way. `It is necessary that S' will be true iff S's subjunctive intension is true at all worlds. `Possibly, T' will be true if T's subjunctive intension is true at some world. This is what we would
expect, given that \`It is possible that T' will be true precisely when \`It might have been that T' is true.

By analogy, epistemic intensions are relevant to the analysis of analogous epistemic contexts. The indicative conditionals 'If P is the case, then Q is the case' or 'If it turns out that P, it will turn out that Q' are true (or assertible) for a subject approximately when the epistemically nearest world that satisfies P's epistemic intension also satisfies Q's epistemic intension, where "epistemically nearest" is defined in a way that depends on the subject's knowledge or perhaps beliefs. (See "The Tyranny of the Subjunctive".) And \`it is a priori that P' will be true if P has a necessary epistemic intension.

(The material from here on is a somewhat more elaborate development of this framework, and can be skipped by those who prefer to move on.)

The subjunctive intension of an expression is always determined by the epistemic intension of the expression and by the character of the actual world. Because of this, it is possible in principle to associate a two-dimensional intension with an expression, which captures how its subjunctive intension will vary, depending on which epistemic possibility turns out to be actual. This two-dimensional intension can be thought of as a function from pairs (V, W) of epistemic possibilities and metaphysical possibilities to extensions.

To evaluate the two-dimensional intension of a statement S at a pair of worlds (V, W), one can ask: if V is actual, then if W were the case, would S be the case? This is reflected in some more natural English constructions: for example \`if water is XYZ, then water could not be H2O'. To determine the truth-value of statements like these, one needs the full two-dimensional intension, as neither epistemic intension nor the subjunctive intension of the terms involved carries information about how to evaluate subjunctive statements under alternative epistemic possibilities. So for a fully general account of sentence's truth-values, one needs at least the full two-dimensional intension, although its full structure will be relevant only in rare cases.

Like an epistemic intension but unlike a subjunctive intension, a two-dimensional intension can be evaluated a priori. One needs no empirical information about the actual world, since all the relevant information is specified in the epistemic possibility. One might hold that the two-dimensional intension represents the true \`cognitive significance' of an expression, if one holds that the difference between the behavior of names and descriptions in counterfactual contexts represents a difference in cognitive significance; so one could hold that the two-dimensional intension is a Fregean \`sense' in some expanded understanding of the term. But we do not need to adjudicate that matter here.

An expression's actual subjunctive intension will correspond to the \`row' of the two-dimensional intension that results when the actual (centered) world is used as the epistemic possibility parameter; this cannot be evaluated a priori precisely because we do not know which epistemic possibility is actual. It is tempting to reconstruct an expression's epistemic intension as the \`diagonal' of the two-dimensional intension, which results when the same centered world is used as the epistemic possibility parameter and (in an uncentered version) as the metaphysical possibility parameter. This depends on just how the worlds are understood, however.
As before, there are two ways of understanding the worlds that function as epistemic possibilities. They can be understood as the same worlds that function as metaphysical possibilities, with the addition of a center. Or they can be understood as a separately defined class of worlds. The first option is more elegant, but requires a substantive philosophical theses about possibility. The second option is more complex, but it requires fewer philosophical commitments. A philosopher who holds that the existence of a god is metaphysically necessary but not a priori can embrace the second option but not the first, for example.

If one takes the second option: then one has two distinct classes of worlds, the epistemically possible worlds and the metaphysically possible worlds. These worlds may have certain relations to each other, but the two sets are nevertheless disjoint. One can evaluate a statement in an epistemically possible world, yielding the value of its epistemic intension there, and one can evaluate it in a metaphysically possible world, yielding the value of its subjunctive intension there. But because the spaces are distinct, there is no natural way to map epistemic possible worlds onto metaphysically possible worlds. As a result, one cannot reconstruct an epistemic intension as the `diagonal' of the two-dimensional intension, and various other elegant properties are removed. This view also has the disadvantage of requiring a strong underlying modal dualism, with distinct modal primitives for each space of worlds.

If one takes the first option: then the worlds that function as epistemic possibilities are the same as the worlds that function as metaphysical possibilities, with the addition of a center. So epistemic intensions and metaphysical intensions are defined over (almost) the same space of worlds. To evaluate an expression's epistemic intension is evaluated at a world, we consider the world as an epistemic possibility: as a way our world might actually be. To evaluate an expression's subjunctive intension at a world, we consider the world as an explicitly counterfactual possibility: as a way our world might have been, but (probably) is not. One can say that in the first case, we consider the world as actual; in the second case, we consider the world as counterfactual.

The first option is compatible with all the familiar cases. Take the case of `water', and consider a Twin Earth world where the watery stuff is XYZ (near the center, if required), and where H2O is not watery. When we consider this world as actual, it is an instance of the epistemic possibility that water is XYZ: if W is actual, then water is XYZ. When we consider this world as counterfactual, it is an instance of the metaphysical possibility that water is H2O: if W had been actual, then water would still have been H2O, not XYZ. Something similar applies in all the familiar cases.

One might ask: is W itself a world where water is XYZ, or a world where water is H2O? On a standard philosophical view, it is the latter, not the former. This is because the phrase `a world in which S' is almost always read as invoking a world W in which the subjunctive intension of S is true, or for which S is true when W is considered as counterfactual. My own view is that this reading is arbitrary, and that the phrase `a world in which S' is ambiguous between readings that invoke epistemic and subjunctive intensions. If so, there is no determinate answer to the question above. To remove the ambiguity one can define new locutions: for example, when the epistemic intension of S is true in W, then W is a world at which S; when the subjunctive intension of S is true in W, then W is a world of which S. In any case, this terminological issue does not matter too much for our purposes. As long as we are always clear about
how we are evaluating statements, and have clear conventions for understanding the relevant phrases, no confusion should result.

If the first option is accepted, various matters become more straightforward. Because there is only one space of worlds (apart from the difference involving centers), one can reconstruct an epistemic intension from the two-dimensional intension as a 'diagonal' intension, where the value of the epistemic intension at W is the value of the two-dimensional intension evaluate at W (considered as actual) and an uncentered version of W (considered as counterfactual). This view is also much simpler metaphysically, since it is compatible with a deep underlying modal monism, with just one space of worlds. Of course there is still a dualism of epistemic and metaphysical possibility in language, but this simply arises from the dual nature of semantic evaluation over a single space of worlds.

Given that any sentence S has an epistemic intension and a subjunctive intension, someone might ask: which of these is the content of S? Which of these gives the truth-conditions of S? What is the proposition expressed by S? My view is that we need not settle these questions one way or another. We can say that the epistemic intension is S's epistemic content and that the subjunctive intension is S's subjunctive content. As for the content of S (unqualified), this is a complex content that subsumes both of these and possibly more. Similarly, S has epistemic truth-conditions (showing how S's truth depends on how the world turns out), and subjunctive truth-conditions (showing how S's truth varies in counterfactual possibilities).

As for propositions, I have avoided this terminology, as it is multiply ambiguous. If one's conception of a proposition is a set of possible worlds (or something similar, such as a structure of intensions), then one could say that S expresses two propositions, an epistemic proposition and a subjunctive proposition. But if one's conception of a proposition is more generally of what remains semantically of S once the arbitrary clothing of a given language is stripped away, then one could say that S expresses a complex proposition with a two-dimensional structure. One should not run these two conceptions together: for example, the fact that an utterance of S expresses two propositions in the first sense in no way entails that the utterance is ambiguous, since ambiguity would involve expressing two propositions in the second sense. For my part, I prefer to use 'proposition' in the second, more general way; but I will largely avoid the expression here.

It is sometimes objected that the epistemic intension cannot be part of the content expressed by S at all, since it is really a matter of the content that S would have expressed had a token of S been present in a different context. This is a mistake. As we saw earlier, the epistemic intension of S can be evaluated in worlds that contain no token of S, and even if a world does contain such a token, its presence is usually irrelevant to evaluating an epistemic intension there. The epistemic intension of S is not defined in terms of counterfactual tokens of S at all. Rather, it is defined in terms of the first-order use of an actual expression S in evaluating various epistemic possibilities. This is precisely analogous to the way that the subjunctive intension of S is defined in terms of the first-order use of S in evaluating counterfactual possibilities. So epistemic intensions and subjunctive intensions are on a par here.

One could define the contextual intension of S as a function that maps centered worlds containing a token
of S at the center to the extension of that token in that world. This might resemble an epistemic intension in some ways, but it would not be an epistemic intension. First, an epistemic intension will be defined over many more worlds. Second, it is unclear just what it takes to be a token of S, and depending on what we require, the contextual intension may give very different results from an epistemic intension. If only orthographic properties are required, then there will be worlds where a token of 'water' refers to horses or to the number two. If the same extension is required, then a token of a name such as 'Hesperus' will pick out the same individual (Venus) in all worlds. Perhaps there is an intermediate requirement that gives roughly the same results as an epistemic intension, but this is not obvious. The obvious suggestion is to presuppose the notion of an epistemic intension, and require that a token of S have the same epistemic intension of S. However one does things, there is not much point in defining such a notion, since we have epistemic intensions to do the job already.

This matter bears on the two-dimensional semantic frameworks developed by Kaplan (1989) and Stalnaker (1974). The framework I have developed here resembles these in obvious respects, and it owes much to them. Epistemic intensions are analogous in certain respects to Stalnaker's "diagonal propositions" and to a version of Kaplan's "character", and subjunctive intensions are much the same as Stalnaker's "propositional content" and Kaplan's "content". But there are crucial differences. First: on Kaplan's and Stalnaker's frameworks, the analogs of epistemic intensions are defined in terms of the analogs of subjunctive intensions, whereas on the framework I have outlined, they are defined quite independently of subjunctive intensions. Second and most important: on Kaplan's and Stalnaker's frameworks, the worlds on the first dimension of evaluation are not considered as epistemic possibilities but as contexts of utterance, where evaluation requires the presence of a token of the expression within the context. As a result, this first dimension of evaluation yields a contextual intension, not an epistemic intension.

These features lead to strong limitations on using these frameworks for epistemic purposes, which both Kaplan and Stalnaker note. Kaplan's framework yields useful epistemic results only for indexicals and demonstratives, and not for names and natural kind terms. This is because the contextual intensions for indexicals and demonstratives behave much like their epistemic intensions, but the contextual intensions for names and natural kind terms behave very differently. (A name arguably picks out the same individual in every context, but it can apply to different individuals within epistemic possibilities.) Stalnaker (1999) argues that his "diagonal proposition" does not reflect matters of apriority directly, partly because of the problems involved in holding the meaning of an utterance constant across contexts. It seems that these frameworks are useful for epistemic purposes precisely to the degree that the notions involved resemble epistemic intensions.

A strong Fregean might criticize this framework from the other side, holding that only epistemic intensions, not subjunctive intensions, are part of the content of a sentence, and the subjunctive behavior can be accounted for by appealing to logical form or to a simpler semantic feature, as above. This matter is not cut and dried, but there are a number of advantages to including subjunctive intensions as an explicit semantic value.

First, subjunctive intensions allow a direct parallel between the treatment of apriority and of necessity,
and between epistemic and subjunctive evaluation. Second, subjunctive intensions give a more general account of subjunctive behavior than accounts that rely on actual extension, and consequently can more easily account for the distinctive subjunctive behavior of certain terms, such as 'cat'. Third, we have at least one content (the subjunctive intension) associated with an expression that is "objective" in the way that Frege required. Fourth, people have intuitions about "what is said" by an expression which at least sometimes better reflect subjunctive intensions than epistemic intensions (e.g. when I say 'I am Australian' and you say to me 'You are Australian', there is a sense in which we say the same thing, although our epistemic intensions differ). Fifth, the presence of subjunctive intensions allows for a degree of continuity with current philosophical frameworks in which a notion of "propositional content" closely tied to subjunctive intensions plays a central role, and allows a Fregean to retain some of the insights of this tradition rather than discarding them completely.

The addition of subjunctive intensions certainly goes beyond Frege's view. But it is a supplement to the view rather than a radical overhaul of the view. Senses, or epistemic intensions, are still present and playing the same role they always played. Sense and extension have merely been supplemented by a further semantic value in order to deal with various subjunctive and modal phenomena. Frege did not address these phenomena directly, so it is hard to know how he would have dealt with them. But I think this framework is compatible with the broad spirit of his views.

7 The epistemological argument

Kripke's second central argument against descriptive views of language is an epistemological argument. Kripke recognizes that a description theorist might accept that names are not modally equivalent to descriptions, but might nevertheless hold that names are epistemically equivalent to descriptions. So he raises some quite different considerations to argue that this is not the case. Again, while these arguments are most explicitly aimed at a description theorist, they are generally taken to have force against any broadly Fregean view.

The argument proceeds roughly as follows. The description theorist will hold that a name N (say, 'Gödel'), as used by a given speaker, is epistemically equivalent to some description or cluster of descriptions D (say, 'the person who proved the incompleteness of arithmetic'). On such a view, 'N (if it exists) is D' will be a priori for the speaker. But Kripke argues that no such sentence is a priori. In effect, he does this by arguing that for any description D, it is epistemically possible for the speaker that N is not D. If so, then N is not epistemically equivalent to D.

Take the name 'Gödel'. A speaker may associate a number of descriptions with her use of the name: 'the person who proved the incompleteness of arithmetic', and so on. But Kripke argues that there are (epistemically possible) scenarios in which the name 'Gödel' will turn out to refer to a person who does not satisfy any of the descriptions. So the speaker cannot know a priori that Gödel (if he exists) satisfies any of the descriptions.

One can put the argument strategy as follows. Take the name 'Gödel' and the description `the man who
discovered the incompleteness of arithmetic'. Then there is an epistemically possible scenario in which the incompleteness of arithmetic was discovered by a man named `Schmidt', and in which the proof was stolen and published by a man named `Gödel', to whom the proof was thereafter attributed. If this scenario is actual, then the speaker's term `Gödel' refers to the second man, not to the first. So it is epistemically possible for the speaker that Gödel did not prove the incompleteness of arithmetic, and there is no a priori equivalence between the name and the description.

Kripke argues that the same can be done for any description associated with the name (such as `the man to whom the discovery of the incompleteness of arithmetic is commonly attributed'). There will always be epistemically possible scenarios such that if they are actual, the speaker's term `Gödel' refers to someone who does not satisfy the description. (For example, a scenario in which the discovery is now commonly attributed to Hilbert, without the speaker realizing.) If this is right, then the name cannot be equivalent a priori to any description.

Kripke argues that there are actual cases in which most of the associated descriptions are false of the referent, as with the case of Peano, who did not discover the axioms associated with him, or with Jonah, who was probably not swallowed by a whale. So here it is not even true, let alone a priori, that the two are coextensive. And he also argues that there are some names such that the speaker has no associated description that could fix reference: a speaker can use the term `Feynman' to refer to Feynman while knowing nothing more than that he is a famous physicist, for example, where that description is satisfied by many individuals. So again, it seems that reference is not fixed descriptively.

Does this argument against the description theory yield an argument against the intensional framework I have been outlining? It seems clear that it does not. This argument works with a conception of descriptions on which they correspond to linguistic expressions. When Kripke argues that the speaker the descriptions that the speaker "associates with" the name cannot fix reference, he always invokes linguistic descriptions that the speaker associates with the name, or at least explicit beliefs. But the intensional framework is not committed to the idea that descriptions always correspond to linguistic expressions; in fact, at least part of the motivation of the framework comes from an independent rejection of this idea. And the intensional framework is not even committed to the idea that the intensions associated with a name correspond to explicit beliefs of the speaker. So there is no clear argument against the intensional framework here.

In fact, Kripke's central method of argument seems to be obviously compatible with the intensional framework. A proponent of this framework could cast the argument strategy as follows. We want to show that for a given name N and description D, `N is D' is not a priori. To do this, we consider an epistemically possible world W with certain properties. We then reflect on a question such as the following: if W turns out to be actual, will it turn out that N is D? And we find that the answer is no. If so, the epistemic intension of `N is D' is false in W. So `N is D' is a priori.

On this interpretation, when we think about the Gödel/Schmidt case, for example, we are tacitly evaluating the epistemic intension of `Gödel' at a world specified as in the example. When we consider that world as an epistemic possibility, it reveals itself as an instance of the epistemic possibility that
Gödel did not discover incompleteness. That is, we find that the epistemic intension of `Gödel' does not pick out the prover in this world; it picks out the publisher. If so, the epistemic intensions of `Gödel' and of `the man who discovered the incompleteness of arithmetic' are distinct.

In a way, what is going on here is analogous to what goes on in the analysis of a term such as `knowledge', as discussed above. Someone might hold that `knowledge' is equivalent a priori to some description, such as `justified true belief'. But then we come up with a scenario such that in that scenario, something falls within the extension of `justified true belief' but not of `knowledge'. So we conclude that the two are not equivalent a priori. The process repeats itself for other descriptions, suggesting that `knowledge' is not a priori equivalent to any such description. This suggests that the intension of `knowledge' cannot be precisely captured in a linguistic description.

In a similar way, Kripke's arguments suggest that the epistemic intension of a name such as `Gödel' cannot be precisely captured in a linguistic description. But they do nothing to suggest that the epistemic intension does not exist. And the epistemic intension still mirrors the cognitive significance of the name. The identity `N is D' is a posteriori precisely because the two expressions have different epistemic intensions; that is, precisely because there is an epistemic possibility where they come apart. And the subject has the ability to evaluate the name's referent within this epistemic possibility, just as can be done with expressions in general.

The intension of an expression such as `knowledge' can at least be approximated by certain linguistic descriptions, such as `justified true belief', and by longer and longer versions that come gradually closer to the true intension. One might wonder whether something similar can be done with a name such as `Gödel'. Can the epistemic intension of the name in the case above at least be approximated by a linguistic description? This is not compulsory for the intentional framework, but it can at least be enlightening to look. A side benefit is that it provides some sort of at least approximate account of the features of the world in virtue of which the epistemic intension applies.

To answer this question, one needs to consider: when speakers use a name such as `Gödel' or `Feynman' in cases such as those above, how do they determine the referent of the name, given sufficient information about the world? For example, if someone knows only that Feynman is a famous physicist and that Gell-Mann is a famous physicist, how will external information allow her to identify the distinct referents of `Feynman' and `Gell-Mann'? The answer seems clear: she will look to others' use of the name. Further information will allow her to determine that members of their community use `Feynman' to refer to a certain individual, and that they use `Gell-Mann' to refer to a different individual. Once she has this information, she will have no problem determining that her own use of `Feynman' refers to the first, and that her own use of `Gell-Mann' refers to the second.

This suggests if we want to approximate the epistemic intension of the speaker's use of `Feynman' in a description, one might start with something like `the person called 'Feynman' by those from whom I acquired the name'.[*] It certainly seems that if relevant information about others' uses is specified in an epistemic possibility, then this sort of description will usually give the right results. The same goes for the `Gödel' epistemic possibility. In all these cases, it seems that a name is being used deferentially: in using
On Sense and Intension

a name, the speaker defers to others who use the name. So maybe the description above is is at least a
good first approximation.[*]

*Kripke considers some potential descriptions in this vicinity. He discusses `the man Jones calls 'Gödel'' (1980, p. 92),
where the speaker believes he acquired the name from Jones, and dismisses it on the ground that the belief may be false.
And he discusses `the man called 'Glumph' from the people from whom I got it (whoever they are), provided that my
present determination of the reference satisfies the conditions sketched in Naming and Necessity and whatever other
conditions need be satisfied' (1980, p. 162), and dismisses it on grounds connected to the second part of the description.
Strangely, he never considers the obvious intermediate description that avoids both of these problems.]

*[*Replies to Kripke's epistemic arguments that appeal to metalinguistic descriptions of this general sort are given by by

There are two sorts of objections that might be made to this sort of description. First, it might be held that
it does not always give the right results. For example, it may be epistemically possible that the speaker
misheard or misremembered the name, and that others were really using the name `Fireman'. In such an
episodic possibility, the description above will give the wrong results. But this is just the sort of thing
that we should expect, given the imperfection of descriptions. As with `knowledge', we could try to move
closer approximations. Perhaps `The referent of the relevant name used by the person from whom I
acquired the antecedent of my current term `Gödel'' would do a better job. But no doubt there would be
further counterexamples, just as with `knowledge'. But as in all these cases, the most this shows is that
any such approximation is imperfect. One refutes these approximations by evaluating the epistemic
intension in certain epistemic possibilities and showing that the approximation gives the wrong results; so
this sort of argument does nothing to show that the epistemic intension does not exist.

Second, it might be held that this sort of description is "circular", perhaps because it appeals to the notion
of reference. The circularity is not obvious, however. If one appealed to the notion of reference in a
definition of `reference', there would be a danger of circularity. But a definition of `reference' is not being
offered here. If the descriptivist were to offer a definition of `reference' it might be something like
whatever satisfies a canonical description D associated with N'. This is a general, uncircular definition
with no appeal to reference (except in the notion of satisfying a description, which presumably is to be
accounted for separately). At worst there is a danger that if a description D involves `reference', it will not
yield a determinate result, since evaluating the description will require evaluating reference, which will
require evaluating another description, which will require evaluating reference, and so on. But a
descriptivist can reply that this is merely a recursive situation, not a circular one, and that the process will
always eventually be grounded in a use of the name whose associated description does not involve
`reference' at all, such as an initial baptism. The descriptivist might even hold that this is a natural way to
capture the insights of the causal theory of reference in a descriptivist framework: reference proceeds
through recursive deference to others, ultimately grounded in an initial baptism.

In any case, this worry does not arise on the intensional framework. The epistemic intension of a name is
simply a function from worlds to individuals that reflects a rational ability to determine a specific
individual in a given epistemic possibility. It is not a description, and so makes no use of `reference'.
Perhaps one might worry that if something like the picture above is right, then evaluating the epistemic intension of a term like ‘Gödel' at a world will require having explicit information about others' reference within that world, and that this would be circular. It is not clear why this would be circular, but in any case, explicit information about reference would not be required. Information about the epistemic intensions that others associate with various names would suffice (along with other information about causal relations, the properties of various objects, and so on). This information might itself be derivable from information about other mental and/or physical states, or it might be some sort of mental primitive; that does not matter. With information about others' epistemic intensions, reference will be determined. And if there is a worry about evaluating others' epistemic intensions given that they are deferential also, then knowledge of epistemic intensions across a whole community (including its history) will suffice, since the deference will ultimately be grounded in a nondeferential use.

So given relevant information about the physical and mental states of individuals in the community, there will be no problem evaluating the epistemic intension. And the use of this information is in no way ad hoc; it corresponds to the information that we use in evaluating reference across various epistemic possibilities. In particular, when a name is used deferentially, information about the linguistic and cognitive practices of others will always be relevant.

Of course not every use of a name is a deferential use, so not every epistemic intension will function in this way. When a name is introduced in an initial baptism, there will be no deferential element involved; to evaluate reference in the actual world (and across epistemic possibilities), the speaker will not usually need information about the cognitive states of others. The same goes for some names used for very familiar referents. Say that a wife uses the name ‘Fred' for her husband and has done so for years. In such a case, even were the speaker to discover (to her surprise) that no-one else in the community used that name for her husband, she would still reasonably hold that the name she uses refers to the spouse. If such a situation turned out to be actual, her utterance 'Fred is my husband' would plausibly be true, not false. This suggests that the epistemic intension of her use of the name has no deferential element.

There are also many intermediate cases, where a name is used with some mixture of deferential and nondeferential elements, so that for a speaker to determine reference of the name, relevant information will include both information about others' usage and independent information about properties of the referent (perhaps corresponding to some of the speakers' beliefs involving the name). This sort of intermediate case will be necessary to account for cases such as ‘Madagasar' (Evans 1977), where the referent of our use of the name (an island) differs from the referent of the usual use (part of mainland Africa). If every use since the initial baptism was entirely deferential, this could not happen. So some uses in the causal chain must have been not entirely deferential, with epistemic intensions that were partly influenced by a speaker's beliefs. It is easy to imagine that even if the beliefs have only a small influence on a given speaker's epistemic intension, the effect of this influence would amplify as a causal chain proceeds. If every speaker in the chain has a small component of influence from the belief, then deference to a speaker whose epistemic intension is also influenced by the belief will increase the effect. In the case of ‘Madagascar', the result might be that uses of the name would initially refer to the mainland location, would proceed through a period of divided reference, and would eventually emerge as referring to the island.
(One other subtlety: to evaluate a deferential use of the name in an epistemic possibility, the speaker may need the name itself (as used by her) to be present in an epistemic possibility, so that she can determine where that name was acquired. This suggests that deferential uses are exceptions to the principle that tokens of an expression need not be present within an epistemic possibility. I think that this sort of case is best handled by having one or more optional marked thoughts (`this thought') present at the center of a world, which be used to trace deferential reference in an epistemic possibility.)

Kripke also gives an epistemological argument against descriptive views of natural-kind terms (1980, pp. 116-23). He argues that it is not a priori that gold is yellow, or that tigers are striped, and so on, in effect because there are epistemic possibilities in which these statements could turn out to be false (if we were suffering from various illusions, for example). In a similar way, Putnam (1975) argues that it is not a priori that cats are animals, since there are epistemic possibilities in which it would turn out that they are robots from Mars. As before, these arguments do not apply to the intensional account: they proceed by evaluating an epistemic intension at various epistemic possibilities, and they show at most that the epistemic intensions is not equivalent to the relevant descriptions. They also suggest that a causal link between the term and the referent plays an important role; so any better descriptive approximation of the intension should give a significant role to this link.

I conclude that the epistemological arguments have no force against an intensional account of Fregean sense.

8 The argument from variability

Another argument against Fregean view is rarely articulated explicitly,[*] but it may lie in the background of some opposition to the Fregean view. This argument notes that different speakers may associate different cognitive significance with the same name. For example, an identity such as "Bill Smith is William Smith" may be cognitively significant for one speaker (e.g. one who has heard of the same person under two names in two different contexts), and cognitively insignificant for another (e.g. the person's partner, who uses both names indiscriminately). So if Fregean sense is to reflect cognitive significance, then the sense of a name must vary between speakers. But if the sense of a name can vary between speakers, it is not part of the meaning of the name at all. The same may apply to other expressions, such as natural kind terms: the cognitive significance of such a term is variable, so its sense must be variable, so its sense cannot be part of its meaning.

[*][Frege himself (19xx) addresses objections based on variability, in the context of indexicals rather than names. Burge (1979) stresses that Frege's conception of sense differs from contemporary conceptions of linguistic meaning, in part because of variability.]

We need not spend much time on the first part of this argument. On the account I have given, it is clear that the epistemic intension of a name can vary between speakers. We saw this in the discussion just concluded: the first user of a name may use the name with one epistemic intension, and later users may use it with a quite different epistemic intension. When Leverrier introduced the term `Neptune' as a term
for whatever planet was perturbing the orbit of Uranus, then the epistemic intension of his use of the term functioned roughly as described. But the next speaker - perhaps his wife, who knew only that Neptune was an astronomical object for which her husband was searching - might have used it with a different epistemic intension. And later users might well use it in a deferential way (as with `Feynman' above), with an epistemic intension that reflects this. So different speakers can clearly have different epistemic intensions for the same name.

The same might apply to natural kind terms, though this is not quite so clear. For example, two speakers might have been exposed to different forms of water: one has only been exposed to water in liquid form (knowing nothing of a solid form), and the other has been exposed only to water in solid form (knowing nothing of a liquid form). It might be that for the first speaker, the epistemic intension of `water' might function to pick out (roughly) a substance that takes on a certain liquid form, and that for the second speaker, the epistemic intension of `water' might function to pick out a substance that takes on a certain solid form. In the actual world, these epistemic intensions both pick out the same substance, but in other epistemic possibilities, their extensions will differ. But arguably both are using the same word `water'. If so, there is no epistemic intension for `water' that is common across all users of the term.

The same applies in an even stronger way to demonstratives such as `that'. Here different uses of the same term by the same speaker can have different epistemic intensions. It is plausible that the epistemic intension of `that' depends at least in part on a speaker's intentions, which may differ between uses of the term: on one occasion, the speaker may intend to refer to an object on her left, and on another occasion, to an object on her right. If so, the epistemic intensions on these different uses may differ. So there is no epistemic intension for `that' that is common across all uses of the term, even for a single speaker.

This suggests that for a general account, epistemic intensions cannot be assigned to expression types but rather must be assigned to expression tokens. There will be some terms for which epistemic intensions are constant across all tokens of an expression type - some descriptive terms and indexicals, for example - in which case an epistemic intension can also be assigned to the type. And for names and natural kind terms, epistemic intensions might be constant at least across an individual speaker's use of an expression (at least within a limited time frame), so there could be an assignment to more limited types. But a fully general account requires that epistemic intensions are assigned to tokens.[*]

[*][[It should be noted that this difference in epistemic intensions between speakers goes along with differences in which sentences are a priori for a given speaker. For example, 'Neptune (if it exists) affects the orbit of Uranus' may be a priori for Leverrier, but not for his wife. Leverrer could use the sentence to express a priori knowledge, but his wife could not. So insofar as the apriority of various sentences is invoked in the analysis of epistemic intensions, it will generally be a speaker-relative notion that is relevant. (This is reflected in Kripke's own discussion (e.g. 1980, p. 73) which usually talks of a sentence being "a priori for a speaker".) Of course the notion is still distinct from the notion of what the speaker knows a priori; it is a notion of what is knowable a priori for a speaker, given ideal rational reflection.]]

What of the second part of the argument: that if epistemic intensions can vary between tokens of a type, then they are not meanings? This issue is largely terminological. If it is stipulated that meanings are constant across all tokens of a type, then epistemic intensions are not meanings. If this is not stipulated,
then epistemic intensions might be meanings. We could distinguish `type meanings' and `token meanings', and allow that epistemic intensions are not (in the general case) type meanings, but they are token meanings. Or we can use a different term, such as `content', for the sort of meanings that can vary between tokens of an expression type. It is not clear that a substantive issue remains once the terminological issue is cleared up.

It might be insisted that if epistemic intensions can vary between tokens of a type, then they are not part of language, they are not an aspect of linguistic content, and that perhaps they do not fall within the domain of the philosophy of language at all. Again, this is a terminological issue. One might say that the epistemic intensions of names are not part of "a language" such as English, where this is considered as what is common between all English speakers. But this is no reason to deny that they are part of language in a broader sense, and they they are in the domain of the philosophy of language. Of course these terminological issues are largely sociological in origin; so if someone resists on all these issues, it may help to point to some historical examples.

First, Frege. As we have seen, Frege himself held that the sense of an expression could vary between tokens of a type, in the case of indexicals and names. Frege's theory of sense is generally taken to be one of the most important theories in the philosophy of language, and Frege himself is perhaps the most important figure in the field. It would be odd to hold that the theory of sense (as sense was characterized on Frege's account) has nothing to do with language, and that Frege's theory is not part of the philosophy of language.

Second, Kripke. It is striking that in all his arguments against the Fregean view, Kripke never mentions an argument from variability. He appears to take it as obvious that on a Fregean theory, the descriptive content of a name will vary between speakers (his relevant formulations are all speaker-relative), and does not mention this as an objection. Given the number of other objections that are developed against a Fregean account, this suggests that Kripke took variability to be no objection to sense as an aspect of language. And it suggests that if the worst problem for a Fregean is variability, then a Fregean view of language would be broadly correct.

Third, Kaplan. Kaplan's theory of character and content (for indexicals and demonstratives) is generally taken to be one of the most important theories in the philosophy of language in recent years. On Kaplan's account, it is clear that both the character and the content of a demonstrative such as `that' will vary between uses of the term.[*] So if epistemic intensions are not an aspect of language, then neither are character or content.

[[Kaplan's formal language for demonstratives deals with this issue by holding that tokens of demonstratives that are associated with different intentions or demonstrations are in fact tokens of a different word. But it is extremely plausible that in a natural language such as English, different tokens of a demonstrative such as 'that' are tokens of the same word; so this formal stipulation still leaves character distinct from linguistic meaning in natural language. See Braun 19xx for critical discussions, and for proposals regarding the linguistic meaning of demonstratives.]]

Someone might object that the epistemic intension of an utterance is not always part of what that
On Sense and Intension

utterance *communicates*, since a speaker and a hearer may associate different epistemic intensions with the same expression, and the hearer may not know what the speaker's epistemic intension is. It is true for that reason, epistemic intensions are not always communicated: a speaker's utterance with a given epistemic intension may cause the hearer to acquire a belief with a different epistemic intension. But it is not clear why this sort of communicative property is a *sine qua non* for any aspect of the content of language. Certainly it is not satisfied by Frege's sense or by Kaplan's character or content, for example. At worst, epistemic intensions are in the same boat as these paradigmatic aspects of linguistic content.

It might also be objected that epistemic intensions are an aspect of "speaker meaning" rather than "semantic meaning". This objection exploits a distinction Kripke (19xx) exploited to deal with Donnellan's (19xx) distinction between the "referential" and "attributive" use of expressions such as `the man in the corner drinking champagne', used by a speaker intended to refer to a man he is looking at in the corner. If the man in the corner is actually drinking a martini, there is a sense in which the expression refers to him (the referential sense), and a sense in which it does not (the attributive sense). Kripke argues that the attributive reading reflects the "semantic reference" of the expression, while the referential reading is merely an aspect of "speaker's reference". Perhaps something similar applies to epistemic intensions?

I think Kripke's analysis of Donnellan's cases is plausible, but it does not generalize to the case of epistemic intensions. As Kripke says:

The semantic referent of a designator is given by a *general* intention of the speaker to refer to a certain object whenever the designator is used. The speaker's referent is given by a *specific* intention, on a given occasion, to refer to a certain object.

It is clear that on this definition, the epistemic intension of a name or natural kind term is more akin to semantic reference than to speaker's reference, since it reflects a general intention on the speaker's part, not a specific intention. Indeed, the epistemic intension of `the man in the corner drinking champagne' in the case above plausibly picks out the semantic referent (no-one), not the speaker's referent (the man in the corner). One might, if one wished, introduce a corresponding difference between "semantic epistemic intension" and "speaker's epistemic intension", where the latter picks out the man who is ostended irrespective of his other properties. But even then, epistemic intensions would be in the same boat as reference, and there would be a clear notion that falls on Kripke's "semantic" side of things.

Perhaps there is some *other* distinction that might be drawn between something one might call "semantic meaning" and something one might call "speaker meaning": for example, if one stipulates that semantic meaning must be constant across all tokens of a type, while speaker meaning can vary between speakers. But that would be a very different distinction from Kripke's, and it would do nothing to suggest that epistemic intensions are in the same boat as Donnellan's 'referential' uses of descriptions.

A final objection might be that epistemic intensions are not part of language, since they derive entirely from the contents of thought. On this view, it is the speaker's *concept* of water that has an epistemic intension, and it is the conceptual content that varies between speakers, not any sort of linguistic content.
In response: one can accept that epistemic intensions are associated with concepts and thoughts, and even that the epistemic intensions of linguistic expressions are derivative in some way on the epistemic intensions of thoughts, but this not entail that epistemic intensions are not also part of the content of language. On my view, all linguistic content is derivative in some way on mental content; this applies just as much to expressions whose content is constant between speakers as to expressions whose content varies. But there is no reason to hold that by definition, linguistic content cannot derive from mental content. If this were so, then my view would entail that there is no linguistic content. Perhaps my view is wrong, but if so, this is a substantive point, not a terminological one. It is also worth noting that Kripke's own discussion above suggests that linguistic content can derive from mental content (a speaker's intensions). So I think that there is no objection to epistemic intension as a sort of linguistic content here.

*[See "The Components of Content", which uses epistemic intensions to give an account of the "narrow content" of thought.]*

Ultimately, the best way to deal with any terminological issue is to reflect on the use to which a term is being put, and to determine which sense is most relevant to a given purpose. It may be that there are some purposes, the most relevant notion of the "meaning" or "content" of linguistic expressions is one on which meaning and content are required to be constant across all tokens of a type. Such purposes might include those of determining what is built into the semantic structure of a language such as English, giving an account of what is required to competently use an expression of a given type, and perhaps addressing certain questions about what an expression will communicate between arbitrary speakers of a language. For these purposes, one can invoke a notion of meaning on which universality is required. On this conception of meaning, epistemic intensions may be part of the meanings of indexicals and some descriptive terms, but they will not be part of the meanings of names and natural kind terms.

For many other purposes, we do not need such a narrow notion of meaning or content, and we often need a broader notion. This includes most of the uses to which the philosophy of language and notions of meaning are put in other areas of philosophy, as well as questions within the philosophy of language itself.

One example: notions of meaning and content are often taken to be central in analyzing questions about necessity and possibility, which in turn play a crucial role in analyzing many metaphysical issues. But for this role, the question of whether meaning or content is constant across speakers is almost entirely irrelevant. It would make very little difference to the deepest issues if there were just one speaker of a language, or if different speakers used terms with different meanings or content. If I use an epistemic intension to reach a metaphysical conclusion about water, the worst possible consequence of variability will be that someone else will not be able to reach a similar conclusion using their term "water". This seems unlikely to happen, due to the common referent. But even if it did, it would do nothing to invalidate my conclusion; it would just mean that someone else would have to express the conclusion differently. Once terminological issues are cleared up (as they often need to be), the substantive points will be as before. So if epistemic intensions are otherwise relevant to answering these questions, as I think they are, it is no objection that they can vary between speakers.
The same goes for many or most applications of the philosophy of language in metaphysics, epistemology, the philosophy of mind, the philosophy of science, and other areas. Some uses to which a notion of meaning or content is naturally put include: questions concerning the rational role of language; questions concerning the connection between language and thought; questions concerning the evolution of meaning as scientific theories develop; questions about scientific explanation; questions concerning the semantics of belief ascription and indicative conditionals; questions about how reference is fixed; questions about the a priori; and so on. For most of these purposes, a requirement that meaning or content is constant over all tokens of an expression type is at best irrelevant, and is at worst harmful. So objections based on variability between speakers will be largely irrelevant to the use of notions of meaning and content in these areas.

9 Conclusion

I have argued that a broadly Fregean account of meaning is tenable. On this account, the notion of an epistemic intension plays the role of a Fregean notion of sense. Epistemic intensions are not the same as Fregean sense in all respects, but they are similar in many respects, and they allow versions of the core Fregean requirements on sense to be satisfied. It may be useful to summarize where the core Fregean theses stand in light of the preceding discussion.

Thesis (1), that every expression has a sense, has been preserved. It has also been augmented by a thesis holding that every expression has a subjunctive intension in addition to its sense (its epistemic intension).

Thesis (2), that sense reflects cognitive significance has been preserved in a slightly modified form. In the modified form, cognitive significance is understood as non-apriority. So when an identity is not a priori, the expressions involved have different senses; when two sentences are not equivalent a priori, they have different senses; and so on.

Thesis (3), that the sense of a complex expression depends on the sense of its parts, has been preserved in a modified form. The thesis as it stands holds for all expressions except those involving modal and subjunctive contexts. To handle such expressions, one needs a slightly modified thesis: that the sense of an expression depends on the semantic values of its parts, where the semantic value may include elements (such as subjunctive intension) that go beyond sense. It is also the case that all aspects of semantic value (extension, epistemic intension, subjunctive intension) of a complex expression depends on the semantic values of the parts.

Thesis (4), that sense determines extension, has been preserved in the version that holds that sense determines extension in combination with the world.

Thesis (5), that the sense of a sentence has an absolute truth-value, has been discarded. The sense of a sentence has a truth-value only relative to a subject and a time. Thesis (6), that expressions refer to their senses in indirect contexts, has also been discarded. A more complex account of these contexts is still required. Thesis (7), that the sense of an expression can vary between speakers and between occasions of
use has been preserved.

I have also argued that the most common objections to Fregean theories can be handled by such an account. At most, these objections show that (i) senses are indexical, (ii) senses should be supplemented by a further semantic value, a subjunctive intension, (iii) senses should be understood as intensions, not descriptions, and (iv) the sense of an expression can vary between speakers and between occasions of use.

I have argued that extension, epistemic intension, and subjunctive intension are all part of the meaning and content of an expression, but I have not argued that these exhaust the meaning or content of an expression. In fact I think that they do not. First, there are plausibly aspects of meaning that have nothing to do with the determination of truth: the difference between `and' and `but' is an example. Second, there may be expressions that are a priori equivalent to each other, but that nevertheless have different meaning due to some fine-grained cognitive difference: the difference between `equilateral triangle' and `equiangular triangle' is an example. To handle this last sort of difference, I think that one may need senses of a variety that are more fine-grained than epistemic intensions. The notion of an epistemic intension might be extended to do this (by moving to a more fine-grained space of epistemic possibilities), but this is a separate story. It may also be that for some purposes, the meanings or contents of complex expressions may need to be taken as structured complexes of extensions and/or intensions; this is entirely compatible with the framework I have outlined.

I have also not given a conclusive demonstration that epistemic intensions of expressions exist and have all the properties I have attributed to them. A conclusive demonstration would require some more precise definitions, and a rebuttal of all counterarguments. I have argued that there is a strong prima facie case that epistemic intensions exist and have the properties I have attributed to them, however, and I have argued that the most obvious counterarguments can be rebutted. It may be that there are other arguments against the view; if so, I would be very interested to hear them. In the meantime, I think that a broadly Fregean approach to meaning holds considerable promise.
The Nature of Epistemic Space

[N.B. A very rough draft, with no notes or citations yet, and almost certainly lots of mistakes.]

1 Ways the world might be

There are many ways the world might be, for all I know. For all I know, it might be that there is life on Jupiter, and it might be that there is not. It might be that Australia will win the next Ashes series, and it might be that they will not. It might be that my great-grandfather was my great-grandmother's second cousin, and it might be that he was not. It might be that copper is a compound, and it might be that it is not.

There are even more ways the world might be, for all I know with certainty. It might be that there are three chairs in this room, and it might be that there are not. It might be that water is H2O, and it might be that it is not. It might be that my father was born in Egypt, and it might be that he was not. It might be that I have a body, and it might be that I do not.

We can say that it is epistemically possible for a subject that P, when it might be that P for all the subject knows. So it is epistemically possible for me that there is life on Jupiter, or that copper is a compound. One can define various different standards of epistemic possibility, corresponding to various different standards for knowledge. For example, one might say that it is epistemically possible in the Cartesian sense (for a subject) that P when it might be that P, for all a subject knows with certainty. So in the Cartesian sense, it is epistemically possible for me that water is not H2O, and it is epistemically possible for me that I do not have a body.

A natural way to think about epistemic possibility is as follows. When it is epistemically possible (for a subject) that P, there is an epistemically possible scenario (for that subject) in which P. We can think of a scenario as a maximally specific way things might be: a sort of epistemically possible world, in a loose and intuitive sense. On this picture, corresponding to the epistemic possibility that Australia will win the next Ashes series are various epistemically possible scenarios in which they win in all sorts of different ways. And corresponding to the Cartesian epistemic possibility that I have no body are various scenarios in which I am disembodied, each epistemically possible by the Cartesian standard: e.g. scenarios in which I am a brain in a vat, or in which I am a disembodied Cartesian mind.
To fill out this picture a bit further, we might imagine that there is an overarching space of scenarios. We can think of these scenarios as constituting *epistemic space*. If a subject did not know anything, all scenarios would be epistemically possible for the subject. When a subject knows something, some scenarios are excluded. Every piece of substantive knowledge corresponds to a division in epistemic space: some scenarios are excluded as epistemically impossible for the subject, while others are left open. More specifically, it is natural to hold that for a given P, there may be scenarios in which P is the case, and scenarios in which P is not the case. Then when a subject knows that P, scenarios in which P is not the case are excluded, while others are left open. The scenarios that are epistemically possible for a subject are those that are not excluded by any knowledge of the subject.

One can naturally suppose that the space of scenarios is equally divided by *belief*, and perhaps that the division by belief underlies the division by knowledge. Every substantive belief, whether or not it qualifies as knowledge, corresponds to a division in the space of scenarios. When a subject believes that P, we might say that some scenarios (in particular, scenarios in which not-P) are ruled out as *doxastically impossible*, while others are left open. A scenario is doxastically possible for a subject if and only if it is not doxastically ruled out by any of the subject's beliefs. When a belief qualifies as knowledge, the scenarios ruled out as doxastically impossible are also ruled out as epistemically impossible.

A picture of this general sort is often present in philosophical discussions of knowledge and belief. Within epistemology, it is common to think of knowledge in terms of the "elimination of possibilities", with some sort of underlying space of possibilities presumed. In discussions of skepticism, for example, the fact that certain skeptical scenarios are not eliminated is used as evidence that certain knowledge claims are not true. And in epistemic logic and the theory of belief revision, it is common to model epistemic possibility using epistemic relations to an underlying space of possible worlds.

It is surprisingly difficult, however, to make the intuitive picture precise. What sort of possibilities we are dealing with here? In particular, what is a scenario? And what is the relationship between scenarios and items of knowledge and belief?

It is natural to think of scenarios as possible worlds, and to think of a scenario in which P as a world in which P. But it is immediately clear that this will not work, at least on the most common contemporary understanding of possible worlds. There are subjects for whom it is epistemically possible that Hesperus is not Phosphorus; but on the usual understanding, there is no possible world in which Hesperus is not Phosphorus. It is epistemically possible for me that my great-grandparents were cousins and it is epistemically possible that they were not; but on the usual understanding, my great-grandparents are cousins either in all worlds in which they exist or in none. In the Cartesian sense, it is epistemically possible for me that water is not H2O, but on the usual understanding (assuming that water really is H2O), there are no possible worlds in which water is not H2O. So if we are to maintain that it is epistemically possible that P iff there is an epistemically possible scenario in which P, we cannot identify a scenario in which P with a possible world in which P, at least on the usual understanding.
Some might react to this by denying the intuitions about what is epistemically possible (e.g. holding that it is never epistemically possible that Hesperus is not Phosphorus), and some might react by denying the coherence of the picture connecting epistemic possibility to epistemically possible scenarios. I think that both reactions would be premature: the first loses touch with the phenomenon we are trying to analyze, and the second assumes that possible worlds as currently understood are the only available tool.

Instead, we should try to understand epistemic possibility on its own terms. We are not dealing here with counterfactual space: the space of ways the world might have been. Here, we are dealing with epistemic space: the space of ways the world might be. This epistemic space calls for its own epistemic tools of analysis. Where the analysis of counterfactual space invokes possible worlds as maximally specific ways the world might have been, the analysis of epistemic space should invoke scenarios as maximally specific ways the world might be. The two notions are quite distinct, although they have a deep underlying relationship.

In this paper, I will explore some ways of understanding epistemic space. I hope to make at least a prima facie case that a version of the notion is coherent, and that there are no decisive problems with it. And I will argue that the notion, if coherent, has a large philosophical payoff in the analysis of the content of thought and the meaning of language. It promises an analysis of the dimensions of meaning and content that are tied constitutively to the epistemic dimension. In particular, it promises an account of a sort of Fregean sense for linguistic expressions, and it promises an account of the narrow content of thoughts.

2 Preliminaries

On the picture suggested above, we might say that the notion of strict epistemic possibility - ways the world might be, for all we know - is undergirded by a notion of deep epistemic possibility - ways the world might be, prior to what anyone knows. Unlike strict epistemic possibility, deep epistemic possibility does not depend on a particular state of knowledge, and is not relative to a subject. Whereas it is strictly epistemically possible (for a subject) that P when there is some epistemically possible scenario (for that subject) in which P, it is deeply epistemically possible that P when there is some deeply epistemically possible scenario in which P. Since all scenarios are deeply epistemically possible on this picture, we can put this more simply: it is deeply epistemically possible that P when there is some scenario in which P.

How can we understand deep epistemic possibility more precisely? A problem immediately presents itself. It might be held that for any proposition P, there is some subject for whom P is strictly epistemically possible. Perhaps there are subjects who are so limited or so confused that they know nothing at all: if so, then any P is epistemically possible for them. Or for any given P, there might be a subject who is so limited or so confused with respect to the domain of P that they know nothing in this domain: if so, it is plausible that P will be epistemically possible for the subject. This may apply even to elementary logical contradictions, and to the negation of trivialities. If so, then if strict epistemic possibility entails deep epistemic possibility, then for all P, it will be deeply epistemically possible that P.
This notion of deep epistemic possibility might be useful for some purposes, but it is not very useful for our purposes. If it is deeply epistemically possible that P for all P, so that there is a scenario in which P for all P, then the structure of epistemic space will be near-trivial. Under certain natural assumptions (of a kind outlined below), for any propositions P, Q, R, ..., there will be distinct scenarios in which P&Q&R&..., P&Q&~R&..., P&~Q&R&..., and so on (including all sorts of scenarios in which P&~P, and so on). So the space of scenarios will be as fine-grained as the power set of the space of propositions. This would rob the space of scenarios of interesting structure, and it would also trivialize the relationship between scenarios and belief. Beliefs and knowledge would divide the space of scenarios only in a trivial way, and there could no nontrivial inferences from uneliminated scenarios to contents of belief or knowledge, or vice versa.

For a more useful notion, we need a more constrained notion of epistemic possibility, one that builds in some degree of rationality, and precludes incoherent possibilities such as those in which P&~P. There are various ways that one might do this, but the most obvious way is to exploit the idea that these incoherent possibilities can be ruled out a priori. We can say that P is deeply epistemically possible when it is not a priori that ~P. On this understanding, if P is a priori false, there will be no scenario in which P. Scenarios will now correspond to maximally specific coherent ways the world might be. We might think of the resulting notion of epistemic space as ideal epistemic space, or rational space.

It is clear that the idealized notion diverges from the ordinary understanding of epistemic possibility, at least within the a priori domain. For example, on the ordinary understanding, negations of complex mathematical and logical theorems can be epistemically possible (I do not know enough to rule them out), but on the idealized understanding above, these negations will be deeply epistemically impossible. Ideal epistemic space is well-suited to analyzing much empirical knowledge and belief, however, and it also yields an elegant system with many useful properties. So I will focus on the idealized notion of deep epistemic possibility and of epistemic space, at least for now. Later, I will discuss ways in which the idealization might be relaxed.

Another question arises: what are the objects of deep epistemic possibility, and what sort of objects are true or false at scenarios? So far I have often talked as if these are propositions. I think that this view is ultimately correct, but the contested nature of propositions raises difficulties in developing the approach. For example, on some theoretical views of propositions (e.g. views involving singular propositions, and some views involving sets of possible worlds), "Hesperus is Hesperus" and "Hesperus is Phosphorus" express the same proposition. But on the face of it, it is deeply epistemically possible that Hesperus is not Phosphorus (we cannot know a priori that Hesperus is Phosphorus), but it is not deeply epistemically possible that Hesperus is not Hesperus (we can know a priori that Hesperus is Hesperus). So it is not easy for these views of propositions to capture this difference: they must either deny the epistemic possibility claim, or accept that the epistemic possibility that P is not to be analyzed as the epistemic possibility of the proposition that P. I think that there is an alternative understanding of propositions that avoids these problems, and that the approach developed in this paper can itself help support such an understanding, but it would be problematic to assume such an understanding at the outset. To avoid this sort of theory-dependent confusion, it is best to start without talking about propositions at all.
Instead, we can associate epistemic possibility, and truth or falsity at scenarios, with something in the vicinity of beliefs and sentences. I will take beliefs to be token mental states: occurrent beliefs will be the paradigm example. The sentences I will be concerned with are sentence tokens that are used to make assertions: call such a token a statement. I will take it that there is a relation of expression between statements and beliefs, and that when a statement expresses a belief, the statement and the belief have the same truth-value. Statements usually express a belief of the subject making the statement, and never express more than one belief of the subject. (We might think of expression here as direct expression: a given statement might indirectly express more than one belief, and indirect expression may allow variation in truth-value.)

When statements do not express a belief (e.g. because the subject is not confident in the truth of what is asserted), I will take it that they express a propositional attitude of a more general sort, one that we might call a thought. To think that P, as I will use the term here, is to entertain the hypothesis that P, and a thought that P is an entertaining of the hypothesis that P. Occurrently believing that P entails thinking that P, in much the same way that knowing that P entails believing that P. Like beliefs, thoughts can be true or false. A statement always expresses exactly one thought, and the thought and the statement will always have the same truth-value.

I will take it that there is a relation of continuance (or persistence) that can hold between thoughts of a subject at different times, and that continuance guarantees that two thoughts that stand in this relation have the same truth-value. I will take it that the thoughts (and derivatively, the statements) of a given subject can stand in a relation of negation to each other, and in a relation of conjunction (and other logical relations) to each other. And I will take it that a thought can come to be accepted, yielding a belief: in this case we can say that the belief is an acceptance of the thought.

We can say that a belief is a priori justified when it is justified independently of experience. A belief is a priori justifiable when it can be justified independent of experience, yielding a priori knowledge. More generally, a thought is a priori justifiable - or more simply, a priori - when it is possible for an acceptance of it to be justified independently of experience, yielding a priori knowledge. Here, apriority abstracts away from contingent cognitive limitations. If there is any possible mental life that starts from a thought and leads to an a priori justified acceptance of that thought, the thought is a priori. A statement is a priori when it expresses an a priori thought. A thought is epistemically possible when its negation is not a priori. A statement is epistemically possible when it expresses an epistemically possible thought. One thought (or statement) implies another when a conjunction of the first with a negation of the second is epistemically impossible.

Note that the uses of "epistemically possible" in the previous paragraph correspond to deep epistemic possibility, in the idealized sense. In the following discussion, I will be setting aside issues concerning strict epistemic possibility, and non-idealized notions of deep epistemic possibility. So from now on, unqualified talk of epistemic possibility should always be taken as talk of deep epistemic possibility in this sense.
3 Principles of epistemic space

On the picture developed at the start, items of knowledge and belief divide epistemic space. Any item of knowledge or belief excludes some scenarios, and endorses others. More generally, any thought can be held to excludes some scenarios and to endorse others. We can put this by saying that for any given thought (or belief, or item of knowledge), there is a class of scenarios that verify the thought and a class of scenarios that falsify the thought. Intuitively, a scenario verifies a thought when it corresponds to a way the world might be that the thought endorses, and a scenario falsifies a thought when it corresponds to a way the world might be that the thought excludes.

(Note that verification and falsification as defined here are not evidential notions. It may be epistemically possible, for example, that there is life in black holes for which we can have no evidence. Intuitively, this epistemic possibility is backed by various scenarios in which life exists unperceived in black holes. My thought that there is life in black holes will be verified by these scenarios, not because these scenarios could provide evidence for the truth of the thought, but because they correspond to ways the world might be that the thought endorses. In effect, verification and falsification are broadly representational notions. If one holds independently that truth is tied constitutively to evidence, as on some anti-realist views, it may be that verification will also be tied to evidence; but this tie is not compulsory.)

If we allow that thoughts can have multiple truth-values (such as true, false, and indeterminate), we should also allow that the verification relation can yield the same truth-values. We might say that there is a function that maps an arbitrary scenario S and thought T to a truth-value \( \text{verifies}(S,T) \). Then S verifies T iff \( \text{verifies}(S,T) \) is true, and S falsifies T iff \( \text{verifies}(S,T) \) is false. When S verifies T, we can say that T is true at S. When S falsifies T, we can say that T is false at S. In other cases, it may be that T is indeterminate at S, or perhaps that T has some other truth-value at S.

It is an important part of the picture I am developing that for any subject at a time, there is exactly one way the world is, relative to that subject and time. More specifically, relative to any thought, there is exactly one way the world is, relative to that thought. (Recall that thoughts are tokens, embedded in a world.) We can put this by saying that exactly one scenario is actualized at the thought. The thought will be true if it is verified by its actualized scenario, and false if it is falsified by its actualized scenario.

So we are postulating a space of scenarios, a function of verification from thoughts and scenarios to truth-values, and a relation of actualization between scenarios and thoughts. These must satisfy at least the following principles of epistemic space:

Plenitude: A thought T is epistemically possible iff there exists a scenario S such that S verifies T.

Actuality: For every thought T, there is a unique scenario S such that S is actualized at T.

Truth: For all S and T, if S is actualized at T, then T's truth-value is \( \text{verifies}(S,T) \).
Compositionality: For all $S$ and $T$, if $T$ is a logical composition $\text{comp}(T_i)$, where $\text{comp}$ is a truth-function, then $\text{verifies}(T,S) = \text{comp}(\text{verifies}(T_i,S))$.

Parsimony: If scenarios $S_1$ and $S_2$ are such that for all possible thoughts $T$, $\text{verifies}(S_1,T) = \text{verifies}(S_2,T)$, then $S_1$ and $S_2$.

For any thought, there will be an associated set of scenarios that verify the thought. More generally, for any thought, there will be an associated function that maps a scenario to the truth-value of thought thought at the scenario. We can call this function the thought's *epistemic intension*. A thought's epistemic intension might be thought of as representing its *epistemic content* - the way that it divides epistemic space. Strictly speaking, we might think of an epistemic intension as defined here - relative to an idealized notion of epistemic possibility - as a thought's *ideal epistemic content*, since any two thoughts that are a priori equivalent will have the same epistemic content. (The latter usage would leave open the possibility of a less idealized notion of epistemic content such that thoughts that are nontrivially a priori equivalent can have distinct epistemic content.) We can define the epistemic intension of an statement in a similar way.

One can also postulate similar principles governing the relationship between scenarios and statements. We can say that a scenario verifies an statement if it verifies the thought expressed by that statement, and that scenario is actualized at an statement iff it is actualized at the thought expressed by the statement. Then analogs of Epistemic Plenitude, Actuality, and Truth for statements follow automatically. An analog of Compositionality will follow as long as we allow that statements have compositional relations that mirror the compositional relations of the thoughts expressed. An analog of Parsimony will follow as long as we allow that every possible thought could be expressed by a possible statement.

Of these, Plenitude is the core principle that captures the general picture set out at the beginning. Actualization and Truth capture the special role of the way the world actually is (relative to a thought), among all the ways the world might be. Compositionality ensures that negations and conjunctions, and other logical compositions of thoughts have the truth-values that one would expect. Parsimony says, in effect, that epistemic space contains no redundancy, so that it is a minimal space that accomplishes its epistemic purpose. Of these, it is arguable that Parsimony is not absolutely essential, but the other four principles seem crucial to the notion of epistemic space.

Of course it would be easy to simply postulate that there is a space of scenarios and relations of verification and actualization that satisfy these principles. But this would raise the question of whether the postulation is coherent. We can make a positive case for coherence by *constructing* epistemic space. That is, we can identify the space of scenarios with a space of abstract objects that we have prior reason to believe is coherent, and we can make the case that there are relations of verification and actualization over this space that satisfy the relevant principles. In the following sections, I explore two ways of making such a construction.

There is a further principle worth mentioning:

http://www.u.arizona.edu/~chalmers/papers/espace.html (7 of 34) [4/7/2002 1:42:42 PM]
The Nature of Epistemic Space

Maximal Thoughts: For every scenario S and every subject, there exists a possible thought T such that for all possible thoughts T' of the subject, S verifies T' iff T implies T'.

We might think of T as the thought that S is actual. Where S is a maximally specific epistemic possibility, T will be a maximally specific coherent thought. Intuitively, S will verify T' iff the thought that S is actual implies the thought that T' (that is, if the thought "S is actual and ~T" is epistemically impossible), and S will falsify T' iff the thought that S is actual is implies the thought that ~T (that is, if the thought that "S is actual and T" is epistemically impossible).

Let us say that a maximal thought is an epistemically possible thought T such that there is no thought T' such that T' implies T while T does not imply T'. (Intuitively, if both conjunctions were coherent, then T could not be a maximally specific coherent thought.) It is easy to see that if Maximal Thoughts is true, then for any S, the corresponding thought T is a maximal thought in this sense. (If it were not, then S would verify both T1 and ~T1 for some T1, so it would verify the epistemically impossible T1&~T1.) We can call T a maximal thought corresponding to S.

The Maximal Thought principle is not essential to the notion of epistemic space. It is not entirely obvious that maximal thoughts can exist, and the idea of epistemic space may still be coherent even if there is a problem with maximal thoughts. But if maximal thoughts can exist, the principle certainly provides a useful aid in the analysis of epistemic space.

4 Scenarios as centered worlds

The most natural way to think of scenarios, at least initially, is as possible worlds. In a way this is trivial - scenarios are defined as possible (in some sense) ways a world might be (in some sense). But the notion of possibility invoked here differs from the notion of possibility that is usually associated with possible worlds: it is a sort of epistemic possibility, whereas possible worlds are usually understood to be associated with a sort of "metaphysical" possibility. Still, the question arises as to whether possible worlds understood in the latter sense might serve to help us model the space of scenarios, at least indirectly. That is: can we use the space of metaphysically possible worlds to construct a space of scenarios, and to make the case for a verification relation between scenarios (so understood) and thoughts?

I think we might. The intuitive idea is simple: to every possible world W, there corresponds a very specific (deep) epistemic possibility: the epistemic possibility that W is actual. Given any specific epistemic possibility of this sort, it will be epistemically compatible with some thoughts, and incompatible with others. One might then proceed as follows: (i) identify the space of scenarios with the space of possible worlds; (ii) say that a world W verifies a thought T when the hypothesis that W is actual is epistemically compatible with T; and (iii) say that a world W is actualized at a thought T when W is the world containing T.

The idea here is intuitive, since I have invoked the intuitive idea of a hypothesis, and of a hypothesis
being compatible with a thought. One could give more flesh to the idea by invoking the thought that W is actual instead, and holding that W verifies T iff the thought that W is actual is epistemically compatible with T (where two thoughts are epistemically compatible when their conjunction is epistemically possible). As with the maximal thought principle, it is not obvious that such specific thoughts can exist for all W, so we do not want to rest the framework on their existence. And even we we take this approach, there is still an intuitive element, in that we have have appealed to the intuitive idea of a thought that W is actual. But in any case, this way of thinking about things at least gives a sense of why one might try to model scenarios with possible worlds.

I think that this sort of approach is on the right track. But there are a few obstacles to understanding scenarios in terms of possible worlds, some of which we have already seen. The obstacles fall into four classes, which we can class under the four headings: indexicality, rigidity, strong necessity, and parsimony.

(1) Indexicality

The first obstacle is a problem for any view that identifies scenarios with objective states of affairs. As a number of philosophers have argued, there are certain questions that may be left open by any amount of objective information about the world. One can put this as follows. Let D be a full objective specification about the world. Let T be an indexical claim, such as "I am a philosopher" or "It is raining here now" or "Today is Friday". Then in each case, it may be that both D&T and D&~T is epistemically possible. That is, the information in D may not enable one to settle the status of T. To settle these indexical claims, one needs to be able to locate oneself and the current location and time with respect to an objective description of the world; and this locating information cannot be derived from objective information. So objective information is not maximal information.

The problem this poses is clear. In these cases, D&T and D&~T are epistemically possible, so both are verified by a scenario; and they are epistemically incompatible, so no scenario verifies both. But if D is a complete objective description of the world, then there will plausibly be only one world (objectively understood) in which D is the case. And even if there is more than one objectively indistinguishable D-world, it seems that there is no room in such a space of objective worlds for a division between worlds in which today is Saturday and worlds in which it is not.

The basic problem is in satisfying Plenitude. Maximal epistemic possibilities are differentiated not just by objective information but also by indexical information, and there are not enough possible worlds to go around. To model epistemic space, we need a more fine-grained space that allows indexical differentiation.

This suggests a natural solution: we need to supplement possible worlds with some further indexical structure. Specifically, we can identify scenarios with centered worlds: worlds marked with a "center" consisting of a subject and a time within the world. (Equivalently, centered worlds might be identified with ordered triples of a world, a subject in that world, and a time in that world.) We can think of the
center as a sort of "you are here" marker, corresponding to a hypothesis about the subject's identity and location. If W' is a centered world, the hypothesis that W' is actual will be a sort of indexical hypothesis about the world and the subject's location within it. Putting things in terms of thoughts: if W' consists of an ordinary world W centered on a subject and a time, my thought that W' is actual will be the thought that I am now at the center of W' (i.e. that W is actual, I am the subject indicated, and now is the time indicated).

When scenarios are modeled by centered worlds, the problems above can be handled straightforwardly. My thought that I am a philosopher will be verified by all centered worlds in which the subject at the center is a philosopher. My thought that it is raining here now will be verified by all centered worlds in which it is raining at the location of the marked subject at the time marked at the center. My thoughts T1 and T2 above will be verified by different classes of centered worlds, with an objective world in common but different locations for the center. And so on. Intuitively, this is just how we would expect these thoughts to divide the space of epistemic possibilities.

It is useful to stipulate that the marking of centered elements in a centered world is optional. This way, we can accommodate the (arguable but plausible) a posteriori of claims such as "Subjects exist" and "The universe is temporal". If we allow centered worlds without marked subjects or times, then there will be subjectless scenarios and timeless scenarios to falsify these claims. There can even be an empty scenario to verify "Nothing exists", which is arguably a deep epistemic possibility. (Here I assume that "I exist" is a posteriori, being justified by experience. If someone holds that "I exist" is a priori, then they can require that centered worlds contain marked subjects.) It may also be that we sometimes need additional optional marked information at the center of a world. For example, for the verification of certain demonstrative thoughts (e.g. Austin's "Two Tubes" puzzle - "that spot is red", in a symmetrical visual field with two spots), one needs to allow one or more marked experiences at the center of a world, to distinguish otherwise indistinguishable contents. (For more discussion, see...) But the general framework is much the same.

(2) Rigidity

The second problem has already been mentioned. There are subjects for whom it is epistemically possible that Hesperus is not Phosphorus: more specifically, there are subjects for whom the statement "Hesperus is not Phosphorus" expresses an epistemically possible thought. But on the usual understanding of possible worlds, "Hesperus" and "Phosphorus" are rigid designators: they pick out the same object (here the planet Venus) in all possible worlds. If so, then there is no possible world satisfying "Hesperus is Phosphorus". Something similar applies to the epistemic possibility that water is not H2O ("water" picks out H2O in all worlds, so no world satisfies "water is not H2O) and the epistemic possibility that my greatgrandparents were or were not cousins (I have the same ancestors in all worlds, so if my greatgrandparents are not cousins, no world satisfies "my greatgrandparents are cousins"). Adding centers to the possible worlds does not help with this. So it may seem that if scenarios are centered worlds, then Plenitude cannot hold: there are cases in which an statement (e.g. "water is not H2O") is epistemically possible, but there is no centered world satisfying the statement.
This conclusion would be premature, however. There will be a problem for Plenitude only on the assumption that a possible world verifies an statement precisely when it satisfies that statement. And this points immediately to a possible solution: we can hold that verification and satisfaction are quite different relations. On such a view, it may be that for epistemically possible statements such as the above (e.g. "water is not H2O"), then although no world satisfies the statement, there are nevertheless worlds that verify the statement.

In fact we have already seen reason to accept that verification and satisfaction are different relations. Above, we saw that "I am a philosopher" is verified by any centered world in which the being at the center is a philosopher. But it is false that any such world satisfies "I am a philosopher". For example, consider a counterfactual world in which David Chalmers is a mathematician and George Bush is a philosopher, and consider a centered version on this world, centered on George Bush. Then by the standard sort of evaluation, this is a world in which I am not a philosopher (instead I am a mathematician) - that is, the world satisfies "I am not a philosopher". But nevertheless, the world verifies "I am a philosopher".

The distinction is also suggested by the intuitive test for verification of a thought T given above: is the hypothesis that W is actual epistemically compatible with T? Take a "Twin Earth" world W that is superficially like our world, and in which the oceans and lakes around the center are filled with (clear, drinkable) XYZ. It is epistemically possible (i.e. not ruled out a priori) that W is actual. The epistemic possibility that W is actual is epistemically compatible with the thought that water is XYZ, and is epistemically incompatible with the thought that water is H2O. If so, then W verifies "water is not H2O". At the same time, Kripke and Putnam have argued that W is a counterfactual world in which XYZ is not water, and in which water is still H2O (if it exists). So W does not satisfy "water is H2O", even though W verifies "water is H2O".

What is going on here? The root of the difference is that satisfaction is a broadly subjunctive notion, concerning ways the world might have been. To determine whether the Twin Earth world satisfies "water is XYZ", we can ask: if the liquid in the oceans and lakes had been XYZ, would water have been XYZ? If Kripke and Putnam are correct, the answer is no. Verification, on the other hand, is a broadly epistemic notion, concerning ways the world might be. To determine whether the Twin Earth world verifies "water is XYZ", we can ask: if the liquid in the oceans and lakes is XYZ, is water XYZ? This indicative conditional behaves epistemically, turning on whether there is an appropriate epistemic relation between the antecedent and the conclusion. And in this case, the epistemic relation is present, so the answer is yes.

The notion of possibility that is operative in most contemporary discussions is what one might call subjunctive possibility: P is subjunctively possible if it might have been that P. (Kripke is quite explicit about this, for example.) The notion of possibility that is operative in the epistemic realm is epistemic possibility: P is epistemically possible if it might be that P. It is already a familiar point that these two notions of possibility behave differently. It is not surprising that there are correspondingly different relations between thoughts, statements, and possible worlds.
The Nature of Epistemic Space

One can use verification and satisfaction to define parallel notions in the epistemic and subjunctive realms. For example, we defined the epistemic intension of an statement \( A \) or a thought \( T \) as the function mapping a scenario \( S \) to \( \text{verifies}(S,A) \) or \( \text{verifies}(S,T) \). If scenarios are centered worlds, then the epistemic intension is a function from centered worlds to truth-values. We can similarly define the subjunctive intension of \( A \) or \( T \) as the function mapping a possible world \( W \) to \( \text{satisfies}(W,A) \) or \( \text{satisfies}(W,T) \) (where we hold that a world satisfies a thought if it satisfies an statement that expresses that thought). If scenarios are centered world, these intensions will have closely related domains (the same up to centering), but for a given thought or statement, the intensions themselves will be very different.

In a similar way, one can postulate both epistemic intensions and subjunctive intensions for concepts and for tokens of expressions smaller than sentences, mapping. When an expression is a rigid designator - such as "I", "water", or "Aristotle" - its epistemic intension and subjunctive intension will usually behave quite differently. The subjunctive intension of a rigid designator will pick out the same object in all worlds, but its epistemic intension will not. For example, the subjunctive intension of my concept "I" will pick out David Chalmers in all worlds (mirroring the subjunctive necessity of "I am David Chalmers" - that is, I could not have failed to be David Chalmers). But the epistemic intension of "I" picks out whichever being is marked at the center of a world, irrespective of whether he is David Chalmers. Similarly, the subjunctive intension of "water" picks out H2O in all worlds (if Kripke and Putnam are correct), but its epistemic intension picks out different substances in different worlds, as we have seen.

The same applies to (tokens of) names such as "Aristotle". The subjunctive intension of a name picks out the same person across worlds, but the epistemic intension cannot. To see this, note that it is (deeply) epistemically possible for me that Plato was Aristotle: this is unlikely, but not ruled out a priori. So there must be a scenario verifying my statement "Plato is Aristotle"; and if scenarios are centered worlds, there must be a centered world verifying "Plato is Aristotle". One such is a world \( W \) in which an individual lived a double life, publishing one set of (familiar-looking) books as "Plato" and another as "Aristotle", and in which the community at the center has no knowledge of that distinctness. Intuitively, the hypothesis that \( W \) is actual is (deeply) epistemically possible, and it epistemically entails the hypothesis that Plato is Aristotle. If Kripke and Putnam are right, this is not a world satisfying my statement "Plato is Aristotle", but it may nevertheless be a world verifying "Plato is Aristotle".

This suggests a broadly two-dimensional approach to meaning and possibility, and as such may recall the two-dimensional approaches developed by Kaplan, Stalnaker, Evans, and others. I have explored the similarities and differences elsewhere. One important difference, however, is that an epistemic intension is not defined in terms of the context-dependence of a thought or statement's truth-value. The epistemic intension is a matter of epistemic dependence, turning on whether a thought \( T \) is epistemically compatible with the hypothesis that \( W \) is actual. Nothing here gives any special role for a copy of the thought \( T \) at the center of \( W \), and the epistemic intension will usually be defined over worlds in which any such token is absent. The epistemic intension will even be defined over worlds in which language and thought are absent altogether. Witness "language does not exist", or "no-one exists", each of which is arguably deeply epistemically possible, and which will be correspondingly verified by languageless worlds and by subjectless worlds respectively.
Note that I have not given a formal definition of what it is for a centered world to verify a thought, but only an intuitive account: W verifies T when the hypothesis that W is actual is epistemically compatible with T. A formal definition would require two things. First, we would have to rigorize talk of the epistemic compatibility of hypothesis and thoughts, either by formally defining and characterizing epistemic possibilities, or by dispensing with hypotheses and appealing to the thought that W is actual instead. Second, we would have give an account of what is involved in the hypothesis that W is actual. One natural way to do this would be to distinguish a sort of canonical way of describing possible worlds, so that for any centered world W there will be a canonical description D (including indexical claims to capture the centering). Then the hypothesis or thought that W is actual might simply be the hypothesis or thought that D.

So one possible formal definition would be the following: a centered world W verifies a thought T when T is epistemically compatible with a thought expressed by D, where D is a canonical description of W. Of course this definition requires an account of canonical descriptions, and it requires that the relevant maximal thoughts can exist. I discuss the details of this and other formal definitions elsewhere. For present purposes, it is sufficient to note that the general approach to verification is prima facie coherent, and that the phenomena of rigidity pose no fatal problems.

(3) Strong necessities

We have seen that the existence of a posteriori necessities such as "water is H2O" poses no deep problem for the picture of scenarios as centered worlds, as long as we distinguish verification from satisfaction. It is not hard to see that all of the a posteriori necessities suggested by Kripke can be handled in a similar way: in these cases, when N is an a posteriori necessity there is plausibly a centered world verifying N. But on some philosophical views, there exist a posteriori necessary truths that do not have this property. We can call these strong necessities.

Consider a theist view on which it is necessary that an omniscient being exists (e.g. because it is necessary that God exists and is omniscient), but on which it is not a priori that an omniscient being exists (e.g. because it is not a priori that God exists). On such a view, "There is an omniscient being" is necessary but a posteriori, and "There is no omniscient being" is (deeply) epistemically possible. On such a view, it will not merely be the case that no possible world satisfies "There is no omniscient being". It seems clear that no world verifies "There is no omniscient being". That is, all possible worlds W are such that the hypothesis that W is actual is epistemically incompatible with the thought that an omniscient being exists. There are no relevant two-dimensional phenomena involving rigidity here: it simply seems that there are not enough worlds to go around. If this view is correct, then a model on which scenarios are centered worlds is incompatible with Plenitude.

There are some other views on which the same applies:

(i) A particular strong "strong laws" view on which the fundamental laws and properties instantiated in
our world are the fundamental laws and properties of every possible world. Let say the view also holds (plausibly) that fundamental laws are a posteriori. On this view, a denial of the law of gravity (say) will be deeply epistemically possible, but there will be no possible world satisfying this denial, and there will also be no possible world verifying the denial.

(ii) A materialist view on which truths Q about experience are necessitated by the conjunction P of physical truths, but on which Q is not a priori derivable from P. Here, a psychophysical conditional "P and not-Q" will be epistemically possible. It is not hard to show that if there is even a possible world verifying this conditional (as in the Kripkean cases), problems for materialism ensue. So some materialists deny that even a verifying world exists. If so, the conditional "If P, then Q" is a strong necessity.

(iii) A view on which there are mathematical claims M - perhaps the Continuum Hypothesis? - that are true and are necessary, but are not knowable a priori by any possible being. On such a view, it seems that M will be a strong necessity: ~M will be epistemically possible, but verified by no possible world.

Other such views could be developed: e.g. one on which moral claims can be true and necessitated by natural truths, without being a priori derivable from natural truths; or a similar view about vague claims. In each of these cases, the distinction between verification and satisfaction does not seem to help. If the views in question are correct, there are simply not enough possible worlds to verify all epistemically possible thoughts and statements.

The simplest response to this problem, and the response that I believe is correct, is to deny that strong necessities exist. In each case, the claim in question about necessity is at least controversial. In some cases, proponents claim support from the Kripkean cases, but these cases give no reason to believe in this much stronger phenomenon. In fact, one can argue in reverse: the fact that the link between epistemic possibility and verification by possible worlds is so strong elsewhere gives reason to believe that these claims are incorrect. One can also argue that there are deeper problems with these views. But I have argued for these claims elsewhere, and will not repeat those arguments here.

It is at least clear that these views provide no clear reason to reject the model of scenarios as centered worlds, since in no case is the view in question clearly true. Still, the existence of these views entails that the claim that scenarios can be modeled by centered worlds will be at least as controversial as the denial of the views. And it would be desirable to give an account of scenarios that even holders of these views could accept. If so, that provides at least some reason to look at other models of scenarios.

(4) Parsimony

So far, we have looked at problems of the sort: there are not enough possible worlds to act as scenarios. But there are also potential problems of the sort: there are too many possible worlds to act as scenarios. That is, while the problems above are mostly problems for Plenitude, one can also raise problems for Parsimony. In particular, it seems that there exist groups of centered worlds such that any possible
thought is equally verified or falsified by any world in the group. If so, it seems that each world in the
group corresponds to the same scenario.

One way this can happen is with symmetrical worlds. Say that a world is mirror-symmetrical, and
consider centered worlds W₁ and W₂ centered on corresponding subjects on each side, at the same time.
Then it seems that there is no thought T such that the thought that I am in W₁ is epistemically compatible
with T, while the thought that I am in W₂ is epistemically incompatible with T. The same goes for a
world with a cyclic Nietzschean eternal recurrence of indistinguishable cycles, extending indefinitely into
the past and the future. If we take a group of centered worlds Wᵢ centered on corresponding subjects and
times in different cycles, then it seems that for any T, if one world Wᵢ verifies T, then all worlds Wᵢ
verify T. In these cases, it seems that the different centered worlds all correspond to the same epistemic
possibility, violating Parsimony.

Parsimony might also be violated if possible worlds can contain inconceivable features. Say that there are
two possible worlds W₁ and W₂ that are otherwise indistinguishable, except that at a certain point they
contain different features F₁ and F₂. And say that F₁ and F₂ are inconceivable, in the sense that there is
no possible concept that refers to F₁, or to F₂. Then it seems that there will be no possible thought T such
that T is verified by W₁ but not W₂.

Finally, suppose that (as some believe) there are qualitatively indistinguishable possible worlds. Take two
identical twins Bill and Bob in the actual world. Some argue that there can be qualitatively
indistinguishable worlds W₁ and W₂ such that only Bill exists in W₁ and only Bob exists in W₂. Then it
is plausible that W₁ and W₂ to not correspond to distinct epistemic possibilities: any thought verified by
W₁ is also verified by W₂. If so, Parsimony is violated.

Of these three cases, the last two are controversial and might be denied. But the first is relatively
uncontroversial, and the other two at least raise problems. So it seems that the space of centered worlds
and the verification relation, as we understand them, do not satisfy Parsimony.

One could respond in different ways. One might simply jettison Parsimony, holding that it is an
inessential principle: certainly it seems less essential than Plenitude. One might also modify the picture
slightly, by identifying scenarios with equivalence classes of centered worlds, where the worlds in groups
such as the above will all fall into the same equivalence class. Either response will still allow a
serviceable construction. Still, both responses suggest that there is at least a mild mismatch between
scenarios and centered possible worlds.

What is the upshot of the four obstacles to identifying scenarios with possible worlds that we have
discussed? The obstacles due to indexicality and rigidity can be overcome relatively easily, by invoking
centered worlds and distinguishing verification from satisfaction. The obstacle due to strong necessity
can be denied, and the obstacle due to parsimony can be dealt with as above.

Still, the last two obstacles suggest that while centered worlds may do a good job of modeling scenarios,
The Nature of Epistemic Space

the match is not perfect. The existence of philosophical views on which there are strong necessities suggests that even if these views are misguided, an analysis of scenarios as centered worlds will be at least mildly controversial. Because it makes a substantive (if plausible) claim about the relationship between possible worlds and epistemic possibility, it goes beyond a surface analysis of epistemic possibility itself. The problems with parsimony also suggest a slight conceptual mismatch between the notions. So while centered worlds may provide a very useful way of thinking about scenarios, it may also be useful to look at other notions.

5 The epistemic construction of scenarios

The obstacles in the previous section all have a common source. They arise because we are taking a class of entities - the possible worlds -- developed in the service of a different notion of possibility (what might have been the case), and adapting it to help analyze the notion of epistemic possibility (what might be the case). It is inevitable that this adaptation will lead to certain complications. An alternative strategy suggests itself. Instead of adapting a different modal space, we might construct the space of scenarios directly, by a construction grounded in epistemic notions. In particular, we might take (deep) epistemic possibility as basic, and proceed from there. In this way, we can give an account of epistemic space in its own right.

The natural way to proceed is to identify scenarios with constructions out of thoughts or statements. We already have a notion of epistemic possibility that applies to these entities, and this notion can be exploited to construct scenarios directly. Of course we will need to appeal to possible thoughts and statements, since it is unlikely that all the thoughts and statements we need will exist in the actual world. For present purposes, I will understand these as subjunctively possible thoughts and statements - thoughts and statements that might have existed. Because of this, our construction of epistemic space will not be entirely independent of subjunctive modal notions, but the relationship will be much more indirect than in the previous constructions, so that the resulting epistemic space may be quite different from subjunctive modal space. An alternative strategy would be to appeal to the epistemic possibility that certain thoughts and statements exist, and bootstrap the construction from there, but I will not pursue that strategy here. Henceforth (to avoid clutter and also to avoid confusion with the existing and distinct notion of an epistemically possible thought), reference to thoughts and statements should be understood as reference to possible thoughts and statements.

I will work here with thoughts rather than statements, but everything here could straightforwardly adapted to statements. The approaches pursued here will start with the possible thoughts of a subject at a time, and so will first define a space of scenarios relative to a given subject and time. After that, we can look at defining a common space across subjects and times.

The simplest strategy is to identify scenarios with equivalence classes of thoughts. In particular, we can appeal to the class of maximal thoughts. As defined previously, a maximal thought is an epistemically possible thought T such that there is no epistemically possible thought T' such that T' implies T while T does not imply T1. We can say that two maximal thoughts T1 and T2 are equivalent if T1 implies T2 and
T2 implies T1. Then we can say that a scenario is an equivalence class (under this equivalence relation) of maximal thoughts, and that a scenario verifies a thought T if a maximal thought in its equivalence class implies T.

It is easy to see that this construction will satisfy Compositionality: this follows from the analogous principle about implication. The construction will also satisfy Parsimony: if two maximal thoughts imply the same thoughts, then they will imply each other, and will be members of the same equivalence class.

In order to satisfy Plenitude, we need the following principle: for every epistemically possible thought T, there is a maximal thought that verifies T. It is not absolutely obvious that this principle is correct: it is not absolutely obvious that maximal thoughts exist (perhaps for every possible thought, there will be a more specific thought?), and it is not absolutely obvious that there will be one for every epistemic possibility. Still, there is no obvious problem with the idea. And it is as least intuitively reasonable to suppose that from a given thought, a maximal thought could be obtained as a sort of maximal conjunction, by conjoining other thoughts or their negations until the limits of epistemic possibility are reached.

It is not obvious how to define the actualization of a thought: the maximal thought corresponding to how things are from the point of view of a given subject at a given time, thinking a given thought. It is tempting to say: a maximal thought M is actualized at a thought T if, were the subject to think M at the same time as T, M would be true. But this cannot work: any M that implies "I am not thinking a maximal thought" will fail this test, but intuitively, an M like this is required to capture how things are for most subjects. In effect, we want M to correctly describe how things were before M was thought. I will not pursue the project of defining actualization here. Instead I will take it that we have a reasonably good intuitive grip on the notion, and I will simply assume a relation of actualization between maximal thoughts and thoughts, such that a thought if true iff it is implied by its actualization.

If one has worries about maximal thoughts, one might also construct scenarios via maximal classes of thoughts. Let us that a class of thoughts is epistemically possible when, intuitively, the conjunction of thoughts in the class would be epistemically possible. Let us say that a complex is an epistemically possible class of thoughts. We can say that a complex C implies a thought T when the union of C with \{\neg T\} is not epistemically possible. A complex C implies a complex D when C implies every thought in D. We can say that a maximal complex is a complex C such that there is no complex C1 such that C1 implies C while C does not imply C1. We can then identify a scenarios with equivalence classes of complexes under mutual implication.

The definition of a complex appeals to the notion of an epistemically possible class of thoughts, which in turn appeals to the notion of the epistemic possibility of an arbitrary conjunction of thoughts. If we allow that for every class of thoughts (that is, of possible thoughts of a subject at a time), there is some possible thought that is their conjunction, then we can define this notion wholly in terms of the epistemic possibility of thoughts. But even if we deny this, perhaps because of in-principle cognitive limitations, it is arguable that the notion of an epistemically possible class of thoughts still makes sense. One could try to define it in various ways (e.g. via the claim that for every thought T that is a conjunction of thoughts in
the class, T is epistemically possible), or one could simply assume the notion. In any case, the claim that every thought is implied by some complex is weaker than the claim that every thought is implied by some maximal thought, so it is useful to have this notion on the table.

In any case, given the assumptions above, we can define the space of scenarios (relative to a subject) out of the possible thoughts of that subject, and the five central principles will be satisfied.

A question arises: will the space of scenarios (so defined) have interesting structure? Or will it have the structure simply of arbitrary classes of thoughts? This question depends on the extent to which thoughts are epistemically related, and to which there is epistemic entailment between different classes of thoughts. The question is too large to say much about here, but we can at least say a little.

Earlier we noted that at least some thoughts (perhaps all) are composed of concepts. Let us say that a thought T is composed from a class C of concepts if T is composed only of concepts in C. Then we can say that a class C of concepts is a basis class if all thoughts are implied by some thought composed from C. (Note that we do not require that all thoughts are equivalent to some thought composed from C.)

It is plausible that basis classes exist. The class of all concepts is plausibly a basis class (unless there are thoughts that are neither composed of concepts nor verified by any thoughts that are composed of concepts). Given any basis class C, then given any maximal thought M, there will be a thought M' composed from C such that M' implies M. Then M implies M' (by maximality of M), and M and M' are equivalent maximal thoughts. It follows that for any basis class C, we can construct arbitrary scenarios using only concepts in C.

The question then arises: how small can a basis class of concepts be? This is one of the deepest questions in philosophy. But here, I will simply note that it is plausible that many concepts are eliminable from a basic class. I have argued elsewhere that for many thoughts (e.g. "water is H2O", "Oswald killed Kennedy") there are statements about the world that are nontrivially sufficient to settle the truth of the thought. The exact form of these statements is not important here (plausible candidates include qualitative descriptions of the world in physical, mental, and indexical terms). What matters is there exist such nontrivially sufficient statements: sufficient in that they imply the thought or its negation, and nontrivially sufficient in that the statements in question do not invoke the main concepts from the original thought (e.g. "water") or their cognates. This phenomenon is not restricted to the actual world: in general, for an arbitrary epistemic possibility, there are statements about that possibility that are nontrivially sufficient to settle the status of the thought with respect to that possibility. If so, it follows that the main concepts in these thoughts are eliminable from a basis set of concepts.

Just how far this can be taken is an open question. I think it is plausible that a basis set can be stripped down quite a long way. I have argued that at least for possibilities in the vicinity of the actual world, a basis set consisting of microphysical concepts, phenomenal concepts, and indexical concepts (plus logical and mathematical concepts and other "framework" concepts) suffices. One might argue that microphysical concepts are themselves eliminable in favor of general spatial, temporal, causal, and
The Nature of Epistemic Space

experiential concepts, and perhaps ultimately in favor of phenomenal concepts plus the concept of causation. But I will not defend any such strong claim here. (Note again that the claim is not quite as strong as it may sound, as we do not require that every thought be equivalent to a basis thought.) What matters is that at least some concepts are eliminable from a basis set. To the extent that there are eliminable concepts, there will be nontrivial structure in the relation between scenarios and thoughts.

Having defined a space of scenarios for each subject at a time, we must now ask: how can we define a common space of scenarios for all subjects? (For ease of discussion, I will talk simply of subjects instead of subjects-at-times.) This requires some principle of translation between the maximal thoughts (or the complexes) of one subject, and those of another. We could simply stipulate that there is a relationship of translation among maximal thoughts, such that for any two subjects, a maximal thought of one subject is translated by exactly one maximal thought of another (at least up to a priori equivalence). This would not be very informative, however. Instead, it is useful to ground translation in some more basic notion of translatability.

To translate maximal thoughts, it suffices to define a translation relation across basis classes of concepts in all subjects. In more detail, let us say that a basic translation relation is an equivalence relation (translation) among a class C of translatable concepts across all subjects - yielding a derivative class of translatable thoughts composed from C, with a translation relation among them - such that:

(i) For any two subjects, any translatable concept of the first is translated by some concept of the second.

(ii) If a thought T1 translates a thought T2, then T1 is epistemically possible iff T2 is epistemically possible.

(iii) For any subject, the translatable concepts of that subject are a basis class.

It is easy to see that any basic translation relation yields a mapping between scenarios across subjects. Given scenarios S1 and S2 of subjects, we can stipulate that S1 translates S2 iff for any pair of translatable thoughts of the two respective subjects, S1 verifies T1 iff S2 verifies T2. Then for any two subjects and any scenarios S1 of the first subject, there will be a unique S2 that translates S1. (To see this, note first as a lemma that if T1' implies T1 and if these two thoughts are respectively translated by T2' and T2, then T2' implies T2: the epistemically impossible T1'&~T1 will be translated by T2'&~T2, which will be epistemically impossible by (ii). Now take any two subjects and a scenario S1 of the first subject. By (iv), there will be a translatable maximal thought T1 associated with S1. By (i), this will be translatable by a thought T2 of the second subject. T2 is maximal: if it were not, it would be implied by a translatable maximal thought it does not imply, so (by the lemma) T1 would be implied by a (translated) thought it does not imply, so T1 would not be maximal. Given two any two translatable thoughts T1' and T2' of the subjects, the lemma entails that T1 implies T1' iff T2 implies T2', so S1 implies T1' iff S2 implies T2'. So S2 translates S1. If any scenario S3 translates S1, then S3 will verify T2 (since S1 verifies T1 and T2 translates T1), so S3 verifies T2, and S3=S2. So S2 is the unique scenario...
So for a common space of scenarios, we need not start with a translation relation over all concepts: a translation relation on a class of basis concepts will suffice. That is, we need a notion of epistemic translatability that clearly applies to some concepts, and is such that the concepts to which it applies forms a basis class. I will not try to define this relation here, but I will say a few words about it.

For two thoughts to be epistemically translatable, then intuitively, they must divide epistemic space in the same way. We can get an initial grip on the notion from the discussion of centered worlds above. Two thoughts "I am a philosopher" by me and a friend will each be verified by all centered worlds in which the being at the center is a philosopher (at least, if there are no relevant differences in our concepts of "philosopher"); so these thoughts will be epistemically translatable. The same goes, plausibly, for two thoughts "my greatgrandparents are first cousins", and the like. In a similar way, for two concepts to be epistemically translatable, they must at least have the same epistemic intension across centered worlds. It seems that any two "I" concepts will be epistemically translatable, and that two "first cousin" concepts are epistemically translatable, and so on.

Clearly, epistemic translatability is not a notion that requires sameness of extension. This is illustrated by the case of "I", and by the more general point that two concepts can have the same epistemic intension across centered worlds but quite different extensions, due to embedding in different centered worlds. The crucial property of epistemic translatability is requirement (ii) above: for this requirement, sameness of extension is irrelevant (and most extension-dependent notions of translatability will not meet it). Rather, what matters is something like sameness of inferential role, and in particular isomorphism of a priori connections.

I will not try to formally define this notion of epistemic translatability here. But even without a formal definition, I think that we have a clear grasp of an epistemic translatability relation over a wide class of concepts. Translatability intuitions become difficult where extension-dependent (or otherwise environment-dependent) concept types are involved, as with the concepts expressed by names and natural kind terms, and also with concepts that are expressed by terms used with semantic deference. But even when these concepts are eliminated, a robust class of concepts remains (such as those above), with a relatively uncontroversial translation relation among them. And it can be plausibly argued that these concepts form a basis class (or something close to it), so that we have a basis translation relation. If so, this yields a common space of scenarios, and a construction of epistemic space.

(There is one obstacle to a basic translation relation here, involving demonstrative concepts in the sort of case mentioned before. Say I demonstrate one of two spots in a symmetrical visual field and think "this is red" (T); and say another possible subject in the same situation thinks two analogous "this is red" thoughts (T1 and T2), one for each spot. Then T plausibly is no better or worse translated by T1 or T2; and T1 or T2 do not translate each other, as they do not imply each other. So T is translated by neither T1 nor T2. More generally, it seems that no possible thought of the other subject is appropriate to translate T. For the same reason, no possible concept of his is appropriate to translate my "this" concept, and there seems to be no underlying translatable basis concept either. I think the moral is that experiential
demonstratives are not strictly translatable, but are sui generis.

If this is right, then the space of scenarios for a subject will involve a common translatable basis plus a further basis of untranslatable demonstratives. We can either have a mildly different space of scenarios for each subject (slightly modifying the original picture), or an extended common space with all possible demonstratives (such that some subjects cannot be related to some scenarios). Either way, demonstrative thoughts will never have identical epistemic content across subjects. But we can define an epistemic isomorphism relation between thoughts and between scenarios, such that T stands in this relation to both T1 and T2, which will allow good enough cross-subject comparisons for most purposes.)

It is worth noting that insofar as we have an independent grasp on a notion of epistemic translatability of (at least some) thoughts, this imposes a further constraint on epistemic space that might be worth listing alongside the original principles of epistemic space:

Translatability: If thoughts T1 and T2 are epistemically translatable, then for all scenarios, S verifies T1 iff S verifies T2.

To be made precise, this principle would require a precise and independently grounded definition of epistemic translatability across some class of concepts and thoughts. But even in the absence of a precise definition, insofar as we have an intuitive grasp of epistemic translatability (at least in clear cases), the Translatability principle yields a substantial constraint that epistemic space should satisfy.

Instead of further pursuing the strategy based directly on epistemic translatability of thoughts, I will instead pursue a closely related linguistic strategy for constructing scenarios instead. This strategy starts with sentences, where these are understood as types within a language rather than as tokens.

It is natural to try to construct scenarios by invoking an epistemic possibility operator over sentences, and proceeding from there. But there is an obstacle: many words and sentences exhibit a sort of epistemic variation, so that one token of a sentence may be a priori and another not. This happens most obviously with ambiguous terms, and terms with context-dependent criteria of application. It can also happen with names and natural kind terms. For example, if Leverrier uses "Neptune" as a name for whatever perturbs the orbit of Uranus, and if his wife picks up the term from him without knowing this, then their two corresponding concepts may have different epistemic intensions. To see this, note that "Neptune perturbs the orbit of Uranus, if it exists" expresses an a priori thought for Leverrier, but not for his wife. So the two statements will have different epistemic intensions, arising from difference in the subjects' concepts of "Neptune". So sentences like this are not well-suited to constructing epistemic space.

To deal with this obstacle, we can restrict attention to a special class of epistemically invariant expressions. This class should at least have the property that if a sentence S contains only epistemically invariant expressions, then if one token of S is epistemically possible, all tokens of S will be epistemically possible (setting aside tokens of S that are used deferentially.) And more generally, these expressions should be such that (intuitively) their epistemic intensions across centered worlds cannot
To obtain such a class, we can exclude names and natural kind terms, which allow phenomena such as the above. We can regiment language to eliminate ambiguity. And we can regiment language to eliminate terms with context-dependent criteria of application (especially criteria that vary with speaker's intentions or with conversational context; simple dependence of extension on the environment is allowable). The terms that remain are epistemically invariant. These terms will include pure indexicals such as "I", "now", and "here", and logical and mathematical terms. Also included will be pure descriptive terms: perhaps terms such as "philosopher", "circle", "justice", "object", "cause", "perceive", and "conscious", at least if these are regimented to avoid contextual variation.

Let us say that a language is epistemically invariant if all terms in it are epistemically invariant. English is not epistemically invariant, although it plausibly contains epistemically invariant sublanguages (by restricting the lexicon). But there are certainly many possible languages that are epistemically invariant, and some of them will have significant expressive power.

If L is an epistemically invariant language and S is a sentence in L, then if one token of S is epistemically possible, all tokens of S are epistemically possible (again, setting aside tokens used deferentially). So here we can associate epistemic possibility with types: a sentence S is epistemically possible if any (nondeferential) token of S is epistemically possible. It is reasonable to hold that any sentence of L can be used in principle by an arbitrary subject, expressing a thought. We can define an implication relation between sentences of L and arbitrary thoughts: a sentence S implies a thought T if the thought that the subject would express with S implies T. The epistemic invariance of L ensures that there is a fact of the matter here. Then the following thesis is attractive:

Invariant Basis Thesis: There is an epistemically invariant language L such that every thought is implied by some sentence of L.

In fact, an apparently weaker thesis would suffice: every thought is implied by some epistemically invariant sentence. We need not require that all the sentences be part of the same language. But given the plausible thesis that for any class of languages, their union constitutes a language, the weaker principle entails the stronger.

I will not defend this thesis at length here. I think, however, that it (or something like it) is plausible. The central intuition behind it is that there is nothing about the variability of language that increases our ability to entertain maximal thoughts: variability simply allows for a certain sort of coarse-graining. And where there is coarse-graining, there are more specific fine-grained states, which can be expressed in a fine-grained language. If so, it is plausible that even if a specific thought cannot be expressed in an epistemically invariant sentence, it will be implied by a more fine-grained thought that can.

(As earlier, the thesis needs qualification to handle demonstrative thoughts. To handle such thoughts, the language can be supplemented by an arbitrary number of experiential demonstratives, different
demonstratives for each subject.)

In any case, if the thesis is true, we can use it to straightforwardly construct epistemic space. The natural approach is to identify scenarios with equivalence classes of maximal sentences (epistemically possible sentences of \( L \) that that are not implied by any sentences that they do not imply), and to say that a scenario verifies a thought when one of the associated maximal sentences implies the thought. As for the actualization relation, formal definitions are subject to the same complications as before, but we given that we have a reasonably firm intuitive grasp on the notion, we can simply assume it.

Is Plenitude satisfied? If every thought \( T \) is implied by a maximal thought \( M \), then \( M \) will be implied by a sentence of \( L \), which will be maximal (given that every sentence expresses a thought), so there will be a scenario verifying \( T \). Even if there is a problem with maximal thoughts, one could construct scenarios from maximal complexes of sentences, assuming we have an epistemic possibility operator over classes of sentences (yielding notions of implication and maximality over complexes), and that any sentence is implied by some maximal complex. Any thought will be implied by some sentence of \( L \), which will be implied by a maximal complex, so the thought will be verified by a scenario.

As for the other principles: Compositionality will be satisfied straightforwardly. Parsimony will be satisfied if every sentence of \( L \) can express a thought; if not, it may be satisfied under other minimal assumptions. Actuality and Truth will be unproblematic, given an appropriate actualization relation. Translatability will be guaranteed, if we take our initial notion of translatability to hold that two thoughts are translatable when they are expressible by the same sentence of \( L \). So if the thesis is true, minor assumptions yield a space of scenarios and a verification relation satisfying the central principles of epistemic space.

It is worth noting that this general discussion of epistemic translatability gives us a general constraint on epistemic space that may be worth noting. The discussion here gives us one way of independently grounding a notion of epistemic translatability among at least a subclass of thoughts: two thoughts are epistemically translatable when they are expressible by the same sentence of an epistemically invariant language.

6 Applications

We have seen that there are various ways in which we might construct a space of scenarios satisfying the principles of epistemic space. As with many such constructions, certain assumptions and/or idealizations are required for the constructions to work and I have not demonstrated the truth of the assumptions and the reasonableness of the idealizations. But the assumptions and idealizations do not look obviously problematic. And as with other constructions of abstract objects, the notion of a scenario should not be seen as hostage to a construction. Rather, the constructions provide a prima facie reason to think that the notion of epistemic space is coherent, and give a sense of how it should behave.

If the notion of epistemic space is coherent, it has a large payoff. One obvious application is in the
analysis of knowledge and of epistemic possibility. But there are also applications in the analysis of the content of thought and language. I will briefly outline three such application in the following: to the analysis of Fregean sense, narrow content, and indicative conditionals. Each of these topics deserves a much extended treatment (see "On Sense and Intension", "The Components of Content", and "The Tyranny of the Subjunctive" for this treatment). But even a brief examination shows that epistemic space has much to offer here.

6.1 Fregean sense

Frege held that every expression was associated with a referent, and also with a sense. The sense of an expression mirrors the cognitive value of the expression: for example, since "Hesperus is Phosphorus" is cognitively significant, "Hesperus" and "Phosphorus" have different senses, although they have the same referent. Frege also held that sense determines reference. In a little more detail, sense was supposed to obey at least the following four principles:

(1) Every expression with a referent has a sense.

(2) Sense reflects cognitive significance: singular terms 'a' and 'b' have different senses if 'a=b' is cognitively significant; sentences 'S' and 'T' have different senses iff 'S iff T' is cognitively significant.

(3) The sense of a complex expression is determined by the senses of its parts.

(4) Sense determines reference.

In contrast to Frege, many contemporary philosophers hold that there is no such thing as sense: nothing satisfies theses (1)-(4).

Epistemic space yields a notion that is closely akin to sense. We have seen that every statement can be associated with an epistemic intension, a function from scenarios to truth-values. Further, every expression token within a statement, can be associated with an epistemic intension, a function from scenarios to extensions. To unify these, let us say that the extension of a statement is its truth-value. Let us say that a statement is epistemically contingent if its negation is epistemically possible. Then epistemic intensions has the following properties:

(1) Every expression token with an extension has an epistemic intension.

(2) Epistemic intension reflects (deep) epistemic contingency: singular terms 'a' and 'b' have different epistemic intensions iff 'a=b' is epistemically contingent; statements 'S' and 'T' have different epistemic intensions iff 'S iff T' is epistemically contingent.

(3) The epistemic intension of a complex expression is (usually) determined by the epistemic intension of
(4) An expression's epistemic intension determines its extension, in conjunction with the actual world.

Principle (1) arises from the general framework. Principle (2) follows from Plenitude and Compositionality. Principle (3) follows from Compositionality. Principle (4) follows from Actuality and Truth.

These four principles are closely related to Frege's, with epistemic intensions playing the role of sense. In (1), senses are associated with expression tokens rather than types, but this seems also to be Frege's view at least of natural languages. In (3), we may need to put minor restrictions on compositionality of epistemic intensions (for reasons below), but it is close to correct. In (4), we must understand determination as determination in conjunction with the world: roughly, that sense provides a condition on extension, which entities in the world may satisfy. This may or may not have been Frege's view of determination, but in any case his view is often understood this way.

The key principle (2) will correspond to Frege's principle if cognitive significance is understood as epistemic contingency. Epistemic contingency behaves very much like cognitive significance: for example, my statement "Hesperus is Phosphorus" is epistemically contingent while "Hesperus is Hesperus is not. More generally, any a posteriori statement will be both cognitively significant and epistemically contingent, while any trivial statement will be neither. There is a difference, however, due to the idealization in the notion of epistemic possibility. Frege held that many a priori statements, such as statements of mathematics, are cognitively significant. As I have defined (ideal deep) epistemic possibility, they are not epistemically contingent but epistemically necessary. It follows that this notion of epistemic contingency departs from Frege's notion of cognitive significance, as it is idealized and less fine-grained. It is nevertheless closely related, and can do much of the work done by cognitive significance. (It is also possible that we can define more fine-grained notions of epistemic possibility and epistemic intension, as we will see.)

In recent years, it has been argued that no broadly Fregean account of the content of linguistic expressions can work. There have been at least three prominent arguments here: the argument from indexicality (Perry), the modal argument (Kripke), and the epistemic argument (Kripke). It can easily be seen that these objections do not apply to the present account.

The argument from indexicality holds that there is no coherent way for a Fregean view to handle the sense indexicals such as "I" and "now". Frege held that these vary between speakers and/or occasions, but this yields a mismatch between sense and cognitive significance. On my approach, these are handled straightforwardly: each token of such an indexical has the same (indexical) epistemic intension, mapping a scenario to the individual or time at the center. This way, sense mirrors cognitive significance. This view departs from Frege's own view: because the sense of an indexical sentence is itself indexical, it will not have an absolute truth-value (as Frege held), but rather a truth-value relative to a subject and time. But the departure ensures consistency, and is still compatible with the spirit of a broadly Fregean view.
The modal argument suggests that a name is not semantically equivalent to any description because of differences in modal contexts. For example, it might have been that Hesperus was not the evening star (e.g. it it had been knocked off course by a comet), so 'Hesperus' is not equivalent to 'the evening star'. And it seems that these cannot have the same sense, since they have different referents in possible worlds. On my view: once we distinguish epistemic from subjunctive notions, all this is compatible with 'Hesperus' and 'the evening star' having the same sense. 'Hesperus is not the evening star' is subjunctively possible but (roughly) epistemically impossible. Correspondingly, 'Hesperus' and 'the evening star' have the same epistemic intension (sense), but different subjunctive intensions. The modal context 'it might have been that ...' is governed by the subjunctive intensions of the expressions, as is the referent of these expressions in alternative possible worlds (considered as ways the world might have been). But all this is compatible with sameness of sense, where sense reflects cognitive significance and determines actual extension.

The epistemic argument suggests that many names are not equivalent to descriptions, because of epistemic differences. For example, 'Gödel' is not equivalent to 'the man who proved the incompleteness of arithmetic': it might turn out that Gödel did not prove incompleteness (perhaps he stole the proof), so it is not a priori that Gödel proved incompleteness. So the name and the description are inequivalent and have different senses. In response: nothing here can show that the name lacks an epistemic intension. In fact, Kripke's argument proceeds by considering an epistemically possible scenario (one in which the man called 'Gödel' steals the proof from a man called 'Schmidt'), and evaluating it as an instance of the epistemic possibility that Gödel did not prove incompleteness. All this is entirely compatible with the epistemic model. At most, it shows that the epistemic intension of a name is not equivalent to that of any associated description; it does not show that names do not have epistemic intensions.

So it seems that the framework of epistemic space provides the basis for a workable Fregean approach to the content of linguistic expressions. These arguments simply suggest that senses must be indexicals, that sense and extension do not exhaust semantic value, and that senses are intensions rather than descriptions. The result differs in some respects from Frege's own view (particularly with regard to the indexicality of senses, and the cognitive significance of a priori statements), but it clearly has much in common.

It should be noted that because epistemic intensions are associated in the first instance with expression tokens rather than types, this does not constitute an account of senses as linguistic meanings: the sort common to all tokens of an expression type. It may be that in some cases (but not all), it could be extended into such an account. But in any case, Frege himself allows that senses could vary between tokens of a type in natural language; and there is much work that a token-relative notion of linguistic content can do.

## 6.2 Narrow Content

Let us say that the content of a thought is *wide* if it depends on the environment: that is, if subjects who are internal (physical and phenomenal) duplicates have corresponding thoughts with different content.
The content of a thought is narrow if it does not depend on the environment, and is the same between duplicates. In contemporary philosophy of mind, it is commonly accepted that many thoughts have only wide content. In response, some have argued that thoughts also have narrow content, and that even when a thought has wide content, it also has narrow content underlying. But no account of narrow content has received widespread support.

I think that the epistemic content of a thought, as I have defined it, is a sort of narrow content. The corresponding thoughts of two internal duplicates will have the same epistemic content. This can be seen initially though examining the cases that are commonly used as arguments for wide content.

(1) Twin Earth (Putnam 1975). Oscar lives on Earth, surrounded by water (i.e. H2O). Twin Oscar lives on Twin Earth, which is much like Earth except that H2O is replaced by superficially identical XYZ, which is not water but twater. Oscar and Twin Oscar are (near) duplicates and are chemically ignorant. Both utter "water is expensive", expressing a belief. Oscar believes that water is expensive, but Twin Oscar does not: he believes that twater is expensive. So their beliefs have different content.

Let B1 and B2 be the respective beliefs of Oscar and Twin Oscar. What is their epistemic content? We can see this by examining four relevant scenarios:

S1: Watery stuff in the environment is H2O, H2O is expensive. S2: Watery stuff in the environment is H2O, H2O is not expensive. S3: Watery stuff in the environment is XYZ, XYZ is expensive. S4: Watery stuff in the environment is XYZ, XYZ is not expensive.

Oscar's belief B1 is clearly verified by S1, and falsified by S2. It is also verified by S3: the thought that S3 is actual implies B1. That is, for Oscar, the hypothesis that S3 is actual and water is not expensive is epistemically impossible: if he accepts that S3 is actual, he will rationally accept that water is expensive. For similar reasons, B1 is falsified by S4.

For symmetrical reasons, Twin Oscar's belief B2 is verified by S3 and falsified by S4, and verified by S1 and falsified by S2. That is, both B1 and B2 are verified by S1 and S3, and falsified by S2 and S4. So at least as far as these four scenarios are concerned, B1 and B2 have the same epistemic intension. But these four scenarios are the crucial scenarios here: if B1 and B2 have the same epistemic intensions across these scenarios, they plausibly have the same epistemic intension overall. So B1 and B2 plausibly have the same epistemic content.

Note that B1 and B2 plausibly have different subjunctive content. B1 is plausibly satisfied only by worlds in which H2O is expensive and not by worlds in which XYZ is expensive, while for B2, the situation is reversed. So B1 and B2 have different subjunctive intensions. The subjunctive content here can be seen as the wide content of B1 and B2, while the epistemic content can be seen as the narrow content.

(2) Arthritis (Burge 1979). Bert and Twin Bert both have a term "arthritis", which they use for a disease whose nature they do not fully understand. Bert lives on Earth, where experts in his community use
"arthritis" for disease D1 (arthritis). Twin Bert lives on Twin Earth, where experts in his community use "arthritis" for disease D2 (twarthritis). Bert and Twin Bert are duplicates: both utter "I have arthritis in my thigh". Bert believes that he has arthritis in his thigh. Twin Bert believes that he has twarthritis in his thigh. So it seems that their beliefs have different content.

Let B1 and B2 be the respective beliefs of Oscar and Twin Oscar. What is their epistemic content? We can see this by examining four relevant scenarios:

S1: Experts use "arthritis" for D1, D1 is in my (center subject's) thigh. S2: Experts use "arthritis" for D1, D1 is not in my thigh. S3: Experts use "arthritis" for D2, D2 is in my thigh. S4: Experts use "arthritis" for D2, D2 is not in my thigh.

(Scenario S1 may be impossible due to the nature of D1, but set this inessential worry aside.) Oscar's belief B1 is clearly verified by S1 (the actualized scenario) and falsified by S2. It is also verified by S3: the thought that S3 is actual implies B1. That is, for Oscar the hypothesis "S3 is actual and arthritis is not in my thigh" is epistemically impossible: if Oscar accepts that S3 is actual, he should rationally accept "I have arthritis in my thigh". For similar reasons, B1 is falsified by S4.

For symmetrical reasons, Twin Bert's belief B2 is verified by S3 (his actualized scenario) and falsified by S4, and verified by S1 and falsified by S2. That is, both B1 and B2 are verified by S1 and S3, and falsified by S2 and S4. So at least as far as these four scenarios are concerned, B1 and B2 have the same epistemic intension. But these four scenarios are the crucial scenarios here: if B1 and B2 have the same epistemic intensions across these scenarios, they plausibly have the same epistemic intension overall. So B1 and B2 plausibly have the same epistemic content.

Again, B1 and B2 may have different subjunctive intensions, so their subjunctive content may constitute wide content. But their epistemic content constitutes narrow content.

All this enables us to reconcile the facts that (a) the truth of a belief ascription such as "Oscar believes that water is expensive" or "Bert believes that he has arthritis in his thigh" depends on the subject's environment, and that (b) the two corresponding beliefs have the same narrow (epistemic) content. To reconcile these, we need only accept that the truth of belief ascription can depend on both the subjunctive content and the epistemic content of a subject's beliefs. Given this dual dependence, the wideness of subjunctive content explains the wideness of belief ascriptions, in a manner that is entirely compatible with epistemic content being narrow. (See "The Components of Content" for more on how this dual dependence works.)

In addition to examining cases, we can also give a principled argument that epistemic content is narrow. All we need are the following two theses:

Duplication Thesis 1: Given any two duplicates A1 and A2 and corresponding thoughts T1 and T2, then T1 is epistemically possible iff T2 is epistemically possible.
Duplication Thesis 2: Given any two duplicates A1 and A2 and corresponding concepts C1 and C2, then if C1 is an epistemically translatable basis concept, C2 translates C1.

The first thesis is extremely plausible, and nothing in arguments for externalism gives reason to deny it. In effect, the claim is that the apriority of beliefs is internally determined. This is what we would expect: whether a belief is a priori depends only on whether it can be nonexperientially justified, and whether a belief can be nonexperientially justified is independent of the environment.

The second thesis is also plausible, for the epistemic translation relation invoked earlier. The sorts of concepts over which translation is invoked are concepts to which externalist arguments do not apply: extension-dependent concept types such as names and natural kind concepts are excluded, and deferential uses of concepts are excluded. For the indexical and purely descriptive concepts that remain, the translation mapping between duplicate individuals will be relatively uncontroversial. And if these concepts form a basis class, this mapping can be extended into a mapping of arbitrary scenarios.

Given these two theses, then take any two duplicates with corresponding beliefs B1 and B2, and consider an arbitrary scenario S. Given that the translatable concepts are a basis class, S will be associated with a translatable maximal thought M1 in the first subject. If S verifies B1, then M will imply B1: that is, the thought "M1&~B1" will be epistemically impossible. The thought corresponding to "M1&~B1" will be "M2&~B2". By the first thesis, M2&~B2 will be epistemically impossible. By the second thesis, M2 will translate M1, so it will also be associated with S. So we can see that S verifies B1 if and only if S verifies B2. So B1 and B2 have the same epistemic content. This holds for arbitrary beliefs, so epistemic content is narrow content.

(As before, there is a mild exception for demonstrative beliefs, whose content is sui generis between individuals. When I attend to a spot in a symmetrical visual field and believe "This is red", and when a duplicate of me does the same, our thoughts will not have exactly the same epistemic content, since there is no canonical translation between experiential demonstratives. Instead, we can say that the thoughts are epistemically isomorphic, and have isomorphic epistemic content. Given the general thesis that corresponding demonstrative concepts are epistemically isomorphic concepts, as is plausible, we can still maintain the thesis that duplicates always have isomorphic narrow contents.)

6.3 Indicative and subjunctive conditionals

There is a striking, although infrequently noted asymmetry between indicative and subjunctive conditionals. Consider the following pairs:

(1a) If Prince Albert Victor murdered those women, he is Jack the Ripper.

(1b) If Prince Albert Victor had murdered those women, he would have been Jack the Ripper.
The Nature of Epistemic Space

(2a) If XYZ is (and has been) the clear liquid in the oceans and lakes, water is XYZ.

(2b) If XYZ had been the clear liquid in the oceans and lakes, water would have been XYZ.

In these pairs, the first member seems intuitively correct. (1a) might reasonably be accepted by a detective investigating the murders. (2a) might reasonably be accepted by someone who is ignorant of the chemical composition of water, or even by someone who knows that water is H2O but is not certain of this. These conditionals pass the Ramsey test: if the antecedent is accepted as a hypothetical premise, the consequent should be accepted as a hypothetical conclusion. Let us say that in these conditions, the indicative conditional is correct. (I will be neutral on whether correctness corresponds to truth, assertibility, or something else.) Clearly, (1a) and (2b) are correct indicative conditionals.

In these pairs, the second member seems intuitively incorrect, at least if Kripke's intuitions are accepted. Given that Prince Albert Victor is not actually Jack the Ripper (as seems likely), then even if he had committed the murders, he would not have been Jack the Ripper. Rather, he would have committed the murders instead of Jack the Ripper. Similarly, given that water is actually H2O, then even if XYZ had been the clear liquid in the oceans and lakes, XYZ would not have been water. Rather, XYZ would have been in the oceans and lakes instead of water.

(I should note that my own intuitions about these subjunctive conditionals are not quite as clear as Kripke's. But for the sake of discussion I will accept the Kripkean intuitions.)

There is one especially striking feature of the asymmetry: it seems that the correct indicative conditionals have a "metaphysically impossible" consequent. How can this be accommodated in a semantic theory? More generally, how can the asymmetry be explained?

Many philosophers hold that one can give a possible worlds account of subjunctive conditionals, along something like the following lines:

"If it had been that S, it would have been that T" is true <-> the closest S-world is a T-world.

Here, closeness is a similarity metric on the space of possible worlds, and the closest S-world is the world such that of all worlds in which S in the case, it is the most similar to the actual world. Note that the closeness metric may vary between contexts, and that one can adjust the definition in various ways, e.g. to allow for multiple closest worlds.

Many philosophers hold that by contrast, one cannot give a possible-worlds account of indicative conditionals, holding that they are deeply epistemic rather than modal. The considerations above are not usually invoked here, but they might be thought to strengthen the case: if correct indicative conditionals can have metaphysically possible antecedents and impossible consequences, then possible worlds are an
However, the framework of epistemic space allows us to give an analysis of indicative conditionals that is parallel to the analysis of subjunctive conditionals, except that we invoke the space of epistemic rather than subjunctive possibility. In particular, one can hold the following:

"If S is the case, then T is the case" is correct $\iff$ the epistemically closest S-scenario is a T-scenario.

I will not attempt an exact analysis of the notion of epistemic closeness here. But it should be understood as something like the following: one scenario is epistemically closer than another (for a subject) to the extent that it is more compatible with the subject's knowledge (or beliefs), or to the extent that it is compatible with a smaller revision of the subject's knowledge-constituting beliefs. Note that epistemic closeness is subject-relative, and depends on what a subject knows (or believes). Whether knowledge or belief should be invoked here is a tricky issue that I will not go into here.

Then in the cases above: there is a wide variety of scenarios in that verify "Prince Albert Victor committed the murders", and all (or almost all) verify "Prince Albert Victor is Jack the Ripper". Similarly, there is a wide variety of scenarios in which XYZ is and has been the liquid in the oceans and lakes. Those most compatible with a subject's beliefs are plausibly those in which things are superficially identical except for the substitution for XYZ for H2O, and these all verify "water is XYZ". So in both cases, the epistemically closest scenarios verifying the antecedent also verify the consequent.

Note that all this is very much compatible with the Ramsey test for the assertibility of indicative conditionals. When we hypothetically accept S, we hypothetically exclude all scenarios verifying $\neg S$, while making minimal revisions to our beliefs. The scenarios we will then be led to hypothetically endorse are those that verify $\neg S$ and that are compatible with a minimal revision of our beliefs. That is, we are led to hypothetically endorse the epistemically closest S-scenarios. We will conclude that T precisely to the extent to which the endorsed S-scenarios are also T-scenarios. So the Ramsey test will be satisfied precisely when the conditions above are met.

(Note that the Ramsey test corresponds to the belief-relative notion of epistemic closeness. Does this mean that our correctness conditions should also appeal to the belief-relative notion? Not necessarily: or only to the extent that correctness and assertibility converge. It is arguable that when an assertible indicative conditional is grounded in false beliefs, the conditional is intuitively incorrect. If so, then it is plausible that correctness conditions should not depend on a subject's false beliefs, and perhaps should depend only on a subject's knowledge.)

The subject-relativity in the notion of epistemic closeness mirrors the often-noted subject-relativity in the correctness conditions of indicative conditionals. To use a version of the "Sly Pete" example: say that Pete holds one card, that I know that Pete has a 3 or a 5, and that you know that Pete has a 5 or a 7 (of course he actually has a 5). Then I can correctly say: if Pete does not have a 5, he has a 3. And you can correctly say: if Pete does not have a 5, he has a 7. It is plausible that I could not correctly assert the
second, and you could not correctly assert the first. The difference results from the difference in our epistemic closeness measure, resulting from the difference in our knowledge. For me, the closest scenarios in which Pete does not have a 5 are scenarios in which he has a 31. For you, the closest scenarios in which Pete does not have a 5 are those in which he has a 7.

Note that the analyses of subjunctive and indicative conditionals are almost exactly parallel, except for the differences between (i) S-worlds vs. S-scenarios, and (ii) counterfactual closeness vs. epistemic closeness. It is natural to hope that many of the tools that have been used to analyze subjunctive conditionals can also be adapted to analyze indicative conditionals.

7 Hyperintensionality

The notion of (deep) epistemic possibility that we have been dealing with is an idealized one: if S is knowable a priori, then it is not epistemically possible that ~S, even when S is far from obvious, and even when no-one in the world knows that S. This has the result that any two sentences that are a priori equivalent will have the same epistemic intension, and the same epistemic content. For example, all a priori sentences, including complex sentences of logic and mathematics, have the same epistemic intension. And all a priori thoughts, including complex logical and mathematical thoughts, have the same epistemic intension.

It is natural to wonder if there is a less idealized notion of epistemic possibility that will a more fine-grained notion of epistemic content. This is a complex issue, but I think there can be.

To develop this notion, we must start with a nonideal notion of deep epistemic possibility. Instead of saying that it is epistemically possible that P when ~P cannot possibly be ruled out a priori, we might say that it is epistemically possible that P when ~P cannot be ruled out through reasoning of a certain sort. Here, there are various possibilities.

We might hold that it is epistemically possible that P when:

(i) it is not obvious a priori that ~P; (ii) P cannot be ruled out by such-and-such amount of a priori reasoning; (iii) P cannot be ruled out through logical reasoning alone; (iv) P cannot be ruled out through non-moral a priori reasoning; (v) it is not obvious that ~P (vi) it is not trivial that ~P (vii) it is not certain that ~P (viii) it is not known that ~P

and so on. Here, the definitions work have different properties. The first four definitions all appeal to varieties of a priori reasoning. These guarantee that if it is epistemically possible that P in the previous sense, it will be epistemically possible that P in the new sense. The last four definitions do not appeal only to a priori reasoning; so it is possible that some P will be epistemically possible in the original sense but not in the new sense (e.g. obvious empirical falsehoods, such as "I do not exist" or "I do not have hands"). Because we are mostly concerned with more fine-grained notions of epistemic possibility here, I will concentrate on definitions in the first class.
Given a notion of non-ideal epistemic possibility, we can attempt to set up a corresponding non-ideal epistemic space, made up of non-ideal scenarios. The principles governing this space will be much as before. The key principle, once again, will be Plenitude: there is a scenario verifying $S$ iff $S$ is epistemically possible. Because many more thoughts and statements will be epistemically possible for non-ideal notions of epistemic possibility, it follows that there will be many more corresponding non-ideal scenarios.

It seems reasonable that the principles of Actuality, Truth, Parsimony, and Translatability should all hold on this model. There is a question about whether Compositionality should be endorsed. If a compositional principle is itself nonobvious, it may be that each $T_i$ can be epistemically possible without $\text{comp}(T_i)$ being epistemically possible. If compositionality holds, it is likely that if a scenario verifies some statements, it will verify all logical consequences of those statements, which may be undesirable. If so, we may wish to do without Compositionality, or restrict it in some fashion to obvious compositions and the like.

The processing of constructing scenarios will be more complex where non-ideal epistemic possibility is concerned. It is clear that centered worlds will be inappropriate here. On natural models of verification, a priori falsehoods will be verified by no centered world; and on any reasonable model of verification, there will not be enough centered worlds to satisfy Plenitude. As for the direct epistemic construction, we will probably need to avoid appeal to maximal statements and thoughts. Maximal statements and thoughts are likely to be indiscriminately epistemically possible, because of their complexity, and they may have no interesting implication relations to ordinary thoughts.

Instead, it may be best to appeal to classes of statements of thoughts: perhaps classes such that no statement or combination of statements is epistemically impossible. Then we can say that a class implies a statement $T$ if some conjunction of $\neg T$ with a set of statements in the class is epistemically impossible, or perhaps if there is some reasoning process of the relevant sort that takes us from a statement or group of statements in the class to $T$. We can say that one class implies another class if it implies every statement in that class. We can say that a class is maximal if it is implied by no class that it does not imply. A maximal class will verify a thought when it implies that thought. There will be difficulties in setting up equivalence relations on maximal classes, due to failures of transitivity in implication, but this problem might be dealt with in a variety of ways. It seems that this sort of approach is at least promising.

If we can set up a non-ideal epistemic space corresponding to a non-ideal notion of epistemic possibility, we will then have a corresponding notion of non-ideal epistemic content. We can say that the non-ideal epistemic content of a thought is the thought's intension over non-ideal scenarios, according to whether those scenarios verify the thought. Then for any two thoughts $T_1$ and $T_2$ such that it is epistemically possible that $T_1$ holds without $T_2$ and vice versa, $T_1$ and $T_2$ will have different non-ideal epistemic content. The same goes for the non-ideal epistemic content of statements.

When this way of thinking is applied to different notions of epistemic possibility, it will yield various different applications. For example, if we are concerned with Frege's notion of cognitive significance, we
can say that $T$ is epistemically possible when $\neg T$ is cognitively significant (perhaps this will be whenever $\neg T$ is nontrivial), and we can set up a corresponding non-ideal epistemic space. This will yield a variety of non-ideal epistemic content that behaves very much like Fregean sense.

Another application: For the ordinary notion of epistemic possibility (strict epistemic possibility) with which we started this paper, it is plausible that $P$ is strictly epistemically possible when one could not easily come to know that $\neg P$ given what one already knows. The corresponding notion of deep epistemic possibility is something like the following: it is deeply epistemically possible that $P$ when one cannot easily know a priori that $\neg P$. From this notion, we will be able to set up a corresponding non-ideal epistemic space. For this space, it is plausible that $P$ is strictly epistemically possible iff there is a $P$-scenario that is not excluded by any item of one's knowledge. So this space is perhaps the closest to delivering the intuitive picture of strict epistemic possibility as discussed at the start of the paper.

Another application: say that we are concerned with hypotheses about the relationship between the nonmoral and the moral. We may think that the connection is ultimately a priori, or we may think that moral beliefs are ultimately not truth-evaluable, but as long as the connection and the non-truth-evaluability is not obvious, there will be an interesting hypothesis space to investigate. To do this, we can invoke notion (iv) above: it is epistemically possible that $P$ when $P$ cannot be ruled out through nonmoral a priori reasoning. This will plausible yield a space of "moral scenarios" which is much like the space of ideal scenarios, except that it may have an additional dimension of variation in the way that it associates moral claims with nonmoral claims. Such a space may be very useful for analyzing the moral domain without presupposing moral views. (This will be closely related to Gibbard's notion of a factual-normative world.)

It may be that there is no canonical notion of nonideal epistemic possibility. If so, there will be no canonical notion of nonideal epistemic content. Instead, we might have a spectrum of notions of deep epistemic possibility, from the ideal to the nonideal, perhaps ending at the notion on which anything is epistemically possible, and on which there are no interesting relations among epistemic content. There will be a corresponding spectrum of epistemic spaces. Every statement might then be associated with a spectrum of epistemic intensions, each of which is an intensions across scenarios within a given epistemic space. For different purposes, different intensions from within this spectrum may be relevant. Between these intensions and these epistemic spaces, there will be enough material to do significant explanatory work in many different epistemic domains.
The Foundations of Two-Dimensional Semantics

*[[A first draft. All comments are extremely welcome.]]

1 Reason, meaning, and possibility

Why is two-dimensional semantics important? One can think of it as the fourth act in a triangular drama involving three of the central concepts of philosophy: reason, meaning, and possibility. In the prologue, Kant linked reason and possibility. In the first act, Frege proposed a link between reason and meaning. But it was not obvious how this link was to be understood. In the second act, Carnap linked meaning to possibility. In conjunction with the Kantian link between reason and possibility, this built a Fregean bridge from reason to meaning. The result was a golden triangle of constitutive connections between meaning, reason, and possibility. In the third act, Kripke severed the link between reason and possibility. The link between meaning and possibility was left intact, but the bridge between meaning and reason was broken.

Two-dimensional semantics promises to restore the golden triangle. While acknowledging the aspects of meaning and possibility that derive from the third act, it promises to explicate further aspects of meaning and possibility that are more closely tied to reason. In particular it promises to look at possibility and the evaluation of possibilities in a different way, and erect a notion of meaning on that basis. In this way, the constitutive connections between meaning, reason, and possibility might be restored.

To date, the restoration has been incomplete. Many different frameworks for two-dimensional semantics have been proposed, and many of them restore the triangle at best partially. It is controversial whether two-dimensional semantics can be understood in such a way that the triangle is fully restored. To see whether a restoration is possible, we need to investigate the foundations of two-dimensional semantics, and explore the many different ways in which the framework can be understood. I think that when the framework is understood in the right way, it can reinstantiate the links between meaning, reason, and possibility.

1.1 Frege, Carnap, and Kripke
We can begin with some background, in the form of a simplified rational reconstruction of history.

First, Frege. Frege held that an expression in a language typically has a referent - or what I will here call an extension. The extension of a singular term is an individual: for example, the extension of the name 'Hesperus' is the planet Venus, and the extension of the description 'the teacher of Aristotle' is Plato. The extension of a general term is a class. And the extension of a sentence is its truth-value.

Frege noted that the extension of an expression does not in general determine its cognitive significance: the role it plays in reasoning and in knowledge. For example, 'Hesperus' (the name used for the evening star) and 'Phosphorus' (the name used for the morning star) have the same referent but have different cognitive significance, as witnessed by the fact that 'Hesperus is Hesperus' is cognitively trivial, while 'Hesperus is Phosphorus' is nontrivial. The same goes for many other pairs of expressions: perhaps 'renate' (creature with a heart) and 'cordate' (creature with a kidney), or 'water' and 'H2O', or 'I' (as used by me) and 'David Chalmers'. In each pair, the members are co-extensive (they have the same extension), but they are cognitively and rationally distinct.

Frege held that meaning is tied constitutively to cognitive significance, so that if two expressions have different cognitive significance, they have different meaning. It follows that there must be more to meaning than extension. Frege postulated a second aspect to meaning: sense. When two expressions are cognitively distinct, they have different senses. For example, the nontriviality of 'Hesperus is Phosphorus' entails that although 'Hesperus' and 'Phosphorus' have the same extension, they have a different sense. We can put the general idea as follows:

**Fregean Thesis:** Two expressions 'A' and 'B' have the same sense iff 'A == B' is cognitively insignificant.

Here, 'A == B' is a claim that is true if and only if 'A' and 'B' have the same extension. Where 'A' and 'B' are singular terms, this will be the identity 'A=B'; where 'A' and 'B' are sentences, this will be the material biconditional 'A iff B'; and so on. As for cognitive significance, we can say at a first approximation that a claim is cognitively insignificant when it can be known trivially by a rational being. As such, we can see this characterization of sense as providing a first bridge between meaning and reason.

The idea that expressions have senses is attractive, but senses are nevertheless elusive. What exactly is a sense? What is cognitive significance? How does one analyze meanings beyond extensions? In the middle part of the 20th century, a number of philosophers, most notably Carnap, had an insight. We can use the notions of possibility and necessity to help understand meaning, and in particular to help understand sense.

There are many possible ways the world might be; and we can use language to describe these possibilities. An expression can be applied to the actual state of the world, yielding an actual extension, or it can be applied to alternative possible states of the world, yielding alternative possible extensions. Take expressions such as 'renate' and 'cordate'. In the world as it actually is, all renates are cordates, so these terms have the same extension. But it is not necessary that all renates are cordates: if the world had been...
different, some renates might have failed to be cordates. Applied to such an alternative possibility, the
two terms have a different extension. We can say: 'renate' and 'cordate' are co-extensive, but they are not
necessarily co-extensive. Carnap suggested that we say two expressions have the same intension if and
only if they are necessarily co-extensive.[*] So 'renate' and 'cordate' have the same extension, but
different intension. We can put the general claim as follows:

Carnapian Thesis: 'A' and 'B' have the same intension iff 'A == B' is necessary.

[*][[See Carnap 1947. The idea is also present in Lewis 1944.]]

What exactly is an intension? Carnap's characterization suggests a natural definition: an intension is a
function from possibilities to extensions.[*] The space of possibilities here correspond to different
possible states of the world. Relative to any possibility, an expression has an extension: for example, a
sentence (e.g. 'all renates are cordates') can be true or false relative to a possibility, and a singular term
(e.g. 'the teacher of Aristotle') picks out an extension relative to a possibility. An expression's intension is
the function that maps a possibility to the expression's extension relative to that possibility. When two
expressions are necessarily co-extensive, they will pick out the same extension relative to all possibilities,
so they will have the same intension. When two expressions are not necessarily co-extensive, they will
have not pick out the same extension relative to all possibilities, so they will have different intensions. So
intensions behave just as Carnap suggests they should.

[[Although this definition of an intension is often attributed to Carnap, I do not see it explicitly in Carnap 1947. [Citations
welcome!] Although he characterizes necessity ("L-truth") initially in terms of state-descriptions, which are akin to possible
worlds, state-descriptions very soon drop out of the discussion, so that intensions are treated in effect as something of a
primitive semantic value. Lewis's suggestion that an intension "comprises whatever must be true of any possible world in
order that the proposition should apply to it or be true of it" suggests at least that intensions determine functions in the
above sense, however.]]

Seen this way, the notion of an intension provides a bridge between meaning and possibility. Just as a
sense can be seen as a sort of meaning that is constitutively tied to reason, an intension can be seen as a
sort of meaning that is constitutively tied to possibility. Furthermore, intensions seem to behave very
much as senses are supposed to behave. Just as two expressions can have the same extension but different
senses, two expressions can have the same extension but different intensions. And just as sense was
supposed to determine extension, intension seems to determine extension, at least relative to a world.

One can make a direct connection by adding an additional claim connecting possibility and reason. It has
often been held that a proposition is necessary if and only if it is a priori (knowable by reason alone) or
trivial (yields no real knowledge of the world). The notions of apriority and triviality are essentially
rational notions, defined in terms of how one comes to know a claim. Carnap himself held a version of the
thesis involving triviality, but it is more useful for our purposes to focus on the version involving
apriority. In this form, the relevant thesis goes back at least to Kant, so we can call it:

Kantian Thesis: A proposition P is necessary iff P is a priori.

http://www.u.arizona.edu/~chalmers/papers/foundations.html (3 of 76) [4/7/2002 1:42:56 PM]
The Foundations of Two-Dimensional Semantics

If we combine the Carnapian Thesis with the Kantian Thesis, we obtain the following:

**Neo-Fregean Thesis:** 'A' and 'B' have the same intension iff 'A == B' is a priori.

If this claim is accepted, then one has recaptured something that is at least close to the Fregean thesis. For apriority is at least closely related to cognitive insignificance. When a proposition is cognitively insignificant, it is plausibly a priori. The reverse is not quite the case, as Frege understood cognitive significance: many logical and mathematical propositions are cognitively significant, even though they are a priori. But in any case, a priority and cognitive insignificance are at least closely related rational notions. Typical cognitively significant identities, such as 'Hesperus is Phosphorus', 'water is H2O', and 'I am David Chalmers' are all a posteriori. If the Neo-Fregean Thesis is correct, it follows that 'Hesperus' and 'Phosphorus' have different intensions, as do 'water' and 'H2O', and 'I' and 'David Chalmers'. So intensions behave quite like Fregean senses.

In effect, the notion of possibility serves as a bridge in explicating the tie between meaning and reason. One constructs a notion of meaning using the notion of possibility, combines this with the claim that possibility is constitutively tied to reason, and ends with a link between all three. The central connection between meaning, reason, and possibility is captured within the core thesis: intension is a notion of meaning, defined in terms of possibility, that is constitutively connected to reason.

This golden triangle was shattered by Kripke, who cut the connection between reason and possibility. Kripke argued that the Kantian Thesis is false: there are many propositions that are necessarily true but not knowable a priori. For example, Kripke argued that given that Hesperus is actually Phosphorus, it could not have been that Hesperus was not Phosphorus: Hesperus is necessarily the planet Venus, and so is Phosphorus. So although 'Hesperus is Phosphorus' is not knowable a priori, it is nevertheless necessary. More generally, Kripke argued that names and natural kind terms are rigid designators, picking out the same extension in all possible worlds. It follows that any true identity involving such terms is necessary. For example, 'water is H2O' is necessary, even though it is a posteriori. The same goes for claims involving indexicals: 'I am David Chalmers' (as used by me) is another a posteriori necessity.

If Kripke is right about the Kantian Thesis, then the Neo-Fregean Thesis is also false. Since 'Hesperus is Phosphorus' is necessary, 'Hesperus' and 'Phosphorus' have the same intension, picking out the planet Venus in all possibilities. But the equivalence between 'Hesperus' and 'Phosphorus' is nevertheless a posteriori and cognitively significant. So cognitively and rationally distinct pairs of expressions can have the same intension: witness 'Hesperus' and 'Phosphorus', 'water' and 'H2O', 'I' and 'David Chalmers'. So the Neo-Fregean Thesis fails, and intensions no longer behave like Fregean senses.

In effect, Kripke leaves intact the Carnapian link between meaning and possibility, but in severing the Kantian link between reason and possibility, he also severs the Fregean link between meaning and reason. This is roughly the received view in contemporary philosophy: meaning and possibility are connected, but both are disconnected from reason.
1.2 Two-dimensional semantics

Although most contemporary philosophers accept Kripke's arguments against the Kantian thesis, many still would like to hold that Frege was right about something. There remains an intuition that 'Hesperus' and 'Phosphorus' (or 'water' and 'H2O', or 'I' and 'David Chalmers') differ in at least some dimension of their meaning, corresponding to the difference in their cognitive and rational roles. One might try to do this by breaking the Carnapian connection between meaning and possibility. Two-dimensional semantics takes another strategy: in effect, it finds another way of looking at possibility that yields a more Fregean aspect of meaning.

The core idea of two-dimensional semantics is that there are two different ways in which the extension of an expression depends on possible states of the world. First, the actual extension of an expression depends on the character of the actual world in which an expression is uttered. Second, the counterfactual extension of an expression depends on the character of the counterfactual world in which the expression is evaluated. Corresponding to these two sorts of dependence, expressions correspondingly have two sorts of intensions, associating possible states of the world with extensions in different ways. On the two-dimensional framework, these two intensions can be seen as capturing two dimensions of meaning.

These two intensions correspond to two different ways of thinking of possibilities. In the first case, one thinks of a possibility as representing a way the actual world might turn out to be: or as it is sometimes put, one considers a possibility as actual. In the second case, one acknowledges that the actual world is fixed, and thinks of a possibility as a way the world might have been but is not: or as it is sometimes put, one considers a possibility as counterfactual. A version of this is commonly put by saying that one can think of a possible world as a context of utterance, or as a circumstance of evaluation. When one evaluates an expression relative to a possible world, one may get different results, depending on whether one considers the possible world as actual or as counterfactual.

The second way of thinking about possibilities is the more familiar in contemporary philosophy. Kripke's arguments rely on viewing possibilities in this way. Take a possibility in which the brightest object in the evening sky is a satellite around the earth, and in which Venus is visible and bright only in the morning. When we think of this possibility as a counterfactual way things might have been, we do not describe it as a possibility in which Hesperus is Mars, but as one in which Hesperus (and Phosphorus) is invisible in the evening. So relative to this possibility considered as counterfactual, 'Hesperus' picks out Venus. Correspondingly, the second-dimensional intensions of both 'Hesperus' and 'Phosphorus' both pick out Venus in this possibility, and in all possibilities in which Venus exists. It is this familiar sort of intension that yields the Kripkean gap between intension and cognitive significance.

The first way of thinking about possibilities is the less familiar in contemporary philosophy. If we take the possibility described above, and think of it as a way the world might actually be, we can say: if the world really is that way, then 'Hesperus' picks out a satellite. So relative to this possibility considered as actual, 'Hesperus' picks out not Venus but the satellite. Correspondingly, the first-dimensional intension of 'Hesperus' picks out the satellite in this possibility, while that of 'Phosphorus' picks out Venus.
'Hesperus' and 'Phosphorus' have different first-dimensional intensions. This difference is tied to the fact that the actual-world reference of 'Hesperus' and 'Phosphorus' is fixed in quite different ways, although as things turn out, their referents coincide. Because of this, it seems that the first dimension may be better suited than the second for a link to reason and to cognitive significance.

The possibilities evaluated in the second dimension are usually thought of as possible worlds. The possibilities evaluated in the first dimension are a little different, as they reflect the nature of a world from the point of view of a speaker using an expression within a world. It is useful for many purposes to see these possibilities as centered worlds: worlds marked with a "center", which is an ordered pair of an individual and a time. We can think of the center of the world as representing the perspective of the speaker within the world.

I have been deliberately vague about just how the relevant intensions are to be defined, since as we will see, there are many different ways to define them. Because of this, giving detailed examples is tricky, because different frameworks treat cases differently. Nevertheless, it is useful to go through some examples, giving an intuitive analysis of the results that two-dimensional semantics might be expected to give if it is to yield something like a Fregean sense in the first dimension. We will later see how this can be cashed out in detail. For now, I will use "1-intension" as a generic name for a first-dimensional intension, and "2-intension" as a generic name for a second-dimensional intension.

First, 'Hesperus is Phosphorus'. In a centered world considered as actual, this is true roughly when the morning star visible from the center of that world is the same as the evening star. In a world considered as counterfactual, it is true when Venus is Venus. 'Hesperus' functions roughly to pick out the evening star in the actual world, so the 1-intension of 'Hesperus' picks out the evening star in a given centered world. Likewise, the 1-intension of 'Phosphorus' picks out the morning star in a centered world. Both of these terms behave rigidly in counterfactual evaluation, so their 2-intensions pick out their actual referents in all worlds. So the 2-intensions of both 'Hesperus' and 'Phosphorus' pick out Venus in all worlds.

Second, 'water is H2O'. In a centered world considered as actual, this is true roughly when the clear, drinkable liquid around the center of that world has a certain pattern of chemical structure. In a world considered as counterfactual, it is true when H2O is H2O. The reference of 'water' is fixed roughly by picking out the substance with certain superficial properties and a certain connection to the speaker in the actual world, so its 1-intension picks out roughly the substance with those properties connected to the center of a given world. Similarly, the 1-intension of 'H2O' picks out the substance with the right sort of chemical structure in a centered world. As in the first case, both expressions behave rigidly in counterfactual evaluation, so their 2-intensions pick out H2O in all worlds.

Third, 'I am a philosopher'. In a centered world considered as actual, this sentence is true when the being at the center of the world is a philosopher. In a world considered as counterfactual, this sentence (or at least my utterance of it) is true if David Chalmers is a philosopher in that world. The actual-world reference of 'I' is fixed by picking out the subject who utters the token; so the 1-intension of 'I' picks out the subject at the center of a given world. 'I' behaves as a rigid designator in counterfactual evaluation, so its 2-intension picks out the actual referent (in this case, David Chalmers) in all possible worlds.
'Philosopher', by contrast, is a broadly descriptive term: both its 1-intension and its 2-intension function to pick out beings with certain characteristic attributes.

Certain patterns seem to emerge. The first two sentences are necessary (at least if Kripke is right), and both of them have a 2-intension that is true in all worlds. The third sentence is contingent, and its 2-intension is false in some worlds. So it seems that a sentence is necessary precisely when it has a necessary 2-intension. This corresponds directly to the Carnapian thesis: 2-intensions, in effect, are defined so that two expressions will have the same 2-intensions when they are necessarily equivalent.

On the other hand, all three of these sentences are a posteriori, and all of them have a 1-intension that is false in some centered worlds. At the same time, a priori sentences such as (perhaps) 'All bachelors are unmarried males' or 'Hesperus (if it exists) is visible in the evening' can plausibly be seen as having a 1-intension that is true in all centered worlds. So it is at least tempting to say that a sentence is a priori precisely when it has a necessary 1-intension. This corresponds to the neo-Fregean thesis: one might naturally suggest that two expressions have the same 1-intension precisely when they are a priori equivalent. To illustrate, one can note that the difference in the 1-intensions of 'Hesperus' and 'Phosphorus', or of 'water' and 'H2O', seems to be closely tied to their a priori inequivalence. All this needs to be analyzed in more depth, but one might at least characterize the general sort of behavior suggested in the examples above, where 1-intensions go along at least roughly with differences in cognitive significance, as quasi-Fregean.

Along with the 1-intension and the 2-intension of a given expression, one can also define a two-dimensional intension. In many cases, just as an expression's extension depends on how the actual world turns out, an expression's 2-intension depends on how the actual world turns out. The expression's two-dimensional intension captures this dependence: it can be seen as a function from centered worlds to 2-intensions, or equivalently as a function from pairs of centered worlds and worlds to truth-values. In the case of 'Hesperus', for example, the two-dimensional intension maps a centered world V to the 2-intension that picks out V's evening star (if it exists) in any worlds W. The actual 2-intension of an expression correspond to the two-dimensional intension evaluated at the actual centered world of the speaker: given that Venus is the actual world's evening star, the 2-intension of 'Hesperus' picks out Venus in all worlds. The 1-intension of an expression can be reconstructed by "diagonalizing" the two-dimensional intension: one evaluates it at a centered world W, and then evaluating the resulting 2-intension at the same world (stripped of its center). One might think of the two-dimensional intension as representing the way that an expression can be used to evaluate counterfactual worlds, depending on which world turns out to be actual.

I will return to these themes later, but for now it must be acknowledged that the situation is much more complicated than I have made things sound. A number of different two-dimensional frameworks have been introduced, and many of these given different results. A partial list of proponents of these frameworks, along with the names they give to their two-dimensional notions, includes:

Kaplan (1974; 1989): character and content
Stalnaker (1978): diagonal proposition and propositional expressed
Evans (1979): deep necessity and superficial necessity
Davies/Humberstone (1981): "fixedly actual" truth and necessary truth
Chalmers (1996): primary intension and secondary intension
Jackson (1998): A-intension and C-intension

There are many differences between these frameworks, some on the surface, and some quite deep. Surface differences include the fact that where Chalmers and Jackson speak of two sorts of intensions, Evans and Davies/Humberstone speak of two sorts of necessity, while Kaplan and Stalnaker speak of propositions. This sort of difference is mostly intertranslatable. Given a notion of necessity and a corresponding way of evaluating possibilities (as with Evans and Davies and Humberstone), one can define a corresponding sort of intension, and vice versa. Stalnaker's propositional content is just a set of possible worlds, which is equivalent to the intension of a sentence, and Kaplan's content is closely related.[*] Kaplan's and Stalnaker's first-dimensional notions are defined over contexts (which are at least closely related to centered worlds), and initially involve a two-dimensional intension: a function from contexts to 2-intensions. Stalnaker diagonalizes this function, yielding a function from contexts to truth-values, or a 1-intension. Kaplan leaves his character as a two-dimensional function from contexts to 2-intensions, but a corresponding step could straightforwardly be taken. So in all these cases, there is a similar formal structure.

[*][Kaplan's content is strictly speaking a singular proposition rather than a set of worlds, but it immediately determines a set of worlds. For our purposes, the difference between singular propositions, other structured propositions, and sets of worlds in analyzing the second dimension of content will not be crucial, so for simplicity I will speak as if the relevant second-dimensional contents are intensions. The discussion can be straightforwardly adapted to other views.]]

At a conceptual level, the frameworks have something further in common. In each case, the first-dimensional notion is put forward at least in part as a way of better capturing the cognitive or rational significance of an expression then the second dimension. And in each case, at least some sort of link between the first-dimensional notion and apriority has been claimed. In Kaplan's and Stalnaker's original publications, it is held that character and diagonal propositions closely reflect matters of apriority, at least in some cases. For Evans and Davies and Humberstone, when a statement of a certain sort is knowable a priori, it is deeply necessary, or true fixedly actually. And for Chalmers and Jackson, when a sentence is a priori, it has a necessary primary intension or 1-intension.

But these similarities mask deep underlying conceptual differences. These frameworks are defined in quite different ways, and apply to quite different items of language, yielding quite different results. Correspondingly, proponents of these frameworks differ greatly in the scope and strength of their claims. Kaplan's analysis is restricted to just a few linguistic expressions: indexicals and demonstratives. He explicitly resists an extension of his framework to other expressions, such as names and natural kind terms. Evans and Davies and Humberstone define their notions for a different narrow class of expressions: descriptive names, and perhaps (in the case of Davies and Humberstone) a few other terms, such as certain natural kind terms. Stalnaker's analysis applies in principle to any sentence; but in recent work, he has explicitly disavowed any strong connection with apriority, and has been skeptical about applications of two-dimensional semantics in that direction. By contrast, Chalmers and Jackson suggest
that their notions are defined for a very wide class of expressions, and make strong claims about the connection between these notions and apriority.[*]

[*][The current paper might be viewed in part as a defense of these strong claims, in light of doubts expressed by Stalnaker and others.]

These differences arise from different interpretations of the formal two-dimensional framework. The framework of worlds and intensions, taken alone, is simply an abstract structure in need of content. Different interpretations flesh out this content in different ways. The interpretations are not necessarily incompatible, although it is possible that some are ill-defined, or rest on false presuppositions. The relations between these interpretations, however, are not well-understood.

The main project of this paper is to explore the different ways in which a two-dimensional framework can be understood. What are the fundamental concepts underlying different interpretations of the framework? How are these related? How do the differences between the foundations of these interpretation explain the differences in the scope and strength of the claims that are made for them? Which interpretations of the framework yield the strongest connections between the first dimension and the rational domain?

The central question on which I will focus is the following. Is there an interpretation of the two-dimensional framework that yields constitutive connections between meaning, meaning, and possibility? That is, is there an interpretation on which the first dimension is tied universally to the rational domain? On this way of thinking, the ideal form of the two-dimensional framework will recapture something like the neo-Fregean thesis: two terms will have the same 1-intension if and only if they are equivalent a priori. To get at this question, we can focus on the following core thesis:

**Core Thesis:** For any sentence S, S is a priori iff S has a necessary 1-intension.

The Core Thesis can be seen as the two-dimensionalist's version of the Fregean or neo-Fregean theses. It links the rational notion of apriority, the modal notion of necessity, and the semantic notion of intension. If the Core Thesis is true, it restores a golden triangle of connections between meaning, reason, and possibility.

If the two-dimensional framework can be understood in such a way that the Core Thesis is true, it promises an account of a broadly Fregean aspect of meaning, tied constitutively to the epistemic domain. It also promises further rewards: perhaps an account of the contents of thought on which content is tied deeply to a thought's rational role (potentially yielding an account of so-called "narrow content" and "modes of presentation" in thought), and perhaps a view of modality on which there are deep links between the rational and modal domains (potentially grounding a connection between notions of conceivable and possibility). So the key question in what follows will be: can we define 1-intensions so that the Core Thesis is true?

To anticipate, my answer will be as follows. There are two quite different ways of understanding the two-
dimensional framework: the contextual understanding and the epistemic understanding. The contextual understanding uses the first dimension to capture context-dependence. The epistemic understanding uses the first dimension to capture epistemic dependence. The contextual understanding is more familiar, but it cannot satisfy the Core Thesis. The epistemic understanding is less familiar, but it can satisfy the Core Thesis. The reason is that only on the epistemic understanding is the first dimension constitutively tied to the epistemic domain.

Within each of these general understandings of the framework, there are various possible specific interpretations. In what follows, I will first explore contextual interpretations, and then epistemic interpretations. Some of these interpretations are closely related to existing proposals, but rather than working directly with existing proposals, I will characterize these interpretations from first principles. This allows us to examine the properties of these interpretations in a clear light, free of problems of textual exegesis. Later in the paper, I will examine how existing proposals fit into this scheme.

(A note before we begin: many of the proposals I will examine assign intensions to expression tokens, such as utterances, rather than to linguistic expression types. So the Core Thesis should be understood as applying to sentence tokens. This requires that apriority be understood as a property of sentence tokens: to a first approximation, we can say that a sentence token is a priori when it expresses a thought that can be justified independently of experience. This also entails that the semantic values we are dealing with are not constrained to be varieties of "linguistic meaning", the sort of semantic value that is common to all tokens of an expression type. I will say more about these things later.)

2 The contextual understanding

On the contextual understanding of two-dimensional semantics, the possibilities involved in the first dimension represent possible contexts of utterance, and the intension involved in the first dependence represents the context-dependence of an expression's extension. There are many ways in which the extension of an expression can depend on the context in which it is uttered. On the contextual understanding, a 1-intension captures the way in which an expression's extension depends on its context. As we will see, this sort of context-dependence can itself be understood in a number of different ways.

To formalize this, we can start by focusing on expression tokens: spoken or written tokens of words, sentences, and other expressions. We can take it that any expression token has an extension. In cases where a token "aims" to have an extension but fails, as with an empty name, we can say that it has a null extension. If there are some expression tokens that do not even aim to have an extension (as perhaps with some exclamations), they are outside the scope of our discussion. A token of a sentence is an utterance; its extension is a truth-value.

Any expression token falls under a number of different expression types. A token may fall under an orthographic type (corresponding to its form), a semantic type (corresponding to its meaning), a linguistic type (corresponding to its type within a language), and various other types. Different tokens of the same expression type will often have different extensions. When two tokens of the same expression type have
different extensions, this reflects a difference in the context in which the tokens are embedded.

For our purposes, contexts can be modeled as centered worlds. The context in which an expression token is uttered will be a centered world containing the token. This can be modeled as a world centered on the speaker making the utterance, at the time of utterance. It is also possibly to model a context by a different sort of centered world with just an expression token marked at the center, but the previous version will work for most purposes, as long as we assume that a subject makes at most one utterance at a given time.

One can now define the contextual intension of an expression type. This is a function from centered worlds to extensions. It is defined at worlds centered on a subject uttering a token of the expression type. At such a world, the contextual intension returns the extension of the expression token at the center.

One can also define the contextual intension of an expression token, relative to a type of which it is a token. This is also a function from centered worlds to extensions. It is defined at worlds centered on a token of the same type, and returns the extension of the token at the center. This contextual intension is the same as the contextual intension of the relevant expression type.

The first-dimensional intensions in the two-dimensional framework are often understood as contextual intensions of some sort. On this way of seeing things, a 1-intension mirrors the evaluation of certain metalinguistic subjunctive conditionals: if a token of the relevant type were uttered in the relevant context, what would its extension be? Of course, for every different way of classing expression tokens under types, there will be a different sort of contextual intension. In what follows I examine some of the relevant varieties of contextual intension.[*]

[*][The discussion in this section owes a significant debt to the work of Robert Stalnaker and Ned Block. Stalnaker has stressed the importance of constructs akin to contextual intensions in a number of writings (e.g. Stalnaker 1978, 1999); at the same time, Stalnaker and Block have both been active critics of the overextension of this framework (e.g. Stalnaker 1990, 2001; Block 1991; Block and Stalnaker 1999). Although I carve up the territory in a different way, a number of the varieties of contextual intension that I mention are touched on explicitly or implicitly by Stalnaker and Block at various points; and one of main points in criticizing contextual intensions as a quasi-Fregean aspect of meaning echoes points made by Stalnaker and by Block in criticizing the use of the two-dimensional framework in accounting for narrow content.]]

2.1 Orthographic Contextual Intensions

We can say that two tokens are tokens of the same orthographic type when they have the same orthography. This holds roughly when they are made up of the same letters or sounds, regardless of their meaning, and regardless of the language in which they are uttered. The exact details of what counts as the same orthography can be understood in different ways, but these differences will not matter for our purposes.

Then: the orthographic contextual intension of an expression token T is defined at centered worlds with a token of T's orthographic type at the center. It maps such a world to the extension of the relevant token in that world.
As an example, let S be Oscar's utterance of 'water is H2O'. Let W1 be Oscar's world (Earth), centered on Oscar making this utterance. Oscar's utterance is true, so S's orthographic contextual intension is true at W1. Let W2 be a universe containing Twin Earth (where everything is just as on earth except that the watery liquid is XYZ), centered on Twin Oscar uttering 'water is H2O'. Twin Oscar's utterance is false (his word 'water' refers to XYZ), so S's orthographic contextual intension is false at W2. Let W3 be a universe containing Steel Earth, where the word 'water' refers to steel, but chemical terms are the same, centered on Steel Oscar uttering 'water is H2O'. Steel Oscar's utterance is false, so S's orthographic contextual intension is false at W3.

(The orthographic contextual intension of a sentence token is quite similar to its diagonal proposition, as defined by Stalnaker (1978). I will return to this matter later.)

It is clear that orthographic contextual intensions do not satisfy the Core Thesis. For every orthographic type, some possible token of that type expresses a falsehood. For example, there are worlds in which the string 'bachelors are unmarried' means that horses are cows. In such a centered world, the orthographic contextual intension of 'bachelors are unmarried' are false. The same goes for any sentence. So no truth has a necessary contextual intension, and in particular no a priori truth has a necessary contextual intension. So if 1-intensions are understood as orthographic contextual intensions, the Core Thesis is obviously false.

2.2 Linguistic contextual intensions

We can say that two expression tokens are tokens of the same linguistic type when they are tokens of the same expression in a language. This assumes that expression tokens belong to languages, and that languages involve expressions such as words, phrases, and sentences. So any two tokens of the English word 'water' share a linguistic type, as do any two utterances of the French sentence 'C'est la vie'.

Then: the linguistic contextual intension of an expression token T is defined at centered worlds with a token of T's linguistic type at the center. It maps such a world to the extension of the relevant token in that world.

As before, let S be Oscar's utterance of 'water is H2O'. If W1 is Oscar's own centered world (Earth): S's linguistic contextual intension is true at W1. If W2 is Twin Oscar's centered world (Twin Earth): it is arguable that Twin Oscar's word 'water' is a different word from Oscar's word 'water'. Certainly if the referent of 'water' is essential to the word, as many theorists hold, then Twin Oscar's 'water' is a different word. If so, S's linguistic contextual intension is not defined at W2. If W3 is Steel Oscar's centered world (where 'water' means steel): here it is reasonably clear that Steel Oscar's 'water' is a different word that has the same orthography. If so, S's linguistic contextual intension is not defined at W3. Applying this sort of reasoning, one reaches the conclusion that S's contextual intension is true at every world in which at which it is defined, since the English word 'water' refers to H2O in every world in which it exists, and so does the English expression 'H2O'.

http://www.u.arizona.edu/~chalmers/papers/foundations.html (12 of 76) [4/7/2002 1:42:56 PM]
If this is right, then linguistic contextual intensions do not satisfy the core thesis. 'Water is H2O' is a posteriori, but it seems to have a necessary contextual intension, true at every world at which it is defined. The same goes even more clearly for sentences involving names, such as 'Cicero is Tully'. It is widely held that names have their referents essentially; if so, the linguistic contextual intensions of true identities of this sort will be true at all worlds at which they are defined. As such, linguistic contextual intensions do not behave at all like Fregean senses. If 1-intensions are understood as linguistic contextual intensions, the Core Thesis is false.

There are some expressions for which linguistic contextual intensions behave more like Fregean senses. One such is 'I': setting certain odd cases aside, any token of the English word 'I' picks out the utterer of that token. So the linguistic contextual intension of 'I' picks out the speaker at the center of any centered world at which it is defined. In this way, it behaves much as we earlier suggested the 1-intension of 'I' should behave. Something similar applies to other indexicals, such as 'today', and to some broadly descriptive terms, such as 'philosopher'. It is in the case of names and natural kind terms that the fit seems to be worst.

(The linguistic contextual intension of an expression is in some respects like its character, as defined by Kaplan, although there are some differences, as we will see.)

2.3 Semantic contextual intensions

We can say that two expression tokens are tokens of the same semantic type when they have the same semantic value. An expression token's semantic value is its meaning or content, or some aspect of its meaning or content. There are many different ways of assigning semantic values to expression tokens, so there are correspondingly many different ways of classing expression tokens under semantic types.

Then: the semantic contextual intension of an expression token T is defined at centered worlds with a token of T's linguistic type at the center. It maps such a world to the extension of the relevant token in that world.

As before, let S be Oscar's utterance of 'water is H2O'. If W1 is Oscar's own centered world (Earth): S's semantic contextual intension is true at W1. If W2 is Twin Oscar's centered world (Twin Earth): at least on many ways of assigning semantic value, Twin Oscar's term 'water' has a different semantic value from Oscar's, so S's semantic contextual intension (for this sort of semantic type) is undefined at W2. If W3 is Steel Oscar's centered world, then Steel Oscar's term 'water' clearly has a different semantic value from Oscar's, so S's semantic contextual intension is undefined at W3. If W4 is a world centered on 'French Oscar', a counterpart of Oscar who speaks French and is uttering 'eau est H2O': then it is plausible that this utterance has the same semantic value as Oscar's, so S's semantic contextual intension is defined at W1 and is true there.

Of course the behavior of a semantic contextual intension will depend on our choice of semantic value. For example, if we stipulate that the relevant semantic value of an expression is its extension, then any...
two co-extensive expressions will have the same semantic contextual intension, and there is no chance that the Core Thesis will be true. There are two choices of semantic value that are a little more interesting, however.

We might stipulate that the relevant semantic value of an expression is its *linguistic meaning*: roughly, the aspect of meaning that is common to all tokens of the expression's linguistic type. If we do this, then an expression's semantic contextual intension will be an extension of its linguistic contextual intension to a broader space of worlds. At worlds centered on a token of the same linguistic type, the intensions will give the same results. But the semantic contextual intensions will also be defined at other worlds, centered on synonyms and translations of the original expression. Nevertheless, if 1-intensions are understood as these semantic contextual intensions, the Core Thesis will be false for the same reasons as in the case of linguistic contextual intension. For example, if the extension of 'water' is essential to the word, then it is part of the word's linguistic meaning. So the semantic contextual of 'water is H2O' will be true at every world where it is defined, and the Core Thesis is false.

Alternatively, we might stipulate that the relevant semantic value of an expression token is its *Fregean or descriptive content*, corresponding roughly to the expression's cognitive significance for the subject. On this reading, the Core Thesis may be more plausible. For example, one might argue that Oscar's and Twin Oscar's terms 'water' have the same descriptive content. If so, then the semantic contextual intension of Oscar's utterance 'water is H2O' is defined at W2 and is false there. On the other hand, Steel Oscar's term 'water' plausibly has a different descriptive content, so the semantic contextual intension of Oscar's utterance is not defined at W3.

Understood this way, semantic contextual intensions behave as we might expect a Fregean 1-intension to behave, at least to some extent. One can argue that when a statement is a priori, any possible statement with the same descriptive content will be a priori and so will be true, so that the expressions semantic contextual intension will be necessary, as the Core Thesis requires. Corresponding, one might suggest that when a statement is not a priori, then there will be possible statements with the same descriptive content that are false, so that the statement's semantic contextual intension will not be necessary, as the Core Thesis requires.

I will argue shortly that this is not quite right. But even if it were right, it is clear that this sort of 1-intension cannot underwrite the full ambitions of the Fregean two-dimensionalists. The Fregean two-dimensionalist, as sketched previously, intends to use the two-dimensional framework to *ground* an aspect of meaning that is constitutively tied to meaning. But semantic contextual intensions as defined here *presuppose* such a Fregean semantic value, and so cannot independently ground such an account. If this is the best a two-dimensionalist can do, then if someone is independently doubtful about a Fregean aspect of meaning, two-dimensionalism cannot help. At best, two-dimensionalism will be a helpful tool in analyzing such a notion of meaning, given an independent grounding for the notion. [*]

[*[This sort of point in made quite clearly, in the context of discussing narrow content, by Stalnaker 1991, Block 1991, and Block and Stalnaker 1999.]]
2.4 A Further Problem

We have seen that orthographic contextual intensions are very far from satisfying the Core Thesis, while linguistic contextual intensions are closer at least in some cases, and some sort of semantic contextual intensions may be closer still. But there is a further problem that arises for any sort of linguistic or semantic contextual intension, suggesting that no such contextual intension can satisfy the Core Thesis.

Let S be a token of 'language exists'. Then S is true. Furthermore, any utterance of the linguistic item 'language exists' is true. Any any utterance that means the same thing as 'language exists' is true. So it seems that S will have a necessary linguistic contextual intension, and a necessary semantic contextual intension, under any reasonable way of classifying linguistic and semantic types. But S is clearly a posteriori: it expresses empirical knowledge of the world, which could not be justified independently of experience. So S is a counterexample to the Core Thesis. So the Core Thesis is false for any sort of semantic or linguistic contextual intension.

The same goes for a number of other sentences. If S1 is 'words exist', then any utterance of the same expression or with the same meaning will be true. So S1 has a necessary linguistic and contextual intension, despite being a posteriori. If S2 is 'I exist', then any utterance of the same expression with the same meaning will be true, so S2 has a necessary linguistic and semantic contextual intension. But (somewhat controversially) S2 is a posteriori, justifiable only on the basis of experience. If S3 is 'I am uttering now', then any utterance of the same expression or with the same meaning will be true. S3 is clearly a posteriori, but has a necessary linguistic and semantic contextual intension.

All these cases are counterexamples to the Core Thesis. All of them are a posteriori and cognitively significant, and many of them seem to be as cognitively significant as paradigmatic expressions of empirical knowledge. But all have necessary semantic and linguistic contextual intensions. So the Core Thesis is false for all such intensions.

The trouble is that apriority and "truth whenever uttered" are fundamentally different notions. The first builds in an epistemic or rational element, but the second builds in no such element. The second build in a metalinguistic element, but the first builds in no such element. It is possible to understand the second in a way that makes it coincide with the first in many cases, in effect by building in an epistemic element into the individuation of the relevant linguistic types. But it is impossible to do so in all such cases, since the second has an ineliminable metalinguistic element that goes beyond the epistemic domain.

I think the moral is that to satisfy the Core Thesis, we must understand the two-dimensional framework in a quite different, non-contextual way. But before doing so, I will more briefly examine some further ways in which one might define a contextual intension.

2.5 Hybrid contextual intensions

Given orthographic, linguistic, and semantic types for expression tokens, it is possible to define hybrid
types corresponding two conjunctions of two or more of these types. One can then define corresponding hybrid contextual intensions.

For example, one might say that two expressions share the same orthographic/semantic type when they share the same orthographic type and the same semantic type. One can then define the orthographic/semantic contextual intension of an expression as the function that maps a world centered on a token of the appropriate orthographic/semantic type to the extension of that token.

Hybrid contextual intensions may be useful for some purposes, but it is clear that they will not satisfy the Core Thesis any better than non-hybrid contextual intensions. So I will set them aside here.

### 2.6 Token-reflexive contextual intensions

It is possible to define a slightly different sort of contextual intension for an expression token by focusing not on the types that the token falls under, but on the token itself. Let us assume that an expression tokens are not tied to their context essentially: a given token might have been uttered in another context. Then we can say that the token-reflexive contextual intension of an expression token T is a function that maps a centered world containing T to the extension of T in that world.

The precise behavior of a token-reflexive contextual intension will depend on what properties an expression token has necessarily. It is plausible that such a token has any properties necessarily, it has its orthographic properties necessarily. If so, its token-reflexive contextual intension will be a restriction of its orthographic contextual intension, obtained by eliminating worlds centered on a different token of the same orthographic type. One might also hold that a token has some semantic value necessarily, or that it has its linguistic type necessarily. If so, its token-reflexive contextual intension will be a restriction of its semantic or linguistic contextual intension. If an expression has more than one of these things necessarily, its token-reflexive contextual intension will be a restriction of a hybrid contextual intension. If it has further properties necessarily (e.g. its speaker), it will be a further restriction of the relevant contextual intension.

It is not obvious how to decide exactly which properties an expression token has necessarily. But however we do this, it is clear that token-reflexive contextual intensions cannot satisfy the Core Thesis. The counterexamples discussed above, such as 'language exists', will apply equally to token-reflexive contextual intensions. Furthermore: insofar as tokens have any properties necessarily, one can likely construct sentence tokens attributing these properties that are true whenever uttered, but not a priori (e.g. 'This token has four words'; 'David Chalmers is speaking now'). And insofar as tokens have few properties necessarily, one can likely construct sentences that are a priori but that are not true whenever uttered (e.g. 'all bachelors are unmarried'). So if 1-intensions are understood as token-reflexive contextual intensions, the Core Thesis is false.

### 2.7 Extended contextual intensions
In an attempt to get around the problems posed by sentences such as "language exists", one might attempt to construct contextual intensions that are defined at centered worlds that do not contain a token of the relevant expression type. The most obvious way to do this is to appeal to certain counterfactual conditionals. Let us say that the extended contextual intension is defined at any centered world, independently of whether a token of the type is present there. At a given centered world, the extended contextual intension returns what the extension of a token of that type would be, if it were uttered at the center of that world.

One can then say that the extended contextual intension of an expression token (relative to a type) is maps a centered world to what the extension of a token of that type would be, if it were uttered at the center of the world. So in principle, one might have extended linguistic contextual intensions, extended semantic contextual intensions, and so on. One could define an extended token-reflexive contextual intension in an analogous way.

An obvious problem here is that in many cases, it is unclear how to evaluate the counterfactual. It may be reasonably straightforward in some cases, such as 'I am a philosopher': true just when an utterance of 'I am a philosopher' by the subject at the center would be true, so true just when the person at the center is a philosopher. But how is one to evaluate what a token of 'water' would refer to if it were used in a world where there is no liquid, and in which nobody speaks a language? How does one evaluate whether an utterance of 'I am speaking loudly' would be true if it were uttered, in a world where the subject at the center is not in fact speaking? In some cases, it seems impossible for a token of the relevant type to be uttered in the relevant context. In other cases, it may be possible, but it is possible in many different ways, yielding many different results. So the truth of the relevant counterfactuals seems to be underdetermined, and an expression's extended contextual intensions seems to be ill-defined.[*]

[[A point of this sort is made by Stalnaker 1990.]]

Another problem: even if extended contextual intensions behave coherently, they give results that are different from what we need. For example, let S = 'language exists'. S is a posteriori, so the Core Thesis requires that its 1-intension be false at some worlds. Intuitively, it is desirable that S's 1-intension be false at a language-free world. Let W be such a language-free centered world. To evaluate S's contextual intension at W, we ask: if S were uttered at the center of W, what would its extension be? It is clear that if S were uttered in W, it would be true. So S's extended contextual intension is true at W, and indeed is true at all worlds. So the Core Thesis is still false for extended contextual intensions.

To get anything like the result that is needed, we would need to evaluate S's extension in W without S being present in W. But it is very hard to do that on the contextual model. On the contextual understanding, 1-intensions are derivative on facts about the extensions of various possible tokens, as uttered in various possible contexts. It seems clear that on such an understanding, the 1-intension of a sentence such as 'language exists' will never be false.

I think that the idea of an extended contextual intension is getting at something important: that we need to be able to evaluate an expression's 1-intension in centered worlds that do not contain a token of the
expression. But this is the wrong way to achieve the goal. To do this properly, I think we need to go beyond the contextual understanding of 1-intensions.

2.8 Cognitive contextual intensions

One might suggest that to capture a token's cognitive significance, we should not focus on a token's broadly linguistic properties, such as its orthography, its semantic value, and its language. Instead, we need to focus on its cognitive properties, which correspond to mental features of the subject that produces the token. Some such features include: the concept or belief that the token expresses; the cognitive role associated with the token; and the intentions associated with the token. Assuming that we have a way of individuating the mental types in question, we can then classify expression tokens under corresponding cognitive types.

For a given scheme of cognitive typing, one can then define the cognitive contextual intension of an expression token as the intension that maps a world centered on a token of the same cognitive type to the extension of that token. In the three cases above: a conceptual contextual intension will be defined at worlds centered on a token expressing the same concept or belief; a cognitive-role contextual intension will be defined at worlds centered on a token associated with the same cognitive role; and an intention-based contextual intension will be defined at worlds centered on a token associated with the same intentions.

Assuming that one can make sense of the relevant typing, there is a natural extension of this idea. One could define a sort of extended cognitive contextual intension, defined at worlds that do not contain the token at all, but merely contain the relevant mental feature. For example, the extended conceptual contextual intension will be defined at any world that contain the relevant concept at its center, irrespective of whether it contains any token, and will return the extension of the concept. (This assumes that concepts have extensions, which seems reasonable enough.) The extended cognitive-role contextual intension might be defined at any world centered on a concept that plays the relevant cognitive role, returning the concept's extension; and the extended intention-based contextual intension will be defined at any world centered on a concept is associated with the same intentions.

This sort of intension has some promise of dealing with the central problems raised so far. In the case of 'language exists': one can make a case that the extended conceptual contextual intension of this expression is false at some centered worlds: those in which a subject has the relevant concepts and the relevant thought, but in which there is no language. So the intension is not necessary, reflecting the aposteriority of the sentence. The same goes for 'words exist', and for 'I am uttering now'. By allowing intensions to be evaluated without relying on language, the metalinguistic element of contextual intensions has been reduced or eliminated.

Still, analogous problems arise. 'I am thinking now' will plausibly have a necessary conceptual contextual intension, but it is plausibly a posteriori: the thought itself is justified only by experience, albeit by introspective experience. The same goes for 'I exist'. And the same will apply to specific attributions of
mental features: a thought such as 'I have the concept concept' will be true whenever it is thought, but it is not justifiable a priori. Something similar applies to thoughts attributing certain cognitive roles or certain intentions. So even here, some a posteriori sentences and thoughts will have a necessary 1-intension.

As for the other main sort of problem discussed so far, that associated with 'water is H2O: a proponent might hold that although Oscar and Twin Oscar do not have the same word 'water', their words express the same concept, at least under one reasonable way of individuating concept types. If so, then the conceptual contextual intension of Oscar's token 'water is H2O' will be false at the world centered on Twin Oscar, as the Fregean conception requires. At the same time, it might be undefined at the world centered on Steel Oscar (since he seems to have a different concept), as required.

It is controversial, however, whether concepts (or roles or intensions) can be individuated in a way that yields these results. Many theorists hold that even a token concept expressed by 'water' has its extension essentially, and that all concepts of the same type have the same extension. If so, then a statement such as 'water is H2O' will have a necessary intension. They might concede that concepts or thoughts can also be individuated syntactically or formally; but on this way of doing things, 'all bachelors are unmarried' will have a contingent intension. So either way, the Core Thesis is false.

One might argue that there is an intermediate way of individuating concept types that yields the right results. But many will deny this. It might be objected that this requires individuating concepts by their narrow content (that aspect of their content that is in their head), and it is highly controversial whether narrow content exists. Some think that the two-dimensional framework can be used to give an account of narrow content; but in this context, it seems illegitimate for the framework to presuppose narrow content. This is a precise analog of the problem that arose for the Fregean version of semantic contextual intensions above.

I think that the situation here is not entirely clear. One could argue with some plausibility that there is an intuitive sense in which Oscar and Twin Oscar have the same concept, where there is no corresponding intuitive sense that they have the same word. If so, one could appeal to this intuitive sort of concept individuation to ground some sort of conceptual contextual intension here. One might arguably be able to do the same sort of thing with cognitive roles, or intentions. But the intuitions in questions are likely to be disputed by many, so this approach will be at best weakly-grounded, unless one can give some sort of independent account of the relevant concept types.

On my view, (extended) cognitive contextual intensions are the sort of contextual intensions that are closest to satisfying the Core Thesis. But ultimately, the central problems arise for them too. So we still need an independent account of the relevant intensions.

(There are numerous other possible notions that resemble cognitive contextual intensions in carrying features of the subject across worlds: an evidential contextual intension, requiring sameness of evidence; a fixing contextual intension, requiring sameness of reference-fixing procedures or intentions; a physical contextual intension, requiring that subjects be physical duplicates; functional, phenomenal, physical-phenomenal contextual intensions, which require that subjects be functional, phenomenal, and physical-
phenomenal duplicates; and so on. It is not hard to see that all of these suggestions are subject to versions of the problems mentioned above.)

2.9 Summary

>From what we have seen, it seems that contextual intensions cannot support the core thesis. Two central problems have arisen repeatedly. First, by building in a token of the relevant mental or linguistic type into the world of evaluation, the constitutive connection with the a priori is lost. Second, for a contextual intension to behave in a quasi-Fregean manner, we need to antecedently classify tokens under some sort of quasi-Fregean type, so that the framework cannot independently ground quasi-Fregean notions, as was originally hoped.

Contextual intensions may still be useful for many purposes. But they do not yield any restoration of the golden triangle, and in particular they do not deliver a notion of meaning that is deeply tied to reason. The fundamental problem is that although some contextual intensions yield a reasonably strong correlation with the epistemic domain, none are constitutively connected to the epistemic domain. To restore the connection between meaning and reason, we need to approach the two-dimensional framework in epistemic terms.

3 The epistemic understanding

3.1 Epistemic dependence

On the epistemic understanding of two-dimensional semantics, the possibilities involved in the first dimension represent *epistemic possibilities*, and the intensions involved in the first dimension represents the *epistemic dependence* of the extension of our expressions on the state of the world.

There are two central ideas here. The first is the idea that there are many ways the world might turn out to be, and that there is a corresponding space of epistemic possibilities. The second is that once we know how the world has turned out, or once we know which epistemic possibility is actual, we are in a position to determine to extensions of our terms. This yields a sort of function from epistemic possibilities to extensions, or an *epistemic intension*.

Taking the first idea first: there are many ways the world might be, for all we know. And there are even more ways the world might be, for all we know a priori. The oceans might contain H2O or they might contain XYZ; the evening star might be identical to the morning star or it might not. These ways the world might be correspond to epistemically possible hypotheses, in a broad sense. Let us say that a claim is *epistemically possible* (in the broad sense) when it is not ruled out a priori. Then it is epistemically possible that water is H2O, and it is epistemically possible that water is XYZ. It is epistemically possible that Hesperus is Phosphorus, and epistemically possible that Hesperus is not Phosphorus.
Just as one can think of metaphysically possible hypotheses as corresponding to an overarching space of metaphysical possibilities, one can think of epistemically possible hypotheses as corresponding to an overarching space of epistemic possibilities. Some possibilities in the space of metaphysical possibilities are maximally specific: these can be thought of as \textit{maximal \textit{metaphysical} possibilities}, or as they are often known, possible worlds. In a similar way, some possibilities in the space of epistemic possibilities are maximally specific: these can be thought of as \textit{maximal \textit{epistemic} possibilities}, or as I will call them, \textit{scenarios}.

*[[The term 'scenario' has been used technically by other philosophers for various purposes, notably by Peacocke (1992). My use differs from Peacocke's, but at least there is a relationship, in that Peacocke's scenarios can be seen as akin to perceptual hypotheses. Peacocke's scenarios correspond to specific \textit{spatial} ways things might be in the vicinity of a perceiver, as presented by a perceptual state. A scenario in Peacocke's sense corresponds to a group of scenarios in my sense such that each verifies certain spatial/indexical claims: in my terms, we might call such an entity a \textit{spatial scenario type}.]]

A scenario corresponds, intuitively, to a maximally specific way the world might be, for all one can know a priori. Scenarios stand to epistemic possibility as possible worlds stand to metaphysical possibility. Indeed, it is natural to think of a scenario as a sort of possible world, or better, as a \textit{centered} possible world. There are some complications here, but to sketch some basic ideas, we can think of scenarios intuitively in such terms for now.

For any scenario, it is epistemically possible that the scenario is actual. Intuitively speaking, for any world $W$, it is epistemically possible that $W$ is actual. And for any centered world $W$, it is epistemically possible that $W$ is actual. Here the center represents a hypothesis about my own location within the world. In entertaining the hypothesis that $W$ is actual, I entertain the hypothesis that the actual world is qualitatively just like $W$, that I am the subject at the center of $W$, and that now is the time at the center of $W$.

For example, let the XYZ-world be a specific centered "Twin Earth" world, in which the subject at the center is surrounded by XYZ in the oceans and lakes. Then no amount of a priori reasoning can rule out the hypothesis that the XYZ-world is my actual world: i.e., that I am in fact living in such a world, where the liquid in the oceans and lakes around me is XYZ. So the XYZ-world represents a highly specific epistemic possibility.

When we think of a world as an epistemic possibility in this way, we are \textit{considering it as actual}. On the epistemic understanding, to consider a world $W$ as actual is to consider the hypothesis that $W$ is one's own world. Of course when one considers such a hypothesis, one does not simply consider $W$ "neat": rather, one must consider $W$ under a description. In effect, one is considering the hypothesis that $D$ is the case, where $D$ corresponds to a \textit{canonical description} of $W$. We might think of $D$ intuitively as a neutral qualitative description of $W$, combined with relevant indexical claims about one's own location at the center. I will return to this matter later.

The second key point is that there is a strong epistemic dependence of an expression's extension on the state of the world. If we come to believe that the world has a certain character, we are in a position to
conclude that the expression has a certain extension. And if we were to learn that the world has a different character, we would be in a position to conclude the expression has a different extension. That is: we are in a position to come to know the extension of an expression, depending on which epistemic possibility turns out to be actual.

If we take the case of 'water is H2O': we can say that given that the world turns out as it actually has, with H2O in the oceans and lakes, then it turns out that water is H2O. So if the H2O-world is actual, water is H2O. But if we were to discover that the oceans and lakes in the actual world contained XYZ, we would judge that water is XYZ. And even now, we can judge: if it turns out that the liquid in the oceans and lakes is XYZ, it will turn out that water is XYZ. Or we can simply say: if the XYZ-world is actual, then water is XYZ.

The same goes more generally. If W1 is a specific scenario in which the morning and evening star are the same, and W2 is a scenario in which the morning and evening star are different, then we can say: if W1 is actual, then Hesperus is Phosphorus; if W2 is actual, then Hesperus is not Phosphorus. The same goes, in principle, for a very wide range of scenarios and statements. Given a statement S, and given enough information about an epistemically possible state of the world, we are in a position to judge whether, if that state of the world obtains, S is the case.

All this is reflected in the way we use language to describe and evaluate epistemic possibilities. It is epistemically possible that water is XYZ. It is also epistemically possible that the XYZ-world is actual. And intuitively speaking, the epistemic possibility that the XYZ-world is actual is an instance of the epistemic possibility that water is XYZ. We can say as above: if the XYZ-world turns out to be actual, it will turn out that water is XYZ. We might also use a straightforward indicative conditional: if the XYZ-world is actual, then water is XYZ. Or we can use the Ramsey test, commonly used to evaluate indicative conditionals: if I hypothetically accept that the XYZ-world is actual, I hypothetically conclude that water is XYZ.

We can put all this by saying that the XYZ-world verifies 'water is XYZ', where verification is a way of expressing the intuitive relation between scenarios and sentences described above. Intuitively, a scenario W verifies a sentence S when the epistemic possibility that W is actual is an instance of the epistemic possibility that S is the case; or when we judge that if W turns out to be actual, it will turn out that S is the case; or if the indicative conditional 'if W is actual, then S is the case' is rationally assertible, or if hypothetically accepting that W is actual leads to hypothetically concluding that S is the case. We can also say that when W verifies S, W makes S true when it is considered as actual. Verification captures the way that we use language to describe and evaluate epistemic possibilities.

This dependence can be represented by the epistemic intension of a sentence S. This is a function from scenarios to truth-values. If a scenario W verifies S, then S's epistemic intension is true at W; if W verifies ~S, then S's epistemic intension is false at W; otherwise, S's epistemic intension is indeterminate at W. So the epistemic intension of 'water is XYZ' is true at the XYZ-world.
Epistemic intensions resemble contextual intensions in some superficial respects, but they are fundamentally quite different. The central difference, as we will see, is that epistemic intensions are defined in epistemic terms. From what we have seen so far, epistemic intensions behave at least somewhat as one would like a quasi-Fregean epistemic intension to behave. But to investigate this matter, we must define the relevant notions more precisely.

3.2 Epistemic intensions

The intuitive picture of the epistemic understanding above can be regarded as capturing what is essential to an epistemic understanding per se. This intuitive picture suffices for some purposes, but nevertheless it calls for a fine-grained analysis to make clear how the picture works in detail. What follows is one way to flesh out the details. Not all of these fine-grained details should be seen as constitutive of an epistemic understanding, but I think they provide a natural way of fleshing out such an understanding.[*]

*[[Note that some of these details are necessarily complex, and some readers may prefer to skim the remainder of this section or skip ahead to section 4 on a first reading. Some other papers cover some of this material in more depth: notably, Chalmers (2002e), which covers the issues in 3.4 in more detail; Chalmers and Jackson (forthcoming), which is especially relevant to the issues in 3.6; and Chalmers (2002p) and (2002s), which discuss a number of aspects of these issues that are not discussed here.]]

The epistemic intension of a sentence token is a function from a space of scenarios to the set of truth-values, defined as follows:

The epistemic intension of a sentence token S is true at a scenario W iff D epistemically necessitates S, where D is a canonical description of W.

When the conditions specified here obtain, we can also say that W verifies S. The epistemic intension of S will be false at W when W verifies ~S, and it will be indeterminate at W when W verifies neither S nor ~S.

It remains to clarify three notions: the notion of a scenario, that of a canonical description, and that of epistemic necessitation. I investigate each of these in what follows.

3.3 Deep Epistemic Possibility and Epistemic Necessitation

First, we need to say more about epistemic possibility. The epistemic understanding of two-dimensional semantics is grounded in a notion of deep epistemic possibility, or equivalently, of deep epistemic necessity. In the ordinary sense, we say that S is epistemically possible roughly when S may be the case for all we know, and that S is epistemically necessary roughly when we are in a position to know that S is the case. A notion of deep epistemic necessity goes beyond this sort of dependence on the shifting state of an individual's knowledge, to capture some sort of rational must: a statement is deeply epistemically
necessary when in some sense, it rationally must be true.

Such a notion can be understood in various ways, but for our purposes there is a natural candidate. We can say that $S$ is deeply epistemically necessary when it is \textit{a priori}: that is, when the thought expressed by $S$ can be justified independently of experience, yielding a priori knowledge (more on this below). Then $S$ is deeply epistemically possible when the negation of $S$ is not epistemically necessary: that is, when the thought that $S$ expresses cannot be ruled out a priori. Henceforth, I will usually drop the modifiers "deep" and "deeply", and speak simply of epistemic possibility and necessity.

In this sense, 'water is XYZ' is epistemically possible: one cannot know a priori that water is not XYZ. In the same way, 'Hesperus is not Phosphorus' is epistemically possible, as is 'I am not a philosopher'. On the other hand, 'Some bachelors are married' is not epistemically possible, and 'All bachelors are married' is epistemically necessary. Similarly, one can argue that 'Hesperus has never been visible in the evening sky' is epistemically impossible, and its negation is epistemically necessary.

A claim is deeply epistemically possible, intuitively speaking, when it expresses a rationally coherent hypothesis about the actual world. The standards of rational coherence here are in one sense weaker than usual: if a hypothesis conflicts with empirical knowledge, it may still be deeply epistemically possible. The standards are in another sense stronger than usual: if a hypothesis can be ruled out only by a great amount of a priori reasoning, it is nevertheless deeply epistemically impossible. It is possible to define notions of possibility that meet different standards, but the current standards are best for our current purposes.

The epistemic necessity operator applies to both sentence types and sentence tokens. We require this as the sentences $S$ whose epistemic intensions we are defining are tokens, and it is possible for two sentence tokens of the same linguistic type to have different epistemic properties (for the reasons, see section 3.8). The canonical descriptions $D$ of scenarios, on the other hand, are sentence types, using expressions whose epistemic properties are fixed by the language. We also need an epistemic necessitation operator between sentence types of this sort and sentence tokens.

An epistemic necessity operator of this sort can be seen as a primitive of the system I am developing. On the picture where epistemic necessity corresponds to apriority, we can characterize its properties intuitively as follows. Let say that \textit{thoughts} are the sort of occurrent propositional attitudes expressed by assertive sentences. Then a sentence token $S$ is epistemically necessary when the thought expressed by $S$ can be justified independently of experience, yielding a priori knowledge. A sentence type $D$ is a priori when it is possible for a token of $S$ to be epistemically necessary. A sentence type $D$ epistemically necessitates a sentence token $S$ when a material conditional 'D $\rightarrow$ S' is epistemically necessary, where this is understood as a possible token material conditional whose constituent token of $S$ expresses the same thought as the original token. I will elaborate and refine these characterizations in section 3.8, but this understanding will suffice for present purposes.

We can now say that a scenario $W$ verifies a sentence token $S$ when $W$'s canonical description $D$ epistemically necessitates $S$. This will hold when a material conditional 'D $\rightarrow$ S' is a priori, where the
conditional is understood as above. On this model, intuitively, a scenario $W$ verifies a sentence $S$ when one could in principle rule out a priori the hypothesis that $W$ is actual but $S$ is not the case.

This definition works naturally with the characterizations we will give of scenarios and of canonical descriptions, but it should be noted that this is not the only possible definition. There are various ways in which an epistemic framework might characterize the required relationship between $D$ and $S$ in other terms. One might appeal to the intuitive heuristics described earlier, for example. First, one could say that $W$ verifies $S$ when the epistemic possibility that $D$ is the case is an instance of the epistemic possibility that $S$ is the case. Second, one could say that $W$ verifies $S$ according to whether the indicative conditional "if $D$ is the case, then $S$ is the case" is intuitively correct. Third, one could appeal to the Ramsey test. Fourth, one might appeal to an underlying epistemic necessity operator other than apriority.

So the epistemic understanding of the two-dimensional framework here is not entirely beholden to the notion of apriority. Even if one rejects apriority, or if one rejects the application of apriority in this context, one should not reject the epistemic understanding. It is simply a prima facie datum that there is an epistemic dependence relations between epistemic possibilities and sentences, of the sort that was intuitively characterized earlier. One who rejects apriority will simply need to capture this dependence in other ways. Still, my own view is that the understanding in terms of apriority runs the deepest.

We can here note a fundamental difference between all of these sorts of epistemic evaluation and contextual evaluation. To evaluate a sentence $S$ in a scenario $W$, there is no requirement that $W$ contain a token of $S$. Even if $W$ contains such a token, in general it will have no special role to play. All that matters is the first-order epistemic relation between $D$ and $S$, not whether $D$ says something metalinguistic about a token of $S$. More generally, metalinguistic facts about how a token of $S$ would behave in certain possible circumstances play no role in defining epistemic intensions. We will see shortly how this enables us to deal straightforwardly with the problem cases for contextual intensions.

### 3.4 Scenarios

Scenarios are intended to stand to epistemic possibility as possible worlds stand to metaphysical possibility. This claim can be expressed by the following:

**Plenitude Principle**: $S$ is epistemically possible if and only if there is a scenario that verifies $S$.

In effect, the Plenitude Principle says that there are enough scenarios to verify every epistemically possible claim, and that no scenario verifies an epistemically impossible claim. It is easy to see that if we understand epistemic necessity as apriority, the Plenitude Principle is equivalent to the Core Thesis. (I give it a different name to leave open the option of understanding epistemic necessity in different terms.) So the only question is whether we can understand scenarios and verification so that the Plenitude Principle is true.
Intuitively, a scenario should correspond to a maximally specific epistemically possible hypothesis, or (for short) a maximal hypothesis: a hypothesis such that if one knew that it were true, one would be in a position to know any truth by reasoning alone. (Note that talk of "hypotheses" here is intuitive; formalizations of the relevant notions will follow.) We might say that a hypothesis H1 leaves another hypothesis H2 open if the conjunctions of H1 with both H2 and its negation are epistemically possible. A maximal hypothesis is one that leaves no possible hypothesis open. To every scenario, there should correspond a maximal hypothesis, and vice versa.

There are two concrete ways in which we might understand scenarios. The first is the way we have already sketched: as centered possible worlds. The uncentered part of the world corresponds to a hypothesis about the objective character of one's world. The centered part is needed to handle indexical claims, such as "I am in Australia". If we are given only a full objective description of a world, numerous indexical hypotheses will be left open, so such a description does not correspond to a maximal hypothesis. Correspondingly, there are numerous epistemically possible (but incompatible) objective-indexical claims: e.g. "the world is objectively thus and I am a philosopher" and "the world is objectively thus and I am not a philosopher". We need distinct scenarios to verify these claims: hence centered worlds.

There is good reason to believe that for every centered world, there is a corresponding maximal hypothesis, at least if we describe worlds under the right sort of canonical description. (It is possible that for certain special indexical hypotheses one may need further information in the center of the world, but I will leave this matter to one side.) And one can easily make the case that an epistemically impossible sentence will be verified by no centered world (if it were so verified, it would not be epistemically impossible). So the residual question is whether there are enough centered worlds to correspond to all maximal hypotheses, and to verify all epistemically possible statements.

The standard Kripkean cases of statements that are epistemically possible but metaphysically impossible can be handled straightforwardly. For each such statement S, there is some way the world could turn out such that if things turn out that way, it will turn out that S is the case; and each of these ways the world could turn out can be seen as a centered world. In the case of 'water is XYZ', the XYZ-world is such a world; something similar applies to other cases. One might worry about how a metaphysically possible world (the XYZ-world) can verify a metaphysically impossible statement ('water is XYZ')? But two-dimensional evaluation makes this straightforward: 'water is XYZ' is true at the XYZ-world considered as actual, but false at the XYZ-world considered as counterfactual. The metaphysical impossibility of 'water is XYZ' reflects the fact that it is false at all worlds considered as counterfactual. But this is quite compatible with its being true at some worlds considered as actual.

I think that on examination, there are no clear cases of epistemically possible claims that are verified by no centered world; and in Chalmers (2002p), I have argued that there are no such cases. Still, some controversial philosophical views entail that there are such cases. For example, some theists hold that it is necessary that an omniscient being exists, but it is not a priori that an omniscient being exists. If so, "No omniscient being exists" is epistemically possible. But on this view there will be no possible world to verify it, so the Plenitude Principle for centered worlds will be false. In effect, on this view the space of
metaphysical possibilities is smaller in some respects than the space of epistemic possibilities.

The same goes for some other philosophical views: some views on which the laws of nature of our world are the laws of all worlds, for example; some views on which a mathematical claim (such as the Continuum Hypothesis) can be necessarily true but not knowable a priori; some views on which apparently indeterminate vague statements are true and metaphysically necessitated by underlying truths, but not epistemically necessitated by those truths; and some views where unconscious physical duplicates of conscious beings are conceivable but not metaphysically possible. If these views are correct, there will be epistemically possible claims that are not verified by any centered metaphysically possible worlds, and the Plenitude Principle for centered worlds (and the Core Thesis for epistemic intensions over centered worlds) will be false.

I have argued elsewhere that all of these views are incorrect, and rest on a false view of metaphysical possibility and necessity. A careful analysis of the roots of our modal concepts supports constitutive links between epistemic and metaphysical modal notions, and thereby supports the thesis that every epistemically possible statement is verified by some centered world. We might call this the Plenitude of Worlds Thesis, or the PW thesis. If the PW thesis is correct, the views above are incorrect, and the Core Thesis is unthreatened. Still, the PW thesis is a substantive and controversial claim about modality, and it would be nice if the defense of the current view did not have to rest on it. So it is useful to have a way of understanding scenarios that does not rest on this substantive claim about metaphysical possibilities.

The alternative is to understand scenarios in purely epistemic terms from the start. One might instead that since we want epistemic intensions to be constitutively connected to the epistemic realm, we need not invoke the metaphysical modality at all, and can instead do things in terms of the epistemic modality. There are a couple of ways one might proceed here. One could introduce the notion of a scenario (a maximal epistemic possibility) as a modal primitive, in the same way that some philosophers introduce the notion of a world (a maximal metaphysical possibility) as a modal primitive. Or one could try to construct scenarios directly out of materials that are already at hand.

I take the second course in Chalmers (2002e), examining a detailed construction. I do not have space to do that here, but I can give a brief idea of how one might proceed. The idea I will outline is a linguistic construction of scenarios, using linguistic items in an idealized language L, and a basic operator of epistemic possibility.

Let us say that a sentence D of L is epistemically complete when (i) D is epistemically possible, and (ii) there is no sentence S of L such that both D&S and D&~S are epistemically possible. When D is epistemically complete, it is in effect as specific as an epistemically possible sentence can be. Let us say that D is compatible with H when D&H is epistemically possible, and D implies H when D&~H is epistemically impossible (that is, when there is an a priori entailment from D to H). Then if D is epistemically incomplete, it leaves questions open: there will be H such that D is compatible with H but D does not imply H. If D is epistemically complete, D leaves no questions open: if D is compatible with H, D implies H. Note that D need not explicitly include every such hypothesis as a conjunct; they need only be implied.
Intuitively, scenarios should correspond to epistemically complete hypotheses, whether or not they are expressible in a language such as English. It is likely that actual languages do not have the expressive resources to express an epistemically complete hypothesis, as they are restricted to finite sentences and have a limited lexicon. So for the purposes of this construction, we need to presuppose an idealized language that can express arbitrary hypotheses. In particular, our language L should allow infinitary sentences (at least infinitary conjunctions) and should have terms that express every possible concept, or at least every concept of a certain sort. It is also important that expressions in L are epistemically invariant, so that there cannot be two tokens S1 and S2 of the same sentence type such that S1 is epistemically necessary and S2 is not. The exact requirements for L raise subtle issues, but we can pass over them here.

We can then focus on epistemically complete sentences of L. By the idealization, every such sentence will express a maximally specific hypothesis, and vice versa. So scenarios should correspond to epistemically complete sentences in L, although perhaps with more than one such sentence per scenario. We can say that two sentences S and T are equivalent when S implies T and T implies S (that is, when S&~T and T&~S are epistemically impossible). Any epistemically complete sentences in L will then fall into an equivalence class. We can now identify scenarios with equivalence classes of epistemically complete sentences in L. To anticipate the definition of verification: we can also say that a scenario verifies a sentence S (of an arbitrary language) when D implies S, where D is an epistemically complete sentence of L in the scenario's equivalence class.

Defined this way, scenarios are tailor-made to satisfy the Plenitude Principle. For any epistemically possible sentence S, one can make a straightforward case that some epistemically complete sentence of L implies S. First, because L has unlimited expressive power, some epistemically possible sentence S1 of L will imply S. Second, it is plausible that any epistemically possible sentence S1 of L is implied by some epistemically complete sentence D of L. Intuitively, to obtain D from S1, one simply conjoins arbitrary sentences that are epistemically compatible with S1 (and other conjoined sentences) until one can conjoin no more. The issue is not completely trivial, there might be endless infinitary conjunction with no maximal point, but under certain reasonable assumptions, such a sentence will exist. If so, then every epistemically possible sentence is verified by some scenario. In reverse, it is clear that any sentence verified by a scenario is epistemically possible. So the Plenitude Principle is plausibly true.

In effect, this construction formalizes the intuitive idea of a maximal hypothesis: a maximal hypothesis is equivalent to an equivalence class of epistemically complete sentences in an idealized language. We might say that where the first-approach takes a world-based view of scenarios, on which they correspond to centered worlds, the second approach takes an epistemic view of scenarios, on which they correspond to maximal hypotheses.

What is the relationship between the two constructions? My own view is there is a close correspondence: every centered world corresponds to a maximal hypothesis, and every maximal hypothesis corresponds to a centered world. (Not quite one-to-one: in certain cases involving symmetrical worlds with symmetrically corresponding centers, there may be more than one centered world per maximal
The hypothesis). If so, then the Plenitude Principle will plausibly be satisfied either way. But some philosophers will deny the close correspondence, because of their views about possible worlds. Such a philosopher should embrace the epistemic view of scenarios. On the epistemic view, the central theses require fewer commitments than on the world-based view; and the view is connected more purely to the epistemic realm. For this reason, one can argue that the second understanding of scenarios is more basic. Centered worlds are more familiar and are useful for various applications, however, so I will use both understandings of scenarios in what follows.

On either understanding, one scenario will be privileged with respect to any statement token as the actualized scenario at that token. On the world-based view, this will be the world centered on the speaker and the time of utterance. On the epistemic view, this will correspond to the maximal hypothesis that is true of the world from the speaker's perspective at the time of utterance. In general, we expect that when an expression token's epistemic intension is evaluated at the scenario that is actualized at that token, the result will be the token's extension.

3.5 Canonical descriptions

When we consider a scenario as actual, in order to evaluate an expression, we always grasp it under a description. This raises an issue. A scenario can be described in multiple ways, and it is not obvious that all such descriptions will give equivalent results. So we have to isolate a special class of canonical descriptions of scenarios under which they must be considered.

If we take the epistemic view of scenarios by the second construction above, the choice will be straightforward. A scenario will correspond to an equivalence class of epistemically complete sentences. Here, we can say that a canonical description of the scenario is any sentence in the corresponding equivalence class. Because all of these sentences are equivalent under implication, they will all give the same results under verification.

If we take the world-based view of scenarios, things are more complicated. Here, we require that a canonical description be a complete neutral description of the world. Both neutrality and completeness need explanation.

First, neutrality. To describe a world, we must choose sentences that are true of it. But will these be sentences true of the world considered as actual, or of the world considered as counterfactual? If we choose the first, there is a danger of circularity, since we need canonical descriptions to define the evaluation of worlds considered as actual. If we choose the second, there is a danger of incoherence: 'Water is H2O' is true of the XYZ-world considered as counterfactual, but we need the XYZ-world to verify 'water is not H2O'. So sentences such as this one need to be disbarred from canonical descriptions.

The solution is to restrict canonical descriptions to semantically neutral expressions. Intuitively, a semantically neutral expression is one that behaves the same whether one considers a world as actual or as counterfactual. We cannot simply define a semantically neutral expression in this way, since the
definition presupposes evaluation in a world considered as actual, which presupposes the notion of a canonical description. But nevertheless we have a good grasp on the notion. For example, 'water' and 'Hesperus' are not semantically neutral; but 'consciousness', 'circle', and 'cause' plausibly are. One could rely on our intuitive grasp of this notion for current purposes, or one could seek to define it.

One promising approach is to define such an expression as one that is not "Twin-Earthable". We can say that two individuals (at times) are twins if they are physical and phenomenal duplicates; we can say that two expression tokens are twins if they are produced by corresponding acts of twin speakers. Then a token is Twin-Earthable if it has a twin with a different 2-intension. This test works for many purposes. A semantically neutral term (in the intuitive sense) is never Twin-Earthable. But the reverse is not quite the case. For example, let L be an expression that functions to rigidly designate the speaker's height. Then any twin of L will have the same 2-intension (since a twin speaker will have the same height), but L is not semantically neutral. One might respond by watering down the requirements of physical and phenomenal duplication (perhaps to some sort of mental duplication), but similar cases will still arise: e.g. if M is an expression that rigidly picks out "1" if the speaker is thinking a certain sort of thought, and "0" if not, then M will be Twin-Earthable even by this sort of standard, but not semantically neutral.[*]

*[[Non-Twin-Earthability is related to Bealer's (1996) notion of semantic stability: "an expression is semantically stable iff, necessarily, in any language group in an epistemic situation qualitatively identical to ours, the expression would mean the same thing" (Bealer 1996, p. 134). It is clear that semantic stability cannot be used to characterize semantic neutrality, for the same sort of reasons as above.]]

Perhaps the most straightforward alternative to is characterize the relevant class of terms negatively. We can say that a semantically neutral term is one that involves no names, natural kind terms, or indexicals (including 'actual') either explicitly or implicitly. This rules out all terms with separate processes of reference-fixation and modal evaluation. We can also rule out all terms with context-dependent behavior, such as "heavy", in order that we can describe worlds using expression types and not just expression tokens. What is left will be purely "descriptive" terms, which are context-independent and nonrigid (at least not rigid de jure), which can be used to neutrally formulate the hypothesis corresponding to a world.

It would be useful to have a more positive characterization than this. The fact that we can tell in cases such as the above which terms are neutral and which are not indicates that we have an independent grasp on the notion. Perhaps the best approach is to characterize semantic wholly in terms of our modal operators of epistemic and metaphysical necessity (i.e., apriority and necessity). This might be done, but there some tricky issues. In the meantime, the optimal characterization of semantically neutral terms remains an open question.

To characterize a centered world, semantically neutral terms must be supplemented by some indexical terms, to characterize the location of a center. The best way to do this is the following. We can say that a statement is in canonical form when it has the form D & 'I am D1' & 'now is D2', where D, D1, and D2 are all semantically neutral, and D1 and D2 are identifying descriptions relative to the information in D (that is D implies 'Exactly one individual is D1' and 'Exactly one time is D2'). We can say that a neutral description of a centered world is a statement in canonical form such that D is true of the world, D1 is
true of the subject at the center, and D2 is true of the time at the center.

(In a few cases involving completely symmetrical worlds, there may be no identifying description of the center in semantically neutral terms. In that case, one can invoke a maximally specific description of the center instead: a description D1 such that for all D2 true of the center, D entails "everything that is D1 is D2". Here, two centered worlds that differ only in symmetrical placement of the center may yield the same canonical description. This is reasonable, as intuitively both worlds correspond to the same maximal hypothesis.)

Second, completeness. We require that a canonical description be a complete neutral description of a centered world. There are two possibilities here. First, we can appeal to a criterion in terms of (metaphysical) necessity. Let us say that a semantically neutral description of a world is ontologically full when it (metaphysically) necessitates all semantically neutral truths about that world, and is minimal among the class of descriptions with this property. For example, if physicalism is true, a full semantically neutral specification of fundamental physical truths will be ontologically full. Then an ontologically complete neutral description of a centered world is a neutral description where the first (non-indexical) component of the description is ontologically full.

Alternatively, we can appeal to epistemic completeness. In this sense, a complete neutral description of a centered world is simply a neutral description that is epistemically complete. This requires the claim that for any centered world, there exists an epistemically complete neutral description. This claims is nontrivial, but there are good grounds to accept it: one can argue that although non-neutral terms are modally distinctive, they do not add fundamentally new epistemic power to a language, so that neutral terms constitute what I call (in Chalmers 2002e) an "epistemic basis" for the space of epistemic possibilities.

It is not hard to see that if the Plenitude of Worlds (PW) thesis from the previous section is correct, then an ontologically complete neutral description will also be a epistemically complete neutral description.[*] If so, we can then use either criterion for a canonical description. There will arguably be more explanatory power, however, in using a complete description in the ontological sense, and then allowing this description to epistemically determine all truths about a world considered as actual.

[*][[The PW thesis requires the notion of verification, which requires the notion of a canonical description. For the purposes of interpreting the PW thesis above, we can assume that the canonical descriptions are required to be epistemically complete. If the PW thesis formulated this way is correct, ontologically complete descriptions will give the same results.]]

If the PW thesis is incorrect, then the two criteria will not coincide. An ontologically complete neutral description will not be epistemically complete, and it will leave some hypotheses unsettled (e.g. the complete physical truth about the world may leave the Continuum Hypothesis unsettled, even if it is necessarily true). If we require that canonical descriptions be ontologically complete, the epistemic intensions of these hypotheses will have an indeterminate truth-value. A consequence may be that when an expression's epistemic intension is evaluated at the actual centered world of the expression, it does not yield the expression's extension (e.g., the epistemic intension of CH may be indeterminate at the actual
world, even if CH is true). If, on the other hand, we require epistemic completeness, then the epistemic intensions of the relevant claims will have a determinate truth-value (e.g. the epistemic intension of CH will be true or false at the world according to whether CH itself is true or false there). One might do things either way, depending on one's purposes, although perhaps the second is best overall. In any case, this situation will not matter much for our purposes, since we already know that if the PW thesis is incorrect, then the Core Thesis will be false when scenarios are understood as centered worlds.

(A third alternative is to require "qualitative completeness", where this is characterized as in Chalmers (2002p) in terms of a notion of positive conceivability. This yields a notion that is usefully intermediate between epistemic completeness and ontological completeness. But I will leave this option aside here.)

It is clear that if scenarios are understood as centered worlds, the characterization of canonical descriptions is significantly more complicated than if scenarios are understood in wholly epistemic terms. This may be another point in favor of the purely epistemic understanding of scenarios.

### 3.6 Scrutability and nontriviality

One might have the following worry: the epistemic intension of an expression may have be well-defined, but it is trivial. The triviality comes from the requirement that descriptions be epistemically complete. In order for a description to be epistemically complete, it will need to specify the truth or falsity of most sentences S explicitly. For example, 'water is H2O' will be true precisely in those scenarios that have 'water is H2O' in their canonical description, and it will be false precisely in those scenarios that have 'water is not H2O' in their canonical description. If this sort of thing is typical, then epistemic evaluation as defined will have an uninteresting structure.

This worry is reasonable enough, but I think that it is ultimately wrong. Epistemically complete descriptions do not need to specify the truth or falsity of most statements explicitly, and epistemic evaluation does not have a trivial structure. To see this, it is useful to focus on the actual world, and consider what an epistemically complete description of this world must contain. The sort of argument I give here is presented in much more depth by Chalmers and Jackson (forthcoming) and Chalmers (2002p); but here I will give the basic idea.

The second principle underlying the epistemic understanding of the two-dimensional framework was that once we know enough about the state of the world, we are in a position to know the extensions of our terms, and the truth-values of our sentences. Furthermore, we usually need not be informed about a sentence explicitly in order to know whether it is true. This might be put as follows:

**Scrutability of truth**: For most terms T used by a speaker, then for any truth S involving T, there exists a truth D such that D is independent of T, and such that knowing that D is the case puts the speaker in a position to know (without further empirical information, on idealized rational reflection) that S is the case.
Here, we can say that $D$ is independent of $T$ when $D$ does not contain $T$ or any close cognates. Of course this notion is somewhat vague, as is the notion of "most" above, but this does not matter for our purposes. To save breath, we can put the claim expressed above as "knowing that $D$... that $S$ is the case" as "$D$ is epistemically sufficient for $S$".

Take the case of 'water'. Here, we can let $D$ be a truth specifying an appropriate amount of information about the appearance, behavior, composition, and distribution of objects and substances in one's environment, as well as information about their relationship to oneself. $D$ need not contain the term 'water' at any point: appearance can be specified in phenomenal terms, behavior and distribution in spatiotemporal terms, composition in microphysical or chemical terms. Then $D$ is epistemically sufficient for 'water is H2O'. When one knows that $D$, one will be in a position to know all about the chemical makeup of various liquids with various superficial properties in one's environment, and will thereby be able to infer that water is H2O. After all, this information about appearance, behavior, composition, and distribution is roughly what we need in the case of ordinary knowledge, to determine that water is H2O. And there is no need for further empirical information to play a role here: even if we suspend all other empirical beliefs, we can know that if $D$ is the case, then water is H2O.

Similarly for terms such as 'Hesperus'. Once again, if $D$ contains appropriate information about the appearance, behavior, composition, and distribution of various objects in the world, then $D$ is epistemically sufficient for 'Hesperus is Venus', for 'all renates are cordates', and so on. The information in $D$ enables one to know that the object that presents a certain appearance in the evening is the same as the object that presents a certain appearance in the morning, and so enables us to know that Hesperus is Phosphorus. Something similar applies to 'heat', 'renate', and so on. Here, the base information need not contain terms such as 'Hesperus' or 'renate', or any cognates. And no further empirical information is required: the information in the base is that is needed.

Something similar applies for terms like 'philosopher', or even names like 'Feynman'. Here, the base information $D$ may need more than in the cases above: for example, it may need to include information about people and their mental states, and the use of certain names, and so on. But once I have this information, I will be in a position to know that Feynman was not a philosopher, even if I had no substantive knowledge of Feynman beforehand. And again, my information need not use the terms 'Feynman' or 'physicist' to do this (it might use the quite different term "Feynman" in order for me to track down the referent via those from who I obtained the name, but that is legitimate in this context).

This may not apply to all expressions. There may be primitive terms such as 'time' or 'cause' or 'conscious' such that to know whether a sentence involving these terms is true, one needs a base that includes those terms or relevant cognates that invoke them implicit. But as long as the principle applies reasonably widely, it is good enough.

By the sort of reasoning above, one can infer a slightly stronger claim. Let us say that a vocabulary is a set of terms, and that a $V$-truth is a truth that uses only terms in $V$. Then we can say: there is a relatively limited vocabulary $V$ such that for any truth $S$, there is a $V$-truth $D$ such that $D$ is epistemically sufficient for $S$. To arrive at $V$, intuitively, we might simply eliminate terms one by one from the language.
according to the first principle, until we cannot eliminate any further. Exactly how limited $V$ must be is an open question, but I think the sort of reasoning above gives good ground to accept that it will involve only a small fraction of the original language. One can put the claim in a slightly stronger form:

**Scrutability of Truth II:** There is a relatively limited vocabulary $V$ such that for any truth $S$, there is a $V$-truth $D$ such that $D$ implies $S$.

Here, we have moved from "$D$ is epistemically sufficient for $S$" to "$D$ implies $S$": that is, that the material conditional $D \rightarrow S$ is a priori. This is a stronger but not a vastly stronger claim, given that epistemic sufficiency involved "no further empirical information". One can argue for it along much the same lines as above, suggesting that even a speaker who suspends all empirical beliefs can know that if $D$ is the case, then $S$ is the case. Chalmers and Jackson (forthcoming) argue in much more depth that this sort of conditional is a priori (for a specific choice of $V$). A points made there is worth noting here: this sort of a priori entailment does not require that there is an explicit definition of the terms in $S$ using the terms in $V$.

(Note that even if one is skeptical about apriority, the general point about epistemic sufficiency is still plausible. So such a skeptic will be able to appeal to alternative sorts of epistemic evaluation, and will find an analogous nontriviality under those sorts of epistemic evaluation to the sorts I find here.)

It is also plausible that there is some $V$-truth $D$ that implies all $V$-truths. Of course $D$ may need to be an infinitary conjunction, but we may as well stipulate that $V$ is part of our idealized language, so this is no problem. We can think of $D$ as a conjunction of the simple $V$-truths about the world, or as a conjunction of all $V$-truths of up to a certain level of complexity. There is plausibly a level such that any more complex $V$-truth will be implied by this sort of conjunction. If so, it follows that $D$ entails all truths about the world. It follows plausibly that $D$ is epistemically complete (if $D$ is compatible with $H$ and $\sim H$, then all truths about the world are compatible with $H$ and with $\sim H$, which is plausibly impossible.)

Exactly what is required for the vocabulary $V$ and the description $D$ is an open question. Chalmers and Jackson (forthcoming) and Chalmers (2002p) argue that a specific description $D$ will work here: PQTI, the conjunction of microphysical and phenomenal truths with certain indexical truths and a "that's-all" truth. If this is right, then $V$ requires only the vocabulary required for PQTI. It is possible that the vocabulary might be stripped down further, if $Q$ is implied by $P$ (as some physicalists hold), or if $P$ is implied by a description in a more limited vocabulary, such as one in terms of space, time, and causal connections. But in any case, this specific claim is not required here. The only claim required is that some limited vocabulary $V$ suffices for this purpose.

What goes for the actual world goes also for any epistemic possibility. There is nothing special about the actual world here. Given any class of epistemically compatible sentences in our idealized language, one can strip down the vocabulary involved in it in the same sort of way as before, until one has a limited vocabulary $V$ such that each of the original sentences is implied by a $V$-sentence. It follows by similar reasoning to the above that for any scenario $W$, there will be a limited vocabulary $V$ such that there is an epistemically complete $V$-truth that corresponds to the scenario. Of course the vocabulary may differ between scenarios. For example, there are presumably epistemically possible scenarios that involve...
conceptually basic kinds that are alien to our worlds. If so, the basic vocabulary $V$ for our world must be expanded to describe this scenario. But the resulting vocabulary will still be limited.

Further, there is good reason to accept that most terms of the idealized language will not be essentially required to describe any scenario. If so, there will be a relatively limited vocabulary $V'$ such that for any scenario, there will be a corresponding $V'$-truth. We can think of $V'$ here as an epistemic basis: the terms in it express a set of concepts sufficient to cover all of epistemic space. Exactly how small $V'$ can be is again an open question, but we have good reason to believe that it need involve only a very small fraction of the terms of the original language. With $V'$ in place, we can think of a scenario as corresponding to an equivalence class of epistemically complete $V'$-sentences, rather than of arbitrary epistemically complete sentences.

In any case: from all this, we can see that epistemic intensions will not be nontrivial. An epistemically complete description need not specify the status of most sentences explicitly. Most terms, such as 'water' and 'H2O', will plausibly not be required in an epistemically basic vocabulary, so sentences involving these terms will be nontrivially true or false in scenarios. For all we have said here, it may be that some claims (e.g. 'there is space') are in a sense trivially true in some scenarios and trivially false in others, but this is perfectly reasonable; it is analogous to the trivial truth or falsity (in an analogous sense) of claims about ontologically fundamental properties in metaphysically possible worlds. So there will be plenty of interesting structure to epistemic intensions in general.

### 3.7 Subsentential epistemic intensions

So far I have defined epistemic intensions only for sentences. It is not too hard to define them for subsentential expressions, such as singular and general terms, kind terms, and predicates, but there are a few complexities. I will take it that we have already decided on independent grounds what sort of extensions these expressions should have: e.g. individuals, classes, kinds, and properties. Differences choices could be made here, but the same sort of treatment will work.

The details depend to some extent on whether we take the world-based view or the epistemic view of scenarios. The difference is that centered worlds already come populated with individuals and the like (or at least we are familiar with how to regard them as so populated), whereas maximal hypotheses do not (or at least we are less familiar with how to populate them).

If we take the world-based view of scenarios: let $W$ be a centered world with canonical description $D$, and let $T$ be a singular term. In most cases, $D$ will imply a claim of the form '$T=T$', where $T$ is a semantically neutral singular term. If so, the epistemic intension of $T$ picks out the referent of $T$ in $W$ (that is, it picks out the individual that $T$ picks out when $W$ is considered as counterfactual). In some symmetrical worlds, it may be that there is no such semantically neutral $T$, but there is a $T$ that involves semantically neutral terms plus 'I' and 'now' (plus other basic indexicals, if any). In this case, one can replace the indexicals in $T$ by labels for the entities at the center of the world, yielding an expression $T'$ such that the epistemic intension of $T'$ picks out the referent of $T$ in $W$. If there is no such $T$, then the epistemic intension of $T$ is
null in W.

One can do the same for general terms, appealing to claims of the form 'For all x, x is a T iff x is a T', and holding that the epistemic intension of T in W picks out the referent of T, for a T that is semantically neutral (perhaps plus indexicals). For kind terms, we again appeal to identities 'T is T'. For predicates, we can appeal to claims of the form 'For all x, x is T iff x is T'. This delivers extensions for the epistemic intensions straightforwardly.

If we take the epistemic view of scenarios: then we need to populate scenarios with individuals and the like. If we simply admit scenarios as a basic sort of abstract object with certain properties, one could simply stipulate that they contain individuals that can serve as the extensions of relevant expressions - much as many of those who introduce possible worlds simply stipulate something similar. But it is useful to go through an explicit construction.

Let W be a scenario with canonical description D. Let us say that two singular terms T1 and T2 are equivalent under W if D implies 'T1 is T2'. Then we can identify every equivalence class of singular terms under W with an individual in W, and hold that the epistemic intension of T in W picks out the individual corresponding to T's equivalence class in W. As for general terms: every general term G will pick out a class of individuals. One of the individuals defined above will be in G precisely when D implies 'T is a G', for some T that picks out the individual. One can do something similar for predicates and kind terms: the details will depend on the precise view one takes of properties and kinds and their relation to individuals, so I will not go into them here.

There is one worry: what if the truth of certain existentially quantified claims in a scenario requires individuals that are not the referent of any singular term? For example, there may be a predicate phi such that D implies 'There exists x such that phi(x)', and D does not imply any claim of the form 'phi(T)', where T is a singular term. Of course since D is epistemically complete, it will tell us exactly how many individuals have phi, whether some individuals with phi also have psi and some do not, and so on. It is not hard to see that this sort of case will ultimately require predicates phi (perhaps an infinitely conjunctive predicate) such that D implies that there exists more than one individual with phi, and such that for all predicates psi, D implies that these individuals are indistinguishable with respect to psi. In this case, the individuals will be indistinguishable even in our idealized language, presumably because of deep symmetries in the world. In such a case, if D implies that there are n individuals with phi, one can arbitrarily construct n individuals, perhaps as ordered pairs (phi', 1) ... (phi', n), where phi' is the phi's equivalence class, and stipulate that all fall under the extension of phi, and of other predicates and general terms as specified by the relevant D-implied universally quantified truths about individuals with phi.

In this way, we can construct the relevant classes of individuals and the like, and specify the extensions of various expressions' epistemic intensions. The construction ensures that where the extension of a complex expression is a compositional function of the extensions of its parts, then the same will be true of the extension of a complex expression relative to a scenario. For a identity (e.g. 'T1=T2'), compositionality will be ensured by the equivalence class construction. For a predication (e.g. 'T is a G', or phi(T)) this will be ensured by the appropriate construction of extensions for general terms (as above) or predicates.
machinations two paragraphs above ensure that existential quantification will work straightforwardly, and universal quantification is guaranteed to work (if D implies Ax phi(x), then every individual constructed above will have phi). Logical compositionality is guaranteed at the sentential level (if D implies S and T, D will imply S&T, and so on). So the epistemic intension of a complex expression will be a compositional function of the epistemic intension of its parts.

Of course once one has engaged in this sort of construction, one need not usually bother with the details again. It is perfectly reasonable thereafter to speak of a scenario as containing individuals and the like, and to speak about terms as picking out various individuals in a scenario, quite independently of the details of the construction. On the epistemic view of scenarios, for most purposes one can think of them as abstract objects that may behave somewhat differently from possible worlds, but that have the same sort of status in our ontology.

### 3.8 Tokens, types, and apriority

As I have approached things, epistemic intensions have been assigned to expression tokens rather than expression types (such as linguistic types). The reason for this is straightforward. It is often the case that two tokens of the same linguistic type can have different epistemic intensions. This difference arises from the fact that different speakers may use the same expression so that it applies to epistemic possibilities in different ways. And this differences corresponds to the fact that different speakers may use the same term with different a priori connections.

For example, it is often the case that two speakers will use the same name with different a priori connections. The canonical case is that of Leverrier's use of 'Neptune', which he introduced as a name for (roughly) whatever perturbed the orbit of Uranus. For Leverrier, 'If Neptune exists, it perturbs the orbit of Uranus' was a priori. On the other hand, later speakers used the term (and still do) so that this sentence is not a priori for them: it is epistemically possible for me that Neptune does not perturb the orbit of Uranus. We can even imagine that when Leverrier's wife acquired the name, she did not acquire the association with Uranus, so that she is in no position to know the truth of this sentence a priori.

How can we characterize the epistemic intension of Leverrier's tokens of 'Neptune'? To a first approximation, we can say that in any scenario, Neptune picks out whatever perturbs the orbit of Uranus in that scenario. How can we characterize the epistemic intension for Leverrier's wife? This is a bit trickier, but we can assume that for his wife to determine the reference of 'Neptune', she would examine Leverrier's own use and see what satisfies it. So to a first approximation, his wife's epistemic intension picks out whatever Leverrier refers to as 'Neptune' in a given scenario. One can find a similar (although less stark) variation in the epistemic intensions of many names, and perhaps natural kind terms.

Something similar applies to many uses of context-dependent terms, such as 'heavy'. What I count as heavy varies with different uses of the term. In some contexts, 'My computer is heavy' may be true, and in other contexts it may be false, even though it is the same computer with the same weight. Correspondingly, the way I apply a term across epistemic possibilities will vary with these uses: if I
suppose that my computer weighs such-and-such, I may hold the utterance true in the first case but not the second.

As we have defined epistemic intensions, they are grounded in the behavior of sentences under an epistemic necessity operator. So the variation in epistemic intensions of two expressions of the same type is traceable to variations in the epistemic necessity of two type-identical sentences. In particular, it will be traceable to variations in the apriority of two type-identical sentences. And this variation is traceable to variations in the apriority of the thoughts that the two sentences express.

Here we need to say a little more about thoughts. Thoughts are understood as the occurrent propositional attitudes expressed by assertive sentences. Sentences typically express occurrent beliefs, but not always, since subjects do not always believe what is said. But when the subject does not believe the relevant content, the subject entertains the relevant content: a thought is an entertaining of this sort. Like beliefs, thoughts are assessible for truth. Thoughts can come to be accepted, yielding beliefs, and thoughts can come to be justified, often yielding knowledge.

On this way of approaching things, we assume a relation of expression between statements and thoughts, and we assume a notion of epistemic necessity as applied to thoughts. The latter notion might be seen as the true conceptual primitive of the approach, but on the account where epistemic necessity is tied to apriority, we can characterize it by saying: a thought is epistemically necessary when it can be justified independently of experience, yielding a priori knowledge. We can then say that a thought is epistemically possible when its negation is epistemically necessary. Two thoughts are epistemically compatible when their conjunction is epistemically possible. One thought implies another when the first is epistemically incompatible with the negation of the second. Here we assume that two thoughts of the same subject can stand in a relation of negation, and that a thought can stand in a relation of conjunction or disjunction to a set of two or more other thoughts of the same subject.

(Note that the notion of apriority involves a rational idealization. A token of a complex mathematical sentence may be a priori even if there is no way for the speaker, with her actual cognitive capacities, to justify the corresponding thought a priori. Apriority idealizes away from these cognitive capacities, by requiring merely that it would be possible for the thought to be justified a priori, perhaps by using cognitive capacities that the speaker does not in fact possess. This notion can be developed in detail in various ways: one such way appeals to the possibility of a mental life in which the initial thought (starting in the context of the original cognitive state) comes to be justified a priori. This sort of characterization is best regarded as a clarification of a basic intuitive notion of the epistemic necessity of a thought, rather than as a definition, in order to avoid a multiplication of primitive notions, and also in order to avoid potential problems arising from views on which certain conceivable cognitive capacities are not metaphysically possible.)

With these notions in hand, we can characterize epistemic necessity and necessitation as applied to sentences. A sentence token is epistemically necessary iff it expresses an epistemically necessary thought. A sentence type is epistemically necessary is any token of the type is epistemically necessary. If D and E are sentence types, we can say that D epistemically necessitates E when D&~E is epistemically
impossible. If D is a sentence type and S is a sentence token: let us say that a thought is a D-thought if it is the sort apt to be expressed by D. Then D epistemically necessitates S when a possible D-thought of the subject will imply the thought expressed by S. Equivalently, D epistemically necessitates S when if the thought expressed by S were to be disjoined with a ~D-thought, the resulting thought would be epistemically necessary.

(It is worth noting that we can use this framework to define epistemic intensions for thoughts as well as utterances. Much as above, we can say that a scenario verifies a thought when disjunction of the thought with a ~D-thought is epistemically necessary, where D is a canonical description of the scenario. This yield a notion of mental content that can be applied to beliefs, thoughts, and any propositional attitude with a mind-to-world direction of fit. One can argue that this is a sort of narrow content, determined by the internal state of the thinker (see Chalmers 2002c). Using the definitions above, we can see that when an utterance expresses a thought, the epistemic intension of the utterance will be identical to the epistemic intension of the thought.)

The framework involving thoughts enables us to see how two tokens of the same type can differ in apriority. If Leverrier says 'If Neptune exists, it perturbs the orbit of Uranus', his statement will presumably express a priori knowledge, and will certainly express a thought that can be justified a priori. If his wife utters the same sentence, no amount of a priori rational reflection alone could justify the thought she expresses. Similarly, if I say 'someone with 1000 hairs on their head is bald' on one occasion, it may express an a priori false thought (one whose negation is a priori justifiable), while if I say it on another occasion, it may express a thought that is not a priori false, and may be plausibly true.

In a similar way, this framework enables us to see how two tokens of the same type can have different epistemic intensions. Let S be the sentence 'Neptune is an asteroid', and let D be a canonical description of a scenario W in which the orbit of Uranus is perturbed by an asteroid and in which no-one has ever used the term 'Neptune'. (We can abstract away from complications involving the intension of 'Uranus'.) Then D epistemically necessitates Leverrier's utterance of S: a thought that D obtains would imply the thought Leverrier expresses with S. But D does not epistemically necessitate Leverrier's wife's utterance of S: a thought that D obtains would not imply the thought that his wife expresses with S. (Note that D itself will not exhibit this sort of variation, as expressions in the idealized language are required to be epistemically invariant.) So Leverrier's utterance of S is verified by W, while his wife's utterance is not. So the two utterances have different epistemic intensions.[*]

*[[The analysis in terms of thoughts also clarifies a worry about sentences such as 'Hesperus is Phosphorus'. Intuitively, such a sentence is a posteriori; but some theorists hold that such a sentence is a priori, as it expresses a trivial singular proposition that can be known a priori (e.g. by knowing that Venus is Venus). On the current definition, tokens of such a sentence are not a priori: the thought expressed by such a token clearly cannot be justified independently of experience, even if a different thought associated with the same singular proposition could be. On this understanding, the apriority of an utterance cannot be understood in terms of the apriority of an associated singular proposition. If it is understood in terms of the apriority of an associated content, the relevant content will be something more akin to an epistemic intension.]]

One might reasonably ask: in languages such as English, what sort of simple terms have epistemic
intensions that vary between speakers and occasions of use? This happens most clearly for: (i) names (such as 'Neptune' and 'Gödel'); (ii) natural kind terms (such as 'water' and 'gold'); (iii) demonstratives (such as 'that' and 'there'); and (iv) many context-dependent terms (such as 'heavy' and 'bald'). For terms like this, it is clear that an epistemic intension is not part of a term's "linguistic meaning", where this is understood as the sort of meaning that is common to all tokens of a type in a language. Instead, it is a sort of "utterance meaning" or "utterance content". Some theorists use the term "meaning" only for linguistic meaning, but this is a terminological matter; it is clear that there is a broader use of the term. What matters is that this framework yields a useful and interesting sort of semantic value in the broad sense; and this much is clear. [*]

*[[See Chalmers (2002s) for more on this matter.]]

Are there terms for which an epistemic intension is common to all tokens of a type? This is perhaps most plausible for indexicals, such as 'I' and 'today' (at least setting aside unusual uses, and any context-dependence at the boundaries). It may also hold for some descriptive terms, such as 'circle'. Most of these have some context-dependence, but this can be regimented out more straightforwardly than the epistemic variability of names and natural kind terms. Finally, it may hold for some descriptive names (e.g. 'Jack the Ripper'), at least for a certain period of their existence. For terms like these, an epistemic intension can be seen as part of their linguistic meaning.

### 3.9 The Second Dimension

I have concentrated almost wholly on the first dimension of the two-dimensional framework. This is because the second dimension is already well-understood. But I will say a few words about it here. It is worth examining how it can be understood in a way that is parallel to the way we have understood the first dimension.

Like the first dimension, the second dimension is founded on a certain sort of possibility and necessity. For the first dimension, this is epistemic possibility and necessity, tied to what might be the case. For the second dimension, this is what we might call subjunctive possibility and necessity, tied to what might have been the case.

We can say that S is subjunctively possible when it might have been the case that S. Kripke is explicit that this is the basic notion of possibility and necessity with which he is working, and almost all of his modal argument are directly grounded in intuitions about what might have been the case.

With this basic modal operator in hand, we can proceed as before. For example, one can define a subjunctively complete sentence parallel to the way we defined an epistemically complete sentence. One can construct equivalence classes of subjunctively complete sentences in an idealized language. One can identify these classes as maximal metaphysical possibilities, or as possible worlds. One can give possible worlds canonical descriptions, which will be subjunctively complete sentences in their equivalence class.
Just as one can consider a scenario as actual, by supposing that it actually obtains, one can consider a world as counterfactual, by supposing that it had obtained. That is, instead of thinking "if D is the case, then...", one thinks "if D had been the case, then..." (where D is a canonical description of a world W). For example, for a given sentence S, one can entertain and evaluate the subjunctive conditional: "if D had been the case, would S have been the case?". In some cases, the answer will intuitively be yes: in this case, we can say that W satisfies S. This is a distinctive sort of counterfactual evaluation. When W satisfies S, we can say the subjunctive intension of S is true at W.

The subjunctive intension of a sentence S is a function from worlds to truth-values, true at W if and only if W satisfies S. Satisfaction can be intuitively characterized as above. Formally, we can say that W satisfies S when D subjunctively necessitates S, where D is a canonical description of W. We could define subjunctive necessitation by the subjunctive conditional heuristic above. Or more formally, one might say that D subjunctively necessitates S when D&~S is subjunctively impossible.

With a possible world as constructed, we can construct a space of individuals much as we did with scenarios. We can then define subjunctive intensions for subsentential expressions straightforwardly.

Subjunctive intensions are defined in the first instance for expression tokens, since subjunctive necessity judgments can vary between tokens of a type. For some expression types, all tokens of the type will have the same subjunctive intension: this is arguably so for names and natural kind terms, logical and mathematical terms, and some descriptive terms (e.g. 'circle'). For other expression types, subjunctive intensions will vary between tokens of the type: this is so for indexicals (e.g. 'I') and many context-dependent terms (e.g. 'heavy'). In the first case, subjunctive intension may be an aspect of linguistic meaning; in the second case, it is not.

The basic ideas here are parallel between the two cases. The explicit construction of possible worlds and the like may seem like heavy weather; but this is only because possible world are more familiar. One might think one does not really need any such construction to legitimize the appeal to possible worlds; but if so, I would say the same applies to scenarios. Both serve as a sort of useful abstraction from a modal notion in much the same way.

There is one important difference between worlds and scenarios. We have a means of reidentifying individuals across worlds, but there is no such means of reidentifying individuals across scenarios. In the case of worlds, these claims are grounded in de re subjunctive intuitions of the form 'T might have been F' - read so that they are distinct in their form from de dicto subjunctive intuitions such as 'it might have been that T was F'. We can use these claims in conjunction with the construction above to identify certain objects in alternative possible worlds as identical to certain objects in the actual world (or alternatively, to identify objects with equivalence classes across worlds; or at least to set up counterpart relations across worlds). There is no analog of a de re modal intuition in the epistemic case: it can be a priori that T is F, but it makes no sense to say that T is such that it is F a priori.

(In the subjunctive case, one can also appeal here to de dicto subjunctive intuitions involving a privileged class of designators, i.e. names. Judgments of the form 'it might have been that N was F' where N is a
name for the relevant object, arguably give the same result for any name of the object, and if so can
ground a sort of crossworld identification. In the epistemic case, there is in general no analog to this
privileged class of designators: different names for an individual are not generally a priori equivalent, so
come apart in different scenarios, and there is no way in general to isolate a privileged class of
epistemically equivalent designators here. At best this may be possible in special cases, such as canonical
designators for phenomenal states and abstract entities. A consequence is that quantified modal claims
will not generally be well-defined in the epistemic case, and quantified modal logic will be largely
inapplicable in this domain.)

In many cases, a term's subjunctive intension will depend on its actual extension, or on other aspects of
the actual world. This is particularly clear in the case of rigid designators such as names and indexicals.
If Kripke is correct, these pick out the same individual in all possible worlds, and so pick out the term's
actual extension in all possible worlds. In these cases, the subjunctive intension of a term itself depends
on the character of the actual world. Here, in effect, a term's subjunctive intension depends on which
epistemic possibility turns out to be actual.

One can naturally encapsulate this behavior in a two-dimensional intension. This can be seen as a
mapping from scenarios to subjunctive intensions, or equivalently as a mapping from (scenario, world)
pairs to extensions. We can say: the two-dimensional intension of a statement S is true at (V, W) if V
verifies the claim that W satisfies S. If D1 and D2 are canonical descriptions of V and W, we say that the
two-dimensional intension is true at (V, W) if D1 epistemically necessitates that D2 subjunctively
necessitates S. A good heuristic here is "If D1 is the case, then if D2 had been the case, would S have
been the case?". Formally, we can say that the two-dimensional intension is true iff nec1 (D1 -> nec2 (D2>
S)), where nec1 and nec2 express epistemic and subjunctive necessity respectively. One can define two-
dimensional intensions for subsentential expressions by an extension of this idea.

(One complication: the construction so far makes the space of possible world derive from subjunctive
modal claims, so if the latter depends on the character of the actual world, the former might, too. If so,
then the space of W's may depend on V. For maximally general results, this might be useful, since some
philosophical theories of modality make this claim. If every possible world can be completely specified in
semantically neutral terms, the conclusion can at least be mitigated by using such a description to identify
the worlds between spaces, although on some views it may still be that whether a given semantically
neutral claim is possible depends on which scenario is actual.

On some views, complete semantically neutral description of possible worlds will not always exist: e.g. if
there can be haecceitistic differences between worlds without qualitative differences. In this case, it is
probably best to see each scenario V as being associated with a relativized space of possible worlds. Note
that this worry about semantically neutral descriptions does not affect their earlier applications to centered
worlds for epistemic purposes: a pair of haecceitically different centered worlds will have the same
canonical description for epistemic purposes, and will in effect function as epistemically equivalent.)

Relative to a scenario, there will be an associated world (in the scenario's space): intuitively, the world
that will be actual if the scenario obtains. If scenarios are centered worlds, a scenario's associated world
will be the scenario stripped of its center. On the epistemic view of scenarios, we can say that (to a first approximation) \( W \) will be associated with \( V \) when \( D_1 \) verifies \( D_2 \), where \( D_1 \) and \( D_2 \) are canonical descriptions of \( V \) and \( W \).

(One worry: on some views, it may be that there are scenarios that do not fully specify worlds, as there are epistemically complete sentences that are ontologically incomplete. For if intrinsic properties exist but can only \textit{in principle} be specified relationally, then an epistemically complete description of a scenario may specify only relations and nothing about the nature of the intrinsic properties (the relevant claims cannot even be expressed), while nevertheless implying that there are such intrinsic properties and that they have some further nature. If this can happen, there may be no \( D_2 \) such that \( D_1 \) verifies \( D_2 \). To handle this, it is probably best to say that there can be multiple worlds associated with a scenario, and that \( W \) is associated with \( V \) when \( D_1 \) and \( D_2 \) are epistemically compatible.)

Given the association relation between scenarios and worlds, one can define the \textit{diagonal intension} of a sentence's two-dimensional intension. This will be a mapping from scenarios to individuals, mapping \( V \) to the value of the two-dimensional intension at \((V, W)\), where \( W \) is associated with \( V \). (If there is more than one such \( W \) for the reasons above, it is not hard to see that they will all give the same results.) The diagonal intension of a sentence will straightforwardly be equivalent to its epistemic intension. One can therefore reconstruct an expression's epistemic intension from its two-dimensional intension by diagonalizing, just as one can reconstruct its subjunctive intension by holding fixed the actualized scenario.

It should be clear, however, that this diagonal construction in no sense gives the \textit{definition} of an epistemic intension. Epistemic intensions are defined in purely epistemic terms: they are in no sense derivative on subjunctive notions. The diagonal construction is conceptually much more complex, involving subjunctive evaluation, association of worlds with scenarios. In effect, the relation is akin to that between the functions \( f(x) = x^3 \), \( g(x, y) = x^3 + \sin(x-y) \), and \( g'(x) = g(x, x) \). Here, \( g' \) is the "diagonal" of \( g \), and is the same function as \( f \). But it would obviously be incorrect to hold that \( f \) is fundamentally the diagonal of \( g \), or that it is derivative on trigonometric notions. For exactly the same reasons, it is incorrect to hold that an epistemic intension is fundamentally a diagonal intension.

There is a sense in which the two-dimensional intension represents the full modal structure of an expression, capturing how it behaves under epistemic evaluation, modal evaluation, and combinations of the two. Just as an epistemic intension can be evaluated a priori, a two-dimensional intension can be evaluated a priori. A subjunctive intension cannot be, but it can be evaluated when the actualized scenario is specified.

We can think of all of these intensions as aspects of the content of a sentence token. A sentence is in no sense ambiguous for having both epistemic intensions and subjunctive intensions; rather, it has a complex semantic value. Different aspects of this semantic value will be relevant to the evaluation of the sentence in difference contexts. In epistemic contexts ("it is a priori that \( S \"; "it might turn out that \( S \"; "if \( S \), then \( T \")'), the epistemic intension will be most relevant. In subjunctive contexts ("it might have been that \( S \"; "if it had been that \( S \), it would have been that \( T \")'), the subjunctive intension will be most relevant. In
combined epistemic-subjunctive contexts, the two-dimensional intension will be most relevant. There is no need to settle the question of which of these, if any, is the meaning or content of an expression.

### 3.10 The Core Thesis

Let me summarize where things stand with respect to the Core Thesis: that S is a priori iff S has a necessary 1-intension.

If S is a priori: then for all W with canonical description D, D implies S. (If S is a priori, D implies S for any D.) So S is verified by all W, and has a necessary 1-intension.

If S is not a priori: then ~S is epistemically possible. Under small assumptions (see 3.2), it follows that there is an epistemically complete D such that D implies ~S. On the epistemic view of scenarios, any epistemically complete sentence describes a scenario, so there is a scenario W that verifies ~S. So S does not have a necessary 1-intension.

On the world-based view of scenarios, then if the PW thesis is true, any epistemically complete D describes a scenario, so S does not have a necessary 1-intension. If the PW thesis is false, this does not follow. Indeed if the PW Thesis is false, some epistemically possible statements will not be verified by any centered world, so the Core Thesis will be false.

It follows that the Core Thesis is true on the epistemic view of scenarios, and is true on the world-based view iff the PW thesis is true. I think there is good reason to hold that the PW thesis is true; but even if it is not, we may simply adopt the epistemic view of scenarios. Either way, the epistemic understanding of two-dimensional semantics plausibly yields an understanding of 1-intensions that satisfies the Core Thesis.

Given that epistemic intensions satisfy the Core Thesis, there are a number of natural applications that I will simply summarize here.

(i) Fregean sense: Because they satisfy the Core Thesis, epistemic intensions also satisfy the Neo-Fregean Thesis: 'A' and 'B' have the same intension iff 'A == B' is a priori. So epistemic intensions behave broadly like a sort of Fregean sense, tied to the rational notion of apriority. There are some differences. First, sentence-level Fregean senses are supposed to be true or false absolutely, but sentence-level epistemic intensions are true or false relative to a speaker and time (witness 'I am hungry now'). Second, apriority is weaker than cognitive insignificance, so epistemic intensions are less fine-grained than Fregean senses.[*]

Nonetheless, it is clear that epistemic intensions serve as a broadly Fregean semantic value. (See Chalmers 2002s.)

[*[One can adapt the current framework to yield a more fine-grained sort of epistemic intension, by starting with a less idealized notion of epistemic possibility and proceeding from there. See Chalmers 2002e for more on this.]]
(ii) Narrow content: One can extend the current framework from language to thought in an obvious way. One can define epistemic intensions for beliefs and thoughts in the manner suggested in 3.8. The result can be seen as a sort of content of thought. It is very plausible that what results is a sort of narrow content, such that two physical and phenomenal duplicates will have thoughts with the same epistemic intension. (This narrowness is grounded in the narrowness of deep epistemic possibility: if a thought is a priori, then the corresponding thought of a physical and phenomenal duplicate will also be a priori.) This sort of content much more closely tied to cognition and reasoning than "wide content", and is well-suited to play a central role in explaining behavior. (See Chalmers 2002c.)

(iii) Modes of presentation: In analyzing the behavior of belief ascription, it is common to appeal to a notion of "mode of presentation", but there is little agreement on what sort of thing a mode of presentation is. Schiffer (1990) suggests that a mode of presentation must satisfy "Frege's constraint": roughly, that one cannot rationally believe and disbelieve something under the same mode of presentation. Because they satisfy the neo-Fregean thesis, epistemic intensions satisfy Frege's constraint perfectly, at least if one invokes an idealized notion of rationality that builds in arbitrary a priori reasoning. So it is natural to suggest that modes of presentation are epistemic intensions. In this way, one can use epistemic intensions to analyze ascriptions of belief.[*] (See Chalmers 2002c.)

[*][The current framework is compatible with a number of different proposals that give modes of presentation a role in belief ascription. I think it is particularly well-suited to so-called "hidden-indexical" accounts (Schiffer 1990). At a first approximation, it is plausible that 'X believes that S' will be true if the subject specified has a belief whose subjunctive intension is that of S, and whose epistemic intension falls into a certain "S-appropriate" class, which may be contextually specified. See Chalmers 2002c.]

(iv) Indicative conditionals: One can use epistemic intensions to give a semantics for indicative conditionals that parallels in certain respects the common possible-worlds semantics for subjunctive conditionals. As a first approximation, one can suggest that an indicative conditional 'If S, then T' uttered by a subject is correct if the epistemically closest scenario that verifies S also verifies T, where epistemic closeness will be defined in terms of the beliefs or knowledge of the subject. (See Chalmers 2002t; see also Weatherson 2001 for an independent development of a similar idea.)

(v) Conceivability and possibility: The Core Thesis makes possible a certain sort of move from conceivability to possibility. If we say that S is conceivable when its negation is not a priori, then when S is conceivable, there will be a scenario verifying S. If we understand scenarios as possible worlds and the PW thesis is true, then when S is conceivable, there will be a centered possible world verifying S. This makes it possible to move from epistemic premises to modal conclusions, as is often done. Of course it is possible to embrace the current framework while rejecting the PW thesis and so rejecting the relevant move from conceivability to possibility. But the current framework at least shows how a certain sort of link between conceivability and possibility is tenable in light of the Kripkean phenomena that are often thought to be the greatest threat to such a connection. (See Chalmers 2002p.)

4 Epistemic intensions and contextual intensions
We have seen that there are two very different ways of understanding two-dimensional semantics: the epistemic understanding and the contextual understanding. On the epistemic understanding, 1-intensions are constitutively tied to the epistemic domain and satisfy the Core Thesis. On the contextual understanding, 1-intensions are not constitutively tied to the epistemic domain and do not satisfy the Core Thesis.

It is useful to examine the relationship between the two in somewhat more depth. First I will examine how the epistemic understanding deals with the problems that arise for the contextual understanding. Then I will examine to what grounds the resemblance of certain contextual intensions to epistemic intensions.

4.1 Problem cases

The first main problem area for contextual intensions involved sentences such as 'Language exists', which are a posteriori, but have a necessary contextual intension. These problems arose because contextual intensions require a token of the evaluated expression in the evaluated world. There is no such requirement for epistemic intensions, so the problem does not arise.

For example, there will be many language-free scenarios: there are many centered worlds with no languages, and there are many epistemically possible hypotheses under which there are no languages. If D is a canonical description of such a scenario, D will verify 'language does not exist'. Intuitively, if we consider such a scenario W as actual, we can say that if W is actual, then language does not exist. So the epistemic intension of 'language exists' will be contingent, as required.

The same goes for 'words exist', and something similar applies to 'I am uttering now'. In the latter case, there will be many centered worlds in which the subject at the center is not uttering, and there will be many epistemically possible hypotheses (for me) under which I am not uttering. If D is a canonical description of such a scenario, D will verify 'I am not uttering now'. So this expression will also have a contingent epistemic intension. The applies even to 'I am thinking now'.

'I exist' is a slightly trickier case. If 'I exist' is a priori, there is no problem. If 'I exist' is a posteriori (as I think is the case), then there will be various epistemically possible hypotheses for me under which I do not exist: for example, a hypothesis under which nothing exists (which is arguably itself not ruled out a priori). So on the epistemic view, there will be corresponding scenarios that verify 'I do not exist', and 'I exist' will have a contingent epistemic intension, as required.

On the world-based view, there is a worry: one might think that any centered world will verify 'I exist', since there is always a subject at the center. This raises a subtlety. In the general case, centering is optional: on the world-based view, the space of scenarios contains worlds without a marked subject and time, and perhaps worlds with only a marked subject or only a marked time. A world without a marked subject will then verify 'I do not exist'. The exact choices here will depend on exactly which indexical claims one holds to be a priori, but it should be possible to arrange things so that there is a verifying
The Foundations of Two-Dimensional Semantics

centered world for every epistemically possible claim.

In any case, we see that problems that arise due to the required presence of a token do not arise here. At most there are problems due to the required presence of a subject in a centered world; but these will not arise on the epistemic view, and can be dealt with reasonably straightforwardly on the world-based view. So the epistemic understanding does not suffer from the problems of the contextual understanding here.

Another problem, at least for orthographic contextual intensions, concerned worlds where the subject at the center uses 'water' to mean something different, such as steel, so that the 1-intension picks out steel there, which is not the desired result. Again, this problem will not arise for epistemic intensions. In general, to evaluate the epistemic intension of 'water' at a scenario, the presence or absence of tokens of 'water' in that scenario will be irrelevant (with one qualification to be outlined shortly). What the epistemic intension of 'water' picks out in a Steel Earth scenario will depend on a number of other factors, especially the appearance and behavior of substances located around the center of the scenario, but there is no danger that it will pick out steel.

Note that this analysis requires that "My term 'water' means water" and similar claims are not a priori. If such a claim was a priori, then because a canonical description of the Steel Earth scenario will contain something like "My term 'water' means steel", the scenario would verify 'water is steel', which is the wrong result. But it is independently plausible that these claims are not a priori - at least if "'water'" is understood in purely orthographic terms. It is a posteriori that the string has any meaning at all, and it is a posteriori that it means what it does. If "'water'" is understood in partly semantic terms, so that it is constitutively tied to a given meaning for 'water', then the claim in question may be a priori; but this is not a problem, since in this sense the Steel Earth scenario will not verify "My term 'water' refers to steel". For more on this matter, see Chalmers (2002p) and Yablo (2002).

Note also that there is one case where evaluating an expression's epistemic intension may turn on the presence of tokens of that expression in a world: expressions used deferentially. It may be that Leverrier uses 'Neptune' to (rigidly) pick out whatever her husband refers to as 'Neptune'. If so, then in a given scenario, the epistemic intension of 'Neptune' will pick out roughly the referent of her husband's term 'Neptune' in that scenario (abstracting away from issues about the epistemic intension of 'my husband', etc). In this case, something like "If Neptune exists, my husband refers to it as 'Neptune'" will be a priori for her. Something similar to this will apply to other terms used deferentially, such as a non-expert's use of 'arthritis', although the details may be less clean. But here, we get only the results that would be expected. For example, if I use 'water' wholly deferentially, then if I consider as actual a Steel Earth scenario where those around me use 'water' for steel, then this scenario verifies 'water is steel' for me. This seems correct: for a deferential user, although perhaps not for a nondeferential user, 'water is steel' expresses an epistemically possible thought.

(Note that even in deferential cases, evaluation turns on the referent of others' use of the expression. It may be that evaluation could also turn on one's own past use of the expression; but it cannot happen that evaluation will turn on the referent of one's own current use of the expression, since such a circular criterion cannot secure a referent. (I set aside pathological nonreferring cases, such as 'the referent of this
expression'.) So even in a strongly deferential case, the epistemic intension of 'water' will not turn on the referent of a use of 'water' at the very center of a scenario.)

There is also the Twin Earth case, where Twin Oscar uses 'water' to refer to XYZ. This was a problem for linguistic and semantic contextual intensions, since these are arguably not defined at such a world, whereas we would like the 1-intension of Oscar's term to return XYZ at this world. Again, the epistemic framework handles this unproblematically. The epistemic intension of 'water' returns XYZ at this world, not because Twin Oscar's term 'water' refers to XYZ (Twin Oscar's term is irrelevant), but because the scenario verifies the claim that XYZ has a certain appearance, behavior, relation to oneself, and so on, which in turn verifies 'water is XYZ'.

Finally, there was the problem of Fregean typing. It seemed that in order for contextual intensions to give roughly Fregean results, then one had to classify expression tokens under some sort of Fregean type. For a semantic contextual intension to give the right results, for example, one needed to appeal to some sort of prior Fregean semantic notion, which is unhelpful in the current context. No such problem applies to epistemic intensions. Because these intensions do not rely on tokens of the same type being present within scenarios, there is no need to isolate the common type under which these tokens fall. All one needs is the expression token itself, and its epistemic properties. This approach may ground an account of a sort of Fregean semantic value, but it need not presuppose any such account.

These advantages of the epistemic account over the contextual account are all grounded in the fact that the contextual understanding is an essentially metalinguistic understanding, while the epistemic understanding is not. The contextual understanding concerns content that an expression might have had; but the epistemic understanding reveals aspects of the content that it has. Everything is grounded in certain first-order epistemic claims, which we use as tools to reveal an expression's content, just as in the familiar modal case, various first-order subjunctive claims are used as tools to reveal an expression's content. As before, the cases are parallel.

4.2 Semantic contextual intensions

We saw earlier that some versions of a semantic contextual intension presupposed a quasi-Fregean notion of content. We can now turn the picture the other way around, and using the quasi-Fregean notion of content developed here to ground a semantic contextual intension.

Let us say that an epistemic contextual intension of an expression is the semantic contextual intension that derives from the use of epistemic intensions as the relevant semantic value. The epistemic intension of an expression token is a function from centered worlds to extensions, defined at worlds that have a token at the center with the same epistemic intension as the original token, and returning the extension of that token in that world.

It is easy to see that at the worlds where it is defined, an expression's epistemic contextual intension yields the same extension as its epistemic intension. If W is a centered world containing a token S' with...
the same epistemic intension as the original token S: let E be the extension of S'. Then the epistemic contextual intension of S returns E at W. Further, the epistemic intension of S' (on the world-based view of scenarios) returns E at W, since W is actualized at S'. By identity of epistemic intensions, the epistemic intension of S also returns E at W. So S's epistemic contextual intension and epistemic intension are coextensive at W. Something similar applies on the epistemic view of scenarios, if we invoke the scenario corresponding to the centered world W.

So an expression's epistemic contextual intension is a restriction of the term's epistemic intension. For this reason, it will give appropriate quasi-Fregean results in many cases. It will not satisfy the Core Thesis: it will have the usual problems with 'language exists' and other metalinguistic claims, as it will not be defined at scenarios without the token at the center, or where the token has a different content. But it will be reasonably close for many purposes.

One could also define a epistemic version of the cognitive contextual intension of a token, defined at all worlds centered on a concept or thought with the same epistemic intension as the token, and returning the extension of that concept or thought. This would again be a restriction of the expression's epistemic intension, but it would be less of a restriction, since it would not require a linguistic token in the evaluated world. The Core Thesis will still be false due to various metacognitive claims and the like; but it will not be far off. I think this last notion is the best approximation that a contextual intension can yield to a quasi-Fregean content that satisfies the Core Thesis. It is clear, however, that this notion is essentially derivative of that of an epistemic intension.

This way of seeing things also helps to explain why some other contextual intensions give approximately Fregean results. It may be that there are various other features of type F of a subject or a token, that at least correlate with an epistemic intension to some degree. We can then set up an F-based contextual intension, defined at worlds centered on a subject or token with the same F features as the original, and returning the extension of the relevant token. Then in each such world, the token at the center will have at least approximately the same epistemic intension as the original token, and so in most cases will return the same or similar extension at that world. So the F-based contextual intension will approximate the behavior of a restriction of the original epistemic intension.

This applies especially to some cognitive contextual intensions. It may be that possession of a concept with a given epistemic intension is itself determined by features such as a concept's cognitive role and/or associated phenomenology, or more deeply by the subject's physical state, or functional state, or physical/phenomenal state. To know exactly which features are crucial would require a solution to the problem of intentionality, which is not yet available. But one can say: insofar as epistemic intensions are determined by features such as cognitive role or physical/phenomenal state, then corresponding contextual intensions (here, cognitive-role contextual intensions or physical/phenomenal contextual intensions) will be restrictions of the original epistemic intension, and so will behave in a quasi-Fregean manner. Again, however, the epistemic intension is the more fundamental notion of content.

4.3 Linguistic contextual intensions
We saw earlier (in section 2.2) that for some expressions, a linguistic contextual intension behaves in a quasi-Fregean manner. We are now in a position to see why this is.

For some expressions, their epistemic intension is part of (or determined by) their linguistic meaning. That is, some linguistic expression types are such that every token of that type has the same epistemic intension. As noted in section 3.7, something like this appears to apply to some pure indexicals, such as 'I', 'now', and 'today', to some descriptive terms, such as 'circular', and to some descriptive names, such as 'Jack the Ripper'.

When an expression token's epistemic intension is part of its linguistic meaning, then the token's linguistic contextual intension will be a restriction of its epistemic intension. This can be seen by the same sort of reason as in the previous section. Or one can simply apply the point there directly: if any token of S's linguistic type has the same epistemic intension, then S's linguistic contextual intension will be a restriction of its epistemic contextual intension, which is a restriction of its epistemic intension.

It follows that in cases such as 'I', 'now', 'circular', and 'Jack the Ripper', the terms' linguistic contextual intensions will be quasi-Fregean. They will not satisfy the Core Thesis because of the restriction to worlds containing relevant tokens, but they will be reasonably close. This explains the phenomenon noted in section 2.2: the quasi-Fregean behavior is a direct consequence of the fact that for these tokens, epistemic intension is an aspect of linguistic meaning. Once again, a contextual intension is interesting largely because of the degree to which it approximates an epistemic intension.

5 Other two-dimensional ideas

With this analysis of the contextual and epistemic understandings on the table, we are now in a position to turn to existing two-dimensional proposals to see how they fit into this analysis, and to use this analysis to help understand their foundations. I should say at the start that although I will occasionally criticize these approaches and argue that the approach I have recommended has certain advantages, any advantages are due largely to building on the insights that these approaches embody.

5.1 Stalnaker's diagonal

The diagonal proposition of Stalnaker (1978) is characterized as follows. We start with an understanding of propositions as sets of possible worlds, and with the idea that any utterance has a proposition as its content. (This propositional content coincides roughly with what I have called a subjunctive intension.) We can then say: the utterance could have had different propositional content. So there are worlds where the utterance has different propositional content. This allows us to define an utterance's propositional concept, which is a function from possible worlds to propositions, defined at any world containing the utterance, returning the propositional content of the utterance at a world. We can then define the utterance's diagonal proposition as the set of worlds such that the utterance's propositional concept, evaluated at that world, yields a proposition that is true at that world.
As defined here, a diagonal proposition is much like a token-reflexive contextual intension. There are minor differences. A token-reflexive contextual intension was defined directly in terms of what an utterance's truth-value would be at a world, rather than in terms whether the proposition it expresses would be true at that world, but it is clear that within the propositional framework, these yield the same results. A diagonal proposition is a set of possible worlds or equivalently a function from worlds to truth-values, whereas a token-reflexive proposition was a function from centered worlds to truth-values. But again, that is a minor difference: one can translate between the relevant worlds and centered worlds either by "marking" the location of the token as a center, or by removing the marked center from the location of the token. (Token-reflexive contextual intensions uniquely do not need a center to specify the relevant token, since the token is independently identified by a sort of transworld identity with the original token.) So diagonal propositions are equivalent to token-reflexive contextual intensions.

The behavior of a token-reflexive contextual intension is not clear unless we know which properties are essential to a token and which properties are inessential. It is clear that Stalnaker holds that a token's semantic properties are not essential to it, since he holds that it could have had different semantic content. It seems plausible that on his picture, a token's orthographic properties are essential to it; at least, in all examples, a token's orthographic properties are held constant across its possible occurrences, so I will assume this in what follows. It is not entirely clear which other properties are essential (language? probably not. speaker? maybe), but this is enough to be going on with.

>From what we have said here, it appears that a token's token-reflexive contextual intension will be a restriction of its orthographic contextual intension, restricted to cases where the orthographically identical token is the original token. One might think that it's general behavior will be very much like that of an orthographic contextual intension: for my utterance 'water is H2O', there will be worlds at which it means that steel is orange; if so, its token-reflexive contextual intension will be defined and presumably false there.

However, this sort understanding is inconsistent with a central point in Stalnaker's original paper, where he says that for a sentence to have a necessary diagonal proposition is for it to be an a priori truth. He also says that an official's utterance of 'this bar is one meter long' could not have expressed a false proposition. It is unclear how this can be justified. Why could not the utterance have meant something like "that boat is two miles long", and been false? It is natural to suppose that that Stalnaker is holding fixed some intuitive sort of meaning and content. (Thus yielding something that behaves like a semantic/orthographic contextual intension, for an intuitive Fregean semantic value.) But it is not clear what aspect this could be: the only content that his account officially recognizes is propositional content, which is explicitly held to vary with possible occurrences of an utterance; and even if there were some further aspect of content, it is unclear why this sort of content should be essential to an utterance and the other sort inessential. Alternatively, it may be that Stalnaker is assuming that some sort of cognitive factor (e.g. associated cognitive role?) is essential to an utterance (thus yielding something that behaves like a cognitive/orthographic contextual intension), but this is nowhere specified. So the claim about apriority and about the meter case appears to be ungrounded within the article.

In later work, Stalnaker retreats from the claim about apriority (although to my knowledge he does not...
address the discussion in the original article), and allows a much wider range of behavior for an utterance across possible worlds. For example, in Stalnaker (1999) he allows where that there are worlds where 'Julius', used in the actual world as a descriptive name for the inventor of the zip, is used instead for the inventor of bifocals. And in Stalnaker (2001) he allows that there are worlds where our word 'tiger' refers to pieces of furniture. In both of these articles he explicitly denies that necessity of diagonal proposition corresponds to apriority, as seems reasonable. In effect, this diagonal proposition behaves very much like an orthographic contextual intension, or a straightforward restriction thereof.

As such, a diagonal proposition is clearly useful. For example, Stalnaker often uses diagonal propositions to model situations of communication, in which a hearer hears an utterance but is unsure what the speaker meant by it, or has false beliefs about what the speaker meant by it. It seems clear that this sort of metalinguistic use requires something quite different from a quasi-Fregean notion, so this is reasonable. It is less clear that diagonal propositions are useful for addressing matters of cognitive significance, rational inference, apriority, and the like, especially when divorced from issues about communication. Stalnaker sometimes suggests this sort of use, but I think the grounds here are weaker.

For example, in a recent paper (2001), Stalnaker holds that the "metasemantic" framework with diagonal propositions can "provide an explanation for the phenomena that Kripke's work brought to light" - where this phenomenon is the distinctive behavior of the class of a posteriori necessities such as 'Hesperus is Phosphorus', 'water is H2O', and so on. This is a surprising claim. What is most distinctive about these phenomena are the differences with standard necessities such as 'all bachelors are unmarried', '2+2=4', and so on. If diagonal propositions function as Stalnaker (1978) suggests, the distinction would be straightforwardly represented by the fact that the second class have necessary diagonal propositions and the first do not. But on the metasemantic understanding, there seems to be no way to draw the distinction using diagonal propositions alone. For both sorts of necessity, there will be many worlds at which the diagonal is false, and there are no clear patterns that are distinctive to the first class. So it is not clear how the "explanation" is supposed to work.

In a brief ensuing discussion of 'Hesperus is Phosphorus', Stalnaker appeals to the fact that there is a world where the diagonal proposition is false. But clearly this holds equally for 'all bachelors are unmarried'. One might find some differences if one focuses on a restriction of the diagonal proposition. It is notable that in the worlds Stalnaker discusses, 'Hesperus' and the like appear to be used with the same reference-fixing intentions as the original term, for example. It may be that under this sort of restriction, the two sorts of necessities behave differently: there are counterexamples to the diagonal for one class but not the other. But the restriction is doing all the work: in effect, it invokes something more like a cognitive contextual intension, rather than a diagonal proposition per se. Such intensions may be able to model the Kripkean distinction at least approximately, if imperfectly. Stalnaker appears to use similar tacit restrictions in some other cases; in all these cases, it seems that in effect a restricted contextual intension does the explanatory work.

The explanatory power of restricted contextual intensions here itself plausibly derives from that of epistemic intensions. Epistemic intensions handle these phenomena straightforwardly: for Kripkean necessities, there is a falsifying scenario, and for standard necessities there is not. For reasons we have
seen, certain restricted contextual intensions approximate epistemic intensions, and so approximate this behavior (with some exceptions). So it is plausible that the usefulness of diagonal propositions in this context derives indirectly from the usefulness of epistemic intensions.

Stalnaker contrasts his "metasemantic" version of the framework with "semantic" versions, on which 1-intensions are an aspect of semantic content, and suggest that the apparent attractions of the latter in explaining these phenomena derive from the attractions of the former. The above suggests that this is not quite right: the attractions of Stalnaker's version of the framework in this domain derive from the attractions of the epistemic version. As for whether the epistemic understanding is itself a "semantic" understanding: this matter depends on what is meant by "semantic". Stalnaker mostly uses the term to contrast with "metasemantic", indicating an aspect of first-order content rather than a metalinguistic dependence: in this sense, epistemic intensions are semantic. Stalnaker also sometimes uses the term to indicate those aspects of content that are built into linguistic expression types, rather than varying across tokens: in this sense, epistemic intensions are not semantic. Stalnaker appears to assume that his opponent's framework is semantic in both these senses;[*] but these are very different distinctions. Epistemic intensions need not be built into linguistic meaning to be a sort of first-order content that does explanatory work.

[*[The only opponent that Stalnaker cites is Chalmers (1996). I note that Chalmers (p. 58) explicitly leaves open the question of whether different speakers might associate different 1-intensions with the same word. Stalnaker also argues that the framework cannot yield an account of the a priori; I agree, and have not claimed that it can.]]

In any case, I think it is clear that diagonal propositions and epistemic intensions both have useful roles to play. Diagonal propositions are best suited to analyzing matters of context-dependence, and epistemic intensions are best suited to analyzing the epistemic domain.

5.2 Kaplan's character[*]

[[I should note that I am less confident about my discussion of Kaplan than about any other section of this paper. Suggestions are welcome!]]

Kaplan's notion of character is set out as follows. We assume a prior notion of the proposition expressed by an utterance: such a proposition is something in the vicinity of a 2-intension, although it may be a singular proposition instead. For some linguistic expression types (e.g. 'I'), utterances of the same type can express different propositions in different contexts. The character of an expression type is a function from contexts to propositions, returning the proposition that an utterance would express in a given context.

At first glance, it may seem that character is much like a linguistic contextual intension. There are some superficial differences. For example, Kaplan's contexts are not quite centered worlds; but in general they include a few parameters (speaker, time, etc) as well as an 'actual-world', and so they can be modeled by centered worlds. Also, character is a function from contexts to propositions, not to extensions. But one
can diagonalize character by evaluating the proposition associated with a given context in the world of that context, yielding an associated function from contexts to extensions.

In specific cases, character behaves quite like a linguistic contextual intension. We have seen that the linguistic contextual intension of indexicals such as 'I', 'now', and 'today' pick out the speaker, time, day (and so on) of the center of all worlds at which they are defined. The same is true for (diagonalized) character, on Kaplan's account). At the same time, we have seen that the linguistic contextual intension of a name arguably picks out the same individual at all worlds where it is defined. Again, the applies to character, on Kaplan's account.

One case where the two apparently behave differently is for demonstratives such as 'that'.[*] If I use 'that' intending to refer to an object in front of me, then its character will pick out (roughly) an object in front of the speaker in all contexts. But the linguistic contextual intension will not: what it picks out in a context will depend on the underlying demonstration or intention of a speaker in that context. But in a way, this is the exception that proves the rule. In Kaplan's formal analysis, he stipulates that different uses of 'that' (roughly, those corresponding to different demonstrations) are tokens of different words: 'that1', 'that2', and so on. Under this stipulation, it is plausible that a linguistic contextual intension for one of these instances of 'that' will behave as characterized above.

[[I will use "demonstrative" for expressions such as 'that', 'he', and 'you', while using "indexical" for expressions such as 'I', 'here', and 'now'.]]

However, there are aspects of Kaplan's discussion that make it clear that character is fundamentally different from a linguistic contextual intension. Kaplan stresses that when we evaluate a sentence's character in a context, we do not evaluate an utterance of that sentence within the context. Rather, we evaluate an occurrence of the sentence at the context. An occurrence is in effect an ordered pair of a sentence and a context. And crucially, the context need not itself contain an utterance of the sentence. In effect, this is to allow that the character of an expression can be evaluated directly at a centered world, whether or not the world contains a token of the original expression or not.

Kaplan's reason for doing this are largely tied to his desire for a logic of demonstratives. He suggested that arguments involving demonstratives should be valid in virtue of their character: that is, a conclusion should follow from premises in virtue of an appropriate relation among their characters. But if the character of a claim were restricted to contexts containing an utterance of that claim, then each premise and the conclusion would be defined across different contexts, so their characters could not stand in the right sort of relation. He also says that there are sentences that express a truth in certain contexts, but in no contexts in which they are uttered: e.g. 'I say nothing'. If so, contexts cannot be required to contain a token of the relevant utterance.

For these purposes, it is natural to suggest that character should be something more like an epistemic intension. Validity, at least as Kaplan uses it here, is a deeply epistemic notion, tied to apriority and to rationally compelling inferences (in Kaplan's discussion, it is clear that validity is not constitutively tied to necessity). The sort of intension that is constitutively tied to validity and to apriority is an epistemic
intension. Similarly, for the intension of 'I say nothing' to be false in the relevant contexts, the best candidate is a something like an epistemic intension.

It is difficult to adjudicate what Kaplan intends, however, since he never specifies how to evaluate an expression's character in a context. He simply stipulates that expressions have a character associated with them, and then discusses character's properties. He does say on some occasions that character picks out what the expression would pick out if uttered in that context, but he retracts this because of the point about occurrences (though presumably when a context contains a relevant utterance, character still returns what the utterance picks out). He also says (p. 505) that character is set by linguistic conventions and determines the content in a context, and he suggests that character is determined by a demonstration (pp. 526-27) or a directing intention (pp. 587-8). But nothing here tells us how to evaluate character in contexts not containing the utterance. In some cases the matter seems reasonably straightforward: 'I' picks out the marked subject in a context, 'you' picks out a marked addressee. But there seems to be no general principle here for assigning an evaluation function to an expression type.[*]

Another complication is that is not entirely clear what is built into the relevant context. On a couple of occasions (p. 528, p. 588) Kaplan entertains the idea that a context explicitly contains a parameter, for a demonstratum to serve as referent. If this is done, it renders the question about how to evaluate character trivial, at cost of trivializing many other aspects of the framework. It also removes any special role for demonstrations and directing intentions in contextual evaluation, and removes the deep connection with cognitive significance. Partly for these reasons, and partly because it eliminates the connection between demonstratives and indexicals, this seems not to be Kaplan's considered view. So presumably a directing intention does the work of picking out a referent in a context in which that referent is not explicitly specified.]

One way to address the question is to ask: is it constitutive of character that validity and apriority are governed by character? Or is this merely a feature that character turns out to have? It seems that this cannot be constitutive, for the obvious reason that in the case of proper names, validity and apriority come apart from character. But now the question arises: what justifies Kaplan's claim that the character of indexicals and demonstratives must be logically well-behaved? In effect, it is this that determines his treatment of occurrences. If the notion of character were constitutively connected to validity, this would be reasonable. But since it clearly is not, this seems less reasonable. If character is independently grounded, it seems that one might equally say: character is reasonably close to reflecting validity and the like, but unfortunately it is imperfect.

Perhaps the most likely diagnosis is: the starting notion of character is not constitutively connected to the domain of validity and apriority. (Perhaps it is something like a linguistic contextual intension.) But at least in the case of indexicals and names, this notion of character turns out to come very close to reflecting this domain. It turns out that a slight modification makes the correspondence precise, so at least in this case we adopt the modified notion. The resulting notion appears to be something quite close to an epistemic intension. It is not exactly an epistemic intension, for example because of the use of further parameters in a context. But it seems to behave in a quite similar way.

This raises the question: why not do the same for names? If character is to be connected to apriority, why
not make character behave something like an epistemic intension in this case? The initial answer is that Kaplan thinks that names do not behave this way: their contents are essential to them, so they do not pick out different contents in different contexts. In discussing the matter, Kaplan notes especially (p. 562) that occurrences of 'Aristotle' that refer to different people are different words. One might respond that this would be relevant if we were defining the contextual intension of names, but we are now dealing with a modified notion. The fact that a name has its referent essentially (and the point about 'Aristotle') is compatible with its epistemic intension picking out different referents in different contexts.[*] But the crucial point may in fact be something different: character is supposed to be a sort of linguistic meaning, but the names as linguistic types do not have epistemic intensions (at best, epistemic intensions vary between tokens).[*] So character cannot be epistemic intension.

[*][Something I have not mentioned is Kaplan's 'Fregean theory of demonstrations', arguing that a demonstration does not have its referent essentially. It seems that this point would be highly relevant to a contextual understanding of demonstratives, but it is not so clear that it is required for an epistemic understanding.]]

[*][This sort of point about the difference in cognitive significance between different tokens of a name is never mentioned explicitly in Kaplan's article, but it may be playing a role implicitly in his claim that names do not have nontrivial character semantically associated with them. A useful diagnostic question would be whether descriptive names (if there are any), such as 'Jack the Ripper', can have nontrivial character. If yes, then variability is plausibly the key reason standard names have trivial character. If no, then essentialness of referent is plausibly the key reason.]]

Still, an obvious response is that the same holds for demonstratives. Kaplan's formal move of stipulating that different tokens of a demonstratives are different words is clearly something of a convenient trick: the force is to suggest that character need not really be associated with a linguistic type, but with a token.[*] If so, then we could say the same for names, perhaps making a similar stipulation, or perhaps not. It is not clear exactly how the cases are relevantly different. One suggestion is that different tokens of a name seem to be more closely tied than different tokens of a demonstrative, with some sort of associated assumption of communication, agreement and disagreement, and so on. If so, then assigning all these name tokens a different linguistic type might be even more counterintuitive than for demonstratives. But it is not clear exactly what the rules are here. And it is not clear why one should not take the real moral of the demonstrative case to be that character is fundamentally a property of tokens rather than linguistic types, in which case it is no longer obvious that names must have trivial character.

[*][See Braun 1996 on this topic. Braun notes that Kaplan also seems to take the informal strategy of taking 'that' to be a single word, and of associating character not with the word but with a word-plus-demonstration pair. This raises the question: since the relevant demonstrations (especially according to the later Kaplan) are a sort of intention, why not analogous associate character with a name-plus-intention pair? Then one will in effect have character for utterances of names.

One might even note: for a use of a name, there can be a directly linked demonstrative. This can happen with "John...he...", or better, simply with "he" while this is simply backed by the intention to refer to John (perhaps this can be a mild counterfactual variant on the original utterance). It does not seem entirely unreasonable to say that this last demonstrative has nontrivial character. If so, one could use this character to motivate a nontrivial character in the vicinity of any token of 'John'. If not, then it seems to follow that the Fregean theory of demonstrations is false in at least some cases, and one wants to know more about the rules for associating character with demonstratives and demonstrations.]]
In any case, my best guess as to what constitutes character is the following: character is something like an epistemic intension in cases where it is reasonable (perhaps at a stretch) to assign epistemic intension to a linguistic type. If not, because of variability of epistemic properties between tokens, then character is something else, perhaps more like a contextual intension, or perhaps stipulated to be a function that returns an expression's actual content (whatever it is) at all contexts. (If character really is something like "epistemic intension insofar as it is associated with a linguistic type", one might equally simply say that names have no character, rather than saying that they have constant character. That does not seem wholly contrary to the spirit of Kaplan's discussion.)

(There are a couple of interesting diagnostic cases. First, what is the character of a descriptive name, such as 'Jack the Ripper'? Second, what is the character of a context-sensitive predicate such as 'heavy'? Kaplan is silent about these matters, but the behavior of character here might help decide among the alternatives above.)

The distinction between contextual and epistemic understanding also helps bears on a recent controversy about occurrences. Garcia-Carpintero (1998) argues for the superiority of a Reichenbachian token-reflexive account of indexicals over an account that relies on Kaplan's occurrences, in effect suggesting that a sort of token-reflexive contextual intension (requiring the token in a context) is truer to the data than an account that does not require tokens. As part of his argument, he denies that there is any reasonable intuition that there are contexts in which 'I am not uttering now' is true. Our discussion makes it possible to render a split verdict here. On a contextual understanding of evaluation in contexts, there is on such intuition. But on an epistemic understanding, there is such an intuition. The intuition, I think, is that 'I am not uttering now' is not false a priori, so that there are epistemic possibilities in which it is true. These epistemic possibilities are scenarios in which the subject at the center is not uttering. The difference between Kaplan's and Reichenbach's frameworks may then be grounded in the fact that Kaplan's semantic value for an indexical is constitutively tied to its epistemic properties, while Reichenbach's is tied to its contextual properties.[*]

[*][Note, though, that on the framework I have suggested, epistemic intensions are fundamentally assigned to utterances, not to occurrences. Occurrences play a role in that epistemic intensions are evaluated at scenarios that need not contain the relevant utterance. This suggests that there are two issues dividing the Reichenbachian and the Kaplanian, involving the assignment and the evaluation of the relevant semantic values, and that these two issues should be separated.]

In any case, it seems plausible that there are elements of both the contextual understanding and the epistemic understanding in Kaplan's account, not always disentangled. Perhaps character is fundamentally an extension of a linguistic contextual intension; perhaps it is fundamentally a sort of epistemic intension; or perhaps there is no fact of the matter. But it is clear in any case that much of the value of character in the case of demonstratives that in this case, it behaves much as an epistemic intension does (whereas in the case of names, it does not). It does not seem unreasonable to hold that character is useful for epistemic purposes precisely to the extent that it approximates or coincides with an epistemic intension.

5.3 Evans' Deep Necessity
In addressing Kripke's problems of the contingent *a priori*, Evans focuses on the case of descriptive names. He introduces the descriptive name 'Julius', whose references is fixed to whoever invented the zip. Then 'Julius invented the zip' seems to be *a priori*. In analyzing the case, Evans distinguishes between two sorts of necessity: "deep necessity" and "superficial necessity". Instances of the "contingent a priori" (such as 'Julius invented the zip') are superficially contingent but deeply necessary; instances of the "necessary a posteriori" are superficially necessary but deeply contingent. Evans says that whether a statement is deeply necessary or contingent depends on what makes it true; and whether it is superficially contingent depends on how it embeds under modal operators.

Superficial necessity is defined as follows. A sentence Q is superficially contingent if 'possibly ~Q' is true, or equivalently, if there is some world W where Q is not true_W. Here, the possibility operator is clearly subjunctive possibility ("it might have been that"), and the possible-worlds evaluation is clearly subjunctive counterfactual evaluation of the Kripkean sort. So superficial necessity is a second-dimensional notion: S is superficially necessary when it has a necessary 2-intension or subjunctive intension.

Deep necessity and contingency are characterized in the following passage toward the end of Evans' article:

We have the idea of a state of affairs, or a set of state of affairs, determines by the content of a statement as rendering it true, so that one who understands the sentence and knows it to be true, thereby knows that such a verifying state of affairs exists. A deeply contingent statement is one for which there is no guarantee that there exists a verifying state of affairs. If a deeply contingent statement is true, there will exist some state of affairs of which we can say both that if it had not existed the sentence would not have been true, and that it might not have existed. The truth of the sentence will thus depend on some contingent feature of reality. (Evans 1979, p. 185)

This passage has a strong epistemic element in the first half; and a strong contextual element in the second half. To understand these we need to examine the discussion earlier in Evans' article.

Evans introduced the notion of the *content* of a sentence earlier as capturing an epistemic element. Evan says that when two sentences have the same content, they are *epistemically equivalent*: a person who understands both cannot believe what one says and disbelieve what the other says. Evans makes a strong distinction between the content of a sentence and the *proposition* expressed by a sentence, which is a function from possible worlds to truth-values of the sort associated with the modal contexts of superficial necessity. He notes that two sentences that express the same proposition can have different contents, and argues that two sentences with the same content can express different propositions: e.g. 'Julius is F' and 'The inventor of the zip is F'.

Evans holds that there is a notion of "making a sentence true" that is tied directly to content (which he
The Foundations of Two-Dimensional Semantics
distinguishes from an alternative sense tied to proposition expressed). He says:

...if two sentences are epistemically equivalent, they are verified by exactly the same state of affairs, and what one believes in understanding the sentence and accepting it as true is precisely that some verifying state of affairs obtains. On this conception, the same set of states of affairs makes the sentence 'Julius is F' true as makes the sentence 'The inventor of the zip is F' true. If x, y, z, ... is a list of all objects, then any member of the set {x's being the inventor of the zip & x's being F; y's being the inventor of the zip and y's being F; z's being the inventor of the zip and z's being F ...} will suffice to make the sentence true. (Evans 1979, p. 180)

On this conception, making a sentence true, at least in the case of a descriptive name, seems to involve something like satisfying its epistemic intension. In the sense of 'verify' that I tied to epistemic evaluation, 'Julius invented the zip' will be verified precisely when the conditions that Evans suggests for "making the sentence true" obtains. The claim that epistemic equivalence entails verification (in Evans' sense) by the same states of affairs also suggests a tie to epistemic intension, and suggests a link between the two notions of 'verification'. If deep necessity is tied to 'making true' in this sense, then at least in the case of descriptive names it seems to be a sort of necessity of epistemic intension. [*]

[[This is not to say that Evans' notion of content is in general a notion of something like an epistemic intension. There is nothing in Evans' account of content that suggests that a term's content is exhausted by its epistemic properties, and especially beyond the case of descriptive names, it may involve elements such as a referent essentially. It may also be that insofar as it applies to the case of names generally, Evans' notion of verification behaves quite differently from the notion I have defined. But at least in the case of descriptive names, there seems to be a close connection.]]

But Evans also characterizes this notion of 'making true' in alternative terms:

But there is an ineliminable modal element in the notion of what makes a sentence true. For what can it mean to say that any one of a set of state of affairs renders a sentence true, other than to say that, if any one of them obtains, the sentence will be true, and if any of them had obtained, the sentence would have been true.

On this characterization, a state of affairs makes a sentence true roughly when it satisfies a sort of contextual intension of the sentence. "Making true" is characterized in terms of a metalinguistic subjunctive about truth-values the sentence could have had. This strongly suggests something like a linguistic contextual intension, as sentences here correspond to linguistic types.

This understanding is reinforced by the claim that Evans goes to some length to argue that if y had invented the zip and had been F, y would have been the referent of 'Julius', and 'Julius is F' would have been true as a sentence of English. He argues that there is no semantic connection between 'Julius' and a particular referent, so one can suppose that the term could have had a different referent without supposing a semantical change in English. He says: "exactly the same theory of meaning serves to describe the language which would be spoken had y invented the zip, as describes the language which is actually
spoken" (Evans 1979, p. 182). If 'making true' is tied to a linguistic contextual intension, this (controversial) claim is crucial to arguing that making true behaves as Evans' suggests. If 'making true' were tied to something like an epistemic intension, this claim would be unnecessary. So this strongly suggests an understanding as a linguistic contextual intension.

How can all this be reconciled? My suspicion is that it cannot be. There are cases when the contextual understanding clearly gives the wrong results. If we let 'L' be a descriptive name for the number of actual languages: then on the first understanding described above (by analogy with what Evans says about 'Julius'), for a state of affairs to make 'L=0' true it suffices for the number of languages to be zero according to that state of affairs. But on the second understanding, to make 'L=0' true it will be required that the sentence 'L=0' be true according to that state of affairs; and clearly this cannot happen. So on the first understanding, there will be a verifying state of affairs, and 'L>0' will be deeply contingent; on the second, there will be no verifying state of affairs and 'L>0' will be deeply necessary.

One might also worry: Evans holds that the same states of affairs make true 'Julius is F' as 'The inventor of the zip is F', but it is not clear how the contextual understanding above can deliver this result, as the states of affairs invoked there seem to require the distinct sentences. One might suggest that Evans is tacitly appealing to counterfactuals such as 'If the state of affairs had obtained and the sentence had been uttered, it would have been true'. This would be in effect to invoke a sort of extended contextual intension, with the various unclarities that come along with that notion. We can also note that it does not help with the case of 'L' above.

The paragraph quoted at the start seems to contain elements of both understandings of deep contingency. One could argue that in this paragraph, the epistemic elements in the first half could be reconciled with an overall contextual understanding, since those elements explicitly make appeal to metalinguistic knowledge, in knowledge of a sentence's truth. But such an understanding is hard to reconcile with Evans' overall project, on which 'making true' is tied to content. Content is tied to something like apriority and epistemic equivalence, and these are tied to something like an epistemic intension, not a contextual intension.

So Evans account contains evidence of both an epistemic and contextual understanding; and there is a clear conflict between the two. My guess is that Evans' attachment to a sort of epistemic understanding of 'making true' and deep necessity for descriptive names runs deeper, and that the attempted clarification of the notion in contextual terms was a mistake that might be jettisoned, leaving a broadly epistemic picture intact. But it is hard to know for sure.

If one jettisons the contextual elements, the notions of 'making true' and of deep necessity that remain in Evans' discussion appear to be broadly compatible with an epistemic understanding, at least in the case of descriptive names. Of course Evans restricts his discussion to the case of descriptive names, and would probably resist an extension of his analysis to other names, as elsewhere there is on corresponding descriptive element in the language's semantics. It is hard to know what Evans would say about the status of 'Cicero is Tully': it is epistemically nontrivial, but it seems that no states of affairs could make it false, on Evans' semantic approach. It may be that Evans intended the notions of deep necessity and 'making
true' to be inapplicable here. But one could argue the seeds are nevertheless present for a more general account.

5.4 Davies and Humberstone's "Fixedly Actually"

Davies and Humberstone (1980) give a "formal rendering" of Evans' distinction between deep and superficial necessity, using independently motivated tools from modal logic developed in Crossley and Humberstone (1977). The formal framework starts with a necessity operator N, and supplements it with an "actually" operator A, meaning "it is actually the case that". This allows one to represents claims such as 'It is possible for everything which is in fact phi to be psi', as 'POSS all (x) (A phi(x) -> psi(x). One naturally give a model theory for these notions by supplementing the space of possible worlds needed for the necessity operator with a designated "actual world", where A alpha is true at a possible world iff alpha is true at the actual world.

This framework naturally suggests a further idea: just as one can ask whether alpha is true with respect to a possible world (holding the actual world fixed), one might ask whether alpha would be true if a different world were designated in the actual world. This notion is modeled by adding a further "fixedly" operator F, where F alpha is true at a world W iff alpha is true at W no matter which world is designated as actual. One can then derive the "fixedly actually" operator FA. Given the definitions of F and A, FA alpha will be true at a world if, when that world is designated as the actual world, alpha is true at that world.[*]

*[[It should be noted that Davies and Humberstone's official model theory for the system with F and A involves one-dimensional evaluation of the relevant propositions at a world, where there is an underlying space of worlds and designated actual world in this space. They note a model theory could also be given using the tools of two-dimensional (or doubly-indexed) modal logic, by holding that alpha is true at (W1, W2) on the doubly-indexed version iff alpha is true at W2 on the singly-indexed version when W1 is designated as the actual world.

So it may not be strictly correct to say, as is often said, that the ideas of two-dimensional semantics are grounded in two-dimensional modal logic. Two-dimensional modal logic per se does not enter essentially into grounding the frameworks of Kaplan, Stalnaker, and Evans; and even in the case of Davies and Humberstone, two-dimensional modal logic is presented merely as an optional means of representation. Of course many of these ideas can be naturally represented using the tools of two-dimensional modal logic, and one there is plausibly a relationship between the conceptual bases of these frameworks and of two-dimensional modal logic.]]

Davies and Humberstone note that "fixed actually" can itself be seen as a sort of necessity, and suggest that it is closely linked to Evans' deep necessity. The formal framework can itself be used to represent some contingent a priori truths, such as 'A phi <-> phi', where phi is a contingent truth. If we call this sentence P, then 'FA P' is true but 'necessarily P' is not. So FA seems to go along with the sentence's apriority in this case, and the behavior of the 'necessarily' operator seems to go along with its contingency. Davies and Humberstone suggests T is superficially contingent when 'necessarily T' is false, and deeply contingent when 'FA T' is false.

In this framework, the behavior of a term such as 'Julius' is directly reflected by that of a term such as 'the
actual F'. For example, 'if anyone invented the zip, Julius did' is closely akin to 'if anything has F, the actual F has F'. The both of these contingent a priori sentences have the same patterns of intuitive evaluation, and the second can be rendered in the formal language as holding fixedly actually but not necessarily. Davies and Humberstone suggests that all descriptive names such as 'Julius' are semantically equivalent to phrases such as 'the actual F', and can be modeled correspondingly by the formal system. In this way, the deep and superficial modal properties of sentences involving 'Julius' are straightforwardly explained.

Davies and Humberstone also suggest that this analysis might be applied to terms such as 'water', 'red', and 'good', at least on certain philosophical views. In all these cases, there is a "actually" involving descriptive expression in the vicinity that yields qualitatively similar behavior, at least with respect to matters of necessity and apriority; and the behavior of those descriptive expressions can be modeled using the formal framework described above. Davies and Humberstone stop short of asserting that the English terms are semantically equivalent to these descriptive expressions, but they note that there is at least a resemblance.

Davies and Humberstone are quite explicit that their account applies only to terms such that their reference is semantically fixed by a description. So it does not apply to proper (non-descriptive) names: in fact, they say that any true identity statement using proper names is both superficially and deeply necessary, since such names are not even implicitly 'A'-involving. They also note that if it became widely known that 'Julius' referred to a certain individual (Tom, say) and the term continued to be used, it would soon cease to be a descriptive name, and claims that were previously deeply contingent (e.g. 'Julius is Tom') would become deeply necessary. It is for this sort of reason that there are doubts about whether the framework applies to terms such as 'water', where there is acquaintance with the referent, and also knowledge of its underlying nature.

Does this framework involve a contextual understanding, an epistemic understanding, or neither? It is somewhat hard to say, since the logical apparatus is a formal framework that does not come interpreted in this sort of way. But in discussing specific examples, such as 'Julius is F', Davies and Humberstone hold that the FA version will be true in a world iff the inventor of the zip is F there, and no special role is given to a token of 'Julius'. In fact considerations about the truth of possible tokens is nowhere invoked in D&H's article, except in giving a truth theory for possible tokens of sentences containing F, A, and the like; but here the tokens simply play the role they do in any truth theory, and there is no suggestion that the truth of FA phi is constitutively tied to the truth of possible tokens of phi.[*] In this respect, it appears that they depart from Evans.[*]

[Rumfitt 19xx addresses the question of whether there is something metalinguistic about D&H's notion of "considering a world as actual", and also gives a negative answer. He notes that Davies and Humberstone's two's modal notions are supposed to be of the same semantic sort, and there is nothing metalinguistic about the standard notion of necessity, so there is plausibly nothing metalinguistic about the novel notion.]]

[Davies and Humberstone (p. 16) do endorse Evans' remark that if a certain state of affairs had obtained, a sentence would have been true even though it is not true with respect to that situation. But here, they are
simply illustrating how possible tokens of sentences such as 'Grass is actually green' behave, and not giving a criterion for the modal evaluation of the sentence in a world.]

It seems that the rules for evaluating a natural-language term in a world considered as actual" are something like the following: if the term is equivalent to 'the actual F', then pick out F; otherwise, pick out what the term would pick out at that world under standard modal evaluation. This suggests that in the case of descriptive names, evaluation here will work as it does on the epistemic understanding. One might hesitate to ascribe too strong an epistemic understanding here, given the treatment of proper names, and also because D&H do not at any point even tacitly invoke the idea of considering that world as an epistemic possibility. Still, at least in the case of a descriptive name, this framework and the epistemic understanding yield largely equivalent results.

5.5 Chalmers' primary intensions

Chalmers[*] (1996, pp. 56-65) presents what he calls a "synthesis of ideas suggested by Kripke, Putnam, Kaplan, Stalnaker, Lewis, Evans, and others". He distinguishes what he calls the "primary intension" and the "secondary intension" of a concept. (A concept appears to be either a token expression or a mental item.) These are initially characterized as follows (p. 57):

there are two quite distinct patterns of dependence of the referent of a concept on the state of the world. First, there is the dependence by which reference is fixed in the actual world, depending on how the world turns out; if it turns out one way, a concept will pick out one thing, but if it turns out another way, the concept will pick out something else. Second, there is the dependence by which reference in counterfactual worlds is determined, given that reference in the actual world is already fixed. Corresponding to each of these dependencies is an intension, which I will call the primary and secondary intensions, respectively.

The secondary intension seems to be the familiar sort of intension (2-intension, subjunctive intension) across possible worlds. The nature of the primary intension is somewhat less clear. The characterization above has both contextual and epistemic elements. The reference to what "a concept will pick out" under certain circumstances suggests a sort of contextual intension; but reference to how the world "turns out" suggests an epistemic element.

Chalmers also says (p. 57) that a concept's primary intension is "a function from worlds to extensions", such that "in a given world, it picks out what the referent of the concept would be if that world turned out to be actual". (The "worlds" are later refined to centered worlds.) This is similar to the characterization
above, although the use of "turned out" and "would be" arguably has a slightly different (more subjunctive, less epistemic?) flavor than the use of "turns out" and "will". Again, the referent to potential reference of a concept suggests some sort of contextual intension. This is also suggested by a later discussion (p. 60) which casts the worlds in the domain of a primary intension as Kaplanian "contexts of utterance", and which asks "how things would be if the context of the expression turned out to be W"?

And again (p. 63): "the primary truth-conditions tell us how the actual world has to be for an utterance to be true in that world; that is, they specify those contexts in which the statement would turn out to be true.

If a primary intension is a contextual intension, what sort of contextual intension is it? The behavior that Chalmers suggests a primary intension should have is very much the sort of quasi-Fregean behavior for a 1-intension suggested initially. It seems clear that a primary intension is not intended to be an orthographic contextual intension: nothing in Chalmers' discussion suggests that in a world where 'water' means steel, the primary intension of our term 'water' picks out steel. It may be intended to be a linguistic contextual intension: footnote 21 on p. 364 suggests that Chalmers is sympathetic with the view that the word 'water' as used on Twin Earth is of the same linguistic type as ours, in which case a linguistic contextual intension may give quasi-Fregean results. It may also be that some sort of cognitive contextual intension is intended, where one holds fixed the epistemic situation of the subject. But the matter is not at all clear.

There are also a number of elements in Chalmers' discussion that suggest an epistemic understanding, however. The expression "what a concept will refer to if the worlds turns out" carries an epistemic flavor that is quite different from the subjunctive "what a concept would refer to if the world turned out"; as Kripke (1980, p. xxx) suggests, there is arguably more plausibility in the idea that it could turn out that 'water' refers to XYZ than that it could have turned out that 'water' refers to XYZ. So perhaps there is a sort of amalgam of epistemic and contextual ideas at work in this phrase.

More clearly, Chalmers' discussion of how to evaluate a primary intension has a strong epistemic element. He says

The true intension can be determined only from detailed consideration of specific scenarios: What would we say if the world turned out this way? What would we say if it turned out that way? For example, if it had turned out that the liquid in the lakes was H2O and the liquid in the oceans was XYZ, then we would probably have said that both were water; if the stuff in oceans and lakes was a mixture of 95 percent A and 5 percent B, we would probably have said that A but not B were water.

Here, the suggestion seems to be that a term's primary intension is constituted to a speaker's or a community's dispositions to apply the term, depending on what is discovered to be the case. This suggests something at least in the vicinity of an epistemic intension. There is still a metalinguistic element in "what would we say?": for this reason, it seems hard to extend this heuristic to such cases as evaluating "language exists" in a language-free world, and so on. But the idea of capturing the dependence of judgments about extension on discoveries about the actual world suggests something fundamentally epistemic.
Further evidence for an epistemic interpretation stems from the fact that Chalmers twice notes (notes 26 and 29, p. 366) that one can evaluate a primary intension in worlds that do not contain the original concept: he gives the example of "I am in a coma", suggesting that the primary intension should be true of centered worlds where the individual at the center is in a coma and not thinking anything. This suggests that a contextual intension is not intended (perhaps Chalmers had an extended contextual intension in mind, but it is hard to see how this could give the right result) and is compatible with an epistemic interpretation.

The strongest evidence is in footnote 21 (p. 364), where Chalmers responds to an objector who holds that 'water' on Twin Earth is a different word:

If one is worried about this ... one can think of these scenarios as *epistemic* possibilities (in a broad sense) and the conditionals as epistemic conditionals, so that worries about essential properties of words are bypassed.

Here Chalmers' response directly suggests an epistemic understanding, although he does not elaborate.[*]

It should also be noted that Chalmers claims (p. 64) that a sentence is a priori when it has a necessary primary proposition (where here a proposition is an intension for a statement). And he also uses primary intensions to make an inference from conceivable to possibility (roughly, from a claim's a priori coherence to the existence of a world satisfying a claim's primary intension). These moves will be invalid in general if primary intensions are contextual intensions. But if primary intensions are epistemic intensions, it is possible that they are correct.

[*][Chalmers (1994), which develops the framework to yield an account of the narrow content of thought, says a bit more here. He says that to evaluate a primary intension, one can ask questions such as "If W turns out be actual, what will it turn out that water is"? This is the sort of "turns-out" conditional, closely related to an indicative conditional, suggested above. He notes that the conditional in superior in a way to "If W is actual, what would the concept refer to?", since it makes clear that the concept is not required to be present in the world. Chalmers (1999) suggests that indicative conditionals can be used to evaluate primary intensions.]]

Overall, it seems that Chalmers' discussion contains elements of both a contextual and an epistemic understanding. It seems likely that what is intended is something closer to an epistemic understanding, but the details are far from clear. But in any case, it seems reasonable to suppose that Chalmers *should* have embraced an epistemic understanding, and that an epistemic approach yields the most coherent overall interpretation of his position.[*]

[*][Autobiographical remarks: I think that I tacitly intended something like an epistemic intension, but the distinction between contextual and epistemic understandings was not sufficiently clear in my mind at the time of writing, and is certainly not clear on the page. (The current paper is in part a mea culpa.) I think that if one interprets primary intensions as epistemic intensions, the uses of primary intensions elsewhere in the book are coherent. The distinction is also not entirely clear in Chalmers (1994), which was written after the relevant sections of Chalmers (1996). It is for this reason that I have not published that paper, although it has been occasionally cited; I hope to publish a revised version eventually.]]
5.6 Jackson's A-intensions

Jackson (1998) discusses "a distinction between two fundamentally different senses in which a term can be thought of as applying in various possible situations". He says:

We can think of the various situations, particulars, events, or whatever to which a term applies in two different ways, depending on whether we are considering what the term applies to under various hypotheses about which world is the actual world, or whether we are considering what the term applies to under various counterfactual hypotheses. In the first case we are considering, for each world $w$, what the term applies to in $w$, given or under the supposition that $w$ is the actual world, our world. We can call this the A-extension of term $T$ in world $w$ - 'A' for actual - and call the function assigning to each world the A-extension of $T$ in that world, the A-intension of $T$. In the second case, we are considering, for each world $w$, what $T$ applies to in $w$ given whatever world is in fact the actual world, and so we are, for all worlds except the actual world, considering the extension of $T$ in a counterfactual world. We can call this the C-extension of $T$ in $w$ - 'C' for counterfactual - and call the function assigning to each world the C-extension of $T$ in that world, the C-intension of $T$.

Here, the talk of "hypotheses about which world is the actual world", and "given or under the supposition that $w$ is the actual world", strongly suggests that we are thinking about these worlds as a sort of epistemic possibility. One might think for a moment that talk of "what the term applies to under various hypotheses" suggests something contextual, but on reflection there is no more reason why that should be the case here than for the corresponding usage about counterfactual worlds.

Jackson does not say much more about evaluating A-intensions than this. He does say one thing that might suggest a contextual element: he says that the A-proposition (A-intension for a sentence) of 'Some water is H2O' is contingent, because the sentence is "epistemically possible in the following sense: consistent with what is required to understand it, the sentence might have expressed something both false and discoverable to be false". The claim about what the "sentence might have expressed" strongly suggests something contextual: together with the talk of understanding, it may suggest a sort of cognitive contextual intension. But this locution is not used elsewhere.

Overall, most of Jackson's discussion is reasonably consistent with an epistemic understanding of A-intensions. Further, the purposes to which he puts the framework strongly suggests constitutive ties with apriority and the epistemic domains, and epistemic intensions work best for these purposes. If so, then A-intensions are probably best interpreted as epistemic intensions.

5.7 Kripke's epistemic duplicates

Although the work of Kripke (1980) provided the impetus for most of the two-dimensional approaches in the literature,[*] Kripke does not embrace a two-dimensional approach himself. There are numerous remarks that suggest a tacit element of two-dimensional thinking: for example, frequent remarks of the form "Given that ...". But there is little that formally and explicitly suggests such an approach. While it is
possible to analyze many of Kripke's epistemic claims using possible worlds, Kripke himself generally stays away from this sort of analysis.

*[[Note that Kripke 1980 was first published in 1972. One exception to this chain of influence may be Kaplan, whose work is independent of Kripke's to a significant degree.]]*

There is one exception, however. Kripke notes that in cases where P is the negation of an a posteriori necessary statement, there is some intuition that "it might have turned out that P", even though P is strictly speaking impossible. For example, when a table is made of wood, there is an intuition that the table "might have turned out to be made of ice", even though that is impossible. Kripke denies the modal claim involving "might have turned out" is false in these cases, but he wants to explain it away. Similarly, Kripke notes that for statements such as 'heat is the motion of molecules', there is a sense of "apparent contingency", even though the statement is strictly necessary. Again, Kripke wants to explain this sense of contingency away.

Kripke suggests the following strategy. In these cases, although a statement is necessary, we can say that under appropriate qualitatively identical evidential situations, an appropriate qualitatively identical statement might have been false. And he suggests this explains the sense of apparent contingency.

What, then, does the intuition that the table might have turned out to be made of ice ... amount to? I think it means simply that there might have been a table looking and feeling just like this one and placed in this very position in the room, which was in fact made of ice. (p. 142)

He applies a similar strategy to 'heat is the motion of molecules', and other cases. The general principle is that when there is an intuition of apparent contingency associated with a necessary truth P, there is a qualitatively identical contingent truth P, such that P might have been false in an evidential situation qualitatively identical to the original situation. Where P is 'heat is the motion of molecules', P might be 'heat sensations are caused by the motion of molecules'.

This apparently innocuous principle packs considerable power: it enables us to reason from epistemic premises to modal conclusions. When P is "apparently contingent", or such that it seems that "it might have turned out that P", P has a distinctive epistemic status: to a first approximation, these claims come to the claim that P is not ruled out a priori. But the conclusion here is a modal one: that a certain state of affairs (involving a subject, evidence, and a statement) might really have obtained. In effect, Kripke reasons from a premise about the epistemic status of a statement to a conclusion about the possible truth of a statement token that shares a type with the original statement.

This reasoning is naturally modeled on the two-dimensional framework, understood contextually. We might say that the evidential contextual intension of a given statement is a function that is defined at centered worlds in which there is a subject with qualitatively identical evidence, uttering a qualitatively identical statement, and that returns the truth-value of that statement. Then Kripke is in effect suggesting that when a statement is "apparently contingent", its evidential contextual intension is contingent.
The intension in question is not completely defined, as Kripke does not define what it is for evidential situations or statements to be qualitatively identical. But it is natural to suggest that two evidential situations are identical when they are phenomenologically equivalent: that is, when what it is like to be in the first situation is the same as what it is like to be in the second. As for qualitatively identical statement: one might first suggest that this occurs when they have similar descriptive or Fregean content, but that suggestion might be inappropriate in the current context. An alternative suggestion is that two statements are qualitatively identical when they (or corresponding thoughts) play similar cognitive roles for the subject. This goes beyond Kripke and is somewhat loose, of course, but it seems at least compatible with his discussion.

Reconstructed this way, Kripke's principle takes on a familiar shape. In effect, the claim is that when a statement is apparently contingent, it has a contingent evidential contextual intension. If one substitutes aposteriority for apparent contingency and rearranges a little, one gets a familiar-looking result: if a statement has a necessary evidential contextual intension, it is a priori.

So Kripke's principle here suggests something in the vicinity of the Core Thesis for an evidential contextual intension. This should raise alarm bells. We have already seen that the Core Thesis appears to be false for any sort of contextual intension. Applying the sort of reasoning from our earlier discussion, one can straightforwardly come up with a counterexample. 'I have such-and-such evidence' is one example. For a more interesting example, let 'Bill' be a name that rigidly designates the phenomenological quality instantiated at the center of my visual field. Let us say that that quality (for me now) is phenomenal blue. Then 'Bill is phenomenal blue' is plausibly a posteriori, but it has a necessary evidential contextual intension.

This point is not simply an artifact of our reconstruction; it equally to Kripke's original claim. 'Bill is phenomenal blue' is apparently contingent in the same sort of way as paradigmatic apparently contingent statements. We have an intuition that it might have turned out that Bill was not phenomenal blue - it might have been that Bill was phenomenal red, for example. This intuition seems to be on a par with our intuitions about the table, heat, and so on. But there is no qualitatively identical evidential situation in which a qualitatively identical statement would have been false. So the Kripkean reasoning is invalid in this case.

Perhaps Kripke could shrug this off and say that the reasoning was never intended to apply in all cases. But this reply would have a significant cost, since the reasoning is crucial to Kripke's argument against mind-body identity theories. We have a strong intuition of apparent contingency associated with 'pain is C-fibers'; and Kripke argues that this cannot be explained away by the claim that in a qualitatively identical evidential situation, a qualitatively identical statement would have been true:

To be in the same epistemic situation that would obtain if one had a pain is to have a pain; to be in the same epistemic situation that would obtain in the absence of pain is not to have a pain. The apparent contingency of the connection between the physical state and the corresponding brain state thus cannot be explained by some sort of qualitative analog as in the case of heat. (p. 152)
Kripke uses this point to argue that as the apparent contingency cannot be explained away, the claim that 'pain is C-fibers' is not necessary at all. It follows that the claim is not true, since if it is true, it must be necessary. But it is clear that everything in the quoted passage applies equally to 'Bill'. To be in the same epistemic situation that would obtain if one had Bill is to have Bill; and so on. So the 'Bill' case equally cannot be explained by Kripke's paradigm. But here, one cannot reason from failure to satisfy Kripke's paradigm to contingency and thus to falsity: 'Bill is phenomenal blue' is clearly true and necessary. So by parity, one cannot apply this reasoning in the case of 'pain'. So Kripke's argument against the mind-body identity theory appears to be invalid.

The moral here seems to me that there is nothing special about one's evidence in diagnosing apparent contingency. This suggests a natural response: one might weaken Kripke's principle, holding simply that when a statement is apparently contingent, an appropriate qualitatively identical statement might have been false. This claim would cover the standard Kripkean cases, and would also encompass cases involving contingency of evidence itself, such as that of 'Bill'. One might think that to do this would be to kill off the argument against the identity theory, which relied crucially on qualitatively identical evidence. But there is another strand in the argument that might still apply.

Immediately after noting the considerations above, Kripke says:

The same point can be made in terms of the notion of what picks out the reference of a rigid designator. In the case of the identity of heat with molecular motion the important consideration was that although 'heat' is a rigid designator, the reference of that designator was determined by an accidental property of the referent, namely the property of producing in us sensation S. It is thus possible that a phenomenon should have been rigidly designated in the same way as a phenomenon of heat, with its reference also picked out by means of the sensation S, without that phenomenon being heat and therefore without its bring molecular motion. Pain, on the other hand, is not picked out by one of its accidental properties; rather it is picked out by the property of being pain itself, by its immediate phenomenological quality. Thus pain, unlike heat, is not only rigidly designated by 'pain' but the reference of the designator is determined by an essential property of the referent.

Kripke says that this is the "same point", but in fact it is not. A close examination suggests that this point has nothing to do with evidence: it does not rely on the notion of a statement in a qualitatively identical evidential situation, but rather on that of a designator with the same manner of reference-determination. So we can apply the weakened principle suggested above, where a "qualitatively identical statement" is understood, perhaps, as a statement with the same reference-fixing intensions. Under this paradigm, the apparent contingency of 'Bill is phenomenal blue' can be explained away, as it is possible for a statement associated with the same reference-fixing intentions to refer to the quality in the center of one's visual field - to be false, for example, in a case where the quality is phenomenal red. But the case of 'pain' cannot be explained away in these terms. So the argument against the identity theory would now seem to go through.

Nevertheless, more problems immediately arise. The reasoning here in effect invokes the claim that an
apparently contingent statement has a contingent *qualitative contextual intension*, where this sort of intension is defined at worlds centered on a statement qualitatively identical to the original, returning the referent of that token. For familiar reasons, there are counterexamples to this claim. One such is 'language exists'. Or let 'L' be a name that rigidly designates the number of actual languages. Then 'L>0' is apparently contingent: it seems that it might have turned out that L was zero, and so on. But 'L>0' has a necessary fixing contextual intension. So the principle is false. Further, it is easy to see that even the weakened Kripkean reasoning suggested above does not apply in the case of 'L>0': it is not possible for a qualitatively identical statement to be true, but the statement is necessary all the same. So even the weakened reasoning, from failure to satisfy the weaker paradigm to contingency, is invalid. So although Kripke's second argument against the identity theory is different from the first argument, it is also invalid.[*]

[[Bealer (1996) develops Kripke's proposal using his notion of a "semantic stable" expression (one such that necessarily, in any language group in an epistemic situation qualitatively identical to ours, the expression would mean the same thing). Bealer suggests that semantically stable expressions are invulnerable to "scientific essentialism". It is not clear exactly what is required for a "qualitatively identical epistemic situation" for a language group, but it is clear that however this notion is understood, terms such as 'L' above will be semantically stable, as will rigid designators for aspects of a group's epistemic situation. So there will be a posteriori necessities involving semantically stable expressions. As in Kripke's discussion and in other cases, a broadly contextual notion (semantic stability) serves as an imperfect substitute for a broadly epistemic notion (semantic neutrality).]]

I think that the moral in both cases is that Kripke's diagnosis of intuitions about apparent contingency is incorrect: they do not turn essentially on intuitions about qualitatively identical evidential statements, and they do not turn essentially on intuitions about intuitions about qualitatively identical statements.[*]

Rather, they turn on intuitions about the direct evaluation of epistemic possibilities. And we have seen that this sort of epistemic evaluation does not turn essentially on the status of possible tokens. This suggests in turn that to reason about apparent contingency, then instead of the Kripkean principles above, which tacitly involve a contextual understanding, one should appeal to principles involving an *epistemic* understanding: for example, that when a statement is apparently contingent, there is some scenario (considered as actual) in which it is false. Or, if we understand scenarios as centered worlds: that when a statement is apparently contingent, there is some centered world in which the statement's epistemic intension is true. I think that once we understand things this way, an argument against the mind-body identity theory of a sort analogous to Kripke's has a chance of succeeding. But I have written about that elsewhere.[*]

[[There is arguably a strand in the passage above that does not turn directly on qualitatively identical statements. This is the claim that while heat is picked out by a property it has accidentally, pain is picked out by a property it has essentially. This suggests that Kripke's "same point" may come down to three different points, with potentially three different arguments in the background. I think that the third argument has the most chance of success. But I think that to make the argument work in the general case, once has to adopt something like the (highly non-Kripkean) framework of epistemic intensions.]]

[[See e.g. Chalmers 2002p, 2002n.]]
In any case, we can see that while Kripke does not explicitly endorse a two-dimensional approach, these issues are quite close to the surface in his discussion. One can even see here an instance of a familiar two-dimensionalist pattern: trying to capture epistemic phenomena under a contextual framework, coming close, but not quite succeeding. I think that once again, the moral is that the epistemic framework is most fundamental for these purposes.

5.8 Other approaches

There are a number of other approaches that either fit within a two-dimensional framework or have something in common with these ideas. I will discuss some of these briefly.

Tichy (1984) suggests that there are two propositions corresponding to any given statement: the proposition expressed and the proposition associated. The proposition expressed by 'Phosphorus is hot' the proposition that Venus is hot. This proposition behaves like a 2-intension. The proposition associated with 'Phosphorus is hot' is the proposition that the sentence 'Phosphorus is hot' says in English that Phosphorus is hot. This proposition behaves like a (modified) linguistic contextual intension: it is true at those worlds corresponding to a centered world where the sentence's linguistic contextual intension is true, and false at all other worlds.

Tichy uses this distinction to argue that there are no necessary a posteriori propositions. He suggests that for truths such as 'Hesperus is Phosphorus', the (trivial) proposition expressed will be necessary and a priori, while the proposition associated will be contingent and a posteriori. Whether the latter is so depends on how sentences and languages are individuated: if 'Hesperus' picks out Venus essentially, then the proposition associated will be necessary. Even if this possibility is set aside (as Tichy does), there will clearly be cases (e.g. 'language exists') of an intuitively necessary a posteriori statement with a necessary associated proposition. Tichy nowhere says that all intuitively a posteriori statements have an a posteriori associated proposition, and his claim that there are no necessary a posteriori propositions is arguably independent of this claim. But this suggests at least that Tichy's dual-proposition account of the Kripkean phenomena does not quite get to the roots of the phenomena.

*[[Tichy sets this possibility aside on the (highly arguable) grounds that Kripke is committed to denying that it is necessary that 'Hesperus' in English picks out Venus, since on Kripke's view all that is essential to 'Hesperus' in English are linguistic conventions involving reference-fixing.]]

*[[The claim that there are no necessary a posteriori propositions is sometimes regarded (e.g. Byrne 1999) as a central aspect of the two-dimensional framework. I think it should be regarded as a further inessential claim. If one stipulates that propositions are sets of possible worlds, such a claim may be reasonable. On my own view, it is better to regard propositions as the contents of sentences (leaving open their nature) and allow that the apriority and the necessity of a statement correspond respectively to the apriority and the necessity of the proposition it expresses. If so, some propositions will be both necessary and a posteriori, and propositions will presumably themselves have a sort of two-dimensional modal structure (although they might not be reducible to this structure).]]

(Insert discussion of Perry's "reflexive content" here.)
Also relevant are some proposals for assigning content to thought rather than to language.[*] One such proposal is Lewis's (1979; 1986; 1994) suggestion that a subject's system of belief can be modeled by the self-attribution of a property, or equivalently, by a class of possible individuals (the subject's "doxastic alternatives"), or by a class of centered worlds. Lewis (1979) assigns this sort of content to specific beliefs, while Lewis (1986; 1994) suggests a content of this sort can be used to represent a subject's total belief system, and then in turn to show how the subject satisfies various belief ascriptions. It is clear from Lewis's discussion that this set of centered worlds behaves at least something like a 1-intension: a subject who believes "I am hungry" will have only worlds centered on hungry subjects in the set; a subject who believes "water is XYZ" will have Twin Earth centered worlds in the set, and so on.

[*][Apart from those mentioned here, some other relevant proposals concerning the narrow content of thought include the "immediate object of belief" of Brown 1986 (roughly: those propositions believed by all intrinsic duplicates), the "notional worlds" of Dennett 1982 (roughly: the set of environments in which the organism as currently constituted will flourish), the "realization conditions" of Loar 1988 (roughly: the set of worlds in which a given thought would be true if it were not a misconception), and the "notional content" of White 1991 (roughly: the class of worlds for which a subject's actions are optimal). All of these have some similarity to 1-intensions, characterized in a broadly contextual way.]

Lewis's proposal is hard to classify directly in the present system, since he does not say much about how the relevant set of worlds (or the relevant property, or the relevant class of alternatives) is defined, apart from saying that it is determined by the subject's behavior and functional organization by the principles of belief-desire psychology (Lewis 1986, pp. 36-40).[*] Lewis says nothing to suggest that a token of specific mental or linguistic states is required at the center of the relevant worlds, however, so there is reason to think he is not invoking a contextual understanding. And Lewis's centered worlds can naturally be seen as representing a sort of epistemic possibility for the subject. So Lewis's discussion seems at least consistent with an epistemic understanding, on which the relevant set of centered worlds is a sort of epistemic intension of a subject's total belief state, consisting to a first approximation of those scenarios that verify all of a subject's beliefs.

[*][For example, the principle that a subject's actions are such that if the subject's beliefs were true, they would tend to fulfill the subject's desires: so the subject's actions constrain the subject's classes of doxastic alternatives and desire alternatives. Related here is Dennett's (1982) suggestion that a subject's "notional world" is the class of environments to which the organism as currently constituted is best fitted, and White's (1991) suggestion that a subject's "notional content" is the class of worlds for which the subjects actions are optimal, relative to available alternatives. Each of these can be seen as a suggestion for naturalizing something like a 1-intension of a subject's total belief state by appeal to the subject's behavior.]

White (1982) sets out a multi-dimensional proposal for understanding the narrow (internally determined) content of thought and language. To simplify a little, White defines the partial character of a word as a function from "contexts of acquisition" (worlds centered on a functional duplicate of the original subject) to the Kaplanian character of the corresponding word in that context. This is actually a three-dimensional function (a function from centered worlds to contexts to worlds to extensions), but one can diagonalize it twice to yield a one-dimensional function: in effect, a functional contextual intension, defined at worlds centered on a functional duplicate of the original subject, returning the extension of the relevant token.
The resulting functional contextual intension will be internally determined by definition, and will be a reasonably good approximation to a Fregean semantic value. It will give anomalous results in a few cases: e.g. cognitively significant claims concerning language ('language exists') or a subject's functional organization ('I have computational structure C') may have a necessary functional contextual intension, and so will have a relatively trivial partial character. But if we assume that the epistemic intensions of a subject's tokens are determined by the subject's functional state, then the diagonalized partial character will give a reasonable approximation of an epistemic intension.

Fodor (1987) gives a related proposal for understanding narrow content. He suggests that the narrow content of a thought is a function from contexts to truth-conditions, where contexts appears to behave like worlds centered on the thought, and truth-conditions behave like 2-intensions. Like White's partial character, Fodor's function is not directly truth-evaluable (this led Fodor to eventually reject the proposal on the grounds that it is not really a sort of content), but as usual one can diagonalize it to yield a truth-evaluable content. The result is something like a conceptual contextual intension, mapping worlds centered on a token of the relevant concept or thought to that token's extension.

As with conceptual (and linguistic) contextual intensions in general, the behavior of Fodor's function will depend on how concepts and thoughts are individuated, in order to know which centered worlds are relevant. If they are syntactic mental types, then one has a sort of orthographic intension, which has uninteresting content. If they are semantic types, then it is unclear how one can specify the relevant semantic value in a noncircular way. These points (and many others) are developed by Block (1991), in a thorough critique of any proposal of this sort in accounting for narrow content.

Block makes a point worth noting here: he suggests that proposals involving a mapping from contexts "often seem to engender a cognitive illusion to the effect that we know what the proposed mapping is". I diagnose things differently. Our judgments about the mapping are grounded in perfectly reasonable intuitions about the evaluation of our terms in epistemic possibilities. The illusion on the part of these theorists is not that they grasp the mapping. Rather the illusion is that the mapping is grounded in context-dependence. Once we recognize the epistemic roots of the mapping, the problems go away.

Whether or not this diagnosis is correct, it seems fair to say that in many of the cases we have discussed, various contextual two-dimensional notions are of interest largely to the extent that they approximate epistemic two-dimensional notions. One might regard contextual notions positively as an inexpensive substitute for the epistemic notions, yielding many of the benefits without as many of the costs. Or one might regard them negatively, as a "distractor" from the more important epistemic notions that can lead to confusion because of their surface similarity. I suspect that there is something to each of these attitudes. But in any case, it seems clear that the epistemic understanding yields the deepest connections with the cognitive, epistemic, and rational domains.

1 Introduction[*]

*[[This is a heavily revised version of a paper first written in 1994 and revised in 1995. Sections 1, 7, 8, and 10 are similar to the old version, but the other sections are quite different. Because the old version has been widely cited, I have made it available (in its 1995 version) at http://consc.net/papers/content95.html.]

What follows is an application of a framework I have developed in other papers. The discussion here often passes over details that are explored in more depth in those papers. (Chalmers 2002b gives the gentlest introduction; Chalmers forthcoming a and b give full details.) The framework presented here has much in common with existing ideas in the philosophy of mind and language, especially Kaplan's (1989) and Stalnaker's (1978) two-dimensional analyses of language, Lewis's (1979) analysis of the contents of thought, and various proposals that have been made about the nature of narrow content. For some connections between these ideas, see section 9 and Chalmers (forthcoming a).]]

Here are six puzzles about the contents of thought.[*]

*[[For background material on the six puzzles, see: (1) Putnam 1975, Burge 1979; (2) Frege 1892; (3) Kripke 1979; (4) Perry 1979; (5) Schiffer 1990; (6) Kripke 1980.]]

(1) *Is content in the head?* Oscar believes that water is wet. His twin on Twin Earth, which is just like Earth except that H₂O is replaced by the superficially identical XYZ, does not. His twin's thoughts concern not water but twin water: Oscar believes that water is wet, but Twin Oscar believes that twin water is wet. This suggests that what a subject believes is not wholly determined by the internal state of the believer. Nevertheless, the cognitive similarities between Oscar and his twin are striking. Is there some wholly internal aspect of content that they share?

(2) *Frege's puzzle.* In thinking that Hesperus is Hesperus, I think about the same objects as in thinking that Hesperus is Phosphorus. But the first thought is trivial and the second is not. How can this difference in cognitive significance be reflected in a theory of content?

(3) *Kripke's puzzle.* In France, Pierre is told (in French) that London is pretty, and he believes it. Later, he arrives in London and thinks it is ugly, never suspecting that "Londres" and "London" name the same...
city. It seems that Pierre simultaneously believes that London is pretty and that London is not pretty. Pierre is highly rational, however, and would never believe a contradiction. What is going on?

(4) **The problem of the essential indexical.** When I believe that I am in danger, I will take evasive action. This belief seems to be essentially indexical, or self-directed; if I merely believe that $x$ is in danger, where (unbeknownst to me) I am $x$, I might do something else entirely. How can we square this indexical aspect with an account of the contents of thought?

(5) **The mode-of-presentation problem.** If Jimmy says "Lois believes that Superman can fly", he speaks truly. If he says "Lois believes that Clark Kent can fly", he speaks falsely. But on many accounts, the proposition that Clark Kent can fly is the same as the proposition that Superman can fly. If so, it seems that to believe that Clark Kent can fly, it is not enough to believe the corresponding proposition; one must believe it under an appropriate mode of presentation. What is a mode of presentation, and how can these be integrated into an account of belief ascription?

(6) **The contingent a priori.** Say it is stipulated that one meter is the length of a certain stick in Paris. Then it seems that one knows a priori that the stick is one meter long, if it exists. But it seems contingent that the stick is one meter long, as it might have been that the stick was longer or shorter than one meter. How can one have a priori knowledge of a contingent truth?

These puzzles are not unrelated. All of them suggest incompleteness in a familiar view of thought content, on which the content of a thought is tied to the external objects one is thinking about. In particular, most of them raise questions about how well such an account of thought content reflects rational or cognitive aspects of thought. Because of the dependence on external factors, this sort of content often seems to be dissociated from the rational relationships between thoughts (as witnessed by puzzles 2, 3, and 6), and from their role in guiding cognition and action (as witnessed by puzzles 1 and 4).

To resolve these and other puzzles, many have postulated a separate dimension of content — so-called "narrow content" — that depends only on the internal state of a thinker, and that is more closely tied to cognition and action.[*] The road from intuition to theory has been a difficult one, however, and no account of narrow content has yet gained widespread acceptance. It is widely held that because narrow content is internal, it lacks the sort of relation to the external world that is required to qualify as content. For example, many have thought that narrow content is not the sort of thing that can be true or false, as the Twin Earth cases show us that truth-conditions are not determined internally.

[*][Arguments for narrow content can be found in Dennett 1981, Fodor 1987, Lewis 1994, Loar 1988, Segal 2000, and White 1982.]

I think that these problems are illusory, and that there is a robust and natural notion of narrow content such that narrow content has truth-conditions of its own. This can be seen by developing the idea that content has two dimensions. On the account I will give here the content of a thought can be decomposed
The Components of Content

into two components: its *epistemic* and *subjunctive* content. Subjunctive content is a familiar external variety of content. Epistemic content has the following properties: (1) it is determined by the internal state of a cognitive system; (2) it is itself a sort of truth-conditional content; (3) it reflects the rational relations between thoughts. The first property ensures that epistemic content is a variety of narrow content. The second ensures that it is a truly semantic variety of content. The third ensures that it is central to the dynamics of cognition and action. Because of these three properties, epistemic content can help to resolve many problems in the philosophy of mind and language.

2 Intensions

In what follows, a *thought* is a token propositional attitude that aims to represent the world: for example, a belief, an expectation, or a hypothesis. Thoughts have truth-values (truth, falsity, and possibly others), and are often expressed in language by sentences. Thoughts are often (perhaps always) composed of *concepts*. Concepts are mental tokens that are often expressed in language by terms. Where thoughts have truth-values, concepts have *extensions*: for example, individuals, classes, or properties. The truth-value of a thought typically depends on the extension of the concepts involved: for example, the truth value of my thought *Hesperus is Phosphorus* depends on whether the object that is the extension of *Hesperus* is the same as the object that is the extension of *Phosphorus*.

It is a familiar idea that concepts and thoughts can be associated with an *intension*: a function from possible worlds to extensions or truth-values. The intension of a concept maps a possible world to the concept's extension in that world: in a given world, the intension of my concept *renate* picks out the class of creatures with a kidney in that world. The intension of a thought maps a world to the thought's truth-value in that world: in a given world, the intension of my thought *all renates are cordates* will be true if every creature with a kidney in that world also has a heart. In effect, a concept's intension captures the way that its extension depends on the nature of the world, and a thought's intension captures the way that its truth-value depends on the nature of the world.

It is a somewhat less familiar idea that a concept or thought can be associated with two intensions. First, there is an *epistemic* intension, picking out a thought or concept's extension across the space of *epistemic* possibilities. This intension captures the epistemic dependence of extension or truth-value on the way the actual world turns out. Second, there is a *subjunctive* intension, picking out a thought or concept's extension across the space of *subjunctive* or *counterfactual* possibilities. This intension captures the subjunctive dependence of extension or truth-value on counterfactual states of the world, given that the character of the actual world is already fixed. On the two-dimensional picture I will develop, a thought's epistemic intension is narrow content, while a thought's subjunctive intension is often wide content.

To give a quick illustration: for my concept *water*, the epistemic intension picks out H₂O in our world (the Earth world), and XYZ in a Twin Earth world. This reflects the fact that if I accept that my actual world is like the Twin Earth world (i.e., if I accept that the liquid in the oceans is and always has been XYZ), I should accept that water is XYZ, drinkable liquid). By contrast, the subjunctive intension of my concept *water*, picks out H₂O in both the Earth world and the Twin Earth world. This reflects the fact...
that given that water is H$_2$O in the actual world, the counterfactual Twin Earth world is best described as one in which water is still H$_2$O, and in which XYZ is merely watery stuff. As a rough approximation, we can say that the epistemic intension of water picks out a substance with certain superficial characteristics (e.g. a clear drinkable liquid) in any given world, while the subjunctive intension of water picks out H$_2$O in all worlds. A similar pattern exists for many other concepts; the basis of the pattern is discussed in what follows.

3 Epistemic Possibilities

Let us say that a thought is epistemically necessary when it can be justified a priori: that is, when there is a possible reasoning process that conclusively justifies the thought with justification independent of experience. A thought is epistemically possible (in a broad sense, related to but distinct from the usual philosophical sense) when it cannot be ruled out by a priori reasoning: that is, when its negation is not epistemically necessary. Intuitively, this holds when the thought does not involve an a priori contradiction. On this understanding, my thought water is H$_2$O is epistemically possible, as is my thought water is XYZ. No amount of a priori reasoning can lead to the justified rejection of either of these thoughts. For all I can know a priori, the world might be such as to make either of these thoughts true.[*]

*[[A few fine details here: (1) We can say that a thought is conclusively justified with it has the sort of justification that carries a guarantee of truth: the sort of justification carried by deduction or analysis, for example, as opposed to the non-conclusive justification carried by induction or abduction. The restriction to conclusive a priori justification is required to exclude, e.g., false mathematical thoughts that might be a priori justified by induction from true thoughts. (2) A priori indeterminate thoughts, if there are such, are neither epistemically possible nor epistemically necessary; the same goes for their negations. To handle such cases, one should say that a thought is epistemically possible when its determinate negation is not epistemically necessary. (3) Certain theoretical view (e.g. Salmon 1986) hold that it is knowable a priori that water is H$_2$O, on the grounds that 'water is H$_2$O' expresses roughly the same proposition as 'H$_2$O is H$_2$O', where this proposition is knowable a priori. Even on these controversial views, however, it is clear that the token thought water is H$_2$O is not epistemically necessary as defined above: that is, there is no reasoning process that can justify this thought a priori.]]

When a thought is epistemically possible, it is natural to hold that there are various specific scenarios compatible with the thought. A scenario can be thought of as a maximally specific epistemic possibility: one with all the details filled in. For example, the mere thought that water is XYZ is compatible with many epistemically possible hypotheses about the precise distribution of XYZ in my environment and about everything else that is going on in the world. Each of these maximally specific epistemically possible hypotheses corresponds to a scenario.

To flesh out this intuition further, it seems reasonable to say that some scenarios (those involving XYZ in certain distributions in my environment) verify my thought that water is XYZ: if I accept that the scenario obtains, I should accept that water is XYZ. Other scenarios (e.g. those involving H$_2$O in my environment) falsify my thought that water is XYZ: if I accept that the scenario obtains, I should deny that water is XYZ. Equivalently, we can say that my thought that water is XYZ endorses scenarios in the
first class, and excludes scenarios in the second class.

In effect, the space of scenarios constitutes my epistemic space: the space of specific epistemic possibilities that are open to me a priori. If I had no empirical beliefs, all of epistemic space would be open to me. As I acquire empirical beliefs, my epistemic space is narrowed down. Any given belief will typically divide epistemic space into those epistemic possibilities that it endorses and those that it excludes. The basic idea I will pursue is that the narrow content of a thought is given by the way that the thought divides epistemic space.

Scenarios are much like possible worlds. For now, we can represent scenarios using possible worlds, though I will consider potential differences later. For example, let the H2 O-world be a world like ours with H2O in the oceans and lakes, and let the XYZ-world be a specific Twin Earth world with XYZ in the oceans and lakes. Then for all I can know a priori, my world might be qualitatively just like the H2 O world, or it might be just like the XYZ-world. So these two worlds each represent highly specific epistemic possibilities for me. We can put this by saying it is epistemically possible (in the broad sense) that the H2 O-world is actual, and that it is epistemically possible that the XYZ-world is actual.

For any given scenario, one can in principle consider the hypothesis that the scenario is actual. For any given world W (on the possible-worlds understanding), it is epistemically possible that W is actual: that is, it is epistemically possible that one's own world is qualitatively just like W. When one considers a world as an epistemic possibility in this way, one is considering it as actual: that is, one is thinking of it as a way one's own world may be.[*]

[[The phrase "consider a world as actual" is due to Davies and Humberstone (1980), developing ideas presented by Evans (1979). The explication given here differs from that given by Davies and Humberstone, who do not talk explicitly about epistemic possibility, but it is in much the same spirit.]]

Any given scenario verifies some thoughts and falsifies others. Here, we can say that a scenario falsifies a thought T when the hypothesis that the scenario is actual is rationally inconsistent with T. A scenario verifies T when the hypothesis that the scenario is actual is rationally inconsistent with the negation of T. For our purposes here, it is natural to say that a thought and a hypothesis are rationally inconsistent when their conjunction is epistemically impossible: that is, when this conjunction can be ruled out by a priori reasoning. On this interpretation, a scenario verifies a thought when acceptance of the hypothesis that the scenario is actual implies the thought: that is, when this acceptance can lead by a priori reasoning to acceptance of the thought.

Take my thought water is H2O. The H2O-world verifies my thought: if I accept that the H2O-world is actual, I must rationally conclude that water is H2O. It would be rationally inconsistent to accept that the H2O-world is actual (i.e., that the liquid surrounding me with a certain appearance and distribution is and always has been H2O, and so on) but deny that water is H2O. By contrast, if I accept that the XYZ-world is actual, I must rationally conclude that water is not H2O. It would be rationally inconsistent to accept
that the XYZ-world is actual (i.e. that the liquid surrounding me with a certain appearance and
distribution is and always has been XYZ, and so on), and at the same time to accept that water is H\textsubscript{2}O. So
the XYZ-world falsifies my thought *water is H\textsubscript{2}O*, and verifies thoughts such as *water is not H\textsubscript{2}O*, or
*water is XYZ*.

There is nothing here that contradicts the claim by Kripke and Putnam that water is necessarily H\textsubscript{2}O.
Kripke and Putnam are dealing with what is often called "metaphysical" possibility and necessity, which
is usually sharply distinguished from epistemic possibility and necessity. Even if it is not metaphysically
possible that water is XYZ, it is epistemically possible that water is XYZ: we cannot rule out the
hypothesis that water is XYZ a priori. If Kripke and Putnam are right, then when the XYZ-world is
considered as a metaphysical possibility (in effect, considered as a counterfactual world different from
ours), it is best described as a world where XYZ is not water. But it is clear that when it is considered as
an *epistemic* possibility (i.e. considered as a way our own world may be), and when verification is
defined as above, it verifies the hypothesis that water is XYZ.

The indexical character of some thoughts forces us to refine the possible-worlds understanding of
scenarios. If we consider an objective world W as actual, this does not yield a fully determinate epistemic
possibility. Take a world W containing both H\textsubscript{2}O and XYZ, in the oceans and lakes of separate planets.
If I consider W as actual, I am not in a position to determine whether water is H\textsubscript{2}O or XYZ, since I do
not know which planet I am on. In effect, a fully determinate hypothesis must include information about
my location within a world. To handle this, we can represent a scenario by a *centered* world: a world
marked with an individual and a time at its "center".[*] A centered world corresponds to a world *from a
perspective*, marked with a viewpoint at its center. In the case above, there will be many centered worlds
corresponding to W, some of which are centered on individuals on the H\textsubscript{2}O planet, and some centered on
individuals on the XYZ planet. Now, when I consider the hypothesis that a centered world W' is actual, I
consider the hypothesis that my world is qualitatively just like W', that I am the individual marked at the
center of W', and that the current time is the time marked at the center of W'. Given that sort of
information in the case above, I will be in a position to determine which planet I am on, and I will be in a
position to determine whether water is H\textsubscript{2}O or XYZ.

[*][[This notion is introduced by Quine (1968), who defines a centered world as a world with a marked space-time point.
The definition above is due to Lewis (1979).]]

4 Epistemic Intensions

Given the above, we can naturally define a thought's *epistemic intension* as a function from scenarios to
truth-values. The epistemic intension of a thought T is true at a scenario W when W verifies T, and is
false at a scenario W when W falsifies T. As before, W verifies T when it is rationally inconsistent to
accept that W is actual and deny T, and W falsifies T when it is rationally inconsistent to accept that W is
actual and accept T.
For a more precise definition of epistemic intensions, we would need to be more precise about what it is to consider a scenario as actual. The informal understanding above suffices for many purposes, but a more detailed account can be given as follows. To consider a scenario W as actual is to consider the hypothesis that D is the case, where D is a canonical description of W. When scenarios are understood as centered worlds, a canonical description will conjoin an objective description of the character of W (including its physical and mental character, for example), with an indexical description of the center's location within W. The objective description will be restricted to semantically neutral terms: roughly, terms that are not themselves vulnerable to Twin Earth thought experiments (thus excluding most names, natural kind terms, indexicals, and terms used with semantic deference). The indexical description will allow in addition indexical terms such as 'I' and 'now', to specify the center's location. We can then say that W verifies a thought T when a hypothesis that D is the case implies T. Or equivalently, where S is a linguistic expression of T, W verifies T when a material conditional 'if D, then S' is a priori. These matters are explored in much more depth in Chalmers (forthcoming a).

*[[On a full account, a canonical description of a centered world is required to be an epistemically complete statement in an idealized language that uses only semantically neutral terms and indexicals. A statement D is epistemically complete when D is epistemically possible and there is no S such that both D ∧ S and D ∧ ¬ S are epistemically possible. A semantically neutral term is one that behaves in the same way under epistemic and subjunctive evaluation. The indexicals allowed include 'I', 'now', and any others required to characterize the center of the world. This treatment requires that for every centered world, there exists an epistemically complete description using only semantically neutral terms and indexicals. This claim can be supported by noting (i) that there will be an epistemically complete description for every world (a consequence of the idealization of the language), and (ii) that semantic non-neutrality does not in itself add expressive power in characterizing epistemic possibilities (at most, it affects the description of metaphysical possibilities). See Chalmers (forthcoming a) for more on this.

Note that there is no requirement that a canonical description be given in a purely microphysical vocabulary or in a purely phenomenal vocabulary, or in a combination of the two. I have defended elsewhere (Chalmers 2002a, Chalmers and Jackson 2001) the claim that a conjunction ('PQTI') of microphysical, phenomenal, indexical, and "that's all" truths about the actual world implies all truths about the actual world. If so, then this sort of description will provide a canonical description of the actual world (at least if we put the microphysical description in semantically neutral form), and an analogous description will plausibly suffice for many other worlds. But this is a substantive claim, and is not built into the definition of a canonical description. If PQTI is not epistemically complete, a canonical description will need to include further information about a world. Of course there may be many canonical descriptions for a single world, but all of these will imply each other, so all will yield the same epistemic intensions.]]

In the case of water is H₂O, the thought's epistemic intension will be true at the H₂O-scenario (a scenario centered on Oscar surrounded by H₂O, say), and will be false at the XYZ-scenario (a scenario centered on Twin Oscar, surrounded by XYZ). On a first approximation, one might suggest that the thought's epistemic intension will be true in a scenario when the dominant clear, drinkable liquid around the center of that scenario has a certain molecular structure. This seems to capture roughly what it takes for us to judge that water is H₂O in the actual world, depending on how things turn out. But this sort of approximation is no replacement for the real intension. The intension itself is best evaluated by considering specific scenarios and determining the consequences for the truth-values of our thoughts.
The Components of Content

The existence of epistemic intensions is grounded in the fact that given sufficient information about the actual world, we are in a position to know whether our thoughts are true. For example, given sufficient information about the appearance, behavior, composition, and distribution of objects and substances in my environment, I am in a position to determine whether water is H₂O. Even if the information had turned out differently, I would still have been in a position to determine whether water is H₂O. So given enough relevant information about a scenario, I am in a position to determine whether, if that information is correct in my own world, water is H₂O. The same goes for all sorts of other thoughts. It may be that in some cases (involving vague concepts such as tall, for example), a complete specification of a scenario does not settle a thought as true or false. In that case, we can say that the thought's epistemic intension is indeterminate at that world. But otherwise, the thought's epistemic intension will be true or false at the world.

To help evaluate an epistemic intension at a world, one can use various heuristics. One useful heuristic for evaluating the epistemic intensions of one's own thought T, expressible by a sentence S, is to intuitively evaluate an indicative conditional: 'if W is actual, is it the case that S?' As with other indicative conditionals, one evaluates this conditional epistemically (by the "Ramsey test"): one hypothetically accepts that W is actual, and uses this to reach a rational conclusion about whether or not S is true.[*] If yes, then W verifies T; if not, then W falsifies T. To stress the epistemic character of the conditional, one can also appeal to "turns-out" conditionals such as the following: 'if W turns out to be actual, will it turn out that S'? For example, it seems reasonable to say that if the XYZ-world turns out to be actual, then it will turn out that water is XYZ.

*[[Note that this heuristic invokes the intuitive correctness conditions (or "assertibility conditions") of an indicative conditional, which are given by the Ramsey test, rather than the truth-conditions, whose nature is disputed. We might think of the intension defined by the indicative conditional heuristic as a "Ramsey intension". Ramsey intensions and epistemic intensions are very similar, but it is arguable that they come apart in some cases (see Yablo 2002, Chalmers 2002a). Ramsey intensions have the advantage that they do not invoke the notion of apriority, and so are available even to Quineans and others who reject this notion; this makes it clear that even a Quinean can accept a version of the general framework here. Still, my own view is that the definition in terms of apriority is more fundamental.]]

Some thoughts have a very straightforward epistemic intension. For example, it is plausible that the epistemic intension of my thought I am a philosopher will be true at precisely those scenarios where the individual at the center is a philosopher. The identity of the individual at the center does not matter: it might be David Chalmers, and it might be Immanuel Kant. After all, my knowledge that I am not Immanuel Kant is a posteriori, so a scenario centered on Kant represents an epistemic possibility for me in the broad sense. It seems clear that if I accept that the Kant scenario is my actual scenario (i.e., that I am Kant philosophizing at the center of that scenario), then I should conclude that I am a philosopher.

As for a thought such as Hesperus is Phosphorus: it is plausible that this thought will be verified by roughly those scenarios where the bright object visible in a certain position in the evening sky around the individual at the center is identical to the bright object visible in the morning sky around the individual at the center. Again, this captures roughly what it takes for us to judge that Hesperus is Phosphorus in the actual world, given sufficient empirical information.
With a mathematical thought such as $2 + 2 = 4$, or *pi is irrational*, the thought's epistemic intension will be true in all worlds. This reflects the fact that these thoughts can be justified a priori, so that the negations of these thoughts will not be rationally consistent with any a posteriori hypothesis (the conjunction will itself be epistemically impossible). The same goes even for complex mathematical thoughts whose truth we are not in a position to know ourselves. The notion of epistemic possibility and necessity involves a rational idealization away from our contingent cognitive limitations. By definition, if it is even possible for a thought to be conclusively justified a priori, then the thought is epistemically necessary. If so, the thought has a necessary epistemic intension.

(This idealization also helps to deal with a naural worry: that in practice human thinkers are too limited to entertain the complete hypothesis that a scenario W is actual. A thought T is verified by W if a possible thought that W is actual implies T; that is, if it is possible for a material conditional thought *if D is the case, then T* to be conclusively justified a priori, where D is a canonical description of W. This possibility may idealize away from the cognitive limitations of the thinker. Intuitively, we can think of the thinker as engaging in ideal reasoning.[*] In practice one can often avoid this sort of idealization by appealing to a relevant partial description D of W, where the thinker can entertain the hypothesis that D is the case, and where this hypothesis rationally settles the status of T.)

[*][[As an alternative aid to the imagination, we might suppose that the thinker is assessing T with the aid of a supercomputer that stores the relevant information about W and carries out necessary a priori calculations. See Chalmers and Jackson 2001, section 4, for more on this idea.]]

It is tempting to say that conversely, when a thought has a necessary epistemic intension, it is knowable a priori. On the centered-worlds understanding of scenarios, this claim is equivalent to the thesis that when a thought is epistemically possible, it is verified by some centered world. I think this thesis is correct, and have argued for it elsewhere, but it is nontrivial, at least when the worlds in question are understood as metaphysically possible worlds. Some philosophical views entail counterexamples to this claim. For example, on some theist views it is metaphysically necessary that a god exists, but the existence of a god cannot be known a priori. If so, then *a god exists* is not a priori, but its epistemic intension will be true in all metaphysically possible worlds. In effect, there are not enough possible worlds on this view to represent all epistemic possibilities. A similar result follows from some views on which the laws of nature in our world are the laws of all worlds: there will be no worlds with different laws to represent the epistemic possibility of different laws. The same goes for some materialist views on which zombies are epistemically possible but not metaphysically possible: on some such views, no possible world will correspond to the zombie epistemic possibility.

All of these views are controversial, and I have argued elsewhere (Chalmers 2002a) that they rest on an incorrect conception of metaphysical necessity. Sometimes these views are presented as drawing support from Kripkean a posteriori necessities such as 'Hesperus is Phosphorus' and 'water is H2O', but the Kripkean examples are all compatible with the thesis that every epistemic possibility is verified by a centered possible world. So these views require a posteriori necessities of a sort much stronger than those discussed by Kripke, and there is reason to doubt that "strong necessities" of this sort exist.
Still, one who accepts any of these views will deny the thesis that every epistemically possible thought is verified by a centered world. Such a theorist could nevertheless preserve the thesis that every epistemically possible thought is verified by a scenario, by understanding scenarios as something other than centered metaphysically possible worlds. For example, one can define a space of maximal epistemic possibilities in purely epistemic terms (perhaps using a construction from epistemically consistent thoughts or sentences), and one can then make the case that every epistemically possible thought is verified by a scenario of this sort. (For example, the theist view above entails that even if there is no godless world, there is still a godless scenario.) I have taken this purely epistemic approach to scenarios elsewhere (Chalmers forthcoming b), as it is more neutral and arguably more philosophically fundamental. For reasons of simplicity and familiarity, I will usually stay with the centered-world approach to scenarios in this paper, but it should be kept in mind that the alternative understanding is available.[*]

*A terminological point: I generally use "epistemic intension" for the intension defined over the space of maximal epistemic possibilities (whether or not these coincide with centered metaphysically possible worlds), while I use "primary intension" for the same sort of intension defined over the space of centered metaphysically possible worlds (whether or not these exhaust the maximal epistemic possibilities). In applications of the two-dimensional framework to metaphysical questions, the restriction to metaphysically possible worlds is often crucial, so in these contexts the issues are cast in terms of primary intensions. A central issue here is the thesis that a thought is a priori iff it has a necessary primary intension; this thesis makes a plausible but substantive claim about metaphysical possibility (one that is false if a god exists is metaphysically necessary but not a priori, for example). In applications of the framework to epistemic and semantic questions (such as the current discussion), the restriction to metaphysically possible worlds is less crucial, so in these contexts the issues are cast in terms of epistemic intensions. Here the claim that a thought is a priori iff it has a necessary epistemic intension can be seen as closer to definitional (if a god exists is necessary but not a priori, we can construe scenarios epistemically so that there will be a godless scenario). Of course if the plausible but substantive thesis above is correct, then every maximal epistemic possibility corresponds to a centered world, and primary and epistemic intensions will come to much the same thing.]]

One important note: It is tempting to suppose that the epistemic intension of a thought \(T\) can be evaluated in a scenario \(W\) by asking: what is the truth-value of \(T\), as thought in \(W\)? But this is not so. On the present proposal, \(T\)'s epistemic intension can be evaluated in scenarios containing no copy of \(T\); even when a copy of \(T\) is present, it usually plays no special role. For example, my thought *I am a philosopher* is verified by a scenario regardless of whether I think I am a philosopher there. To take a more extreme example, the epistemic intension of my thought *someone is thinking* is false in a scenario that contains no thoughts. In these cases, all that matters is the epistemic relation between the hypothesis that \(W\) is actual and the thought \(T\). Nothing here requires that \(T\) be present in \(W\). One might define a different intension (a "contextual intension"; see section 9 and Chalmers forthcoming a) using the heuristic above, but such an intension behaves in a quite different way, and will not have the same sort of epistemic properties as an epistemic intension. This will be important later.

One can define epistemic intensions for *concepts* as well as for thoughts. A concept's epistemic intension picks out its extension in a scenario considered as actual. A precise definition involves some tricky details (see Chalmers forthcoming a), so here I will simply illustrate the idea intuitively. Let us take a
singular concept C expressible by a term B. To evaluate C's epistemic intension in a scenario W, one considers the hypothesis that W is actual, and uses B to ask: 'what is B?' (Here B is used rather than mentioned.) One can appeal to the indicative conditional 'if W is actual, what is B?'. Alternatively, one can appeal to the rational consistency of judgments of the form C is such-and-such with the hypothesis that W is actual.

For example, in the XYZ-scenario, the epistemic intension of my concept water picks out XYZ. As before, I can say: if the XYZ-scenario is actual, then water is XYZ. In the H2O-scenario, on the other hand, the epistemic intension of my concept water picks out H2O. More generally, one might say as a first approximation that in a given scenario, the epistemic intension of my concept water picks out the dominant clear, drinkable liquid found in the oceans and lakes around the individual at the center. As before, however, this is just an approximation, and the true intension corresponds to the results of considering and evaluating arbitrary scenarios as epistemic possibilities.

One can do something like this for an arbitrary concept. Even for a seemingly nondescriptive concept, such as Gödel, it will still be the case that given full information about a scenario and given the hypothesis that this information obtains in the actual world, one will be in a position to make a rational judgment about the identity of Gödel under that hypothesis. This mirrors the fact that given relevant information about the actual world, one is in a position to determine the identity of Gödel, and more generally is in a position to determine the extension of arbitrary concepts. This rational dependence of judgments about extension on information about the character of the actual world can be encapsulated in an epistemic intension.[*]

[*][For this reason, the current framework can be seen as neutral between "causal" theories of reference (on which reference is determined by a causal chain) and "descriptive" theories of reference (on which reference is determined by a description). Even a causal theorist should allow that relevant information about the actual world dictates rational judgments about our concept's extension. This methodology underlies Kripke's own arguments for the causal theory: in effect, he considers epistemic possibilities that we could discover to obtain (e.g., that a man called 'Gödel' stole the proof of the incompleteness of arithmetic from a man called 'Schmidt'), and reaches judgments about a term's extension on that basis (here, we judge that 'Gödel' will pick out the stealer, not the prover). So even on the causal theory, a term will plausibly have an epistemic intension: it is just that this epistemic intension may have a causal element. For example, for the epistemic intension of my concept Gödel to pick out a given individual in a scenario, it may be required that that individual stand in the right sort of causal relation to the subject at the center of the scenario. See Chalmers 2002b for more here.]

These epistemic intensions are often difficult to characterize in independent terms, but for some concepts this characterization is straightforward. If we take a quasi-descriptive concept such as Hesperus (where we assume this functions to rigidly pick out the evening star in the actual world), we can say that the epistemic intension of Hesperus picks out the evening star around the center of an arbitrary scenario. Or if Julius functions to rigidly pick out the inventor of the zip, the epistemic intension of Julius will pick out the inventor of the zip in a given scenario.

The epistemic intension for an indexical concept is also very simple. The epistemic intension of my
concept $I$ picks out the individual at the center of a scenario. The epistemic intension of $now$ picks out the time at the center. The epistemic intension of $here$ picks out the location of the individual at the center, at the time at the center. The epistemic intension of $today$ picks out (roughly) the day that includes the time at the center. And so on.

When a thought is composed from concepts, its truth-value typically depends on the concepts' extensions. In such a case, the thought's epistemic intension will equally be determined by the concepts' epistemic intensions. For example, the epistemic intension of $A$ is $B$ will be true at a world when the epistemic intensions of $A$ and $B$ pick out the same individual there. One will find a similar compositionality of epistemic intensions wherever one finds compositionality of extensions.

5 Subjunctive Intensions

In contemporary philosophy, epistemic intensions are less familiar than what I will call subjunctive intensions. To evaluate a thought's subjunctive intension, one evaluates it in a world considered as counterfactual. To consider a world as counterfactual, one considers it as a subjunctive possibility: as a way things might have been, given that the character of the actual world is already fixed. In our world as it actually is, the liquid in the oceans and lakes is $H_2O$. Nevertheless, the liquid in the oceans and lakes might have been $XYZ$. So we can say that the $XYZ$-world might have obtained, and that the $XYZ$-world represents a subjunctive possibility.

The subjunctive intension of a thought $T$ in a world $W$ picks out the thought's truth-value in $W$ when $W$ is considered as counterfactual. Here, we grant that the character of the actual world is already fixed and ask what would have been the case if $W$ had obtained. If $T$ is expressible by a sentence $S$, we can evaluate $T$'s subjunctive intension at $W$ by using $S$ to ask: 'if $W$ had obtained, would it have been the case that $S$?' If yes, then $T$'s subjunctive intension is true at $W$; if no, then $T$'s subjunctive intension is false at $W$. When $T$'s subjunctive intension is true at $W$, we can say that $W$ satisfies $T$.

For example, if the $XYZ$-world had obtained — that is, if the liquid in the oceans and lakes had been $XYZ$ — then (if Kripke and Putnam are correct) $XYZ$ would not have been water. $XYZ$ would merely have been watery stuff, and water would still have been $H_2O$. If so, then the $XYZ$-world satisfies my thought $water$ is $H_2O$, and the subjunctive intension of my thought is true at the $XYZ$-world. More generally, if Kripke and Putnam are correct, then the subjunctive intension of my thought $water$ is $H_2O$ is true at all possible worlds.

[[I think that it is not obvious that Kripke and Putnam are correct about this, and a case can be made that it might have been that water was $XYZ$. For the purposes of this discussion, however, I will go along with the common view that Kripke's and Putnam's intuitions are correct. I also think that even if Kripke and Putnam are right about language, it is not...]]
The Components of Content

obvious that this extends to thought. But again, for the purposes of this discussion, I will go along with the common view that the modal properties of a term such as 'water' mirror modal properties of the underlying concept water that the term expresses.]

It is clear that subjunctive intensions can behave quite differently from epistemic intensions. We have seen that the XYZ-world verifies water is not H2O, but it satisfies water is H2O. This difference is rooted in the difference between epistemic and subjunctive possibility, and the corresponding difference between considering a world as actual and as counterfactual. This is mirrored in the different behavior of indicative and subjunctive conditionals: it seems reasonable to say indicatively that if the liquid in the oceans and lakes is XYZ, then water is XYZ; but if Kripke and Putnam are right, it is not reasonable to say that if the liquid in the oceans and lakes had been XYZ, then water would have been XYZ. In considering a world as counterfactual, empirical facts about the actual world make a difference to how we describe it. In considering a world as actual, they do not.

Something similar goes for an indexical thought such as I am David Chalmers. If Kripke is right, it could not have been that I was not David Chalmers. If so, then I am David Chalmers is true in any world considered as counterfactual (or at least in any world where I exist). Note that there is no special need for a center in the world here: once we know all the objective facts about a counterfactual state of affairs, we know all that we need to know, even to settle indexical claims. So subjunctive possibilities can be represented by ordinary uncentered worlds, and subjunctive intensions are defined over uncentered worlds.

We can associate subjunctive intensions with concepts in a similar way. A concept's subjunctive intension picks out its extension in a world considered as counterfactual. For a concept C expressible by a term B, we can use B to ask: 'if W had been actual, what would B have been?' For example, in the case of water, we can say that if the XYZ-world had been actual, then water would still have been H2O. So the subjunctive intension of water picks out H2O at the XYZ-world, and plausibly picks out H2O in all possible worlds.

For many concepts, the concept's subjunctive intension picks out its actual extension in all possible worlds. This applies in particular to rigid concepts: those expressible by rigid designators, such as names or indexicals, picking out the same object in all worlds. For example, Kripke argues that 'Hesperus' is a rigid designator: if Hesperus is actually Venus, then it could not have been that Hesperus was other than Venus. If so, then the subjunctive intension of Hesperus picks out Venus in all possible worlds. Similarly, given that 'I' is a rigid designator, the subjunctive intension of my concept I picks out David Chalmers in all possible worlds.

For a purely descriptive concept such as circular or the inventor of the zip, by contrast, the subjunctive intension is plausibly very similar to the epistemic intension. For example, both the epistemic and subjunctive intensions of the inventor of the zip plausibly pick out whoever invented the zip in a given world. Note the difference with Julius, which has the same epistemic intension but whose subjunctive intension picks out the actual inventor in all worlds. The difference reflects the intuition that if (for
The Components of Content

example) Ned Kelly had invented the zip, he would have been the inventor of the zip, but he would not have been Julius. (Compare: if Ned Kelly actually invented the zip, then he is Julius.) Some concepts behave in an intermediate manner: for example, the subjunctive intension of the discoverer of water does not pick out the actual extension in all worlds, but it is nevertheless quite different from the epistemic intension, due to the presence of the rigid concept water as a constituent.

The subjunctive intension of a concept or thought always depends in some way on the concept's epistemic intension and the actual world. For a purely descriptive concept, the subjunctive intension may simply be a copy of the epistemic intension, across uncentered worlds. For a rigid concept, the subjunctive intension will correspond to the value of the epistemic intension at the actual world, projected across all possible worlds. In other cases, the dependence may be somewhat more complex, but it will still exist.

We can encapsulate this dependence by associating concepts and thoughts with a two-dimensional intension. This intension maps an ordered pair (V, W) consisting of a scenario and a world to an extension or a truth-value in W. When a thought T is evaluated at (V, W), it returns the truth-value of T in the counterfactual world W, under the assumption that V is actual. (If a sentence S expresses T, we can use this heuristic: 'if V is actual, then if W had obtained, would it have been the case that S'? ) Like an epistemic intension, a two-dimensional intension can plausibly be evaluated without relying on empirical knowledge, since all the empirical knowledge one needs is given in the first parameter V. To evaluate a thought's subjunctive intension at W, one evaluates its two-dimensional intension at (A, W), where A is the actual scenario. If we understand scenarios as centered worlds, the value of a thought's epistemic intension at a scenario W will coincide with the value of its two-dimensional intension at (W, W'), where W' is an uncentered version of W.[*] This two-dimensional intension is useful for certain purposes, but most of the time we need only appeal to a thought's epistemic and subjunctive intensions.

*[[In this way the epistemic intension can be seen as equivalent to the "diagonal" of the two-dimensional intension, in a manner reminiscent of the "diagonal proposition" of Stalnaker 1978. But see section 9 for reasons why epistemic intensions are not fundamentally diagonal intensions.]]

Within this framework, we can analyze the Kripkean "necessary a posteriori". Let us say that a sentence S is subjunctively possible when it is possible in the familiar Kripkean sense: that is, when a modal sentence such as 'it might have been the case that S' is true. A thought is subjunctively possible when it is expressible by a subjunctively possible sentence. Subjunctive necessity is defined correspondingly. Then it is easy to see that when a thought is subjunctively necessary, its subjunctive intension is true in all worlds, and vice versa. Cases of the Kripkean "necessary a posteriori" (e.g., water is H2O) arise when a thought has a necessary subjunctive intension (the thought is true in all worlds considered as counterfactual) but a contingent epistemic intension (the thought is false in some world considered as actual). Cases of the Kripkean "contingent a priori" (e.g. Julius invented the zip) arise when a thought has a contingent subjunctive intension but a necessary epistemic intension.

There should be no question of whether the epistemic or the subjunctive intension is the intension
associated with a given concept. The full story can only be given two-dimensionally. One or the other may be more useful for various specific purposes. In matters of linguistic content across a community, the subjunctive intension often plays a central role: different users of a name or natural kind term often have quite different associated epistemic intensions while sharing the same subjunctive intension. For questions about the rational properties of thought and its role in governing action, however, we will see that the epistemic intension is central.

6 Wide and Narrow Content

Let us call a thought or concept's epistemic intension its *epistemic content*, and a thought or concept's subjunctive intension its *subjunctive content*. Let us say that when a thought or concept's content depends only on the intrinsic state of the thinker (that is, when every possible intrinsic duplicate of the thinker has a corresponding thought or concept with the same content), the content is *narrow*. Let us say that when content does not depend only on a thinker's intrinsic state (that is, when an intrinsic duplicate could have a corresponding thought or concept with different content), the content is *wide*. One can make the case that epistemic content is narrow, while subjunctive content is often wide.

It is clear that subjunctive content is often wide. For example, Oscar (on Earth) and Twin Oscar (on Twin Earth) are more or less intrinsic duplicates (abstracting away from differences due to the presence of H₂O and XYZ in their bodies), and have corresponding concepts that they express by saying 'water'. But the subjunctive intension of Oscar's concept *water* picks out H₂O in all worlds, while the subjunctive intension of Twin Oscar's concept *water* picks out XYZ in all worlds. Something similar applies to most rigid concepts, including *Hesperus* and even *I*. Here, a subjunctive intension depends on a concept's extension, which usually depends on a subject's environment, so two intrinsic duplicates can have different subjunctive intensions. In other cases, subjunctive content will not depend on the environment. For example, purely descriptive concepts such as *circular* and *the inventor of the zip* will plausibly have subjunctive intensions that are shared between duplicates. But in cases where a concept or thought's subjunctive intension depends not just on its epistemic intension but on the way the actual world turns out, we can expect that subjunctive content will be wide content.

This environment-dependence does not extend to epistemic content. A concept's epistemic content is usually quite independent of its actual extension, and of the way the actual world turns out more generally. An epistemic intension encapsulates the way in which our rational judgments about extension and truth-value depend on arbitrary empirical information; so the intension can be evaluated without knowing which epistemic possibility is actual. The factors that make subjunctive content wide content appear to be irrelevant to epistemic content.

This can be illustrated by looking at familiar cases. Take Oscar's and Twin Oscar's respective thoughts T₁ and T₂, expressed by saying 'there is water in my pool.' Let W₁ be the Earth scenario centered on Oscar, with H₂O in the oceans and lakes and H₂O in Oscar's pool. Let W₂ be the Twin Earth scenario centered on Twin Oscar, with XYZ in the oceans and lakes and XYZ in Twin Oscar's pool. Then clearly, W₁
The Components of Content

verifies $T_1$ and $W_2$ verifies $T_2$. But also, $W_2$ verifies $T_1$: if Oscar hypothetically accepts that $W_2$ is actual, he must rationally accept $T_1$. Equally, $W_1$ verifies $T_2$: if Twin Oscar hypothetically accepts that $W_1$ is actual, he should rationally accept $T_2$. So the epistemic intensions of $T_1$ and $T_2$ are on a par with respect to these worlds.

Something similar applies to other scenarios. Let $W_3$ be a Twin Earth scenario centered on Twin Oscar with XYZ in the oceans and lakes, but an isolated amount of $H_2O$ in Twin Oscar's pool. Then $W_3$ falsifies both $T_1$ and $T_2$. If Oscar accepts that $W_3$ is actual, he should reject $T_1$; if Twin Oscar accepts that $W_3$ is actual, he should reject $T_2$. The same goes for any other world: if $W$ verifies $T_1$, it will also verify $T_2$, and vice versa. The same goes equally for any intrinsic duplicate of Oscar. We can even imagine Vat Oscar, who is a brain in a vat receiving artificial stimulation. Vat Oscar can entertain the hypothesis that his environment is just like $W_1$ (or $W_2$ or $W_3$) and can reach rational conclusions on that basis, and the conclusions that he reaches will mirror those of Oscar and Twin Oscar. So Vat Oscar has a thought with the same epistemic intension as Oscar's.[*] The same holds for intrinsic duplicates in general; so the epistemic content of Oscar's thought is narrow.

[[Thus even a brain in a vat might have thoughts with epistemic content. This can be used to address Putnam's (1981) anti-skeptical argument that if he were a brain in a vat, he could not think \textit{I am a brain in a vat}. A brain in a vat could think a thought with the appropriate epistemic content, if not the appropriate subjunctive content. It could also think a thought such as \textit{I am in a skeptical scenario}, which has more or less identical epistemic and subjunctive content. The epistemic contents of such a thought seems sufficient to express a significant skeptical possibility, true only in worlds in which the individual at the center lacks the usual sort of epistemic contact with the surrounding world.]]

The same goes for other thoughts and concepts. For example, even though I may have a twin whose concept expressed by 'Hesperus' has a different extension and subjunctive intension, his concept nevertheless has the same epistemic intension as mine, picking out roughly the evening star near the center of any scenario. Similarly, although the \textit{I} concepts of my twins will have an extension and subjunctive intension that differs from mine, they will have the same epistemic intension, picking out the individual at the center of any scenario.

One can even apply this analysis to the cases used by Burge (1979) to argue for the social nature of mental content. Bert has a belief that he expresses by saying 'arthritis sometimes occurs in the thighs.' In fact, arthritis is a disease of the joints and cannot occur in the thigh, so it seems that Bert has a false belief about arthritis. Twin Bert, an intrinsic duplicate of Bert, also has a belief that he expresses by saying 'arthritis sometimes occurs in the thighs'. But Twin Bert lives in a community in which the word 'arthritis' is used for a different disease, one that affects the muscles as well as the joints: we might call it 'twarthritis'. It seems that Twin Bert has a true belief about twarthritis. Where Bert believes (falsely) that he has arthritis in his thigh, Twin Bert does not: Twin Bert believes (truly) that he has twarthritis in his thigh. Burge concludes that in this sort of case, belief content is not in the head.

Here, the crucial factor is that Bert uses the term 'arthritis' with \textit{semantic deference}, intending (at least
The Components of Content tacitly) to use the word for the same phenomenon for which others in the community use it. We might say that this term expresses a deferential concept for Bert: one whose extension depends on the way the corresponding term is used in a subject's linguistic community. It is clear that for deferential concepts, extension can depend on a subject's environment, as can subjunctive intension. The subjunctive intension of Bert's concept arthritis picks out arthritis in all worlds, while the subjunctive intension of Twin Bert's concept picks out twarthritis in all worlds.

Let $T_1$ and $T_2$ be the thoughts that Bert and Twin Bert express by saying 'arthritis sometimes occurs in the thighs.' Let $W_1$ be Bert's own centered world, with a surrounding community that uses the term `arthritis' to refer to a disease of the joints. Let $W_2$ be Twin Bert's centered world, with a surrounding community that uses `arthritis' to refer to a disease that can occur in the thigh. Then clearly $W_1$ falsifies $T_1$ and $W_2$ verifies $T_2$. At the same time, $W_2$ verifies $T_1$: if Bert accepts that $W_2$ is actual — that is, if he accepts that his linguistic community uses 'arthritis' for a disease that can occur in the thighs — then (since his concept is deferential) he should rationally accept that arthritis can occur in the thighs, and so should accept $T_1$. Similarly, $W_1$ falsifies $T_2$: if Twin Bert accepts that $W_1$ is actual — that is, if he accepts that his community uses 'arthritis' only for a disease of the joints — then he should reject his thought $T_2$. So the epistemic intension of $T_1$ is false at $W_1$ and true at $W_2$, and exactly the same is true for $T_2$.

Something similar applies to any other scenarios that Bert and Twin Bert evaluate. In general, the epistemic intension of their arthritis concepts in those scenarios will pick out the extension of the term 'arthritis' as used in the linguistic community around the center of those scenarios. (In worlds where the term is not used, the epistemic intension will arguably be empty or indeterminate.) And the same goes for any intrinsic duplicate of Bert. Any such duplicate can entertain the hypothesis that a given scenario $W$ is actual, and will rationally reach conclusions similar to Bert's.

One can apply the same reasoning to Putnam's case of 'elm' and 'beech', in which a subject can use the terms with different referents despite users having no substantive knowledge to differentiate the two. In this case, the terms are being used deferentially: the epistemic intension of the subject's concept elm picks out roughly whatever is called 'elm' around the center of a scenario, and the epistemic intension of her concept beech picks out roughly whatever is called 'beech' around the center of a scenario. Here again, the epistemic intension is independent of the environment. So we can see that semantic deference and "the division of linguistic labor" is quite compatible with thoughts and concepts having internally determined epistemic content.

Putnam suggests that terms such as 'water' and 'elm' show that if a concept's intension is internally determined, it cannot determine the concept's extension. The current analysis shows that this is only half-true. The epistemic intension of a concept determines its extension, and the epistemic intension is internally determined. Of course, the epistemic intension is a centered intension, taking a centered world as argument, at least on the possible-worlds understanding of scenarios. So Putnam's claim still holds for uncentered intensions. But any intension requires facts about the actual world to determine extension,
and it is most natural to regard the actual environment of a thinker as centered, so an internally determined centered intension is very useful here.

Why is epistemic content narrow? On the surface, this is because a thought's epistemic content is rationally prior to any knowledge of a subject's environment: it captures the way a thought's truth-value depends on the character of the environment, and so is independent of the environment itself. More deeply, it may be because epistemic content is defined in terms of the rational properties of thoughts, where the relevant rational properties are internally determined. For example, if one subject has a thought that is justifiable a priori, a corresponding thought in any intrinsic duplicate of that subject will also be justifiable a priori; if so, a thought's epistemic necessity is determined by the internal state of the thinker. This observation can be combined with the observation that when one subject entertains the hypothesis that a scenario W is actual, a duplicate of that subject must also be entertaining the hypothesis that W is actual. This second observation can be grounded in the fact that these hypotheses involve semantically neutral descriptions of scenarios, so there is no possibility of a "Twin Earth" difference between thinkers here. Putting these two observations together, it follows that if the hypothesis that W is actual epistemically necessitates a thought in one subject, it will also epistemically necessitate the corresponding thought in any duplicate subject. So epistemic content is narrow.

(Of course, the epistemic content of a thought will almost always depend causally on the external world, but it will not depend constitutively on the external environment. Whenever the external environment affects the epistemic contents of our thoughts, it will do so by affecting the internal state of the thinker.)

As promised, this sort of narrow content is truth-conditional. The epistemic content of a thought delivers conditions that one's actual centered world must satisfy in order for one's thought to be true. We might think of these as a thought's epistemic truth-conditions, as opposed to a thought's subjunctive truth-conditions, which govern truth across counterfactual worlds. Of course these truth-conditions can come apart at a given world: at the XYZ-world, the epistemic truth-conditions of water is XYZ are satisfied, but the subjunctive truth-conditions are not. This is to be expected, given the different functions of epistemic and subjunctive evaluation. One might worry that because of this, a thought could turn out to be both true and false in the actual world, but this is impossible. When evaluated at the actual world, epistemic intensions and subjunctive intensions always give the same results.

7 The Advantages of Epistemic Content

In recent times, the "content" of a thought has usually been identified with something like its subjunctive content;[*] but the epistemic content seems to be an equally good candidate. As before, there is no need to decide which is the content. That being said, there are a number of ways in which the epistemic content of a thought is responsible for the explanatory work that we would expect a notion of content to do.

[*][Alternatively, content is often identified with a structured proposition composed from either subjunctive intensions of the concepts involved, or from the extensions of the concepts involved (when the concepts are rigid). This sort of
structured content is more fine-grained than a subjunctive intension, but it has the same truth-conditions, and depends on
the environment in a similar way. What I say below about subjunctive intensions applies equally to structured
propositions. Likewise, what I say about epistemic intensions can easily be adapted to a view on which the contents of
thoughts are structures composed from epistemic intensions of concepts.]

First, epistemic content reflects the rational relations between thoughts. If one thought implies another
thought a priori, the epistemic intension associated with the first entails the epistemic intension
associated with the second (that is, in all scenarios in which the first intension is true, the second
intension is also true). If I know that it is hot where I am now, I know that it is hot here, and vice versa;
this is reflected in the fact that the epistemic contents of the two thoughts are the same. The subjunctive
contents of the thoughts are very different, however. The subjunctive intension of the first thought is true
at a world if it is hot where DJC is at time \( t \) in that world; the subjunctive intension of the second thought
is true at a world when it is hot in place \( p \) in that world (where \( t \) and \( p \) are the time and place of the actual
thoughts). The epistemic contents of the thoughts reflect their rational relationship, but the subjunctive
contents do not.

It is straightforward to see why this is so. If one thought entails another a priori, then any scenario that
verifies the first will verify the second. Conversely, it is plausible that if the epistemic intension of one
thought entails that of another, a thinker should in principle be able to infer the second from the first by
(idealized) a priori reasoning. (As before, if scenarios are identified with centered worlds and if strong
necessities exist, this converse claim will be false. For example, the epistemic intension of \( a \ god \ exists \)
might be entailed by any intension without the thought being a priori. Again, on such a view the claim
can be preserved by moving to the purely epistemic understanding of scenarios.) This is not so for
subjunctive intensions: entailments between these may turn on facts about the external world that are not
accessible to the thinker.

This can be applied straightforwardly to explain the informativeness of a thought such as \( \text{Hesperus is Phosphorus} \). Although its subjunctive intension is equivalent to that of the trivial \( \text{Hesperus is Hesperus} \),
its epistemic intension is quite distinct, so it is not cognitively trivial. In effect, epistemic intension here
plays the role of Fregean sense. Again, it is epistemic intensions that reflect the rational properties of
thoughts.

We can also invoke epistemic content in the case of Kripke's Pierre, who paradoxically seems to believe
that London is pretty and that London is not pretty, without any breakdown in rationality. Pierre's
concepts \( \text{Londres} \) and \( \text{London} \) have quite different epistemic intensions: in a given scenario, the first
picks out (roughly) the famous city called 'Londres' that the individual at the center has heard about,
whereas the second picks out (very roughly) the grimy city in which that individual has been living. The
subjunctive intensions are identical, picking out London in every world. So Pierre's two beliefs \( \text{Londres is pretty} \) and \( \text{London is not pretty} \) have contradictory subjunctive intensions, but their epistemic
intensions are quite compatible. Rational relations are determined by epistemic content, so contradictory
subjunctive intensions support no charge of irrationality.

Intuitively, Pierre's two beliefs are rationally compatible because there are specific ways the actual world
The Components of Content could be that are consistent with both. There is a scenario in which 'Londres' names a faraway, beautiful city (maybe it is in India), and in which the individual at the center inhabits an entirely distinct ugly city called 'London'. For all Pierre knows and believes, such a scenario could be actual: this scenario verifies both of Pierre's beliefs. As long as there is such a scenario, satisfying the epistemic intensions of all of Pierre's thoughts, the epistemic contents of these thoughts will be compatible, and Pierre's rationality will not be in danger.

This brings out the relation between this account and Dennett's (1981) suggestion that the narrow content of a thought is reflected in the notional world of the thinker. We can take the notional world to be a scenario (really a class of scenarios) that verifies all of a subject's beliefs, or at least as many as possible.[*] Pierre's notional world is a world in which there is a beautiful faraway city called 'Londres', and a grimy city close at hand called 'London'. If Pierre really lived in his notional world, he would be right about everything and rarely surprised.

[*][Dennett suggests that the relevant worlds are "the environment (or class of environments) to which the organism as currently constituted is best fitted." This class may be quite different from the class of worlds that verify all of a subject's beliefs: subjects are sometimes better fitted to worlds that falsify their beliefs (when they are pessimistic or altruistic, for example); they often have beliefs about distant matters that are irrelevant to fitness; and their fitness often turns on matters about which they have no beliefs. See also the criticisms in Stalnaker 1989 and White 1991, and White's more refined account. Dennett's and White's suggestions might be seen as a first attempt at giving a naturalistic reduction of something in the vicinity of epistemic content. Such a reduction is likely to be a major project in its own right.]]

On similar grounds, one can make the case that epistemic content reflects the cognitive relations between thoughts. Here there is an important qualification: epistemic content as I have defined it does not distinguish the various cognitive relations that might hold between thoughts that are deductively equivalent. From the point of view of epistemic content, a complex mathematical proof is as trivial as modus ponens; the fine-grained cognitive dynamics of deduction lies beyond the reach of epistemic content as I have defined it here. I think a more fine-grained variety of epistemic content can handle these cases better (see Chalmers forthcoming b). I will set these issues aside here, as subjunctive content does not handle them any better, and they are largely independent of the issues at play in this paper.

A qualified thesis would be the following: insofar as epistemic content or subjunctive content reflect the cognitive relations between thoughts, the contribution of epistemic content screens off the contribution of subjunctive content. That is, in cases where two thoughts are cognitively related, then (1) in related cases where the epistemic content of the thoughts is held constant but the subjunctive content is varied, the cognitive relations are preserved (except insofar as cognitive relations can be affected by varying factors independent of both epistemic and subjunctive content, as in the deductive case); and (2) in related cases in which the subjunctive content is preserved but epistemic content is not, the cognitive relations are damaged. One can make this case straightforwardly by examining cases; the details parallel those of the discussion of the explanation of behavior, below, so I will not duplicate them here.

A third advantage of epistemic content is its suitability for a role in the explanation of behavior. It is often noted that subjunctive content seems slightly out of synchrony with what one would expect of an
The Components of Content

explanatory psychological state. To use an example of Kaplan's (1989), if you are watching me and my
pants catch fire, our respective beliefs that my pants are on fire now will have the same subjunctive
content (true in all worlds in which DJC's pants are on fire at time $t$), but will lead to very different
actions (I might jump into a river, while you just sit there). The difference between our actions does not
seem to be something that a characterization in terms of subjunctive content alone can explain. In a
similar way, belief states can produce very similar behavior for apparently systematic reasons, even when
the beliefs have very different subjunctive content: witness the behavior that my twin and I produce when
we think about twin water and water respectively, or the similarity between the actions of two people
who think $I$ am hungry. It seems that a whole dimension of the explanation of behavior is hard for
subjunctive content to explain.

These explanations can be easily handled in terms of epistemic content. If you and I think $I$ am hungry,
the epistemic contents of our thoughts are the same, and that similarity is reflected in the similarity of our
actions. When you and I both believe that my pants are on fire, on the other hand, our epistemic contents
are very different, and our actions differ correspondingly. Note that this provides a straightforward
solution to Perry's problem of the essential indexical: it is epistemic content, not subjunctive content, that
governs action, and epistemic content, consisting in a centered intension, is a sort of indexical
content.[*]

*[[Perry (1979) considers the possibility that centered ("relativized") propositions might provide a solution, but dismisses
it on the grounds that believing that such a proposition $P$ is "true for me" does not distinguish me from third parties who
also believe that $P$ is true for me, but act differently. The trouble is that Perry's locution "true for me" introduces an
unnecessary extensional element. What distinguishes me from the third parties is rather that I believe $P$ simpliciter, or
better, that my belief has $P$ as its epistemic content.]]

Epistemic content also accounts for the similarity of action between twin cases; this similarity reflects the
fact that my beliefs about water and my twin's beliefs about twin water have the same epistemic content.
But we need not move to the realm of science fiction to see the point. Two thoughts can share epistemic
content even when two thinkers are quite different, as our thoughts $I$ am hungry show. Even in these
cases, similarities in epistemic content will lead to similarities in action, other things being equal.
Suppose I think that Superman is across the road, and I want to have Superman's autograph: then other
things being equal, I will cross the road.[*] If you have thoughts with similar epistemic content to mine,
then you will do the same. If your thoughts share only subjunctive content with mine, while having
different epistemic content — perhaps you think that Clark Kent is across the road, but want Superman's
autograph — then your corresponding behavior may be quite different.

*[[To simplify the discussion, I make the happy assumption that Superman is actual and is identical to Clark Kent.]]

In general, whenever the content of a thought is causally relevant to behavior, its contribution is screened
off by that of epistemic content in the following sense. If an alternative thought had the same epistemic
content but different subjunctive content, the resulting behavior would have been physically indiscernible
(except insofar it might be affected by changing factors independent of both sorts of content); whereas if
it had the same subjunctive content but different epistemic content, the resulting behavior might have
been quite different.
To see the latter point, we need only examine cases like those above. The thoughts *I am hungry* and *The guy over there is hungry* (unknowingly looking in a mirror) will lead to very different behavior, even though their subjunctive content is the same. When Lois Lane is trying to cut Clark Kent’s hair, her observation "Clark’s hair breaks the scissors" will prompt a reaction very different from that provoked by a corresponding thought concerning Superman. If I hear that Cary Grant is starring in a movie, I might be more likely to watch than if I hear that the movie stars Archie Leach. In all these cases, different reactions are provoked by a difference in the epistemic content of a thought. In general, whenever the epistemic content of a thought is varied, different consequences can be expected, even if subjunctive content is preserved throughout.[*] Given that epistemic content is central to cognitive relations and that cognition governs action, this is just what we would expect.

*[Of course, thoughts like *Cary Grant is in the movie* and *Archie Leach is in the movie* might lead to the same actions despite their different epistemic content, if I know that Cary Grant is Archie Leach. But even here, there exist circumstances under which the thoughts might play a different role: imagine someone telling me that Cary Grant is not Archie Leach after all. In general, whenever two thoughts have different epistemic content, there are at least hypothetical circumstances under which the action-governing roles of the thoughts will differ.]]

By contrast, if the subjunctive content of a thought is varied but epistemic content is kept constant, behavior stays indistinguishable throughout. Perhaps, unbeknownst to me, Cary Grant is an elaborate hoax, a co-operative construction by avant-garde animators and the mass media. In such a case, my thought about Cary Grant will have no nontrivial subjunctive content, but as long as it has the same epistemic content, my behavior will be indistinguishable from the case in which he is real. Or perhaps Cary Grant is really Ludwig Wittgenstein in disguise: if so, the thought has a very different subjunctive content, but the same behavior results. Similarly, when my twin and I think *I need some more water for this pot*, the subjunctive contents of our thoughts differ, but we both go to the sink.

We can make a similar point within a single system. Take Evans' example of 'Julius', which functions to rigidly designate whoever invented the zip. Then the epistemic intensions of my concepts *Julius* and *the inventor of the zip* will be the same, but the subjunctive intensions will be very different. Despite the difference in subjunctive intensions, however, it is clear that any thoughts of the form *Julius is such-and-such* and *The inventor of the zip is such-and-such* will play very much the same role in directing cognition and action. The rigidification and consequent difference in subjunctive intension is largely irrelevant. One exception: the two concepts may behave differently in subjunctive thought, as when one judges that Julius might not have been the inventor of the zip, but not that Julius might not have been Julius. But even here the difference is accounted for by a difference in the internally determined two-dimensional intension, rather than by a difference in subjunctive content *per se*.

Some might object that there are cases in which we individuate behavior extrinsically — for example, Oscar drinks water while Twin Oscar drinks twin water — so there is a dimension of behavior that escapes epistemic content. But even in this sort of case, subjunctive content does not usually help. Even Twin Oscar, with his different subjunctive content, would drink water if he was in Oscar's present environment. What is relevant to behavior here is not subjunctive content but current environment, as we
can see by an extension of the varying-factors strategy; and I certainly do not wish to deny that current environment is relevant in the explanation of behavior.

The only cases in which there is a direct tie between subjunctive content and behavior are cases in which behavior is individuated by an intentional object: for example, Oscar searches for a glass of water, whereas Twin Oscar searches for a glass of twin water. This connection holds across all environments, as behavior only counts as water-searching if it is caused by water-thoughts. But for the same reason, this is a very weak sort of relevance for subjunctive content: as Fodor (1991) notes, in these cases the subjunctive contents of thoughts are not causally relevant to action, but instead are conceptually relevant, in effect determining the category the action falls under.[*] Subjunctive content gives us very little purchase in the explanation of action here, as we will only know that some behavior is water-searching if we already know that water-thoughts lie behind it. In a causal (as opposed to a conceptual) explanation of the action, epistemic content will still play the central role.

*[[See Fodor 1991 for a detailed argument along these lines. I note also that one can individuate this sort behavior intentionally but still narrowly if one individuates by epistemic content.]]

Why is epistemic content primary? To answer this question, it is useful to think of my belief contents as constituting a model of my world, a kind of map by which I steer. This is a model of the world as I find it, a centered world with me at the center, and my beliefs are constraints on that world. Beliefs constitute a model by constraining epistemic space: the space of epistemic possibilities that were open to me a priori. One belief rules out one group of epistemic possibilities as a candidate for the world where I am, another belief rules out another group, until only a limited class of worlds is left. I operate under the assumption that my world is one of those worlds, and if I am lucky I will not be too surprised.

My world-model is ultimately a notional world: a set of epistemic possibilities, such that none of these would overly surprise me if they turned out to be actual. The constraints on these possibilities are those of epistemic content. Any further constraints imposed by subjunctive content are not useful to me. The subjunctive content of my belief that the liquid in thermometers is mercury endorses only those worlds in which thermometers contain the element with atomic number \(x\), but this constraint is so distant that if it turned out that the liquid has atomic number \(y\), I would not be in the least surprised. In an important sense, this constraint is not reflected in my world-model at all. Insofar as my world-model is useful to me in guiding cognition and action, the constraints on it are entirely those of epistemic content.

In making a case for the primacy of epistemic content, I have not appealed to any a priori methodological principles such as the dictum that what governs behavior is in the head. The case for epistemic content has been made directly, independently of questions about physical realization. Indeed, nothing I have said implies that facts about a thinker's environment are irrelevant to the explanation of behavior. Facts about the proximal environment will clearly play an important role insofar as they affect a thinker;[^*] facts about the current environment are crucial to explaining the success or failure of various actions; and facts about environmental history will at least be central to a causal explanation of a thinker's current cognitive state. All that follows from the present framework is that the environment is not relevant to the
The Components of Content

explanation of behavior in virtue of its role in constituting subjunctive content. The kind of content that governs behavior is purely epistemic.

*[[It may even be that in certain cases, epistemic content can itself be constituted by an organism's proximal environment, in cases where the proximal environment is regarded as part of the cognitive system: if a subject's notebook is taken to be part of a subject's memory, for example (see Clark and Chalmers 1998). Here, epistemic content remains internal to a cognitive system; it is just that the skin is not a God-given boundary of a cognitive system. This is another way in which the issue between epistemic and subjunctive content runs deeper than the issue between internalism and externalism.]]

8 Belief Ascription and Psychological Explanation

All this raises a puzzle about the role of belief ascriptions in psychological explanation. If what has gone before is correct, the kind of content that governs cognition and action is epistemic content, which is narrow. But at the same time, there is strong evidence that the kind of content attributed by belief ascriptions is often wide. Does this mean that the common-sense framework of explanation of behavior in terms of belief ascription should be discarded? Alternatively, is the success of the common-sense framework evidence that something in these arguments has gone badly wrong?

Neither conclusion is justified. The present framework shows how it can at once be true that (1) belief ascriptions ascribe wide content, (2) narrow content governs action, and (3) belief ascriptions explain action. In short: belief ascriptions ascribe a combination of epistemic and subjunctive content. It is in virtue of the subjunctive component that the ascribed content is wide, and it is in virtue of the epistemic component that the ascribed content is explanatory.

A full justification of this answer requires two things. First, we need an analysis of what is attributed in belief ascriptions, so that we can see precisely what sorts of epistemic and subjunctive content are attributed. Second, we need an analysis of the role of belief ascriptions in psychological explanation, so that we can see that even in ordinary practice, it is the epistemic content attributed that carries the explanatory burden. I cannot provide anything like a complete treatment of these matters — the analysis of belief ascriptions deserves entire volumes of its own — but I can provide a preliminary sketch.

It is easy to see that ordinary belief ascriptions ascribe both epistemic and subjunctive content. If I say 'Ralph believes that Clark Kent is muscular', then in order for my utterance to be true, Ralph must have a belief that satisfies two sorts of constraints. First, the belief must have the subjunctive content of the proposition that Clark Kent is muscular (perhaps we can allow a certain amount of variation in the subjunctive content, if for example his concept of muscularity is slightly different from the norm). But that alone is not enough: a belief that Superman is muscular would have the same subjunctive content, but would not make my ascription true. As is often noted (e.g. Schiffer 1990), for the ascription to be true, the belief must involve a concept that refers to its object (Clark Kent) under an appropriate mode of presentation.[*]

*[[Some views (e.g. Salmon 1986) take ascriptions such as 'Lois believes that Clark can fly' to be strictly speaking true, so...]]
that modes of presentation are irrelevant to truth. Even if these highly counterintuitive views are accepted, the current
account can be viewed as an account of the (pragmatic) intuitive correctness conditions of belief ascriptions. Either way, we
need an account of these intuitive correctness conditions to explain the function of belief ascriptions in psychological
explanation.]

In the current framework, modes of presentation are naturally seen as epistemic intensions. If Ralph
refers to Clark Kent under an epistemic intension that picks out whoever is called 'Clark Kent', or one
that picks out whoever is that reporter with glasses at the Daily Planet, or some more complex intension
in the vicinity, my belief ascription will be true. If Ralph refers to Clark Kent under an epistemic
intension that picks out the guy in the cape, or one that picks out the strongest man in the world, my
belief ascription will be false. One might say that for the ascription to be true, Ralph must refer to Clark
Kent under a 'Clark Kent'-appropriate epistemic intension. Here, the conditions on a 'Clark Kent'-
appropriate epistemic intension are somewhat vague and unclear, and they may well be context-
dependent, but it is clear from an examination of cases that they are substantive.

To take another case, if I am right in saying 'Tom believes that he is hungry', then Tom must have a
belief with more or less the appropriate subjunctive content, true of all those worlds in which Tom is
hungry at time \( t \). But there is also a strong constraint on epistemic content. In particular, Tom must refer
to himself via the epistemic intension that picks out the individual at the center in every scenario. If he
sees someone in the distance clutching their belly, without realizing that he is in fact looking into a
mirror, then a thought that that person is hungry has the right subjunctive content, but on the most natural
reading it does not make my ascription true. The ascription will only be true if Tom's belief refers to
himself under a self-concept, which requires a very specific sort of epistemic content. One might say that
here, Tom must refer to himself under a 'he'-appropriate epistemic intension, where in context the only
'he'-appropriate epistemic intension is the purely indexical intension.

The general principle here is something like the following. A belief ascription 'x believes that S' is true
when the ascribee has a belief with the subjunctive intension of S (in the mouth of the ascriber), and with
an S-appropriate epistemic intension. Here, the epistemic intension is usually much less strongly
constrained than the subjunctive intension. The conditions on S-appropriateness may well be complex
and context-dependent; their precise nature is one of the hardest questions in the theory of belief
ascriptions. Still, one can make a few generalizations. Much of the time, an epistemic intension that is
not too different from the ascriber's will be S-appropriate, and much of the time, an epistemic intension
that involves the terms in S itself will be S-appropriate. But this does not yield any sort of general
condition. Rather, the appropriateness-conditions are best revealed by careful investigation of judgments
of the ascription's truth in specific cases involving various different epistemic intensions.

In effect, this yields truth-conditions on belief ascriptions that parallel those of what Schiffer (1992) calls
a "hidden-indexical" theory of belief ascription (although I have remained neutral on the ascriptions' logical form), with epistemic intensions playing the role of modes of presentation.[*] If something like
this is correct, then epistemic intensions yield a solution to Schiffer's "mode of presentation" problem.[*]
Epistemic intensions are perfectly suited to satisfy what Schiffer (1990, p. 252) calls "Frege's constraint" on modes of presentation: roughly, that a rational person may both believe and disbelieve that y is such-
and-such only if the two beliefs involve different modes of presentation of $y$. If "rationality" is interpreted to involve idealized a priori reasoning, then the satisfaction of this constraint follows from the fact that epistemic intensions reflect a priori connections between thoughts.

*[[See also Crimmins 1991 and Richard 1990. Many of the insights of these and other philosophers on the semantics of belief ascription should be straightforwardly adaptable to the present framework.]]

*[[This sort of possibility is not mentioned in Schiffer's (1990) otherwise thorough survey of potential modes of presentation.]]

We can apply this to the case of Pierre, and the ascriptions 'Pierre believes that London is pretty' and 'Pierre believes that London is not pretty.' To satisfy these ascriptions, Pierre must have beliefs with the specified subjunctive intension, referring to London under a 'London'-appropriate epistemic intension. Pierre's London and Londres concepts have different epistemic intensions, but both intensions are 'London'-appropriate. So by virtue of his belief Londres is pretty, Pierre satisfies the first ascription, and by virtue of his belief London is not pretty he satisfies the second. Before, we explained Pierre's beliefs by noting that his two beliefs have contradictory subjunctive intensions but compatible epistemic intensions, where only the latter is relevant to rationality. Now, we can explain the apparent contradiction in the belief ascriptions by noting that two different epistemic intensions can both be 'London'-appropriate, so the two ascriptions do not in fact ascribe a rational contradiction to Pierre.[*]

*[[So Kripke's "Principle of Non-Contradiction" is false: someone can rationally believe that S and believe that not-S, as long as the beliefs involve different epistemic intensions both of which satisfy the appropriate constraints.]]

We have seen that content decomposes naturally into epistemic and subjunctive content; we now see that belief ascription puts strong constraints on both. Ideally, a full theory of belief ascription will specify the nature of these constraints for any given ascription, telling us the conditions that beliefs' epistemic and subjunctive contents must satisfy in order to make the ascription true. We can think of a belief ascription as marking out a subspace in the space of ordered pairs of epistemic and subjunctive content.

Given that epistemic content governs action, it follows that if belief ascriptions are to causally explain action, it must be in virtue of the epistemic content ascribed; the subjunctive content ascribed is redundant to the explanation. To make this case properly requires examining many specific cases, but the general point can be straightforwardly illustrated. One way to see the primacy of epistemic content is to consider belief ascriptions involving empty names, such as 'Santa Claus'. These ascribe no nontrivial subjunctive content, but ascription of beliefs about Santa Claus seem to function in precisely the same way in the explanation of action as do ascriptions of beliefs about real people. We might explain Karen's agitation on Christmas Eve in terms of her belief that Santa Claus is coming, that he will not fit down the chimney, and so on. Santa's non-existence and the corresponding absence of subjunctive content make little difference to the success of such an explanation. What governs Karen's actions are her notions of Santa Claus; and what governs the success of the explanation is the epistemic content that these ascriptions ascribe to her. This is a typical case of the role of belief ascriptions in explanation: even when
non-trivial subjunctive content is ascribed (as when the referent of the name exists), it makes little
difference to the patterns of explanation.

In a very wide variety of cases in which content explains action, we can see that the explanation succeeds
even if the subjunctive content attributed is ignored. For instance, if we explain my opening the
refrigerator in terms of my belief that there is water in the refrigerator and my desire for a glass of water,
we never need to invoke the H2O-involving subjunctive content. The explanation gains sufficient
purchase from the epistemic content ascribed alone — roughly, the content that there is some of the
liquid with the appropriate properties in the refrigerator, and that I want some of that liquid, and so on.[*]

*I leave aside here the important question of the epistemic content of desires, and the semantics of desire attributions.
On my view, the epistemic content of a desire cannot in general be represented by a simple intension. Rather, it is a sort of
two-dimensional intension that can endorse a different set of worlds depending on which scenario is actual. This is clearest
in cases such as "I wish I were two inches taller" or "I want to be over there". The moral is that the content of desires is
perhaps more deeply two-dimensional than the content of beliefs.]

It might be objected that there are cases in which the constraints on the epistemic content ascribed by a
belief ascription are weak, so that subjunctive content must be doing any explanatory work. I think that
ascriptions putting weak constraints on epistemic content are rare, but let us assume they can occur:
perhaps an attribution of a belief about Smith constrains the relevant epistemic intension very little.[*]
Even so, if we look at explanatory practice, we see that epistemic content is still doing the real work. For
example, perhaps we explain why Bev goes to the pub by saying that she wants to see Smith and believes
that Smith is at the pub. Leaving aside constraints in the concepts of seeing, the pub, and so on, there is a
constraint on epistemic content implicit in the 'Smith' attributions. It is implicit here that the two 'Smith'
concepts in Bev's thoughts have the same epistemic intensions. If her belief and her desire had very
different epistemic content associated with 'Smith' — perhaps she wants to see Batman and believes that
Smith is at the pub, not knowing that Smith is Batman — the inference from those states to her action
would fail. So there is a strong joint constraint on epistemic content: despite a lack of constraint on the
individual beliefs, Bev is implicitly ascribed the belief that a person she wants to see is at the pub. It is
this ascribed belief that is doing the real explanatory work, and this ascription clearly puts a heavy
constraint on epistemic content. To make the case that all such examples can be similarly analyzed
requires a detailed treatment, but this illustrates the general pattern.

*[[How should one analyze so-called de re belief attributions, of the form 'S believes of x that it is F'? In the current
framework, one might adopt the proposals of Kaplan 1967 and Lewis 1979 by holding that such an ascription is true when
S has a belief with the appropriate subjunctive intension, true in worlds where A has property P, where A is the referent of
'x' and P of 'F', and when the belief involves a concept that picks out A under a de-re-appropriate epistemic intension.
Here, a de-re-appropriate intension is one that entails acquaintance: this requires that in any scenario in which the
intension yields an extension, the subject at the center is acquainted (in the contemporary non-Russellian sense) with this
extension.]]

It follows that the centrality of narrow factors in the causation of action need not overthrow the role of
belief ascriptions in explaining behavior, as some (e.g. Stich 1983) have suggested it should. At most we
have shown that belief ascriptions are a somewhat rough-edged tool: they wrap both components of content into a single parcel, bringing the idle subjunctive content into play alongside the epistemic content that does all the work. But this should not surprise us; we cannot expect a folk theory to be maximally efficient.[*]

[[Why is subjunctive content ascribed at all? I think the reasons are tied to language. First, we ascribe beliefs in the same language we use to describe the world, and when we use world-involving language to ascribe epistemic content, world-involving constraints come along naturally in the package. Second, subjunctive content is important to understanding the success of communication and of collective action. When I tell you that I have a cold, you acquire a thought whose epistemic content is different from mine, but whose subjunctive content is the same. Communication very frequently involves transmission of subjunctive content, and our collective cohesion (if not our individual actions) can often be understood in terms of shared subjunctive content. But both of these points deserve a much more extensive development.]]

In moving from common-sense psychology toward a developed cognitive science, we might expect that the kind of content that is invoked will become more purely epistemic, and that subjunctive content will be relegated to a secondary role or dropped entirely.[*] We might also expect that better tools will be developed to specify the epistemic contents of thoughts than the current rough-and-ready language of belief ascription. This might qualify as a revision of our folk notion of belief, emphasizing and refining the elements of epistemic content that are already present within it. But precisely because those elements are already present and playing a central role in our practices, such a development would fall well short of elimination.

[[It is arguable that cognitive psychology is already mostly concerned with epistemic content rather than subjunctive content, insofar as it is concerned with content at all. For example, the psychological literature on concepts seems to be largely concerned with how concepts are applied to the actual world, concentrating on something like the epistemic intensions of the concepts involved. See Smith and Medin 1981 and Patterson 1991.]]

9 Connections and Objections

The framework outlined here is related to a number of existing proposals. There is a clear structural resemblance to other broadly two-dimensional frameworks, such as proposals by Kaplan (1989) and Stalnaker (1978) for analyzing the content of language, and proposals by White (1982) and Fodor (1987) for analyzing the contents of thought. The idea that this sort of proposal can be used to yield a sort of narrow content has been criticized by Block (1991), Stalnaker (1989; 1990), and others, and extended to an earlier version of the present proposal by Block and Stalnaker (1999). So we need to examine the relationship between these proposals, to see whether the criticisms apply. I think that on examination, the current framework differs in fundamental respects from the others, so that their problems do not arise here.

The relationship can be brought out by contrasting epistemic intensions with contextual intensions. A thought's contextual intension is defined by the heuristic discussed earlier: T is true in a centered world W (with T present at the center) if T is true as thought at the center of W. Likewise, the contextual intension of a concept C will return C's extension in worlds with C at the center. (One can define...
contextual intensions for sentences and other linguistic expressions similarly.) There are various possible variations here: one might have different requirements for what counts as a token of T in a world, or one might require only a token of T's type (for some relevant type) rather than T itself. But however one does things, the centered worlds here are functioning as contexts in which a thought (or concept) occurs, and a contextual intension encapsulates the context-dependence of a thought's truth-value or a concept's extension.

As we saw before, contextual intensions are quite different from epistemic intensions. An obvious difference: epistemic intensions give no special role to thought tokens within a scenario, and can be evaluated in scenarios without any such tokens at the center. Thus the epistemic intension of *I am a philosopher* can be true at a scenario regardless of what the being at the center is thinking. A thought such as *someone is thinking* has an epistemic intension that is plausibly false at some centered worlds (e.g., those without any thoughts), although its contextual intension (on a natural understanding) is true at all centered worlds in which it is defined. A deeper difference: where contextual intensions represent context-dependence, with centered worlds representing contexts of thought, epistemic intensions represent epistemic dependence, with centered worlds representing epistemic possibilities. This is a very different conception, and yields quite different behavior. The frameworks of Kaplan and Stalnaker illustrate this. Kaplan defines the character of a linguistic expression type as a function from a context of utterance to the expression's content (roughly, subjunctive intension) relative to that context. In some ways this resembles the two-dimensional intension discussed above (in effect a function from centered worlds to subjunctive intensions), but the underlying ideas and resulting behavior are quite different. For example, on Kaplan's framework names such as 'Hesperus' and 'Phosphorus' have identical characters, picking out the same content in all contexts. This happens because the referent of a name is essential to that name, so any use of the name in any context will have the same referent. For this reason, Kaplan notes that his framework cannot provide a solution to Frege's puzzle in the case of names, natural kind terms, and the like. But as we have seen, the epistemic intension associated with a subject's use of a name behaves very differently, often picking out different individuals in different centered worlds (whether a name has its referent essentially is irrelevant on a non-contextual understanding), and holds out much more hope of dealing with Frege's puzzle.

Stalnaker defines the diagonal proposition of an expression token as a function from a world containing the token to the truth-value of the proposition that the token expresses in that world, as evaluated in that world. This bears a formal resemblance to an epistemic intension, which can be seen as equivalent to the diagonal of a two-dimensional intension. But again, the underlying ideas and resulting behavior are different. On Stalnaker's framework, the diagonal proposition of an expression is defined at worlds where it has a very different meaning. At a world where 'water is solid' means that snow is white, for example, the diagonal proposition of 'water is solid' will be true if snow is white in that world. This is quite different from an epistemic intension: if my usage is nondeferential, the use of terms such as 'water' in a scenario will be irrelevant to epistemic intensions. Stalnaker (1999) notes that because of this, diagonal propositions are not closely connected to a priori truth. This seems correct, but the problem does not generalize to epistemic intensions, which have a built-in connection to a priori truth.

White (1982) and Fodor (1987) generalize these analyses to the contents of thought. Fodor defines the
narrow content of a thought as a function from a context of thought to a thought's (wide) content in that context. White does something similar, although his account is slightly more complex and he requires that a functional duplicate of the original thinker be present in the relevant context. As before, these proposals are based on context-dependence, and give results that differ correspondingly: witness the intensions of *I am a philosopher* and *someone is thinking.*[*]

*[[Related proposals for understanding narrow content in broadly contextual terms are given by Brown 1986 and Loar 1988.]]

Block (1991) gives a number of objections to proposals of this sort. White's proposal is subject to a charge of holism: no two different subjects can have thoughts with the same narrow content, unless they are functional duplicates. Further, it seems that the narrow contents of a subject's thoughts all change every time the subject acquires a new belief, or indeed every time that anything happens in the mind of the subject. This problem does not apply to epistemic intensions. There is no problem with quite different thinkers having thoughts with the same epistemic intension: for example, very different people can have *I am a philosopher* thoughts with the same epistemic intension. Further, epistemic intensions will not usually change with the acquisition of new beliefs. A change in epistemic intension requires a change in a subject's rational pattern of judgments about scenarios considered as actual: a change in belief may change the subject's judgments about which scenarios are actual, but it will not usually change a subject's rational judgment about what will be the case if a given scenario is actual. It may be that epistemic intensions sometimes drift over time, or that corresponding thoughts of different thinkers sometimes have different epistemic intensions, but this falls well short of a general holism.

Block charges Fodor's proposal with underdetermination: it is left unclear how to evaluate the mapping across worlds. The main problem is that of "what is held constant". That is, to know which worlds fall in the domain of the intension, one needs to know just what features of the original thought must be present in the thought token at the center. If only a sort of mental syntax is held constant, the result will be an intension that delivers wildly varying results across worlds: there will be worlds where the mapping for *water* picks out steel, if a token with that mental syntax has a different meaning. If extension is held constant, then the intension will be trivial: the mapping for *water* picks out H2O in all worlds. For better results, one might suggest that the token's narrow content be held constant, but that presupposes what we are trying to explain. So it seems very difficult to set things up so that the mapping yields a notion of narrow content that behaves in an appropriate way.

Again, epistemic intensions do not have this problem. There is no issues concerning what to "hold constant" across worlds here, since there is no need for the original token to be present in different worlds. Rather, we simply appeal to the original thought, and to its epistemic relations with the hypothesis that a given world is actual. These epistemic relations are well-defined, being grounded in the idealized rational judgments of the subject. They also do not presuppose any theoretical notion of narrow content; but they can be used to ground such a theoretical notion.

Fodor himself (1987, p. 50) raises the problem that his sort of narrow content is not semantically
evaluable (for truth and falsity), and so is not really content; rather, it is just potential content, delivering a content in a context. (He later rejects narrow content for this reason.) Again, epistemic content is immune to this problem. An epistemic intension is a sort of first-order content, placing direct constraints on the world, with truth-conditions of its own. Epistemic intensions can also stand in semantic relations such as entailment, and can be analyzed using semantic frameworks involving possible worlds, which allows for significant explanatory power.

Stalnaker (1990) considers the idea that some version of his diagonal proposition (or "realization conditions") might yield an account of narrow content, and raises three criticisms. First, he suggests that we cannot identity a thought independently of its content, so we cannot ask what the content of a belief would have been had it been a belief on twin earth. Second, he notes that diagonal propositions are defined only in worlds containing the relevant thought token, and cannot easily be extended to worlds without the thought token. Third, he notes that on this proposal narrow content is derivative on wide content (since a diagonal proposition is defined using a two-dimensional matrix which is defined using wide content), so it presupposes rather than explains wide content. In response, it is fairly clear that the first two objections apply only to contextually defined narrow content, and not to epistemically defined narrow content. On the epistemic proposal, we never need to ask what the content of a belief would have been if it had been a belief on twin earth, and narrow content is defined in a straightforward way at worlds that do not contain the relevant thought token.

In discussing his second objection, Stalnaker raises a case that is worth addressing. If Bert uses his semantically deferential concept to think my father has arthritis in his thigh, how can we evaluate this thought in a world in which there is no word 'arthritis' in Bert's language, and in which Bert has no thoughts about his father's health? On the epistemic framework, it is most natural to say that the epistemic intension of Bert's arthritis concept picks out nothing in this world. In effect, the use of a semantically deferential concept presupposes that one lives in a community that uses the relevant term, just as a notion such as The present king of France presupposes that there is a king of France. If I discover that those assumptions do not hold in my actual scenario, it is reasonable to judge that my thoughts involving these concepts lack truth-value. The same goes for alternative scenarios. In Bert's case, the epistemic intension of his thought is indeterminate in the relevant worlds. In effect, Bert's thought partitions the space of scenarios in which the background assumptions are satisfied, and says nothing about those worlds in which the assumptions are false.[*]

*[[ Other concepts whose epistemic intensions have a limited domain of determinacy include perceptual demonstratives. When I think something like That is pretty, the referent of my demonstrative is often picked out (very roughly) as the cause of such-and-such experience. In a centered world in which there is no appropriate experience at the center, the epistemic intension may lack truth-value. This raises another subtlety: to capture the content of perceptual demonstratives, one may need to build in a "marked" experience to the center of the class of actual-world candidates, as one builds in a marked individual and time. Building this into the center will sometimes be needed to secure reference to otherwise indistinguishable experiences and their perceptual objects, as with (perhaps) a speckle in a large field, or one of the symmetrical red spots in Austin's (1990) "Two Tubes" puzzle (to which the present framework then provides a solution). In certain cases, centers may also require more than one experience, and perhaps a marked thought ("this very thought"). One might suggest that the contents of a center involve objects of "unmediated" reference: oneself, the present moment, the current thought, and perhaps certain experiences and orientations. This matter is closely connected to Russell's
suggestions about direct reference; I hope to explore it in more depth elsewhere (see also Chalmers 2002c).

As for Stalnaker's third objection: narrow content may be derivative on wide content on the diagonal understanding, but not on the epistemic understanding. Epistemic content can be defined quite independently of subjunctive content, and our definition of epistemic intensions makes no appeal to subjunctive evaluation. For this reason, an epistemic intension is not fundamentally a diagonal intension. After the fact, one can see an epistemic intension as equivalent to the diagonal of a two-dimensional intension involving both epistemic and subjunctive notions; but this complex construction is quite unnecessary to define epistemic intensions. One can characterize the first dimension of the framework in entirely epistemic terms, independently of the second dimension.

If any sort of content is derivative in the current framework, it is wide content. We have already seen that the subjunctive intension of a concept is determined by the epistemic intension in conjunction with the environment. In some cases it is a near-copy of the epistemic intension, as for simple descriptive concepts; in other cases it is determined by rigidifying the actual-world extension of the epistemic intension. By contrast, we can tell the entire story about the epistemic intension without ever involving the subjunctive intension. It therefore seems that if either intension is more fundamental, it is the epistemic intension. Still, there is no need to make too strong a claim here: both epistemic and subjunctive content are important, and both have a role to play in different domains.

Block and Stalnaker (1999) give a number of objections to the version of this framework put forward in Chalmers (1996). Many of these objections echo the objections above, and turn on interpreting the proposal via a contextual rather than an epistemic understanding. Another objection is that the formal two-dimensional apparatus alone does not yield intensions with the relevant properties. This is clearly correct; but on my approach it is a substantive characterization of the intensions, not just the formal apparatus, that yields the properties in question. Block and Stalnaker also argue that the two-dimensional approach cannot explain or ground a notion of a priori truth. I have not suggested that the framework can do this; rather, I have used the notion of apriority in defining the framework. The notion of apriority, and the specific uses of it in grounding the framework, can be defended on quite independent grounds. The use of apriority in capturing the dependence of judgments about extension and truth-value on sufficient information about the world is defended at length by Chalmers and Jackson (2001).

The current proposal also bears a resemblance to "descriptive" accounts of narrow content. It has sometimes been suggested that the narrow content of a concept such as water corresponds to the content of an associated description such as 'the dominant clear drinkable liquid in the environment', or some such. In response, a number of philosophers (LePore and Loewer 1986; Taylor 1989; White 1982) have...
objected that even if such descriptions exist, terms such as 'liquid' are themselves susceptible to Twin Earth scenarios (e.g., where liquids are replaced by superficially identical masses of sand), so that the content of such a description is wide rather than narrow. One might think that this objection will apply to the present proposal, since I have used descriptions of this sort to characterize epistemic intensions. But importantly, the description merely provides a rough handle on the intension for the purposes of illustration. The real narrow content is a function from scenarios to extensions, and can be characterized fully only by specifying its value at specific scenarios. As soon as we move to a summarizing description in language, imperfections are introduced, and the narrowness of the content is impurified. But the intension itself remains narrow; we should not mistake the linguistic description for the real thing.[*]

*[[This might suggest that epistemic content is "ineffable". But the real problem is simply that it is difficult to capture the epistemic content of one expression with the subjunctive content of another. Just as one can capture the subjunctive content of a concept such as water by appealing to the equivalent subjunctive content of an expression such as 'H2O', one might capture its epistemic content by appealing to the equivalent epistemic content of an expression such as 'the clear, drinkable liquid...'. It is hard to see why the second is any more objectionable than the first, or why it makes epistemic content any more "ineffable". Thanks to Frank Jackson for discussion on this point.]]

One would obtain a more closely related sort of "description" theory of epistemic content if one abstracted away from linguistic characterizations and regarded the relevant "descriptions" simply as properties that a referent must satisfy, or better, as relations to the thinker. If we speak merely of properties and relations, the linguistic contamination is avoided. Schiffer (1978) suggests a description theory of this sort, on which there is irreducibly de re reference by a thinker to himself or herself, with reference to everything else mediated by a property or relation. If we map the irreducible self-reference here to the appeal to centered worlds, and map the properties and relations to epistemic intensions, the resemblance between the accounts is clear, although Schiffer does not appeal to a two-dimensional framework, and addresses his proposal largely to the question of accounting for de re thought.

Another closely related idea is Lewis's (1979) proposal that belief involves the self-ascription of a property. The set of individuals satisfying a property corresponds directly to a class of centered worlds, as Lewis notes. Lewis (1994) argues that this sort of content is narrow and is primary in explanation. In effect, Lewis advocates a one-dimensional view of content, where apparent wide content is an artifact of belief ascriptions. While Lewis does not advocate understanding these contents in epistemic terms, and does not give a general characterization of the set of worlds associated with a belief, his examples suggest that these sets of worlds closely resemble those of an epistemic intension. So the present proposal appears to be highly compatible with Lewis's framework.

A residual problem for the present account is the problem of hyperintensionality. It seems that two beliefs — mathematical beliefs, for example — can have the same epistemic and subjunctive intensions, while nevertheless having intuitively different content, and playing quite different roles in cognition and action. To handle these issues, one needs a more fine-grained sort of epistemic content that goes beyond epistemic intensions as I have defined them. One might appeal to intensions over a more fine-grained space of epistemic possibilities, defined using a more demanding epistemic necessity operator that requires more than mere apriority (see Chalmers forthcoming b for some ideas here).[*] One might also
The Components of Content

appeal to a more basic sort of content that lies behind and determines an epistemic intension. Epistemic and subjunctive intensions are aspects of the contents of thoughts, but I have not suggested that they exhaust these contents. The nature of a complete characterization of thought contents, if such a thing can be given, remains an open question.

[[For example, one might hold that a thought is (non-ideally) epistemically necessary when it is trivial, in a sense to be elucidated. One could then use this notion to set up a more fine-grained epistemic space of non-ideal epistemic possibilities, and could then associate concepts and thoughts with non-ideal epistemic intensions over this space. Then two concepts or thoughts that are nontrivially a priori equivalent will have the same epistemic intension as defined in the paper, but different non-ideal epistemic intensions as defined here.]]

Another open question: is it possible to reductively explain the epistemic content of a subject's thoughts in naturalistic terms, in the way that some have attempted to explain wide content in causal or teleological terms? Certainly no such explanation is currently available. A first attempt might exploit the idea that epistemic content is mirrored in the idealized rational dispositions of the subject: perhaps a subject's actual dispositions will yield epistemic content by idealization? The normative character of the idealization may pose an obstacle to reduction, however, as will the fact that these dispositions are themselves characterized by appeal to content. My own view is that epistemic content is ultimately determined by a combination of a subject's functional organization and phenomenology.[*] If so, any attempt at explanation will need to appeal to these factors. In any case, it is arguable that if wide content depends heavily on narrow content, as the current account suggests, any adequate reductive theory of wide content will require a reductive theory of narrow content first.[*]

[[For an argument that phenomenology is essential to the epistemic content of at least some concepts, see Chalmers 2002c. See also Horgan and Tienson (this volume, chapter 49) for arguments for phenomenally constituted narrow content that can be seen as complementing the current approach.]]

[[Arguably, contemporary causal theories of content have been unsuccessful precisely because they attempt to account for wide content directly, without taking into account the crucial epistemic dimension involved in its determination.]]

10 Conclusion

What of the six puzzles at the start? To summarize:

(1) A thought's content decomposes into epistemic and subjunctive content, given by its epistemic and subjunctive intensions. Oscar's and Twin Oscar's thoughts differ in their subjunctive contents, and as a result ground different belief ascriptions, but their epistemic contents are the same.

(2) My thoughts that Hesperus is Hesperus and that Hesperus is Phosphorus have the same subjunctive intension but distinct epistemic intensions, as the Hesperus and Phosphorus concepts have different epistemic intensions. The triviality of the former does not imply the triviality of the latter, as it is epistemic content that governs rational relations.
The Components of Content

(3) Pierre's two beliefs have contradictory subjunctive intensions but compatible epistemic intensions. The apparently contradictory belief ascriptions arise because of the contradictory subjunctive intensions and because his two concepts of London have distinct epistemic intensions that can each make 'London'-involving belief ascriptions true. Rationality is governed by epistemic intensions, so there is no rational contradiction here.

(4) The essential indexicality of belief reflects the fact that epistemic content, not subjunctive content, governs action, and that epistemic content, unlike subjunctive content, is an indexical centered intension.

(5) The modes of presentation central to a theory of belief ascription are epistemic intensions. Belief ascriptions specify a believer's subjunctive content, and constrain the believer's epistemic content.

(6) Instances of the contingent a priori have a necessary epistemic intension but a contingent subjunctive intension. One's cognitive world-model is constrained by epistemic content, not by subjunctive content; so a contingent subjunctive intension does not indicate a cognitive achievement.

There are many problems about the contents of thought that are not resolved by this framework. These include the problems of hyperintensionality, of a full account of belief ascriptions, and of giving a naturalistic explanation of content. Some of these matters are likely to be much more difficult than the puzzles at issue in this paper, but the two-dimensional approach at least clarifies the lay of the land.

Acknowledgments

Thanks to too many people to mention, but especially Ned Block, Curtis Brown, Frank Jackson, David Lewis, Mark Sainsbury, Robert Stalnaker, and two reviewers. Thanks also to audiences at talks between 1994 and 1997 at Arizona, Cornell, Memphis, Princeton, Rice, UCLA, UC Santa Barbara, UC Santa Cruz, Washington University, Yale, and the Australasian Association of Philosophy. For comments on the revised version, thanks to Torin Alter, Chris Evans, Brie Gertler, and Daniel Stoljar.

1 Introduction

Here are six puzzles about the contents of thought.[*]

[*][For background material on the six puzzles, see: (1) Putnam 1975, Burge 1979; (2) Frege 1892; (3) Kripke 1979; (4) Perry 1979; (5) Schiffer 1990; (6) Kripke 1980.]

(1) Is content in the head? I believe that water is wet. My twin on Twin Earth, which is just like Earth except that H2O is replaced by the superficially identical XYZ, does not. His thoughts concern not water but twin water: I believe that water is wet, but he believes that twin water is wet. It follows that that what a subject believes is not wholly determined by the internal state of the believer. Nevertheless, the cognitive similarities between me and my twin are striking. Is there some wholly internal aspect of content that we might share?

(2) Frege's puzzle. The thought that Hesperus is Hesperus seems to express the same proposition as the thought that Hesperus is Phosphorus, but the former is trivial and the latter is not. How can this difference in cognitive significance be reflected in a theory of semantic content?

(3) Kripke's puzzle. In France, Pierre is told that "Londres est jolie", and he believes it. Later, he arrives in London and thinks it is ugly, never suspecting that "London" and "Londres" name the same city. It seems that Pierre simultaneously believes that London is pretty and that London is not pretty. But Pierre is highly rational, and would never believe a contradiction. What is going on?
(4) **The problem of the essential indexical.** When I believe that I am in danger, I will take evasive action. This belief state seems to be essentially indexical, or self-directed; if I merely believe that \( x \) is in danger, where \( x \) happens to be me, I might do something else entirely. How can we square this indexical aspect with a propositional account of the contents of thought?

(5) **The mode-of-presentation problem.** If Jimmy says "Lois believes that Superman can fly", he speaks truly. If he says "Lois believes that Clark Kent can fly", he speaks falsely. But on many accounts, the proposition that Clark Kent can fly is the same as the proposition that Superman can fly. If so, it seems that to believe that Clark Kent can fly, it is not enough to believe in the corresponding proposition; one must believe it under an appropriate mode of presentation. But what is a mode of presentation, and how can these be integrated into an account of belief ascription?

(6) **The contingent a priori.** Say it is stipulated that one meter is the length of a certain stick in Paris. Then one knows *a priori* that the stick is one meter long, if it exists. But the corresponding proposition is contingent, as the stick might have been longer or shorter. How can one have *a priori* knowledge of the truth of a contingent proposition?

These puzzles are not unrelated. All of them suggest an incompleteness in a propositional view of thought content, on which the content of a belief that \( P \) is identified with the conditions under which \( P \) is true, or with some other version of the content of the proposition that \( P \). In particular, most of them raise questions about how well a propositional account of thought content reflects *rational* or *cognitive* aspects of thought. Because a thought's propositional content is strongly tied to the external objects of the thought, a propositional account seems to have trouble capturing the rational relationships between thoughts (as witnessed by puzzles 2, 3, and 6), and their role in guiding cognition and action (as witnessed by puzzles 1 and 4).

To resolve these and other puzzles, many have postulated a separate internal dimension of content - so-called "narrow content" - that is more closely tied to cognition and action. But the road from intuition to theory has been a difficult one, and no account of narrow content has yet gained widespread acceptance. Perhaps the greatest difficulty is that because narrow content is internal, it seems to lack the sort of relation to the external world that is required to qualify as content. Many have thought that narrow content is not the sort of thing that can be true or false, for example, as the Twin Earth cases show us that truth-conditions are not determined internally.

*[[Arguments for narrow content can be found in Fodor 1987, Lewis 1994, Loar 1988, and White 1982.]]*

*[[Even supporters of narrow content have often conceded this point: e.g. Fodor 1987, Block 1988.]]*
I think that these problems are illusory, and that there is a robust and natural notion of narrow content such that narrow content has truth-conditions of its own. This can be seen by developing the insight, implicit in much contemporary work in the philosophy of mind and language, that content is two-dimensional. It turns out that the content of a thought can be decomposed into two components: its notional and relational content. Relational content is the familiar external variety of propositional content. Notional content is the additional component, with the following properties: (1) it is determined by the internal state of a cognitive system; (2) it is itself a sort of propositional content, with its own truth-conditions; (3) it governs the rational relations between thoughts. The first property ensures that notional content is a variety of narrow content. The second ensures that it is a truly semantic variety of content. The third ensures that it is central to the dynamics of cognition and action. These three properties together, placed within the two-dimensional framework, allow many problems in the philosophy of mind and language, including the six puzzles above, to be straightforwardly resolved.[*]

[[The framework I outline was suggested by a reading of Kripke 1980 and Putnam 1975, but it has much in common with other existing ideas in the philosophy of mind and language that I will point to along the way. Most obviously there is a clear relationship to the two-dimensional accounts of the semantics and pragmatics of language given by Kaplan (1989) and Stalnaker (1978), but there are deep links to many other ideas besides. I hope that it is a virtue of the present proposal that it suggests direct links between ideas that might at first glance seem only distantly related.]]

2 Primary and Secondary Intensions

In what follows, an intension is a function over the space of possible worlds, taking a world as argument and returning an entity in that world. A centered world is a possible world with a marked individual and time (the "center" of that world).[*] W and W^* are the spaces of possible worlds and centered worlds respectively, and R is the space of entities in those worlds. A concept, pre-theoretically, is an element of a specific thought, of the sort that is an appropriate candidate for reference - that is, it either refers or has empty reference. (Note that a concept is a token rather than a type, tied to a specific thinker on a specific occasion.) A concept, in thought, is the analog of a term in language. For ease of exposition I will restrict attention to concepts that are associated with terms in the thinker's language ("I", "water", "arthritis"), but the account can be easily extended to concepts without linguistic counterparts.

[[This notion is introduced by Quine (1968), who defines a centered world as a world with a marked space-time point. The definition above is due to Lewis (1979).]]

It is a familiar idea that every concept has an associated intension, mapping a possible world to the referent of the concept within that world. It is less commonly acknowledged that there are in fact two intensions associated with a concept, although this point is implicit in much recent work on meaning and reference. It is central to the work of Kripke and Putnam, for example, that there are two ways in which the reference of a concept in a world can depend on that world. First there is a dependency whereby reference is fixed in the actual world, depending on how the world turns out. My concept "water" refers to H2O given that the world has turned out one way, but if it had turned out differently my concept might have referred to XYZ. Second, there is a dependency whereby reference in counterfactual worlds is
determined, given that the actual world is held constant. For example, given that the actual world turns out as it has, my concept "water" picks out H2O in all counterfactual worlds. Corresponding to these two dependencies are two intensions, a concept's primary and secondary intensions.

The primary intension of a concept is a function \( f_1: W^* \rightarrow R \) from centered worlds to referents. At a centered world \( w \), the primary intension returns the referent of the concept in \( w \) when \( w \) is considered as actual - that is, when it is considered as a candidate for the actual world of the thinker. This captures the way the reference of the concept is fixed, depending on how the actual world turns out - that is, depending on which centered world turns out to be the thinker's actual world. We can think of the primary intension as encapsulating what it takes for an entity in the actual world to qualify as the concept's referent.

*[[This phrase is due to Davies and Humberstone (1980). It is a familiar idea from two-dimensional modal logic that statements about possible worlds can be evaluated differently depending on whether the worlds are considered as actual or counterfactual. The basic idea is presented in Evans 1979.]]

To evaluate a concept's primary intension at a centered world \( w \), we can ask as a heuristic: to what would the concept refer, if \( w \) turned out to be actual? For example, if the actual world turned out to contain XYZ as the dominant clear liquid in the oceans and lakes on my planet, then my concept "water" would refer to XYZ. So the primary intension maps the XYZ-world to XYZ. On the other hand, given that the actual world turns out as it has, with H2O in the oceans and lakes, my concept "water" refers to H2O. So the primary intension maps the H2O-world (the real actual world) to H2O.

*[[This is another construction familiar from two-dimensional modal logic (Davies and Humberstone, p. 10), to make explicit the fact that of the various worlds that might turn out to be actual, one of them is actual.]]

An alternative heuristic for determining the primary intensions of one's own concepts (such as "water") is to ask questions analogous to: if \( w \) turned out to be actual, what would it turn out that water is? There is a clear sense of the "turns out" locution on which it is reasonable to say that if the XYZ-world turned out to be actual, it would turn out that water is XYZ; this is the sense that is relevant in the heuristic. (On this reading, "it would turn out that" creates an intensional context even for a rigid designator.) I avoid this locution for the most part, as it can be interpreted in different ways, but once the ambiguity is resolved this heuristic seems quite clear. (In one way it may be better than the heuristic above, as it makes it clearer that the concept itself need not be present in \( w \), as discussed below.)

*[[Sometimes philosophers resist this intensional reading of the "turns out" locution under the influence of Kripke (1980), but the commonsense reading remains viable even once Kripke's main point is granted. Kripke himself (p. 143) allows a sense in which gold could turn out not to have atomic number 79, although he insists that gold could not have turned out not to have atomic number 79. (To my ear, "could have turned out that" sounds ambiguous in a similar way). The notion that it would turn out that water is XYZ if the XYZ-world turned out to be actual is entirely compatible with the claim that water is necessarily H2O. Again, this is simply a commonsense reading of the "turns out" locution, a reading on which it behaves differently from a standard modal locution.]]
*[[One must be careful to ask the question from the personal point of view, rather than from a community's point of view, to handle the cases of semantic deference discussed below. That is, we must adopt the (reasonable) reading of the locution on which I can say truly (in a case where I defer to my community) that if it turned out that the community uses "elm" to refer to X-trees, it would turn out that elms are X-trees.]]

There is often an element of indexicality in the fixation of reference, so the location of a center must be specified for reference in an actual-world candidate to be determined. For example, if it is specified that an actual-world candidate contains both H2O and XYZ on otherwise similar planets, the referent of my concept "water" is undetermined until we specify where in that world my "viewpoint" - the center - is located. This indexicality is most obvious for a concept such as "I", whose primary intension picks out the individual at the center of a centered world. In general, an actual-world candidate is a world-as-I-find-it, marked with a viewpoint at its center.[*]

*[[Actual-world candidates resemble the "contexts of utterance" of Kaplan 1989, although the resemblance is imperfect. Counterfactual-world candidates, discussed below, correspond to Kaplan's "circumstances of evaluation".]]

The primary intension of a concept is determined independently of the concept's actual referent; it must be, as the intension itself specifies the way in which the referent depends on how the world turns out. This is reflected in the a priori thought-experimental methodology in the investigation of primary intensions. Given my concept "Gödel", I can ask (with Kripke): to what would it refer if it turned out that a man named "Schmidt" had proved the incompleteness of arithmetic, before the proof was stolen and published by a man named "Gödel"? Empirical knowledge about the actual world is irrelevant here, as specification of the basic facts about the centered world in question gives me all the facts that could possibly be relevant.

It is a central fact about concepts that for a wide range of actual-world candidates, the referent of a concept in such a world is both determinate and accessible to the thinker. To see this, note that once we know all about the qualitative structure of the actual world and our location within it, we have all the information we need to ascertain the nature and existence of our concepts' referents (think of "Hesperus", "water", "Jack the Ripper"). And if the actual world had turned out differently, we could have done the same. Information about the world's structure and our location within it would have sufficed, in principle, for knowledge of reference. Given this ability, we can do the same in cases of counterfactual speculation about actual-world candidates, provided that we are supplied with the relevant information about those worlds. Indeed, such thought-experiments are the basic currency of the theory of reference. The primary intension of a concept is therefore accessible in principle to the thinker, and accessible prior to investigation of the thinker's external world.

We need not require that an actual-world candidate itself contains a copy of the concept in question. A primary intension specifies what it takes for an entity in the actual world to qualify as the referent of the concept; these conditions of application will often build in no requirements about the presence of the concept itself. In evaluating the referent at an actual-world candidate, we retain the concept from the real actual world. For example, in an actual-world candidate in which the individual at the center is in a coma, the primary intension of my concept "I" (from the real actual world) picks out the comatose individual.
Intuitively, we would say that if this world turned out to be actual, it would turn out that I am comatose, in the same sense in which if the XYZ-world turned out to be actual, it would turn out that water is XYZ. Not all concepts are so straightforward. We will see later that the primary intensions of some concepts are not determinate across all centered worlds, picking out a referent only if certain background conditions are satisfied. All that matters for now, however, is that the primary intension of a concept is a non-trivial partial function, determinate across a large class of worlds.

The secondary intension of a concept is more familiar, but works quite differently. This is a function \( f_2: W \rightarrow R \) from uncentered worlds to referents, returning the referent of the concept in a world when it is considered as counterfactual, given that the actual world has already been fixed. To evaluate the secondary intension of one's concept "water" at a world \( w \), one asks: what is water in \( w \)? The same goes for other concepts, mutatis mutandis.[*] In the case of "water", if we accept the intuitions of Kripke and Putnam, then given that water is H2O in the actual world, water is H2O in all worlds, so the secondary intension of the concept picks out H2O in all worlds. Similarly, if Putnam and Kripke are correct, I am DJC in all counterfactual worlds, so the secondary intension of my concept "I" picks out DJC in all worlds. Note that these counterfactual worlds require no center; in evaluating the secondary intension at a world, the viewpoint of a thinker within that world is irrelevant.

[*][So the rules-of-thumb for determining primary and secondary intensions each have two formulations, depending on whether the concept is mentioned or used. On the "mention" formulation: the primary intension picks out the referent of a concept in \( w \) when it is considered as actual, whereas the secondary intension picks out the referent of a concept in \( w \) when \( w \) is considered as counterfactual. On the "use" formulation, the primary intension picks out what (for example) it would turn out that water is if \( w \) turned out to be actual (where the "turns out" locution is interpreted appropriately), whereas the secondary intension picks out what water is in \( w \).]

Unlike the primary intension, the secondary intension is often determined by a posteriori factors, as it depends on how the world of the thinker turns out. Given that the liquid in the oceans and the lakes in this world is H2O, the secondary intension of my concept "water" picks out H2O in all worlds, but if the liquid had turned out to be XYZ, then the secondary intension would have picked out XYZ in all worlds instead.

The full story about a concept can be summed up in a two-dimensional intension \( F: W^* \times W \rightarrow R \), where \( F(v,w) \) is the referent of the concept in \( w \), if \( v \) turns out to be actual (for \( v \in W^* \) and \( w \in W \)). The primary intension is \( f_1: v \mapsto F(v,v') \), where \( v \in W^* \) and where \( v' \) is the uncentered world obtained by "unmarking" the center of \( v \). The secondary intension is \( f_2: w \mapsto F(a,w) \), where \( a \) is the actual world of the thinker. Because \( f_2 \) depends on \( a \), it is in general accessible only a posteriori. Note that the primary intension and the secondary intension always pick out the same referent in the actual world: \( f_1(a)=f_2(a')=F(a,a') \).

The secondary intension of a concept is usually determined by the primary intension and the actual world, but the way in which it is determined depends on the concept involved. There are a few basic patterns of determination, corresponding to different types of concepts.[*] The simplest case is that of ordinary "descriptive" concepts - perhaps "doctor" and "circle", although semantic intuitions differ - for which the
conditions of application in a counterfactual world are the same as they are in the actual world. For these concepts, the secondary intension is simply a copy of the primary intension, over the space of uncentered worlds: \( f_2(w) = f_1(v) \), where \( v' = w \). This requires \( f_1(u) = f_1(v) \) for all \( u, v \in W^* \) such that \( u' = v' \) - that is, the value of the primary intension at a centered world cannot depend on the position of the center - so the primary intensions of such concepts cannot be in any way indexical. In these cases, the secondary intension is independent of \textit{a posteriori} factors.

*[[I count at least four basic patterns: those for descriptive concepts, rigid designators, natural kind concepts, and semantically deferential concepts. There may be others. The pattern itself is independent of \textit{a posteriori} factors; for example, the fact that we use "water" to pick out in counterfactual worlds whatever has the common underlying structure of the stuff in the actual world (if such a common structure exists) is conceptually prior to investigation of the empirical details. We can think of these patterns as written into the \textit{a priori} two-dimensional structure of a concept.]]

More interesting are cases in which the secondary intension differs significantly from the primary intension, and is determined only \textit{a posteriori}. The most straightforward version of this phenomenon occurs with concepts corresponding to rigid designators, such as indexicals and names. For such concepts, the secondary intension is determined by \textit{rigidifying} the primary intension - that is, by evaluating it at the actual world, and picking out the same referent in all possible worlds. For example, it turns out that the primary intension of my concept "I" picks out DJC at the actual world, so the secondary intension picks out DJC at all worlds in which he exists. A similar dependence, with minor complications, holds for natural kind terms.[*]

*[[Strictly speaking, natural-kind concepts are not rigid designators: "cat" does not pick out the same referent at every world, as there are different cats in each. One way around this is to stipulate that "cat" picks out the property of cathood at every world. Less artificially, we can give a two-stage story according to which "cathood" picks out the same property in each world, and "cat" picks out the objects satisfying the property in that world. Or we might simply say that "cat" picks out the objects with the same underlying explanatory structure as the cats in the actual world. I will ignore these complications in what follows.]]

For rigid-designator concepts, the structure of the secondary intension is easy to characterize, but the structure of a primary intension is generally more complex. Often the best one can do is give a rough summary. For example, it is not too far off the mark to say that the primary intension of my concept "water" picks out the dominant clear, drinkable liquid in the environment that stands in an appropriate causal relation to the center of a world, but this is far from perfect. One can characterize the primary intension more carefully by considering difficult cases (what would the referent be if there was both XYZ and H2O in the lakes? what would it be if the liquid that falls from the sky turns out to differ from the liquid we drink, due to a complex reaction? what if most "liquids" turned out to be made of fine particles of sand?), but we cannot expect to arrive at a perfect characterization of any manageable length. Indeed, a perfect finite characterization may be impossible. It is sometimes useful to appeal to rough-and-ready characterizations for the purposes of illustration, but it must be stressed that the real object of interest is always the full intension, to which any such descriptive characterization is a mere approximation.

It should be noted that this picture is entirely neutral between "causal" and "descriptive" theories of reference. On \textit{any} account of how reference is fixed, there will be some way in which the referent of a
concept depends on how the actual world turns out: if the actual world turns out this way, then "elm" refers to these things; if it turns out another way, then "elm" refers to those things. That is, on any theory of reference a concept will have a primary intension. The subject matter of the theory of reference is the precise structure of primary intensions; this is something about which the present account is neutral. [*]

When I occasionally characterize a primary intension in descriptive terms, this is only an approximation for the purposes of illustration, and nothing will depend on the details.

*[[Some may think that an account involving primary intensions "feels" like a description theory, and perhaps it does. But note that even Kripke's (1980) argument against description theories presupposes something like a primary intension. It proceeds by considering the referent of a concept such as "Gödel" at various actual-world candidates, thus evaluating the primary intension, and arguing that any given description gives the wrong result. It follows that either an account involving primary intensions need not be a description theory, or there is a class of description theories that Kripke's arguments do not refute. The choice between these conclusions presumably depends on just what one takes a description theory to be.]]

The framework applies equally to concepts that are used with semantic deference. As Putnam and Burge have pointed out, my concepts of "elm" and "arthritis" can refer appropriately despite my knowing very little about the relevant subject matter. In these cases, I refer via the division of linguistic labor. At a first approximation, if those around me (and especially the "experts" in my community) refer to X-trees by "elm", then my concept "elm" refers to X-trees; if they refer to Y-trees by "elm", then I refer to Y-trees, and so on. The concept therefore determines a perfectly good primary intension. To characterize this primary intension even approximately, we have to involve the name of the concept: thus, at a first approximation, my concept "elm" picks out whatever trees those around me (particularly experts) refer to as "elms". As always, reference of a concept depends on how the actual world turns out; it is just that in these cases, some of the relevant facts about the actual world are linguistic.

Putnam suggests that concepts like "water" and "elm" show that the intension of a concept cannot determine the extension, if an intension is internally determined. The two-dimensional analysis shows that this is only half-true. The primary intension of a concept determines its extension, and the primary intension is internally determined. Of course, the primary intension is a centered intension, taking a centered world as argument, so Putnam's claim still holds for uncentered intensions. But any intension requires facts about the actual world to determine extension, and it is most natural to regard the actual world of a thinker as centered, so it is no surprise that centered intensions should be central in the fixation of reference.

In some ways, the primary intension of a concept resembles a Fregean sense. It is the primary intension that fixes reference in the actual world, and the primary intension is generally cognitively accessible. We will see that instances of Frege's puzzle arise precisely when the concepts involved have different primary intensions, so insofar as senses are introduced to solve these problems, primary intensions can play the role. On the other hand, Frege required that senses determine reference non-indexically, stipulating that the sense of a concept such as "here" is tied to a particular place. Here, the secondary intension seems to be a closer fit. Many have noted that nothing can satisfy all Frege's requirements on sense, [*] and it may be fruitful to view the present account as dividing the notion of sense into two distinct components. Alternatively, one might make the case that Frege's requirement of non-indexicality is misguided, and that
primary intensions can do much of the important work that senses are introduced to do, despite this and other differences of detail with Frege's account.

*[[E.g., Perry 1977.]]*

There should be no question of whether the primary or secondary intension is the intension associated with a given concept. The full story can only be given two-dimensionally. One or the other may be more useful for various specific purposes. In matters of linguistic content, the secondary intension may play the major role, as different users of a term may have quite different associated primary intensions, whereas the secondary intension will generally be constant. This is particularly clear in the case of names, for which primary intensions can vary wildly across a community. For questions about thought and its role in governing action, however, we will see that the primary intension is central.

3 Notional and Relational Content

So far we have been concerned with the semantics of concepts. Now we move to the central topic, the semantics of thoughts, which stand to concepts roughly as sentences stand to terms. As before, I will be concerned with thoughts (usually beliefs) that are associated with sentences in the thinker's language, but the account generalizes. Just as concepts are associated with intensions, thoughts are associated with propositions, which here will be regarded as functions from possible worlds into truth-values, or more simply as sets of possible worlds. (The framework can be adapted to other accounts of propositions, e.g. on which they are seen as structured groups of intensions.) Propositions be regarded as the contents of thoughts and of sentences, just as intensions can be regarded as the contents of concepts and of terms.

Just as there are two intensions associated with every concept, there are two propositions associated with every thought. The primary proposition is a centered proposition - a set of centered worlds, or a function from centered worlds to truth-value. At a centered world \( w \), it returns the truth-value of the thought in \( w \) when \( w \) is considered as actual.\[*\] As a heuristic, we can ask: would the thought be true, if \( w \) turned out to be actual?\[*\]

\[*[[Stalnaker (1978) introduces a proposition like this as the "diagonal proposition" associated with an utterance. Just as the primary intension can be seen as the "diagonal" of a two-dimensional intension - \( f_I(v) = F(v, v') \) - the primary proposition can be seen as the diagonal of a "two-dimensional proposition", or a function from \( W^\times W \) into truth-values. For reasons that will become clear, however, I find this terminology misleading in its suggestion that primary intensions and propositions are in some way derivative on secondary intensions and propositions.]]*

\[*[[As before, we might also ask questions analogous to "if \( w \) turned out to be actual, would it turn out that water is wet?", where the "turns out" locution is read as before. As before, with either heuristic we retain the thought from the real actual world.]]*

For example, the primary proposition associated with my thought "I am a philosopher" is the set of centered worlds in which the individual at the center is a philosopher. Or consider my thought "There is water on this table". If the actual world turned out to contain XYZ as the dominant liquid in the oceans
and lakes, and if there were a table in front of me supporting a glass of XYZ, then my thought would be true. As things really are, the world contains H2O in the oceans and lakes, and there is only an empty glass on the table in front of me, so my thought is false. At a rough approximation, the primary proposition associated with my thought is the set of centered worlds in which there is a sample of the dominant clear liquid in the environment on a table in front of the individual at the center, although as usual the approximation is no substitute for the proposition itself, which can be obtained only from careful consideration of cases.

The secondary proposition is an uncentered proposition, returning at $w$ the truth-value of the thought at $w$ when $w$ is considered as counterfactual. As a heuristic, we can ask questions of the form: "in $w$, is it the case that water is wet?", and similarly *mutatis mutandis* for other thoughts. Like secondary intensions, secondary propositions are often determined only *a posteriori*, as they depends on how the actual world turns out. For example, the secondary proposition of my thought "I am a philosopher" is the set of worlds in which DJC is a philosopher. Or take my thought "there is water on this table". Given that the actual world turns out as it has, with H2O in the oceans, my study table $T$ in front of me, and with my thought occurring at time $t$, the secondary proposition is that set of worlds in which there is a sample of H2O on table $T$ at time $t$.

The primary proposition associated with a thought can usually be determined by composing the primary intensions of the concepts involved.[*] For example, the primary proposition of a thought "Hesperus is Phosphorus" will be true at a centered world if the individual picked out by the primary intension of "Hesperus" in that world is also picked out by the primary intension of "Hesperus" in that world - that is, roughly at those worlds in which the morning star is the evening star. A similar relation holds between secondary intensions and secondary propositions. The secondary intensions of "Hesperus" and "Phosphorus" pick out the same object in all worlds in which the referent of either exists, so the secondary proposition of "Hesperus is Phosphorus" is true of all such worlds.

[*][[This does not require a "language of thought": it requires only that thoughts are semantically composed of concepts, not that they are syntactically composed of concepts. Even the assumption of semantic compositionality is inessential, although it eases discussion. The definition of primary and secondary propositions requires only that thoughts are the kind of thing that can be true or false of the world.]]

I will call the primary proposition associated with a thought the thought's *notional content*, because it most directly reflects how things seem from the point of view of the thinker. I will call the secondary proposition the thought's *relational content*, as it often (although not always) depends on the relations that the thinker bears to objects in the external world. For example, when you think "I am hungry" and I think "You are hungry", our thoughts have different notional content, but similar relational content. When we both think "I am hungry", the situation is reversed.

Importantly, the notional content of a thought is determined entirely by the internal state of the thinker.[*] Like the primary intension, the primary proposition cannot depend constitutively on the external world, as the proposition itself specifies how the truth of a thought depends on how the actual world turns out. I can investigate the primary proposition associated with my thought without investigating the environment: all
I need to do is ask, *if* the environment turns out like so, will my thought be true? This is an entirely internal enterprise; facts about the actual environment have no role to play. Of course, the notional content of a thought will almost always depend *causally* on the external world, but whenever the external world affects the notional contents of our thoughts, it will do so by affecting the internal state of the thinker.

*[[Thus even a brain in a vat might have thoughts with notional content. This can be used to defuse Putnam's (1981) anti-skeptical argument that if he were a brain in a vat, he could not think "I am a brain in a vat". A brain in a vat could think a thought with the appropriate notional content, if not the appropriate relational content, and the notional content of the thought would seem sufficient to express a significant skeptical possibility, true only in worlds in which the individual at the center lacks the usual sort of epistemic contact with the surrounding world.]]*

Every thought has both notional and relational content. As notional content is internally determined, we may stipulate that a thought's *narrow content* is its notional content. Similarly, we can stipulate that a thought's *wide content* is its relational content. It should be noted, however, that relational content is not always dependent on the environment. In particular, if a thought involves only non-rigid concepts used without semantic deference, the associated secondary proposition will be a simple twist on the primary proposition, so that relational content will be internally determined.[*]

*[[For similar reasons, this differs from Quine's usage on which "notional" and "relational" belief properties correspond to those attributed by *de dicto* and *de re* ascriptions respectively. *De re* belief properties and relational content come apart where nonrigid concepts are concerned: the relational content of my belief that the shortest spy is a spy might be shared by many twins in different environments, but the corresponding *de re* belief property requires a specific referent. Further, *de dicto* belief ascriptions often ascribe a combination of notional and relational content, as I discuss later.]]*

As promised, this sort of narrow content is truth-conditional. The notional content of a thought delivers the conditions a centered world must satisfy, in order for the thought to be true in that world. The notional content of my thought "There is water on the moon" is true in a centered world with XYZ in the oceans and lakes and XYZ on the moon, even though the relational content of my thought is false there. At a rough approximation, the notional content will be true in those centered worlds in which the dominant clear liquid found in the oceans and lakes surrounding the center can also be found on the heavenly body bearing the appropriate relation to the center. We can think of the notional truth-conditions of a thought as expressing the way the actual world has to be, in order for the thought to be true.

The notional truth-conditions of a thought are often very different from the relational truth-conditions. One might worry that a thought could then turn out to be both true and false, but this is impossible. Just as the primary and secondary intensions pick out the same referent in the actual world, the primary and secondary propositions share the same truth-value there, so there is no danger of a thought's being both true and false in actuality. It is only at other worlds that the truth-conditions will give different results, and this is a consequence of the way those worlds are treated. In evaluating the primary proposition they are considered as actual, whereas in evaluating the secondary proposition they are considered as counterfactual. We might say that notional truth-conditions tell us what it is for a thought to be true *in* a world, whereas relational truth-conditions tell us what it is for a thought to be true *of* a world.

The distinction between notional and relational truth-conditions parallels Kripke's distinction between the
A thought is knowable \textit{a priori} if its notional content is true in all centered worlds; and it is necessarily true, in Kripke's sense, if its relational content is true of all worlds. Cases of the contingent \textit{a priori}, such as the thought that the stick in Paris is a meter long if it exists, are cases in which a thought has a necessary primary proposition but a contingent secondary proposition. Cases of the necessary \textit{a posteriori} are the reverse.

\[[A related two-dimensional account can be given of the corresponding phenomenon in language, yielding in a certain sense a semantic explanation of \textit{a posteriori} necessity. I develop such an account in Chalmers 1996, where it is used to analyze some applications of \textit{a posteriori} necessity in the mind-body problem. Upon analysis, the two-dimensional account suggests that some of the more ambitious applications of \textit{a posteriori} necessity (in defence of certain sorts of materialism and of certain sorts of moral realism, for example) are unlikely to succeed.\]

4 The Advantages of Notional Content.

In recent times, the "content" of a thought has generally been identified with its relational content; but the notional content seems to be an equally good candidate. As before, there is no need to decide which is \textit{the} content; but that being said, there many ways in which the notional content of a thought is responsible for most of the explanatory work that we would expect a notion of content to do.

First, notional content determines the rational relations between thoughts. If one thought implies another thought \textit{a priori}, it is because the primary proposition associated with the first implies the primary proposition associated with the second. If I know that it is hot where I am now, I know that it is hot here, and vice versa; this is reflected in the fact that the notional contents of the two thoughts are the same. The relational contents of the thoughts are very different, however: there is no obvious relation between the proposition that it is hot where DJC is at time \(t\) and the proposition that it is hot at place \(P\) then.

It is straightforward to see why this is so. If one thought implies another \textit{a priori}, then in any centered world in which the first turns out to be true, the second will turn out to be true, so the notional content of the first will imply the notional content of the second. Conversely, if the notional content of one thought implies the notional content of another, then a thinker should in principle be able to infer one from the other \textit{a priori} (setting aside problems with complex mathematical statements and the like\[*\]), as the relationship between the thoughts is independent of facts about the external world. This is not so for relational content: the relational content of a thought may depend on facts about the external world that are unknown to the thinker, so that relations between thoughts in virtue of their relational content may lie outside the realm of cognitive access.

\[[The hard cases involve thoughts that are true in all contexts, but whose truth is extremely difficult for us to determine; perhaps Goldbach's conjecture is such a case. How these cases should be treated depends on whether we regard our limitations here as arising from imperfect rationality. If so, the link between notional content and rational relations remains precise; if not, it needs a small qualification. In any case, this issue arises only in rare cases.\]]

This can be applied straightforwardly to explain the informativeness of a statement such as "Hesperus is Phosphorus". Although its associated secondary proposition is equivalent to that of the trivial "Hesperus
is Hesperus", its associated primary proposition is quite distinct, so it is not cognitively trivial. If a thought is notionally equivalent to a thought that is knowable a priori, it will itself be knowable a priori,[*] but an equivalence in relational content carries no such guarantee.

*[[Subject to the qualification in the previous note.]]

We can also invoke notional content in the case of Kripke's Pierre, who paradoxically seems to believe that London is pretty and that London is not pretty, without any breakdown in rationality. The two-dimensional framework shows why there is no paradox. Pierre's concepts "Londres" and "London" have quite different primary intensions - in a given centered world, the first picks out (approximately) the famous city called "Londres" that the individual at the center has heard about, whereas the second picks out the grimy city in which that individual has been living. The secondary intensions are identical, of course, picking out London in every world. Pierre's two beliefs, then, have contradictory associated secondary propositions, but their primary propositions are compatible. Contradictory secondary propositions support no charge of irrationality, as rational relations are determined by the first dimension of content.

Intuitively, Pierre's two beliefs are rationally compatible because there is some way the world could turn out such that both are true. There is a centered world in which "Londres" names a faraway, beautiful city (maybe it is in India), and in which the individual at the center inhabits an entirely distinct ugly city called "London"; and for all Pierre knows and believes, such a world could be actual. As long as there is such a world, satisfying the notional content of all Pierre's thoughts - that is, as long as the notional contents of his thoughts are compatible - his rationality is not in danger.

This brings out the relation between this account and Dennett's (1981) suggestion that the narrow content of a thought is reflected in the notional world of the thinker. The notional world we can take to be a world (really a class of worlds) in which all of a thinker's beliefs (or as many as possible, in cases of irrationality) would be true.[*] A notional world is to be thought of as a world as the thinker finds it, so of course it is a centered world; and beliefs are to be evaluated in that world according to their primary propositions. Pierre's notional world is a world in which there is a beautiful faraway city called "Londres", and a grimy city close at hand called "London". If Pierre really lived in his notional world, he would be right about everything and rarely surprised.

*[[Dennett suggests that the relevant worlds are "the environment (or class of environments) to which the organism as currently constituted is best fitted." I think that this gives imperfect results in some cases, most obviously for beliefs about the past; see also the criticisms in White 1991, and the more refined account put forward there. Dennett's and White's suggestions here are in effect first attempts at giving a naturalistic reduction of notional content. Such a reduction is likely to be a major project in its own right.]]

On similar grounds, one can make the case that notional content governs the cognitive relations between thoughts. Here there is an important qualification, however, as notional content as I have defined it does not distinguish the various cognitive relations that might hold between thoughts that are deductively equivalent. From the point of view of notional content, a complex mathematical proof is as trivial as
modus ponens; so the fine-grained cognitive dynamics of deduction lies beyond the reach of notional content. Perhaps a refined variety of notional content might handle these cases, but in any case I will set these issues aside here, as relational content does not handle them any better, and they are largely independent of the issues at play in this paper.

A qualified thesis would be the following: insofar as notional content or relational content governs the cognitive relations between thoughts, it is notional content that does the work. This can straightforwardly by seen by examining cases in which thoughts are cognitively related, and by observing that (1) in related cases in which relational content of these thoughts is varied but notional content is held constant, the cognitive relations are preserved (except insofar as cognitive relations can be affected by varying factors independent of both notional and relational content, as in the deductive case), and that (2) in cases in which the relational content is preserved but the notional content is not, the cognitive relations are often destroyed. The details here parallel those of the discussion of the explanation of behavior, below, so I will not duplicate them here.

A third advantage of notional content is its suitability for a role in the explanation of behavior. It is often noted that relational content seems slightly out of synchrony with what one would expect of an explanatory psychological state. To use an example of Kaplan's,[*] if you are watching me and my pants catch fire, our respective beliefs that my pants are on fire now will have the same relational content (they are true in all worlds in which DJC's pants are on fire at time t), but will lead to very different actions (I might jump into a river, while you just sit there). The difference between our actions does not seem to be something that a characterization in terms of relational content alone can explain. In a similar way, belief states can produce very similar behavior for apparently systematic reasons, even when the beliefs have very different relational content - witness the behavior that my twin and I produce when we think about twin water and water respectively, or the similarity between the actions of two people who think "I am hungry". A whole dimension of the explanation of behavior seems out of the reach of relational content.

These explanations can be easily handled in terms of notional content. If you and I think "I am hungry", the notional contents of our thoughts are very similar - our thoughts are associated with similar primary propositions, although different secondary propositions - and that similarity is reflected in the similarity of our actions. When you and I both believe that my pants are on fire, on the other hand, our notional contents are very different, and our actions differ correspondingly. Note that this provides a straightforward solution to Perry's problem of the essential indexical: it is notional content, not relational content, that governs action, and notional content, unlike relational content, is a centered proposition.[*]

[*][Perry (1979) considers the possibility that centered ("relativized") propositions might provide a solution, but dismisses it on the grounds that believing that such a proposition P is "true for me" does not distinguish me from third parties who also believe that P is true for me, but act differently. The trouble is that Perry's locution "true for me" introduces an unnecessary element of relational content. What distinguishes me from the third parties is rather that I believe P simpliciter, or better, that my belief has P as its notional content.]]

Notional content also accounts for the similarity of action between twin cases; this similarity reflects the fact that my beliefs about water and my twin's beliefs about twin water have the same associated primary
propositions. But we need not move to the realm of science fiction to see the point. Two thoughts can share notional content even when two thinkers are quite different, as our thoughts "I am hungry" show, and even in these cases, similarities in narrow content will lead to similarities in action, other things being equal. Say I think that Superman is across the road, and I want to have Superman's autograph; then other things being equal, I will cross the road.[*] If you have thoughts with similar notional content to mine, then you will do the same. But if your thoughts only share relational content with mine, but have different notional content - say you think that Clark Kent is across the road, but want Superman's autograph -- then your behavior may be correspondingly quite different.

[*][To simplify the discussion, I make the happy assumption that Superman is actual and is identical to Clark Kent.]

In general, whenever the content of a thought is causally relevant to behavior, its contribution is screened off by that of notional content in the following sense: if the thought had had the same notional content but different relational content, the behavior would have indiscernible (except insofar it might be affected by changing factors independent of both sorts of content), whereas if it had had the same relational content but different notional content, the behavior might have been quite different.

To see the latter point, we need only examine cases like those above. The thoughts "I am hungry" and "The guy over there is hungry" (unknowingly looking in a mirror) will lead to very different behavior, even though their relational content is the same. When Lois Lane is trying to cut Clark Kent's hair, her observation "Clark's hair breaks the scissors" will prompt a reaction very different from that provoked by a corresponding thought concerning Superman. If I hear that Cary Grant is starring in a movie, I might be more likely to watch than if I hear that the movie stars Archie Leach. In all these cases, different reactions are provoked by a difference in the notional content of a thought. In general, whenever the notional content of a thought is varied, different consequences can be expected, even if relational content is preserved throughout.[*] Given that notional content governs cognition and that cognition governs action, this is just what we would expect.

[*][Of course, thoughts like "Cary Grant is in the movie" and "Archie Leach is in the movie" might lead to the same actions despite their different notional content, if I know that Cary Grant is Archie Leach. But even here, there exist circumstances under which the thoughts might play a different role - if someone tells me that Cary Grant is not Archie Leach after all, for instance. In general, whenever two thoughts have different notional content, there are at least hypothetical circumstances under which the action-governing roles of the thoughts will differ.]

By contrast, if the relational content of a thought is varied but notional content is kept constant, behavior stays indistinguishable throughout. Perhaps, unbeknownst to me, Cary Grant is an elaborate hoax, a co-operative construction by avant-garde animators and the mass media. In such a case, my thought about Cary Grant will have no relational content at all, but as long as it has the same notional content my behavior will be indistinguishable from that in the case in which he is real. Or perhaps Cary Grant is really Ludwig Wittgenstein in disguise: if so, very different relational content, but the same behavior. Similarly, when my twin and I think "I need some more water for this pot", the relational contents of our thoughts differ, but we both rush for the sink.
We can make a similar point within a single system. To use an example of Evans', let Julius be a name that functions to rigidly designate whoever invented the zip. Then the primary intensions of my concepts "Julius" and "the inventor of the zip" will be the same, but the secondary intensions will be very different. Despite the difference in secondary intensions, however, it is clear that any thoughts that "Julius is P" will play the same role in directing cognition and action as thoughts that "The inventor of the zip is P". The rigidification and consequent difference in secondary intension is simply irrelevant.[*]

*[[With one slight exception: the two concepts will behave differently in modal thought, as when one judges that it is necessary that Julius is Julius but not necessary that Julius is the inventor of the zip. But even here the difference is accounted for by a difference in the internally determined two-dimensional intension, rather than by a difference in relational content per se.]]

Some might object that there are cases in which we individuate behavior extrinsically - for example, my twin and I might behave differently in that I drink water where he drinks twin water - so that there is a dimension of behavior that escapes notional content. But even in this sort of case, relational content does not usually help. Even my twin, with the different relational content, would drink water if he was in my present context. What is relevant to behavior here is not relational content but current context, as we can see by an extension of the varying-factors strategy; and I certainly do not wish to deny that current context is relevant in the explanation of behavior.

The only cases in which there is a direct tie between relational content and behavior are cases in which behavior is individuated by an intentional object, such as that in which we say that search for a glass of water whereas my twin searches for a glass of twin water. This connection holds across all contexts, as behavior only counts as water-searching if it is caused by water-thoughts. But for the same reason, this is a very weak sort of relevance for relational content: as Fodor (1990) notes, the relational contents of thoughts are not causally relevant to action here, but instead are conceptually relevant, in effect determining the category the action falls under.[*] And relational content gives us very little purchase in the explanation of action here, as we will only know that some behavior is water-searching if we already know that water-thoughts lie behind it. In a causal (as opposed to a conceptual) explanation of the action, notional content will still play the central role.

*[[See Fodor 1990 for a detailed argument along these lines. I note also that one can individuate this sort behavior intentionally but still narrowly if one individuates intentional objects notionally.]]

Why is notional content primary? To answer this question, it is useful to think of my belief contents as constituting a model of my world, a kind of map by which I steer. My model is a model of the world as I find it, a centered world with me at the center, and my beliefs are constraints on that world. One belief might rule out these centered worlds as a candidate for the world where I am, another might rule out these, until only a limited class of worlds is left. I operate under the assumption that my world is one of those worlds, and if I am lucky I will not be too surprised.

My world-model is ultimately a notional world: a set of centered worlds, such that none of these would overly surprise me if they turned out to be actual. The constraints on this model are those of notional
content. Relational content puts some additional constraints on the world, but these are not constraints that are useful to me. The relational content of my belief that the liquid in thermometers is mercury endorses only those worlds in which thermometers contain the element with atomic number \(X\), but this constraint is so deeply inaccessible to me that if it turned out that the liquid has atomic number \(Y\), I would not be in the least surprised. In an important sense, this constraint is not reflected in my world-model at all. Insofar as my world-model is useful to me, the constraints on it are entirely those of notional content; and insofar as content is useful to me, it is notional content that carries the burden.

It is worth noting that in making a case for the primacy of notional content, I have not appealed to any \textit{a priori} methodological principles such as the dictum that what governs behavior is in the head. The case for notional content has been made directly, independently of questions about physical realization. Indeed, it should be stressed that nothing I have said implies that facts about a thinker's environment are irrelevant to the explanation of behavior. Facts about the proximal environment will clearly play an important role insofar as they affect the thinker;[*] facts about the current environment are crucial to explaining the success or failure of various actions; and facts about environmental history will at least be central to a causal explanation of a thinker's current cognitive state. All that follows from the present framework is that the environment is not relevant to the explanation of behavior \textit{in virtue of its role in constituting relational content}. The kind of content that governs behavior is purely notional.

[*[It may even be that in certain cases, notional content can be constituted by an organism's proximal environment. For example, one could argue that the contents of a notebook with a list of addresses can constrain my notional world in the same way that my memory might. In these cases, one is effectively individuating the cognitive system as a coupled system whose boundaries lies beyond the skin, with notional content internal to the \textit{coupled} system. Of course one could always keep the notional contents within the skin by insisting that the relevant contents are of the form "the address in this notebook" rather than "53rd Street", but in some cases one may gain explanatory purchase by taking the broader view of the system and the more constrained view of its notional worlds. This kind of consideration leads to an "externalism" very different from that deriving from considerations about relational content, and arguably more relevant to the explanation of behavior; it is discussed in much more detail by Clark and Chalmers (1995). Of course notional content remains internal in the deepest sense; it is just that the skin is not a God-given boundary of a cognitive system. Still, this is another way in which the issue between notional and relational content runs deeper than the issue between internalism and externalism.]]

5 Belief Ascription and Psychological Explanation

This raises something of a puzzle about the role of belief ascriptions in psychological explanation. If what has gone before is correct, the kind of content that governs cognition and action is notional, and therefore narrow. But at the same time, there is strong evidence that the kind of content attributed by belief ascriptions is at least sometimes wide. Does this mean that the common-sense framework of explanation in terms of belief ascription should be discarded? Alternatively, is the apparent success of the common-sense framework evidence that something in these arguments has gone badly wrong?

Neither conclusion is justified. The present framework shows how it can at once be true that (1) belief ascriptions ascribe wide content, (2) narrow content governs action, and (3) belief ascriptions explain action. In short: Belief ascriptions ascribe a combination of notional and relational content. It is in virtue of the relational component that the ascribed content is wide, and it is in virtue of the notional component
that the ascribed content is explanatory.

A full justification of this answer requires two things: first, an analysis of what is attributed in belief ascriptions, so that we can see precisely what sorts of notional and relational content are attributed; second, an analysis of the role of belief ascriptions in psychological explanation, so that we can see that even in ordinary practice, it is the notional content attributed that carries the explanatory burden. I cannot provide anything like a complete treatment of these matters - the analysis of belief ascriptions deserves entire volumes of its own - but I can provide a preliminary sketch.

It is easy to see that ordinary belief ascriptions ascribe both notional and relational content. If I say "Ralph believes that Clark Kent is muscular", in order for my utterance to be true Ralph must have a belief that satisfies two sorts of constraints. First, the belief must have the relational content of the proposition that Clark Kent is muscular (perhaps we can allow a certain amount of variation in the relational content, if for example his concept of muscularity is slightly different from the norm). But that alone is not enough: a belief that Superman is muscular would have the same relational content, but would not make my ascription true. For the ascription to be true, his belief must involve a concept that refers to Clark Kent under an appropriate primary intension: perhaps an intension that picks out whoever is called "Clark Kent", or one that picks out whoever is that reporter with glasses at the Daily Planet, or more likely some complex intension in the vicinity. A variety of primary intensions will do, in order for the ascription to be true, but still a narrow class compared to all the primary intensions that in fact refer to Clark Kent.[*] A rigidified concept whose primary intension picks out the guy in the cape, or the strongest man in the world, might refer to Clark Kent, but the thought that the person in question is muscular would not make my ascription true.

More straightforwardly, if I am right in saying "Tom believes that he is hungry", then Tom must have a belief with more or less the appropriate relational content, true of all those worlds in which Tom is hungry at time \( t \), but there is a strong constraint on notional content too. In particular, Tom must refer to himself via the primary intension that picks out the individual at the center in every centered world. If he sees someone in the distance clutching their belly, without realizing that he is in fact looking into mirrors, then a thought that that person is hungry has the right relational content, but on the most natural reading it does not make my ascription true. The ascription will only be true if Tom's belief refers to himself as himself; that is, only if its notional content is appropriate.

We have seen that content decomposes naturally into notional and relational content; we now see that belief ascription puts strong constraints on both. The precise nature of these constraints is the subject matter of a theory of belief ascription. Ideally, such a theory will yield, for any given ascription, the conditions that a beliefs' notional and relational contents must satisfy in order to make the ascription true. We can think of a belief ascription as marking out a subspace in the space of (notional content, relational content) ordered pairs.

The constraints on relational content are generally fairly straightforward, as the examples above show. Usually, these constraints can be derived from the reference or meaning of the terms involved in the ascription. The constraints on notional content are vaguer and more subtle. Certainly not every primary
intension referring to Clark Kent qualifies a concept to play a role in making a "Clark Kent" belief ascription true, but the precise restrictions on what counts as a "Clark Kent" primary intension are not at all obvious. Similarly, to believe that water contains hydrogen atoms, it presumably does not suffice to have a relevant belief about H2O (imagine a very theoretical chemist who only knows about H2O's chemical properties); a "water"-appropriate primary intension is required, but just what are the conditions here? This is a matter for careful linguistic investigation. The constraints on notional content will be somewhat indeterminate in intermediate cases, and they will probably be context-sensitive, but they will be there, and they will generally be quite strong.

This provides a solution to the fifth puzzle mentioned at the start. The "modes of presentation" central to a theory of beliefs ascription can be seen as primary intensions and primary propositions. To satisfy a belief ascription, a believer must not only have a belief with the appropriate (secondary) proposition, but must also believe it under an appropriate mode of presentation in this sense. As a bonus, the fact that modes of presentation are themselves intensional or propositional allows for a certain elegance and symmetry in the theory of belief ascriptions, as well as potentially allowing a specificity of analysis that might not otherwise be present.

[[This possibility seems to have been widely overlooked. For example, it is not mentioned in Schiffer's (1990) otherwise thorough survey of potential modes of presentation, even though primary intensions seem tailor-made to satisfy what Schiffer calls "Frege's constraint" on modes of presentation.]]

[[Thus we are left with a framework for the semantics of belief ascription of the same general form (ascription of a propositional content plus constraint of a cognitive element) as the proposals described in Crimmins 1991, Richard 1990, and Schiffer 1992, although I have left the question of the logical form of these ascriptions open. Many of the insights of these and other philosophers on the semantics of belief ascription should be straightforwardly adaptable to the present framework.]]

(The fact that the constraints on primary intensions are only partial helps us to explain how Kripke's Pierre can believe that London is pretty and that London is not pretty without contradiction. What is going on is that Pierre's two concepts of London have different primary intensions (as we saw earlier), so that the beliefs' notional contents are compatible, but the primary intensions are both the sort that can make a "London" belief ascription true. Thus, what Kripke calls the "Principle of Non-Contradiction" is false: someone can rationally believe that P and believe that not-P as long as the beliefs involve two different primary intensions both of which satisfy the appropriate constraint.)

Given that notional content governs action, it follows that if belief ascriptions are to causally explain action, it must be in virtue of the notional content ascribed; the relational content ascribed is redundant to the explanation. To make this case more directly requires an examination of many specific examples wherein belief ascriptions are used to explain action, but the general point can be straightforwardly illustrated. One way to see the primacy of notional content is to consider beliefs involving empty names, such as "Santa Claus". These beliefs have no non-trivial relational content, and no non-trivial relational content is ascribed by the corresponding ascriptions, but ascription of beliefs about Santa Claus seem to function in precisely the same way in the explanation of action as do ascriptions of beliefs about real
people. We might explain young Karen's agitation on Christmas Eve in terms of her belief that Santa Claus is coming, that he will not fit down the chimney, and so on. Santa's non-existence and the corresponding absence of relational content make little difference to the success of such an explanation. What governs Karen's actions are her notions of Santa Claus; and what governs the success of the explanation is the notional content that these ascriptions ascribe to her. And this is a typical case of the role of belief ascriptions in explanation: even when non-trivial relational content is ascribed (as when the referent of the name exists), it makes little difference to the patterns of explanation.

In a very wide variety of cases in which content explains action, we can see that the explanation succeeds even if the relational content attributed is ignored. For instance, if we explain my opening the refrigerator in terms of my belief that there is water in the refrigerator and my desire for a glass of water, we never need to invoke the H2O-involving relational content. The explanation gains sufficient purchase from the notional content ascribed alone - roughly, the content that there is some of the liquid with the appropriate properties in the refrigerator, and that I want some of that liquid, and so on.

It might be objected that there are cases in which the constraints on the notional content ascribed by a belief ascription are weak, so that relational content must be doing any explanatory work. I think that ascriptions putting weak constraints on notional content are rare, but assume they occur - perhaps an attribution of a belief about Smith constrains the relevant primary intension very little. Even so, if we look at how such an ascription can be used in explanatory practice, we see that notional content is still doing the real work. For example, perhaps we explain why Bev goes to the pub by saying that she wants to see Smith and believes that Smith is at the pub. Leaving aside constraints in the concepts of seeing, the pub, and so on, there is even a constraint on notional content implicit in the "Smith" attributions. For notice: it is implicit here that the two "Smith" concepts in Bev's thoughts have the same primary intensions. If her belief and her desire had very different notional content where "Smith" is concerned - perhaps she wants to see Batman and believes that Smith is at the pub, not knowing that Smith is Batman - the inference from those states to her action would fail. So there is a strong joint constraint on notional content: despite a lack of constraint on the individual beliefs, Bev is implicitly ascribed the belief that a person she wants to see is at the pub. It is this ascribed belief that is doing the real explanatory work, and this ascription clearly puts a heavy constraint on notional content. To make the case that all such examples can be similarly analyzed requires a detailed treatment, but this illustrates the general pattern.

It follows that the centrality of narrow content in the causation of action need not overthrow the role of belief ascriptions in explaining behavior, as some have suggested it should. At most we have shown that belief ascriptions are a somewhat rough-edged tool, due to the way they wrap both components of content into a single parcel, bringing the idle relational content into play alongside the notional content that does all the work.[*] But this should not surprise us; we cannot expect a folk theory to be maximally efficient.

[[One might wonder why relational content is ascribed at all, given its explanatory idleness. I think there are two answers, both tied to language. First, given that we ascribe beliefs in the same language we use to describe the world, it is natural to do so in a world-involving way. When we use world-involving language to ascribe notional content, constraints on relational content come along for free. Second, relational content is important to understanding the success of communication and of collective action. When I tell you that I have a cold, you acquire a thought whose notional content is different from mine, but whose relational content is the same. Communication very frequently involves transmission of...]]
relational content, and our collective cohesion (if not our individual actions) can often be understood in terms of shared
relational content. But both of these points deserve a much more extensive development.]

In moving from common-sense psychology toward a developed cognitive psychology, we might expect
that the kind of content that is invoked will become more purely notional, and that relational content will
be relegated to a secondary role or dropped entirely.[*] We might also expect that better tools will be
developed to specify the notional contents of thoughts than the current rough-and-ready language of belief
ascription. This might qualify as a revision of our folk notion of belief, emphasizing and refining the
notional elements that are already present within it. But precisely because those elements are already
present and playing a central role in our practices, such a development would fall well short of
elimination.

[*][It is not implausible to argue that cognitive psychology is already most concerned with notional content rather than
relational content, insofar as it is concerned with content at all. For example, the psychological literature on concepts seems
to be largely concerned with how concepts are applied to the actual world, concentrating on something like the primary
intentions of the concepts involved. See Smith and Medin 1981 and Patterson 1991.]

6 Related Suggestions and Some Objections

There are various existing proposals to which the framework I have suggested is closely related. Perhaps
the most obvious relationship is to Kaplan's (1989) two-dimensional framework for the semantics of
demonstratives. Kaplan defines the "content" of a statement or term as a function from circumstances of
evaluation into extension, and defines its "character" as a function from context of utterance into content.
Kaplan's circumstances and contexts play the much same role as the uncentered and centered worlds used
here. His content is just relational content as I have defined it, and something like a primary intension can
be recovered from character by evaluating character in a centered world and evaluating the resulting
content in the same world.

Because it is tied to language rather than thought, however, Kaplan's account has some marked
differences with the account I have presented. On Kaplan's account, a name or a natural-kind term has the
same content in any context, so that its character is relatively trivial. The English term "water" picks out
H2O in all contexts, for example. (Twin Earth "water" picks out XYZ, but it is a different word in a
different language.) For similar reasons, co-referential names such as "Hesperus" and "Phosphorus" have
identical character. As Kaplan notes, this means that his account does not have the resources to handle
cognitive puzzles such as Frege's in general, although it works well in the case of indexicals and
demonstratives. And because character often depends on reference, this does not yield an account of
narrow content.

A generalization to thought has been made by Fodor (1987) (and in a related suggestion by White (1982)),
who defines the content of a thought the usual way (as relational content), and defines the narrow content
of a thought as a function from contexts to content. Unlike its linguistic counterpart, a "water" thought can
have different contents in different contexts, so the results are more fine-grained than on Kaplan's
account. The resulting formalism is similar to the present one, with the crucial difference that by making
relational content primary, narrow content becomes entirely derivative and its independent semantic function is lost. Fodor says as much:

Indeed, if you mean by content what can be semantically evaluated, then what my water-thoughts share with Twin "water"-thoughts isn't content. Narrow content is radically inexpressible, because it's only content potentially; it's what gets to be content when - and only when - it gets to be anchored. We can't - to put it in a nutshell - say what Twin thoughts have in common. This is because what can be said is ipso facto semantically evaluable; and what Twin-thoughts have in common is ipso facto not. (Fodor 1987, p. 50.)

Fodor and White nowhere suggest that narrow content has truth-conditions of its own. Despite the formal similarities, these accounts miss the crucial point that by making narrow content a function from context into truth-value (or from context into referent, for concepts), narrow content becomes semantically evaluable in its own right, along an independent semantic dimension. This small difference is entirely responsible for the explanatory power of the current framework. By allowing semantic relations such as implication between narrow contents, for example, it allows us to draw the direct link between narrow content and rationality. It is also this that allows us to analyze narrow content in terms of the worlds that the content endorses.

Another related suggestion that is canvassed occasionally (e.g. in Fodor (unpublished)) is the proposal that the narrow content of a concept such as "water" corresponds to a surface-level description of its referent, or a list of its apparent properties, such as "the clear, potable, thirst-quenching liquid found in the oceans and lakes". But as many have pointed out,[*] this strategy suffers from the problem that the resulting content is not narrow but wide. The content of a term like "liquid", for instance, may be bound to the empirical internal structure of liquids. We can construct a twin case, where liquids are replaced by superficially identical masses of fine grains of sand. Intuitively, my twin does not share even the content specified above with me, as his beliefs are not about liquids at all.

[*][E.g., LePore and Loewer 1986; Taylor 1989; White 1982.]

It might be thought that this criticism applies to the present approach. After all, I have said that the primary intension of "water" picks out approximately the clear liquid with the properties mentioned. But importantly, this is only to get a rough handle on the intension for the purposes of illustration. The real narrow content is an abstract function from centered worlds into extensions, and is only imperfectly captured by a given description. We can only characterize the intension fully by detailed consideration of its value at specific worlds. As soon as we move to a summarizing description in language, imperfections are introduced, and the narrowness of the content is impurified. But the intension itself remains narrow; we should not mistake the linguistic description for the real thing.[*]

[*][This might suggest that notional content is "ineffable", but the real problem is that linguistic descriptions of intensions are usually read relationally, and it is hard to capture one concept's notional content in terms of others' relational content. To express notional contents, we might use a device such as square brackets to indicate that descriptions of intensions are to be read notionally (when the relevant linguistic expressions have an associated notional content, as many do). For example, we
might say that the notional content of my "water" concept is approximately the function that picks out [the dominant clear liquid in my environment] in a given centered world; that is, the referent of the former in an actual-world candidate is approximately the referent of the latter. This way all relational elements are removed. Of course this is characterizing a notional content in terms of another notional content, but it is hard to see why this is any more objectionable than characterizing a relational content in terms of another relational content. (Thanks to Frank Jackson for discussion on this point.)]

One would obtain a more closely related sort of "description" theory of notional content if one abstracted away from linguistic characterizations and regarded the relevant "descriptions" simply as properties that a referent must satisfy, or better, as relations to the thinker. If we speak merely of properties and relations, the linguistic contamination is avoided. Schiffer (1978) gives a description theory of this sort, on which there is irreducibly de re reference by a thinker to himself or herself, with reference to everything else is mediated by a property or relation. If we map the irreducible self-reference here to the appeal to centered worlds, and map the properties and relations to primary intensions, the resemblance between the accounts is clear, although Schiffer does not appeal to a two-dimensional framework, and addresses his proposal largely to the question of accounting for de re thought.

An even closer relationship to notional content as I have described it is present in Lewis's (1979) proposal that belief is a self-ascription of a property. The set of individuals satisfying a property corresponds directly to a class of centered worlds, as Lewis notes, and the relevant worlds are of the notional-world variety, so that for example "water" beliefs endorse individuals in H2O-worlds and XYZ-worlds equally. Lewis (1994) argues that this sort of content is narrow and is primary in explanation. Lewis's account is one-dimensional, but he indicates various ways in which wide content can be seen to be derivative.

Something very like the present two-dimensional proposal has been canvassed by Stalnaker (1990), in a paper that is generally critical of narrow content. Stalnaker takes wide (relational) content to be primary, and defines the "diagonal" proposition associated with a thought as the function that evaluates a thought's wide content in its own context. He suggests that the diagonal proposition might be what advocates of narrow content have in mind. The diagonal proposition is of course very similar to the primary proposition, which I have suggested is the notional content of a thought.

In his brief but rich discussion, Stalnaker makes three objections to this construal of narrow content, all of which are worth addressing. The first is as follows.

First, this explanation makes clear that the determination of narrow content presupposes that we can identify a thought independently of its content. [...] It is not at all clear in the case of beliefs, intentions, and other states and attitudes that one can identify something that is the belief and intention in abstraction from its content, something about which we can ask, what would the content of that belief have been if it had been a belief I had on twin earth. (Stalnaker 1990, p. 135.)

This is surely misguided. If we could not fix reference to a thought by something other than its content, it would be impossible for us to have non-trivial knowledge of any thought's content; any knowledge that a
thought has a given content would be trivial, like our knowledge that Julius is the inventor of the zip. In practice, we identify mental states in all sorts of ways - as something like *this* belief, or the belief expressed by such-and-such an utterance - and then we notice how they behave under evaluation. We can evaluate a thought in worlds one way, and thus determine its relational content; and we can evaluate the thought in centered worlds another way, thus determining its notional content. The situation with respect to the two kinds of content are quite symmetrical. It is even possible for us to fix reference to a particular belief by wide content, and then investigate its notional content. For example, we can talk about "Pierre's belief that London is pretty", and ask how its truth-value and relational content might vary in different centered worlds.

Someone might argue that relational content is so central to a thought that we cannot even talk about how the thought's reference and relational content might vary if different centered worlds are considered as actual. For example, it might be held that any concept that could potentially refer to XYZ in a different centered world could not be *our* concept "water"; perhaps we are inadvertently importing our twins' *different* concept instead. But this is to trivialize the case against notional content, and also to lose contact with common sense. It is clear that there is at least a way of individuating concepts and thoughts so that we can speak of how their reference and truth-value might vary in this way depending on how the actual world turns out; the very fact that we have solid intuitions about how we would describe various potential actual-world scenarios indicates this. To ignore this fact is to ignore a central aspect of our conceptual structure. Even if there are other ways of individuating concepts that yield different results, the question of which of these is the one true "concept" is not a question that needs to be answered.

Stalnaker's second objection is the following:

Even if these questions receive satisfactory answers, it will remain true that the narrow content or realization conditions of a thought, explained as I have explained them, will be defined only relative to a very limited set of possible worlds: specifically, only for possible worlds containing the thought token. The realization conditions for the thought are satisfied in a given possible world if and only if the proposition expressed by the thought *in that possible world* is true. Suppose the thought I am thinking could be naturally expressed as follows: "There is a hole in the ozone layer". If I focus on the wide content, then I can consider not only whether this thought is true in the actual world, where I am thinking it, but also whether it would be true if, say, human beings had never existed to pollute the atmosphere. But we can't evaluate the realization conditions in such a possible world, since the thought won't exist there. We might try to extend the procedure to apply to possible worlds not containing the thought by asking a counterfactual question about the thought: what *would* the content of the thought be if it were thought there? This would work in some cases, but it is likely to leave a large amount of indeterminacy in the narrow content of our thoughts. Consider a version of another one of our stories: Bert, who is a little confused about arthritis, thinks his father has this disease in his thigh. [...] Now consider a possible world in which both the language and the state of medical knowledge are quite different. In this world, there is no word like `arthritis', in Bert's language, and Bert has no thoughts about his father's health. Are the realization conditions for Bert's actual thought satisfied in
this counterfactual world? Bert didn't have the belief there, but if he had, would it have been true? So far as I can see, there is no way to tell. (Stalnaker 1990, pp. 136-7.)

In language of this paper, this comes to the objection that the primary intension of a concept and the notional content of a thought will be indeterminate when evaluated at many centered worlds. There are a number of things to say to this. First, as Stalnaker observes, the truth-value of a thought in a centered world will be most straightforward when the centered world contains the thought at its center, but we have seen that this is not required. For example, a world with an artichoke at its center is precisely the sort of actual-world candidate that is endorsed by my thought "I am an artichoke", even if the artichoke is not thinking. In these cases we can retain the thought from the real actual world and simultaneously ask evaluate its truth-value in other actual-world candidates without any loss of coherence.[*]

We can handle Stalnaker's second example in a similar way. If Bert's actual world turned out to be a world in which no-one used any terms like "arthritis", then to what would his semantically deferential concept "arthritis" refer? It seems most natural to say that it would refer to nothing at all. This would be a world about which his background assumptions would be very mistaken. The use of many concepts depends on background assumptions, as Russell's example "The present King of France" shows. If those assumptions do not hold in the actual world, it is reasonable to say that thoughts involving these concepts lack truth-value. When Bert uses a concept such as "arthritis" with semantic deference, he makes a background assumption that people in the community around him use the word or something like it. If they do not, then all bets are off.

In any case, Bert's thoughts involving "arthritis" still have a significant notional content. They rule in and rule out certain centered worlds in which the background assumptions are satisfied. They take no stand on worlds in which the background assumptions are not satisfied, but that was never their purpose. For the usual explanatory purposes, the inclusion and exclusion of worlds relative to those assumptions will suffice. Centered worlds in which those assumptions fail will usually be ruled out by other beliefs, such as Bert's metalinguistic beliefs in these very assumptions (for example, his belief that the term "arthritis" is used by the community around him), so that his attitude toward these worlds can be handled in other ways. For the usual explanatory purposes, however, a belief ascriber will be concerned with a thinker's attitude toward worlds that are closer to home, so it is not a problem that notional content and primary intensions are only partial functions.

Another class of concepts whose primary intensions have a limited domain of definition are perceptual demonstratives. When I think something like "That is pretty", the referent of my demonstrative is often picked out (very roughly) as the cause of such-and-such experience.[*] In a centered world in which a pretty thing is appropriately responsible for the relevant experience at the center, the thought will be true; in a world in which an ugly thing is responsible, the thought is false; but in a world in which there is no appropriate experience at the center, the thought may lack truth-value. In this case fixation of reference relies on the fact that such an experience is present, just as fixation on reference in the "arthritis" case relies on the existence of a surrounding community using the term. Again, it is not a problem that worlds are ruled in and ruled out only relative to a background condition. If for some purpose we wish to invoke the thinker's attitudes to other worlds (a world where the experience is absent, for instance), we can rely
on the notional content of other thoughts in the vicinity, such as "The object in front of me is pretty".

[*[This raises another subtlety: to capture the content of certain perceptual demonstratives, one may need to build in a "marked" experience to the center of the class of actual-world candidates, as one builds in a marked individual and time. This is reflected in characterizations such as "cause of this experience", which may be irreducible in a way analogous to "next to me". (This parallels Russell's idea that reference to our experiences and to ourselves is irreducibly direct.) Building in this property of a center may secure reference to otherwise indistinguishable experiences and their perceptual objects, as with (perhaps) a speckle in a large field, or one of the red spots in Austin's (1990) "Two Tubes" puzzle (to which the present framework then provides a solution). In certain cases, centers may also require a marked thought ("this very thought"), further marked experiences, and perhaps marked orientations (e.g. to distinguish left and right). In general, what is built into a center corresponds to the things to which one can intuitively make "unmediated" reference: one's world, oneself, the present moment, the current thought, and perhaps certain experiences and orientations (though some of these might be seen as derivative on others). This is a matter I hope to explore elsewhere.]]

The precise domain of definition for the notional contents of particular thoughts is an important issue, for which there will be different answers depending on the thoughts in question. Some concepts, such as pure indexicals ("I", "here", and "now"), have primary intensions that are defined across all centered worlds. Pure non-indexicals - concepts whose referent at a centered world does not depend on the position of the center - will also have a wide domain of definition. It is concepts in between, for which the existence of a referent depends on background assumptions about how things are around the center of a world - as with semantically deferential concepts and certain demonstratives - that will have a restricted domain. This is a deep issue that deserves a detailed treatment of its own, but for now it suffices to note it is no objection to this account to note that the relevant functions are often partial.

It is occasionally suggested that there is something odd about the idea of evaluating a thought in an actual-world candidate that does not contain a copy of the thought itself. After all, we are considering the centered world as actual, but still retaining the thought from the actual world (the real actual world). But this seems simply to reflect how our thoughts work: they can endorse certain centered worlds as potential environments (that is, as actual-world candidates) without requiring those worlds to contain specific thoughts at the center. The thought "I am comatose" provides a clear example, as does a thought such as "Julius was a genius". Certainly it seems mistaken to require that a thinker's notional world-model contains a perfect copy of all of his or her thoughts.

This reflects itself in the fact that we have solid intuitions about how to (notionally) describe actual-world candidates even when those candidates do not contain the relevant thoughts. Consider a centered world in which I am at the center thinking about watermelons, and in which the inventor of the zip is not the actual-world inventor (who died at birth here) but Albert Einstein (who is as smart as ever). Then I can say: if that world turned out to be actual, it would turn out that Julius was a genius (using the "turns out" location in the usual notional way). Correspondingly, this world is among the actual-world candidates that my thought "Julius was a genius" endorses. (Of course it is not among the worlds that the relational content of my thought endorses.) The very fact that we have these solid intuitions is evidence that something is going on. Any semantic theory is grounded in the evidence of our intuitions, so these basic data should not be ignored.
The alternative would be to require a copy of the thought or the concept at the center of every world, but this would be to greatly limit the value of the framework in accounting for the contents of our thoughts, as it ignores the fact that our thoughts are involved in taking attitudes to notional worlds in which the thoughts are absent. This would also raise the problem of just what we would have to "hold constant" in copying a thought between centered worlds: a problem raised for Fodor's account by Block (1991) and Stalnaker (1991), but which the current framework avoids entirely. It seems much more satisfactory not to involve a thought itself in its conditions of application, even to actual-world candidates.[*]

*[[Of course, the application-conditions of some thoughts will involve the presence of a thought (although usually not presence of the thought). In these cases we can build in the presence of a thought as a background condition. "This thought" provides an example: it is a background condition that there is a "marked" thought at the center. Perhaps a semantically deferential concept such as my concept "vanadium" gains its link to the community by picking out whatever is causally responsible for my own use of the concept; if so, it may be a background condition that there is a marked concept labeled "vanadium" at the center. In these cases, evaluation in centered worlds in which relevant concepts are not present at the center will be indeterminate. As before, if we want to explain our attitude to those worlds, we will have to use other concepts.]]

Finally, Stalnaker suggests:

The source of all these problems with this procedure for defining narrow content is the fact that according to this account, narrow content is derivative from (actual and possible) wide content. The explanation of realization conditions takes for granted that somehow, the external and internal facts about a mental event or state that we have identified determine a content (in the ordinary sense) for that state. Then from the actual wide content, together with the facts about what the wide content would be under various counterfactual circumstances, we extract the narrow content. Narrow content, as defined by this procedure, presupposes rather than explains wide content. (Stalnaker 1990, p. 137.)

This, it seems to me, is false and importantly so. Perhaps narrow content is derivative on wide content when it is indirectly defined by Stalnaker's "diagonal" construction, but as I have characterized notional content, it is in no way derivative. There are two basic notions - what it is for a thought to be true in a world and what it is for a thought to be true of a world - and neither of these is obviously derivative on the other. Only if we have already adopted a framework in which relational content is primary will we determine the notional content of a thought by first determining its relational content in centered world and then evaluating that relational content in the same world. It is in many ways more natural to determine notional content directly, and to directly evaluate the truth of a thought in a world.

Indeed, in many ways relational content seems to be derivative on notional content. We can see this most clearly by looking at concepts rather than complete thoughts. We have already seen that the secondary intension of most concepts generally depends on the primary intension. In some cases it is a near-copy of the primary intension, as for simple descriptive concepts, and in other cases it is determined by rigidifying the actual-world evaluation of the primary intension. By contrast, we can tell the entire story about the primary intension without ever involving the secondary intension. It therefore seems that if either intension is to be fundamental, it is the primary intension. If we see notional and relational content as
composed from primary and secondary intensions respectively, and if we see secondary intensions as derivative on primary intensions, then it seems that narrow content may explain wide content rather than *vice versa.*[*

*[[This suggests that in order to have a naturalistic theory of wide content, for example, we will probably need a naturalistic theory of notional content first. Arguably, the reason that contemporary causal theories of content have been unsuccessful is that all these attempts to account for relational content without first accounting for notional content.]]

It is unclear why the assumption that relational content is primary is so common in the recent literature. One reason is no doubt a concern with language: relational content is often more stably associated with a term than is notional content. Perhaps a second reason is an aversion to indexical accounts of content, grounded in Frege's insistence that the truth-value of a thought cannot depend on a thinker's location in a world. A third reason is that the structure of relational content is more naturally described in language than that of notional content, making notional content more difficult to discuss.[*]

*[[A vulgar psychohistory: since Frege it has been recognized that intensions are central to the analysis of content, to deal with cognitive puzzles, the fixation of reference, and the like. For a long time, the intensionality of reference-fixing was not clearly distinguished from that of modal contexts, so it was natural to characterize the relevant intensions with modal contexts such as "what is water in w?". After Kripke separated the two sorts of intensionality, philosophers continued to concentrate on the latter sort, even though it is ill-suited to play the main roles that intensionality was introduced into semantic theories to play. The deepest sort of intensionality lies in the fixation of reference; the sort that governs description of counterfactual scenarios is much less fundamental.]]

Whatever the reasons, the emphasis on relational content has been misplaced. In many ways, notional content is more central to thought than relational content: it is cognitively accessible, it governs the cognitive and rational relations between thoughts, and it governs behavior. But we need not dismiss relational content entirely. Its utility is still an open question, and it may have a central role at least in a theory of communication. The most satisfactory overall picture will emerge if we allow the two kinds of content to co-exist in a two-dimensional conception of meaning.

6 Conclusion

What of the six puzzles at the start? To summarize:

(1) A thought's content decomposes into notional and relational content, given by its associated primary and secondary propositions respectively. My twin and I differ in the relational contents of our thoughts, but our notional contents are the same.

(2) The thoughts that Hesperus is Hesperus and that Hesperus is Phosphorus have the same associated secondary proposition but distinct associated primary propositions, as the "Hesperus" and "Phosphorus" concepts have different primary intensions. The triviality of the former does not imply the triviality of the latter, as it is notional content that governs rational relations.
(3) Pierre's two beliefs have contradictory secondary propositions but compatible primary propositions, as his two concepts of London have different primary intensions, although they are both the sort of intension that can make "London"-involving belief ascriptions true. It is only contradictory primary propositions that imply irrationality.

(4) The essential indexicality of belief reflects the fact that notional content, not relational content, governs action, and that notional content, unlike relational content, is a centered proposition.

(5) The modes of presentation central to a theory of belief ascription are primary intensions and primary propositions. Belief ascriptions constrain not just the relational content but the notional content of the believer.

(6) Instances of the contingent a priori have a necessary primary proposition but a contingent secondary proposition. It is notional content that constrains one's world-model, so a contingent secondary proposition does not indicate a cognitive achievement.

There are many problems about the contents of thought that are not resolved by this framework. Most notable are problems with hyperintensionality: how do we accommodate cognitive differences between thoughts that have the same notional and relational contents, such as beliefs in different mathematical truths? That may require a new, refined kind of content, perhaps one that lies behind notional content and determines it in turn. There is also much work to be done in providing a full account of the semantics of belief ascription; and I have left the project of providing a naturalistic reduction of this sort of content almost entirely untouched. Some of these matters are likely to be much more difficult than the puzzles at issue in this paper, but the two-dimensional framework at least clarifies the lay of the land.

Philosophy of Mind: Classical and Contemporary Readings

Edited by David J. Chalmers

A new anthology of articles in the philosophy of mind, Philosophy of Mind: Classical and Contemporary Readings will be published by Oxford University Press in July 2002. This is intended as a comprehensive collection that can be used in university courses at all levels (introductory, advanced undergraduate, graduate). The volume concentrates on foundational issues about the metaphysics of mind, consciousness, and mental content. (There will eventually be a companion volume on the philosophy of cognitive science.) I am told that the book (paperback, around 700 pages, $44.95) will be published on July 19, in plenty of time to be used for courses in fall 2002.

The table of contents for the volume is below. By publication date, I will flesh out this web page with additional information and links useful for readers of the book.

TABLE OF CONTENTS

Preface

PART I: FOUNDATIONS

Introduction

A. Dualism

1. Rene Descartes, Meditations on First Philosophy (II and VI).

2. Rene Descartes, Passions of the soul (excerpt).

3. Thomas H. Huxley, On the hypothesis that animals are automata, and its history (excerpt).

B. Behaviorism

5. Gilbert Ryle, Descartes' myth.
6. Rudolf Carnap, Psychology in physical language (excerpt).

C. The identity theory

8. U.T. Place, Is consciousness a brain process?

10. Herbert Feigl, The "mental" and the "physical" (excerpt).

D. Functionalism

15. Martine Nida-Rümelin, Pseudonormal vision: An actual case of qualia inversion?

E. Other psychophysical relations

17. Donald Davidson, Mental events.

18. Jerry A. Fodor, Special sciences.

19. Jaegwon Kim, Multiple realization and the metaphysics of reduction.

20. Terence Horgan, From supervenience to superdupervenience: Meeting the demands of a material world (excerpt).

21. Frank Jackson, Finding the mind in the natural world.

F. Mental causation
PART II. CONSCIOUSNESS

Introduction

A. General

25. Thomas Nagel, What is it like to be a bat

26. Daniel C. Dennett, Quining qualia.

27. David J. Chalmers, Consciousness and its place in nature.

B. The knowledge argument

28. Frank Jackson, Epiphenomenal qualia.

31. Daniel Stoljar, Two conceptions of the physical.

C. Modal arguments

32. Saul A. Kripke, Naming and necessity (excerpt).

34. Grover Maxwell, Rigid designators and mind-brain identity (excerpt).

D. The explanatory gap

38. Colin McGinn, Can we solve the mind-body problem?

E. Higher-order thought and representationalism

40. Fred Dretske, Conscious experience.

41. Christopher Peacocke, Sensation and the content of experience: A distinction.

42. Michael Tye, Visual qualia and visual content revisited.

43. Sydney Shoemaker, Introspection and phenomenal character.

PART III. CONTENT

Introduction

A. The nature of intentionality

44. Franz Brentano, Mental and physical phenomena (excerpt).

45. Roderick M. Chisholm, "Intentional inexistence".

46. Fred Dretske, A recipe for thought.

47. Ruth Millikan, Biosemantics.

B. Propositional attitudes

50. Wilfrid Sellars, Empiricism and the philosophy of mind (excerpt).
51. Jerry A. Fodor, Propositional attitudes.

52. Daniel C. Dennett, True believers: The intentional strategy and why it works.

53. Paul M. Churchland, Eliminative materialism and the propositional attitudes.

**C. Internalism and externalism**

54. Hilary Putnam, The meaning of "meaning" (excerpt).

55. Tyler Burge, Individualism and the mental (excerpt).

57. Michael McKinsey, Anti-individualism and privileged access.

58. Anthony Brueckner, What an anti-individualist knows a priori.

**PART IV: MISCELLANEOUS**

Introduction

60. Derek Parfit, Reductionism and personal identity.

63. John R. Searle, Can computers think?
Does Conceivability Entail Possibility?

David J. Chalmers

chalmers@arizona.edu

There is a long tradition in philosophy of using a priori methods to draw conclusions about what is possible and what is necessary, and often in turn to draw conclusions about matters of substantive metaphysics. Arguments like this typically have three steps: first an epistemic claim (about what can be known or conceived), from there to a modal claim (about what is possible or necessary), and from there to a metaphysical claim (about the nature of things in the world).

We find this structure in many different areas of philosophy: in arguments about whether the mental is reducible to the physical (or vice versa), about whether causation and laws are reducible to regularities in nature, about whether knowledge is identical to justified true belief, and so on. Many arguments in these domains first seek to establish an epistemic gap between two phenomena (e.g. that we can know or conceive of one without the other), argue from there to a modal gap (e.g. that it is possible that one could exist without the other), and step from there to a metaphysical gap (e.g. that one is not reducible to the other).

Here, I will mostly be concerned with the second step: the bridge between the epistemic and modal domains. The most popular bridge here is the method of conceivability. One argues that some state of affairs is conceivable, and from there it is concluded that this state of affairs is possible. Here, the kind of possibility at issue is metaphysical possibility, as opposed to physical possibility, natural possibility, and other sorts of possibility. Metaphysical conclusions turn most directly on matters of metaphysical possibility: if one domain is reducible to another, the facts about the second should metaphysically necessitate the facts about the first. So it is metaphysical possibility that is relevant in the three-step argument above. And there is at least some plausibility in the idea that conceivability can act as a guide to metaphysical possibility.

By contrast, it is very implausible that conceivability entails physical or natural possibility. For example, it seems conceivable that an object could travel faster than a billion meters per second, but this may be physically and naturally impossible, because it contradicts the laws of physics and the laws of nature. This case may be metaphysically possible, however, since there might well be metaphysically possible worlds...
with different laws. If we invoke an intuitive conception of a metaphysically possible world as a world
that God might have created, if he had so chosen: it seems that God could have created a world in which
an object traveled faster than a billion meters per second. So in this case, although conceivability does not
mirror natural possibility, it may well mirror metaphysical possibility.

In recent years, conceivability arguments have faced considerable opposition. Many philosophers hold
that the step from conceivability to metaphysical possibility has been shown to be invalid, not least due to
a number of apparent counterexamples. Things are complicated by the fact that the term "conceivability"
means many different things to different people. In some senses of the term, an entailment from
conceivability to possibility is out of the question; in other senses things are not so clear. To properly
assess this matter, we first have to clarify what is meant by "conceivability".

Here I will isolate three dimensions of difference between notions of conceivability: prima facie vs. ideal
conceivability, primary vs. secondary conceivability, and positive vs. negative conceivability. These
distinctions are largely independent of each other, so there may be up to eight sorts of conceivability in
the vicinity: prima facie primary positive conceivability, and so on. By making these distinctions, I think
at least one plausible and defensible conceivability-possibility thesis can be formulated, free of any clear
counterexamples.

As I will be using the term here, conceivability is a property of statements, and the conceivability of a
statement is in many cases relative to a speaker or thinker. I think that conceivability is more deeply a
property of propositions, but I will not talk that way here, since many philosophers have theoretical views
about propositions that can confuse these issues. For a statement S, we will have eight or so ways of
disambiguating the claim that S is conceivable for a given subject. I will first give rough characterizations
of the various dimensions of difference. Then I will examine various specific notions of conceivability
that result, and address the question of the extent to which these notions of conceivability support an
entailment from the conceivability of S to the possibility of S. For ease of discussion, I will use sentence
symbols such as 'S' loosely, allowing context to disambiguate whether the corresponding sentence is being
used or mentioned.

**PRIMA FACIE vs. IDEAL CONCEIVABILITY**: S is prima facie conceivable for a subject when S is
conceivable for that subject on first appearances. That is, after some consideration the subject finds that S
passes the tests that are criterial for conceivability. The specific criteria will depend on a substantive
notion of conceivability, as outlined in the discussion of the remaining dimensions of conceivability, to
remove the apparent circularity. For example, one substantive notion of conceivability (a version of
negative conceivability) holds that S is conceivable if no contradiction is detectable in the hypothesis
expressed by S. Under this notion, S will be prima facie conceivable for a subject when that subject
cannot (after consideration) detect any contradiction in the hypothesis expressed by S.

S is ideally conceivable when S is conceivable on ideal rational reflection. It sometimes happens that S is
prima facie conceivable to a subject, but that this prima facie conceivability is undermined by further
reflection showing that the tests that are criterial for conceivability are not in fact passed. In this case, S is
not ideally conceivable. Given the substantive notion of (negative) conceivability above, for example, S
Does Conceivability Entail Possibility?

will be ideally conceivable when ideal rational reflection detects no contradiction in the hypothesis expressed by S; or equivalently, when \( \neg S \) is not a priori.

An example is provided by any mathematical statement \( M \) whose truth-value is currently unknown, but which will later be proved to be true. Here \( \neg M \) is prima facie conceivable in the sense above (i.e. prima facie negatively conceivable) at least for current subjects, but it is not ideally conceivable, as ideal reflection will rule out \( \neg M \) a priori.

The notion of ideal rational reflection remains to be clarified. One could try to define ideal conceivability in terms of the capacities of an ideal reasoner - a reasoner free of all contingent cognitive limitations. Using this notion, we could say that \( S \) is ideally conceivable if an ideal reasoner would find it to pass the relevant tests (if an ideal reasoner could not rule out the hypothesis expressed by \( S \) a priori, for example). A strategy like this is taken by Menzies (1998). One trouble is that it is not obvious that an ideal reasoner is possible or coherent. For example, it may be that for every possible reasoner, there is a more sophisticated possible reasoner. Alternatively, one can dispense with the notion of an ideal reasoner, and simply invoke the notion of undefeatability be better reasoning. Given this notion, we can say that \( S \) is ideally conceivable when there is a possible subject for whom \( S \) is prima facie conceivable, with justification that is undefeatable by better reasoning. The idea is that when prima facie conceivability falls short of ideal conceivability, then the claim that the relevant tests are passed will either be unjustified, or the justification will be defeatable by further reasoning. For ideal conceivability, one needs justification that cannot be rationally defeated.

I will not try to give a substantive characterization of what good reasoning consists in, or of what counts as a cognitive limitation to be idealized away from. I suspect that any such attempt would end up being open-ended and incomplete. In general, my approach in this paper is to take certain rational notions as primitive, and to what sort of connection to modal notions emerges. In this case, I am simply appealing to our intuitive grasp of notions of reasoning, and of when one reasoning process defeats another. I note that the notion of undefeatability here invoked here is also implicit in our concept of knowledge: it is generally held that if one's justification for a belief that \( P \) is defeatable by better reasoning, then one does not know that \( P \). So the notion of conceivability is not obviously worse off than the concept of knowledge.

There is also a fairly direct parallel between the idealization present in the notion of ideal conceivability and that present in the familiar notion of apriority. If I cannot know that \( P \) independent of experience, but another less limited being could do so, then it is a priori that \( P \). And if I believe that \( P \), but the justification for my belief is defeatable by better reasoning, then it is not a priori that \( P \) (unless there is another undefeatable justification). So the notion of apriority idealizes away from cognitive limitations in much the same way as the notion of ideal conceivability. This is not to say that either of these idealizations are perfectly clear, but at least the idealization is a familiar one. And in practice, the idealizations are easy to apply. We will see that there are certain difficult cases on the far end of idealization where things get tricky; but dealing with such cases may allow us to to further clarify the idealization.

There are a couple of things that should be clarified in advance, however. First, it is important that "better reasoning" about conceivability not be defined even in part as reasoning that better tracks possibility.
Such a criterion would trivialize the link between ideal conceivability and possibility. Fortunately there is no reason to expect that such a criterion will come into play, at least on most of the substantive notions of conceivability we will be considering. Where conceivability is defined in terms of what is ruled out a priori, for example, we have an entirely independent grounding for the notion. Only if conceivability is directly defined in terms of possibility - perhaps as what a subject judges to be possible - will there be a danger of triviality.

Second, in most cases (with an exception to be discussed later), the reasoning in question is restricted to a priori reasoning, and the further reasoning involved in the idealization will remain within the a priori domain. Sometimes this will be an automatic consequence of a given notion of conceivability (e.g. the negative notion of conceivability above), and sometimes it can be seen as a stipulation. Either way, this restriction is important if this issue is to shed light on the issue of a priori access to modality.

**POSITIVE vs. NEGATIVE CONCEIVABILITY:** Negative notions of conceivability hold that S is conceivable when S is not ruled out. For example, a popular sense of "conceivable" in common usage holds roughly that S is conceivable when it is not ruled out by what one knows, or by what one believes. I will set this popular usage aside as tangential to our main purposes here: philosophers are usually concerned with senses in which S can be conceivable even when one knows that S is not actually the case. More relevant notions of negative conceivability can be obtained by constraining the ways in which S might be ruled out.

The central sort of negative conceivability holds that S is negatively conceivable when S is not ruled out a priori, or when there is no (apparent) contradiction in S. One can disambiguate the notion depending by applying the distinction between prima facie and ideal conceivability, as above. We can say that S is prima facie negatively conceivable for a subject when that subject, after consideration, cannot rule out S on a priori grounds. And we can say that S is ideally negatively conceivable when it is not a priori that \( \neg S \).

One subtlety concerns cases of indeterminacy. For some S (perhaps statements that are not truth-evaluable, or some statements involving vague predicates), it may be a priori that it is indeterminate whether S. If so, it is not a priori that \( \neg S \). In such a case, is S negatively conceivable? For various reasons, it seems best to say that it is not: in these cases, the possibility that S is not truly left open. To handle such cases, one can say that S is negatively conceivable when \( \neg \text{det}(S) \) cannot be ruled out, and that S is ideally negatively conceivable when it is not a priori that \( \neg \text{det}(S) \). Here \( \text{det} S \) expresses the claim that S is determinately the case, and \( \neg \text{det}(S) \) expresses the claim that S is false or indeterminate. (In other frameworks for dealing with indeterminacy, one can adopt a corresponding definition.) In the case of a priori indeterminacy above, it will be a priori that \( \neg \text{det}(S) \), so S will not be ideally negatively conceivable.

Positive notions of conceivability require that one can form some sort of positive conception of a situation in which S is the case. One can place the varieties of positive conceivability under the broad rubric of imagination: to positively conceive of a situation is to in some sense imagine a specific configuration of objects and properties. It is common to imagine situations in considerable detail, and this imagination is often accompanied by interpretation and reasoning. When one imagines a situation and reasons about it, the object of one's imagination is often revealed as a situation in which S is this case, for some S. When
Does Conceivability Entail Possibility?

this is the case, we can say that the imagined situation verifies $S$, and that one has imagined that $S$. Overall, we can say that $S$ is positively conceivable when one can imagine that $S$: that is, when one can imagine a situation that verifies $S$. (This definition, and the following discussion, is indebted to the discussion of conceivability in Yablo 1993.)

Different notions of conceivability correspond to different notions of imagination. One such notion is tied to perceptual imagination. A subject perceptually imagines that $S$ when the subject has a perceptual mental image that represents $S$ as being the case. This happens roughly when the image relevantly resembles a perceptual experience that represents $S$ as being the case (see Gendler/Hawthorne, this volume[?]). For example, one can perceptually imagine that a pig flies by forming a visual image of a flying pig, where this can be understood as an image that relevantly resembles a visual experience as of a flying pig.

Perceptually imagining that $P$ differs from supposing that $P$, or from entertaining the proposition that $P$, in that it involves not just an attitude toward $P$, but toward some specific situation that stands in a certain relationship to $P$. To perceptually imagine that pigs fly, we form a mental image that represents a specific situation (one with a certain configuration of animals), and we take this to be a situation in which pigs fly. Here, we can say that the imagined situation verifies "pigs fly". More generally, one can say that when one perceptually imagine that $P$, one perceptually imagines a situation that verifies $P$. Unlike entertaining or supposing that $P$, the phenomenology of perceptually imagining that $P$ has a mediated objectual character, with an attitude toward an intermediate mental object (here, an imagined situation) playing a crucial role. This objectual character (noted by Yablo 1993) is distinctive of positive conceivability.

This objectual character is present in cases of imagination that are no grounded in imagery. There is a sense in which we can imagine situations that do not seem to be potential contents of perceptual experiences. One can imagine situations beyond the scale of perception: e.g. molecules of H2O, or Germany winning the Second World War. One can imagine situations that are unperceivable in principle: e.g. the existence of an invisible being that leaves no trace on perception. And one can imagine pairs of situations that are perceptually indistinguishable: e.g. the situations postulated by two scientific hypotheses that make the same empirical predictions, or arguably the existence of a conscious being and its zombie twin (an unconscious physically identical duplicate).

In these cases, we do not form a perceptual image that represents $S$. Nevertheless, we do more than merely suppose that $S$, or entertain the hypothesis that $S$. Our relation to $S$ has a mediated objectual character that is analogous to that found in the case of perceptual imaginability. In this case, we have an intuition of (or as of) a world in which $S$, or at least of (or as of) a situation in which $S$, where a situation is (roughly) a configuration of objects and properties within a world. We might say that in these cases, one can modally imagine that $P$. One modally imagines that $P$ if one modally imagines a world that verifies $P$, or a situation that verifies $P$. Modal imagination goes beyond perceptual imagination, for the reasons above, but it shares with perceptual imagination its mediated objectual character.

"Modal imagination" is used here as a label for a certain sort of familiar mental act, and like other such categories, it resists straightforward definition. But its phenomenology is familiar. One has a positive
intuition of a certain configuration within a world, and takes that configuration to satisfy a certain description. When one modally imagines H2O molecules, for example, one imagines a configuration of particles. To modally imagine Germany winning the Second World War, one might imagine a world in which certain German armies win certain battles and go on to overwhelm Allied forces within Europe. When one reflects on these imagined (parts of) worlds, they reveal themselves as (parts of) worlds in which there are H2O molecules, or in which Germany won the Second World War.

Just as modally imagining that S goes beyond entertaining the proposition that S, modally imagining a world that verifies S goes beyond entertaining a proposition (even a highly specific proposition) that implies S. If this were all there were to modal imagination, then we could modally imagine any proposition trivially: just take the proposition itself, and conjoin with further propositions if necessary. But there are many propositions that we cannot easily modally imagine: complex unknown mathematical propositions M, for example. In these cases, we have no intuition of a world verifying M, even though we can entertain many specific propositions that imply M. So imagining a world is not merely entertaining a description. Of course it may be that imagining a world involves standing in some relation to a detailed description of that world (one presumably uses one's conceptual resources to imagine a world), but if so, this relationship goes beyond mere entertaining or supposing. Rather, it is a relation that is distinctive of modal imagination.

We can say that an imagined situation verifies S when reflection on the situation reveals it as a situation in which S. Understood this way, verification is a broadly epistemic relation, tied to certain rational processes. Importantly, verification is stronger than a mere evidential relation. We have seen that one can imagine situations in which no perceptual evidence is involved, as with the case of the nuclear force above. One can also imagine a situation in which one has strong evidence that S, such that the imagined situation is nevertheless epistemically compatible with ~S: a situation where experimental results point to a certain sort of particle behavior, for example, or where usually reliable witnesses testify that someone committed a crime. In such cases, consideration of the imagined situation alone does not reveal that it as a situation in which S (as opposed to a situation in which there is strong evidence for S), so the imagined situations do not verify S. In this respect, verification of a statement by an imagined situation is broadly analogous to an entailment of one statement by another (a priori entailment, in the central cases): if it is coherent to suppose that the situation obtains without S being the case, then the situation does not verify S.

Just as imagining a unicorn does not entail the existence of the imagined unicorn, imagining a situation does not entail the existence of the imagined situation, and imagining a world does not entail the existence of the imagined world. Nothing here entails that one should be ontologically committed to situations or worlds at all. Rather, for our purposes these can be regarded as mere intentional objects, useful in characterizing the cognitive or phenomenological structure of modal imagination. It should also be noted that nothing here presupposes that when one imagines a situation or a world, there is a metaphysically possible situation or world that corresponds to the object of one's imagination. Again, these can simply be seen as apparent situations or worlds, of the sort represented in an act of imagination. For all that has been said so far, the imagination of situations and worlds may greatly outstrip the bounds of metaphysical possibility.
Indeed, it is arguable that one can modally imagine S when S involves an a priori contradiction. An example may be a case in which one imagines a geometric object with contradictory properties. In cases like this, one imagines a situation in something less than full detail. Another example may be a case when one imagines that a true mathematical claim (Goldbach's conjecture, perhaps) is false, by imagining a situation in which experts announce it to be false. In this sort of case, one might misinterpret the imagined situation as a situation in which S; here, the situation is merely one in which one has evidence for S.

To avoid cases like these, one can isolate a notion of coherent modal imagination. In this sense, S is positively conceivable when one can coherently modally imagine a situation that verifies S. A situation is coherently imagined when it is possible to fill in arbitrary details in the imagined situation such that no contradiction reveals itself. To coherently imagine a situation that verifies S, one must be able to coherently imagine a situation such that reasoning about the imagined situation reveals it as a situation that verifies S. This notion is our core notion of positive conceivability: I will henceforth say that S is positively conceivable when it is coherently modally imaginable.

One can then introduce prima facie and ideal versions of positive conceivability. S is prima facie positively conceivable when one can modally imagine a situation that one takes to be coherent and that one takes to verify S. S is ideally positively conceivable when S is prima facie positively conceivable and this positive conceivability cannot be undermined on idealized reflection. In effect, we can distinguish prima facie coherence from true coherence, and prima facie verification from true verification, where the "true" notions involve idealization on rational reflection. True coherence requires that arbitrary details can be filled in with no contradiction revealing itself on idealized reflection, whereas prima facie coherence requires merely the appearance of coherence. True verification requires that the imagined situation is revealed as a situation in which S even on idealized reflection, whereas prima facie verification requires merely the appearance that the imagined situation is a situation in which S. Then (invoking the "true" notions) one can say that S is ideally positively conceivable when one could coherently imagine a situation that verifies S.

When S is ideally positively conceivable, it must be possible in principle to flesh out any missing details of an imagined situation that verifies S, such that these details are imagined clearly and distinctly and such that no contradiction is revealed. It must also be the case that arbitrary rational reflection on the imagined situation will not undermine the interpretation of the imagined situation as one in which S is the case. These strictures are demanding, but they are not unreasonable. They are the strictures typically demanded of good thought-experiments, for example.

A typical philosophical thought-experiment starts with prima facie positive conceivability. A subject does not imagine a situation in fine detail: microphysical details are usually left unspecified, for example. Instead, a subject imagines a situation with certain important features specified, notes that a situation of this kind appears to verify S, and judges that the remaining details are not crucial: they can in principle be filled in to yield a full coherent conception of a situation that verifies S. For the thought-experiment to yield the intended conclusion, this prima facie judgment must be be correct, so that S is ideally positively conceivable. If better reasoning would reveal that the details cannot be coherently filled in, or that the
Does Conceivability Entail Possibility?

situation does not truly verify S, then the thought-experiment will typically fail in its purpose. If the prima facie judgment is not defeatable in this way, however, then the thought-experiment succeeds, and S is ideally positively conceivable.

Clear cases of prima facie positive conceivability without ideal positive conceivability are surprisingly hard to come by. Possible examples might include the two cases above: imagining an impossible object, and imagining a situation in which mathematicians announce that M (for some false M). In these cases, however, even a moment’s reflection is enough to undermine the positive conceivability. In the first case, one can easily detect a contradiction (or the inability to fill in crucial detail). In the second case, reflection reveals the situation as one in which one has evidence that M, but as not necessarily a situation in which M. So these cases will be prima facie positively conceivable under only the most superficial of reasoning processes.

A slightly better example of prima facie without ideal positive conceivability may be the Grim Reaper paradox (Benardete 1964; Hawthorne 2000). There are countably many grim reapers, one for every positive integer. Grim reaper 1 is disposed to kill you with a scythe at 1pm, if and only if you are still alive then (otherwise his scythe remains immobile throughout), taking 30 minutes about it. Grim reaper 2 is disposed to kill you with a scythe at 12:30 pm, if and only if you are still alive then, taking 15 minutes about it. Grim reaper 3 is disposed to kill you with a scythe at 12:15 pm, and so on. You are still alive just before 12pm, you can only die through the motion of a grim reaper's scythe, and once dead you stay dead. On the face of it, this situation seems conceivable - each reaper seems conceivable individually and intrinsically, and it seems reasonable to combine distinct individuals with distinct intrinsic properties into one situation. But a little reflection reveals that the situation as described is contradictory. I cannot survive to any moment past 12pm (a grim reaper would get me first), but I cannot be killed (for grim reaper n to kill me, I must have survived grim reaper n+1, which is impossible). So the description D of the situation is prima facie positively conceivable but not ideally positively conceivable.

Note that the mathematical case is a case in the subject has coherently imagined a situation but in which the imagined situation does not verify S on reflection, while the Grim Reaper and impossible object cases are cases in a situation has not been coherently imagined. Of course in both these cases, the problem is revealed by a little reflection. One might say that in this case (and in the mathematical case above), even if we have prima facie positive conceivability, we do not have secunda facie positive conceivability.

Cases of secunda facie positive conceivability without ideal positive conceivability seem to be extremely thin on the ground. Perhaps the best candidates involve rational but false beliefs in an a priori domain such as mathematics. In general, the details of an imagined situation will be irrelevant to the positive conceivability of a mathematical claim, since reflection suggests that the truth of the mathematical claim is independent of the imagined goings-on in the world. Rather, a mathematical claim will be positively conceivable insofar as there is rational reason to accept that claim; in that case, any imagined situation can be taken to verify the claim. One will have secunda facie positive conceivability without ideal positive conceivability when these reasons stand up to secunda facie scrutiny, but are undermined by ideal reflection. Frege's set of all sets may be such a case: Frege had good a priori reasons for accepting it that survived considerable reflection, but ideal (or at least Russellian) reflection reveals a deep contradiction.
If S is positively conceivable, S is negatively conceivable (in both the prima facie and ideal cases). If one can coherently imagine a situation verifying S, then one cannot rule out that S (though this interacts a little with the primary/secondary distinction below). The reverse is not the case, at least where prima facie conceivability is concerned: many statements are prima facie negatively conceivable without being prima facie positively conceivable. For example, as we saw above, many complex mathematical statements M are such that one cannot rule out M's truth, but one cannot imagine any situation (any part of a world) that verifies S. Something similar goes for statements in other a priori domains. And even in empirical domains, it may be that one cannot rule out M, but one cannot conceive of a situation in which M, due to limited powers of imagination, for example.

Clear cases of ideal negative conceivability without ideal positive conceivability are much harder to find. One might try mathematical statements that are true but not knowable a priori by any possible being. If there were such statements, they and their negations would be ideally negatively conceivable, but probably not ideally positively conceivable. But it is far from clear that there are any such statements. I will return to this matter later.

Positive conceivability, rather than negative conceivability, seems to be what most philosophers have had in mind when discussing conceivability. It is positive conceivability that corresponds to the sort of clear and distinct modal intuition that Descartes had in mind, and which reflects the practice in the method of conceivability as used in contemporary philosophical thought-experiments. When Yablo (1993) dismisses the first Goldbach example as not really being an instance of conceivability, he is in effect saying that negative conceivability is not true conceivability, and there is something to this.

Still, it must be conceded that negative conceivability is at least better defined than positive conceivability. The characterization of positive conceivability that I have given here, invoking the notion of a modally imagining a situation, cannot be considered a reductive definition. At best, it is something of a clarification. Nevertheless, there seems to be a reasonably clear intuitive notion in the vicinity, which most people seem to have a grasp on. It may be that the notion can be given a more rigorous definition, or it may be that it should be taken as primitive; this is one of the central open questions in the area.

The distinction between positive and negative conceivability bears at least some relation to van Cleve's (1983) distinction between strong and weak conceivability. According to van Cleve, P is strongly conceivable for a subject when the subject sees that P is possible; and P is weakly conceivable when the subject does not see that P is impossible. There is an obvious link between one reading of "seeing that S is impossible" and the idea of ruling out the hypothesis that S. And the notion of "seeing that S is possible" can be read as a sort of modal intuition that S of the sort that goes along with modally imagining that S.

I think that it is best not to import the notion of possibility so directly into a definition of conceivability, to avoid the threat of trivializing the link with possibility. In particular, there is a threat that the idealized version of seeing that S is possible will collapse into correctly judging that S is possible, which will be linked trivially to possibility. Still, the idea is closely related to the idea of coherently imagining a world (or a part of a world) that verifies S: both involve a sort of modal appearance. The main advantage of the
Does Conceivability Entail Possibility?

construal I have given is that it builds in no presupposition that the imagined world is metaphysically possible, or even that it seems metaphysically possible. It builds in some broadly modal elements, in the ideas of imagining a world, of coherence, and of verification. But importantly, the modalities here are cognitive or epistemic, and presuppose no tie to the metaphysical. To imagine a world is simply to engage in a distinctive and familiar sort of mental act; and the notions of coherence and verification are wholly grounded in rational notions. So there is no danger of trivializing the link between positive conceivability and possibility.

PRIMARY vs. SECONDARY CONCEIVABILITY. This distinction draws its motivation from Kripke's discussion of the necessary a posteriori. In the wake of Kripke's arguments that a posteriori statements such as "Hesperus is Phosphorus" are necessary, it has become a familiar observation that there is a sense in which "Hesperus is not Phosphorus" is conceivable, and a sense in which it is not. The first of these senses corresponds to primary conceivability; the second to secondary conceivability.

We can say that S is primarily conceivable (or epistemically conceivable) when it is conceivable that S is actually the case. We can say that S is secondarily conceivable (or subjunctively conceivable) when S conceivably might have been the case. This corresponds to two different ways of thinking about hypothetical possibilities: epistemically, as ways the world might actually be, and subjunctively, as counterfactual ways the world might have been. I have written more on these distinctions elsewhere, but I will give a short characterization here.

It is simplest to start with the case of positive conceivability. When one imagines a situation, one can consider it as actual (as a way the world might actually be), or one can consider it as counterfactual (as a way the world might have been). It is often the case that one will describe a situation differently depending on whether one considers it as actual or as counterfactual. We can say that S is primarily positively conceivable when one can coherently imagine a situation that verifies S when considered as actual, and that S is secondarily positively conceivable when one can coherently imagine a situation that verifies S when considered as counterfactual.

Primary conceivability is grounded in the idea that for all we know a priori, there are many ways the world might be. The oceans might contain H2O or they might contain XYZ; the evening star and the morning star might be the same or distinct; and so on. We can think of these ways the world might be as epistemic possibilities, in a broad sense according to which it is epistemically possible that S if the hypothesis that S is not ruled out a priori. When S is epistemically possible, there are usually a number of imaginable situations such that if they actually obtain S will be the case. These situations can be taken to verify S, when they are considered as actual.

For example, it is epistemically possible in this sense that Hesperus is not Phosphorus (it is not a priori that Hesperus is Phosphorus). In the background of this epistemic possibility are many specific epistemically possible situations in which the heavenly bodies visible in the morning and evening are distinct. Upon consideration, these epistemically possible situations are revealed as instances of the epistemic possibility that Hesperus is not Phosphorus. There is a clear sense in which these situations verify the claim that Hesperus is not Phosphorus: for example, if one hypothetically accepts that such a
Does Conceivability Entail Possibility?

situation actually obtains, one should rationally conclude that Hesperus is not Phosphorus. This sort of relation among epistemic possibilities plays a central role in our thought.

When we consider situations as actual, we consider and evaluate them in the way that we consider and evaluate epistemic possibilities. That is, we say to ourselves: what if the actual world is really that way? One hypothetically assumes that the situation in question is actual, and considers whether, from that assumption, it follows that S is the case. If so, then the situation verifies S, when considered as actual. In the case above, for example, the situations in question (considered as actual) verify "Hesperus is not Phosphorus". So "Hesperus is not Phosphorus" is primarily positively conceivable.

(Primary conceivability is related to what Yablo (1993) calls "conceivability_ep", which requires that one can imagine believing something true with one's actual P-thought, but it is not quite the same. One difference is that primary conceivability does not require that a conceived situation contain a P-thought. So it is primarily conceivable that nothing exists, or that no-one thinks - these are not ruled out a priori, and are verified by certain situations considered as actual - but they are not conceivable in Yablo's sense.)

Negative, positive, prima facie, and ideal versions of primary conceivability are easy to formulate. We can say that S is primarily negatively conceivable when it is not ruled out a priori that S is actually the case, or more briefly, if S is not ruled out a priori. Positive primary conceivability, by contrast, requires coherently imagining a situation (considered as actual) that verifies S. Prima facie and ideal versions of these notions can be straightforwardly formulated as in the previous section. Primary positive conceivability implies primary negative conceivability, for both the prima facie and ideal versions, but the reverse is not obviously the case.

Primary conceivability is always an a priori matter. We consider specific ways the world might be, in such a way that the true character of the actual world is irrelevant. We can think of epistemic possibilities being entertained in such a way that empirical knowledge is suspended, and the reasoning that goes into evaluating them is a priori reasoning.

Secondary conceivability works quite differently. It is grounded in the idea that we can conceive of many counterfactual ways the world might have been, but is not. When we consider imagined situations as counterfactual, we consider and evaluate them in the way that we consider and evaluate counterfactual possibilities in the subjunctive mode. That is, we acknowledge that the character of the actual world is fixed, and say to ourselves: if the situation had obtained, what would have been the case? If we judge that had the situation obtained, S would have been the case, then we judge that the situation verifies S when considered as counterfactual.

Take an imagined situation in which the morning star is distinct from the evening star. Along with Kripke, we can say that if this situation had obtained, it would not have been the case that Hesperus was not Phosphorus. So when this situation is considered as counterfactual, it is revealed not as a situation in which Hesperus is not Phosphorus, but rather as a situation in which at least one of the objects is distinct from both Hesperus and Phosphorus (at least if we take for granted the actual-world knowledge that Hesperus is Phosphorus, and if we accept Kripke's intuitions). The reason is that (if Kripke is right) the
Does Conceivability Entail Possibility?

application of a term like "Hesperus" to a counterfactual situations depends on whether the actual Hesperus (i.e. the planet Venus) is present within that situation, and of course the actual Hesperus and the actual Phosphorus are one and the same. So when considered as counterfactual, this conceivable situation does not verify "Hesperus is not Phosphorus". More generally (if Kripke is right), there is no coherently imaginable situation, considered as counterfactual, that verifies "Hesperus is not Phosphorus". If so, "Hesperus is not Phosphorus" is not secondarily positively conceivable.

Unlike primary conceivability, secondary conceivability is often a posteriori. It is not secondarily conceivable that Hesperus is not Phosphorus, but one could not know that a priori. To know this, one needs the empirical information that Hesperus is actually Phosphorus. This aposteriority is grounded in the fact that the application of our words to subjunctive counterfactual situations often depends on their reference in the actual world, and the latter cannot usually be known a priori.

There are various ways to formulate prima facie and ideal versions of secondary conceivability. One might say that a subject prima facie secondarily conceives of S when the subject imagines a situation and judges that if that situation had obtained, S would have been the case. One can say that S is ideally secondarily conceivable if S is prima facie secondarily conceivable and if the secondary conceivability is not defeatable by idealized rational reflection and complete empirical knowledge. To avoid trivializing a link between conceivability and possibility here, it is probably best to restrict the empirical knowledge in question to nonmodal knowledge.

This characterizes positive versions of secondary conceivability. One might say that S is negatively secondarily conceivable when a priori reflection and empirical nonmodal knowledge reveals no incoherence in the hypothesis that S might have been the case. In any case, as secondary conceivability turns on a posteriori considerations, it will not be our central concern, and most of these varieties can be set to one side.

GAPS BETWEEN CONCEIVABILITY AND POSSIBILITY

With the distinctions above in play, it relatively easy to classify potential gaps between conceivability and possibility.

(1) *Prima facie conceivability is an imperfect guide to possibility.*

Given that there is a gap between prima facie and ideal conceivability, it is only to be expected that there is a gap between prima facie conceivability and possibility. Prima facie conceivability judgments are sometimes undermined by continued rational reflection, isolating a contradiction or a misdescription in an apparently conceivable state of affairs. When this happens, then any grounds that the conceivability judgment provided for a claim of possibility will also be undermined.

This gap is widest in the case of prima facie negative conceivability judgments. When such a judgment is not backed by a corresponding prima facie positive conceivability judgment, it provides at best weak
Does Conceivability Entail Possibility?

Evidence for possibility. Mathematical cases, such as the prima facie negative conceivability of both Goldbach's conjecture and its negation, provide an obvious source of gaps here. So likewise does any domain in which one might expect to find deep a priori truths.

Prima facie positive conceivability is a much better guide to possibility, but it is still imperfect. The case where one conceives of mathematicians announcing a proof of Goldbach's conjecture (or its negation) is best seen as a case where a superficial prima facie positive conceivability judgment is undermined by a moment's reflection. Other cases of prima facie conceivability without possibility may be provided by the Grim Reaper paradox and the case of impossible objects.

Cases of secunda facie positive conceivability, where a prima facie positive conceivability judgment survives a reasonably searching process of rational reflection, are a still stronger guide to possibility. In the great majority of cases with a gap between prima facie and ideal positive conceivability, the prima facie judgment is easily undermined by a little reflection. Gaps between secunda facie positive conceivability and ideal positive conceivability seem to be very rare, although perhaps the Frege case is an example.

In any case, if we are looking for a notion of conceivability such that conceivability tracks possibility perfectly, we must focus on ideal conceivability. In this sense conceivability is not a merely psychological notion; it is a rational notion, in much the same way that a priority and rational entailment are rational notions. If there is to be a plausible epistemic/modal bridge, it will be a bridge between the rational and modal domains.

(2) **Primary conceivability is an imperfect guide to secondary possibility.**

The other standard source of gaps between conceivability and possibility arises from Kripkean cases. It is often said that it is conceivable that Hesperus is not Phosphorus, or that water is not H2O, or that heat is not the motion of molecules, but none of these states of affairs are in fact possible. In these cases we have a posteriori necessities and impossibilities, out of the reach of a priori methods.

There are a couple of things to be said here. Clearly, the main sense in which these states of affairs are conceivable involves primary conceivability. As discussed earlier, the states of affairs in question are not secondarily conceivable. At best, they might be prima facie secondarily conceivable for a subject lacking relevant empirical knowledge. They will not be prima facie secondarily conceivable for a subject with the relevant knowledge, and they will not be ideally secondarily conceivable as that notion is spelled out above.

One might then try to save a conceivability/possibility link by suggesting that ideal secondary conceivability entails possibility. This thesis is not implausible, but it is not helpful for our purposes here. The reason is that secondary conceivability, and especially ideal secondary conceivability, is deeply a posteriori. So even if secondary conceivability is a guide to possibility, it will yield no a priori access to modality.
Does Conceivability Entail Possibility?

(Around this point, it seems to me that the otherwise excellent discussions of conceivability and possibility by Menzies (1998), van Cleve (1983), and Yablo (1993) all give up too soon, settling for conceivability/possibility theses that are more attenuated than necessary.)

If we are interested in modal rationalism, we should instead focus on ways in which primary conceivability might still be a guide to possibility. Even if it is conceded that strictly speaking, it is not possible that water is H2O, it can still be argued that the primary conceivability of "water is not H2O" is revealing something about metaphysical possibility. When we apparently conceive of a world in which water is not H2O, we conceive of a situation in which some other substance (XYZ, say) is the clear liquid surrounding us in the oceans and lakes, and so on. And this situation is indeed metaphysically possible - so our act of conceiving has indeed yielded access to a possible world. It is just that in a certain sense we have misdescribed it in calling it a world where water is not H2O, or a world in which water is XYZ. If Kripke is right, it is in fact a world in which XYZ is watery stuff but not water, and a world in which the only water that exists is H2O.

Further: there remains a sense in which a world with XYZ in the oceans can be seen as satisfying the statement "water is not H2O". Here, I will give a very brief version of a story that I have told in more detail elsewhere (e.g. Chalmers 1996, forthcoming b; see also Evans 1977, Davies and Humberstone 1980, and Jackson 1998).

As discussed earlier, there is clearly a broad sense in which it is epistemically possible that water is not H2O, in that the hypothesis is not ruled out a priori. Intuitively, there are ways our world could turn out such that if they turn out that way, it will turn out that water is not H2O. And if we consider the XYZ-world as an epistemic possibility - that is, we consider the hypothesis that the world with XYZ in the oceans is our world - then this epistemic possibility can be seen as an instance of the epistemic possibility that water is not H2O. We can rationally say "if our world turns out to have XYZ in the oceans (etc.), it will turn out that water is not H2O". This might be put as a simple indicative conditional: "if XYZ is in the oceans and lakes (etc.), then water is XYZ". Compare: "if Prince Albert Victor committed those murders, then he is Jack the Ripper". Here, the indicative conditional "if P, then Q" can be evaluated using the Ramsey test: if one hypothetically accepts the belief that P, does one arrive at the conclusion that Q?

All this reflects the fact that we have a systematic way of evaluating and describing epistemic possibilities that differs from our way of evaluating and describing subjunctive counterfactual possibilities. In both cases, we consider and describe worlds, but in the epistemic case, we consider them as actual, whereas in the subjunctive case, we consider them as counterfactual. And these two modes of consideration of a world yield two ways in which a world might be seen to satisfy a sentence. When the XYZ-world is considered as actual, it satisfies "water is XYZ"; when it is considered as counterfactual, it does not.

Given a statement S and a world W, the \textit{primary intension (or epistemic intension)} of S returns the truth-value of S in W considered as actual. Three heuristics for evaluating the primary intension of S in W correspond to the three tests mentioned above. One can appeal to direct evaluation of epistemic possibilities: is the epistemic possibility that W is actual an instance of the epistemic possibility that S? One can appeal to indicative conditionals (evaluated by the Ramsey test): if W is the case, is S the case?"
Or one can appeal to the "turns out" locution: if W turns out to be actual, will it turn out that S?

Primary intensions can be formally defined in terms of a priori entailments. In particular, we can say that the primary intension of S is true in W if the material conditional "if W is actual, then S" is a priori: that is, if the hypothesis that W is actual and S is not the case can be ruled out a priori. S's primary intension is false in W if the conditional "if W is actual, then ~S" is a priori; and S's primary intension is indeterminate at W is neither of these conditionals priori. For example, the hypothesis that the XYZ-world is actual and water is H2O can plausibly be ruled out conclusively by rational reflection alone. If so, the material conditional "if the XYZ-world is actual, then water is not H2O" is a priori, and the primary intension of "water is H2O" is false in the XYZ-world. For more on the definition of primary intensions, see the further discussion below.

Primary intensions are grounded in the epistemic evaluation of statements in worlds: that is, the evaluation of statements in worlds considered as actual. One can also define the notion of a secondary (or subjunctive) intension, grounded in the subjunctive evaluation of statements in worlds: that is, the evaluation of statements in worlds considered as counterfactual. The secondary intension of a statement S is the function that maps a world W to the truth-value of S in W considered as counterfactual. These correspond to a much more familiar notion of intension in contemporary philosophy, so I will say less about them here.

To characterize secondary intensions with a heuristic, one can appeal to subjunctive conditionals: if W had obtained, would S have been the case? Or one can appeal directly to intuitions about counterfactual possibilities: is W a counterfactual possibility in which S would have been the case? Heuristics of this sort are frequently invoked by Kripke in his evaluation of possible worlds; and his corresponding influential claims about possibility are almost always grounded in subjunctive claims about what might have been the case. So the intensional notions that arise from Kripke's work are all closely tied to secondary intensions.

A paradigmatic example involves the subjunctive evaluation of a statement such as "water is XYZ" at the XYZ-world, a world that is similar to our own except that the watery liquid in the oceans and lakes is XYZ. If Kripke and Putnam are correct, then if the watery stuff in the oceans and lakes had been XYZ, it would nevertheless not have been the case that water was XYZ: at best, XYZ would have been watery. Corresponding, W does not seem to represent a counterfactual possibility in which water is XYZ. So the secondary intension of "water is XYZ" is false at the XYZ-world.

We can then say that S is primarily possible (or 1-possible) if its primary intension is true in some possible world (i.e. if S is true in some world considered as actual). S is secondarily possible (or 2-possible) if its secondary intension is true in some possible world (i.e. if S is true in some world considered as counterfactual). Primary and secondary necessity can be defined analogously.

Secondary possibility and necessity correspond to the standard conception of what it is for a statement to be metaphysically possible or necessary. For example, "water is H2O" is plausibly 2-necessary, and "water is XYZ" 2-impossible, reflecting their metaphysical necessity and impossibility (as standardly
Does Conceivability Entail Possibility?

understood) of respectively. On this understanding, we can say that a statement is metaphysically necessary iff it has a necessary secondary intension.

Primary possibility and necessity correspond much more closely to epistemic notions such as apriority. It is clear that when S is a priori, it will have a necessary primary intension, so it will be 1-necessary. Whether the reverse entailment (from 1-necessity to apriority) holds is one of the central issues in this paper, but for now we can note that at least the clearest cases of 1-necessary statements are all plausibly a priori: witness "2+2=4", or "Hesperus, if it exists, is visible in the evening" (1-necessary and a priori), as opposed to "tables exist" and "water is H2O" (1-contingent, and a posteriori).

The existence of primary and secondary intensions suggests that expression tokens have a complex semantic value that involves both intensions. These intensions will play important roles when the expression is embedded in different contexts. In constructions such as "it might have been the case that S" and subjunctive conditionals, S's secondary intension will be relevant. In constructions such as "it is a priori that S" and indicative conditionals, S's primary intension will be relevant. Both intensions are part of the content of S in both contexts: it is just that the different contexts exploit different aspects of S's content. The propositional content of S might be understood in a number of different ways, but if one holds that the apriority and necessity of S is a function of the proposition that S expresses, then the proposition expressed by S will be reducible to neither its primary intension nor its secondary intension, but will rather be something that involves at least the structure of both.

We can now see how primary conceivability can act as a guide to possibility. When we find it conceivable that water is not H2O, there is no possible world that satisfies "water is not H2O" when the world is considered as counterfactual, but there is a possible world that satisfies "water is not H2O" when the world is considered as actual. Put differently, the secondary intension of "water is H2O" is true in no world, but the primary intension is true in some (centered) worlds. The XYZ-world, and other centered worlds that we might conceive of when we conceive that water is not H2O, all satisfy the primary intension of "water is H2O".

We can put this by saying that primary conceivability is an imperfect guide to secondary possibility, but is a much better guide to primary possibility. In all the Kripkean cases in which S is primarily conceivable, S is also primarily possible (or at least Kripke's discussion gives no reason to deny this). There is a (centered) possible world satisfying the primary intension of "Hesperus is not Phosphorus" (e.g. a world where heavenly bodies visible from the center in the morning and the evening are distinct), of "heat is not the motion of molecules" (e.g. a world where something else causes heat sensations), and so on. These worlds are all first-class metaphysical possibilities.

So Kripke's examples are entirely compatible with the thesis that conceivability is a guide to possibility. We just need to make sure that the relevant notions are aligned: primary conceivability is a guide to primary possibility, and secondary conceivability is a guide to secondary possibility. This is no surprise: it would be odd to expect conceivability of a situation considered as actual to be a guide to possibility of a world considered as counterfactual, or vice versa! So we are still left with significant a priori access to the space of possible worlds.
Sideline: On Defining Primary Intensions

Primary intensions are intensions that capture the distinctive way a statement is used to describe and evaluate epistemic possibilities. The primary intension of a statement could be defined in various ways, but the most useful definition is that in terms of a priori entailments: the primary intension of S is true at W if the material conditional "if W is actual, then S" is a priori. I elaborate and defend this conception of a primary intension in other work; here I will make a few observations about the definition of primary intensions and about their properties. This material can be skipped by those who are not interested in the fine details of the two-dimensional framework.

(i) For a world to be considered as actual, it must be a centered world: a world marked with a specified individual and time. The reason is that an epistemic possibility is not completely determined until one's "viewpoint" is specified. For example, an objective description of the world will not allow me to settle the question of whether I am in Australia or in the US, but a "centered" specification will do this. The hypothesis that a centered world W is actual, for me, will include the hypothesis that I am the being marked at the center and that now is the time marked at the center. A primary intension can then be seen as a function from centered world to truth-values. The primary intension of "I am a philosopher", for example, will be true at those centered worlds in which the subject at the center is a philosopher.

(ii) The evaluation of a conditional involving "If W is actual..." requires a canonical description of W. We can say that the primary intension of S is true at W if the material conditional "if D, then S" is a priori, where D is a canonical description of W. The notion of a canonical description can be elaborated in various different ways, which are too complex to discuss in detail here. One needs to isolate a sort of neutral vocabulary in which worlds can be described, and to require a certain sort of complete description within this vocabulary. On the first point, a neutral expression might be seen intuitively as one which behaves the same way in epistemic and subjunctive evaluation (plus indexicals such as "I" and "now" to handle centering). On the second point, one might require a complete description to be ontologically complete, or qualitatively complete, or epistemically complete, in the terms from later in this paper. If the theses of this paper are correct, these different notions of completeness are coextensive. If the theses of this paper are incorrect, these notions may come apart, yielding different primary intensions. In that case, it is probably best to require epistemic completeness in the definition.

(iii) Primary intensions are defined here as functions over (centered) possible worlds. One can also define a closely related intension as a function over an independently characterized epistemic space of maximal epistemic possibilities. Epistemic space is not defined in terms of metaphysical possible worlds, but rather in terms of epistemic notions such as apriority: maximal epistemic possibilities correspond roughly to maximally specific a priori consistent hypotheses concerning the actual world. One can define an intension over this space much as one defines a primary intension. In other work (e.g. Chalmers forthcoming a,b), I have called this an epistemic intension.

What is the relationship between the two notions? This relationship turns on the relationship between epistemic space and the space of centered possible worlds, which in turn is closely tied to the relationship...
between ideal negative conceivability and primary possibility. If this paper's theses are correct, there is a direct correspondence between the two spaces, so that primary intensions as defined here and epistemic intensions are almost identical. If this paper's theses are incorrect, then the definitions come apart: there will be maximal epistemic possibilities that correspond to no centered possible worlds, so the intensions will be defined over different spaces.

For many purposes, especially within the epistemic domain, the notion of an epistemic intension is more fundamental. For example, necessity of epistemic intension is constitutively tied to apriority and other epistemic notions, independently of any views about metaphysical possibility. So epistemic intensions can be used for epistemic purposes regardless of one's further views. For present purposes, however, the link between the epistemic and metaphysical domain is the central focus, so I focus here on primary intensions understood as functions over metaphysically possible worlds. If what I say in this paper is correct, the two intensions ultimately collapse into one.

(iv) The primary intension of some terms can vary between speakers. For example, Leverrier might use "Neptune" to pick out whatever causes certain orbital perturbations within a world, whereas an acquaintance might use it to pick out (roughly) whatever Leverrier refers to with the name, irrespective of any perturbing role. If so, their primary intensions will vary accordingly. All this reflects the fact that certain conditionals of the form "if W is actual, then Neptune is such-and-such" are a priori for Leverrier but not for his acquaintance. This happens not because of any difference in their rational capacities (which we are idealizing away from), but because of differences in the inferential roles associated with the term. Something similar can happen with most names and natural kind terms.

It follows that primary intensions are not candidates for linguistic meaning, the sort of meaning common to all tokens of an expression type, at least where names and natural kind terms are concerned. (See Chalmers forthcoming a.) To accommodate this phenomenon, primary intensions should be associated in the first instance with expression tokens (or perhaps with types as used on occasions), not with expression types. We can define primary intensions more precisely by saying that the primary intension of a statement token S (used by a speaker) is true in W if the material conditional "if W, then S" is a priori for the speaker. Here, a sentence T will be a priori for a speaker if the belief (or the hypothesis) that the speaker expresses with T could be conclusively justified, on ideal rational reflection, with justification independent of experience. On this account, different material conditionals will be a priori for Leverrier and his wife, so their primary intensions for "Neptune" will differ accordingly.

Note that the notion of apriority (whether speaker-relative or speaker-independent) requires the same sort of rational idealization as that present in the notion of ideal conceivability. I have defended the claim that relevant conditionals are a priori elsewhere (see also the discussion of scrutability later in this paper). If someone is skeptical about this, or skeptical about the very notion of apriority, it may nevertheless remain plausible that the material conditionals in question have some distinctive epistemic status which can be used to define a corresponding notion of primary intension.

(v) To evaluate the primary intension of S in W, it is not required that W contain a token of S. The heuristics and definition above give no special role for such a token, even when it is present. One could
define the *contextual intension* of $S$ as a function defined across worlds containing a token of $S$ at the center, returning the truth-value of that token. This would be a useful notion, but it would be quite different from the current notion, which is grounded in the epistemic domain. Contextual intensions turn on the context-dependence of a statement's semantic value, while primary intensions turn on the use of a statement in evaluating epistemic possibilities. Contextual intensions are more closely related to Kaplan's notion of "character" and Stalnaker's notion of a "diagonal proposition" than the current notion of a primary intension.

To see some differences, note that the contextual intension of statements such as "language exists" will plausibly be nowhere false, but the primary intension of "language exists" will be false in many (language-free) centered worlds. This reflects the (broad) epistemic possibility of such worlds: it is not a priori that language exists. Something similar applies to "nothing exists" (whose primary intension is true of an empty world) and many claims about thinkers and about language. The contextual intension also requires an account of what it takes for a token to count as an instance of $S$'s type, raising problems (pointed out by Block and Stalnaker 1999), that tend to break the link between contextual intensions and epistemic notions. If we individuate $S$'s type orthographically, "bachelors are unmarried" has a contingent contextual intension; if we individuate by familiar sorts of semantic content, "water is XYZ" has a necessarily false contextual intension; if we individuate by "narrow content" or some such, then we need an independent account of that sort of content. This issue does not arise for primary intensions. The effect is that primary intensions are much more directly connected to the epistemic domain than are contextual intensions.

(vi) Yablo (this volume) considers various ways in which the epistemic evaluation of statements in worlds might be defined. He rejects both the indicative conditional heuristic and the "turns out" heuristic, on the grounds that they give the wrong result in certain metalinguistic cases. For example, `tail are wings' should be false in a world (considered as actual) where `tail' is used to refer to wings. But Yablo suggests that the indicative conditional "if `tail' refers to wings, then tails are wings' is intuitively correct, as is "if it turns out that `tail' refers to wings, then it will turn out that tails are wings'.

I think these judgments of intuitive correctness are unclear, and I think there is at least a reasonable reading of the locutions on which the conditionals in questions are incorrect. (Compare the reasonable: "if `tail' refers to wings, 'tail' does not refer to tails"). But even if Yablo were right about this, it would show only that the heuristics are imperfect, giving the wrong results in special cases. The problem does not arise for the definition I have given here, in terms of a priori material conditionals.

To see this, note that the claim that 'tail' refers to tails is not a priori, but represents substantive a posteriori metalinguistic knowledge. It is a posteriori that the orthographic string 'tail' means anything at all, and it is a posteriori that it means what it does. So there is no a priori entailment from claims involving "'tail'" to corresponding claims involving 'tail'. And in particular, there is no a priori entailment from "'tail' refers to wings" to 'tails are wings'. More generally, there are plausibly no substantive a priori connections between claims about the orthographic string 'tail' and claims about tails, since any inferential connections between these claims rest on a posteriori metalinguistic knowledge. If so, the way that 'tail' is used in such a world will be irrelevant in evaluating the primary intension of statements such as 'tails are wings' in that world.
In particular, there is no danger that 'tails are wings' will be true in a world (considered as actual) in which 'tail' refers to wings.

Someone might suggest that there is a semantic concept of "tail" that builds in semantic constraints as well as orthographic constraints, so that it is a priori that 'tail' refers to tails. But then the worlds Yablo considers, in which the orthographic string 'tail' refers to wings, will not be worlds in which 'tail' (construed semantically) refers to wings, so there is no danger that they will be worlds (considered as actual) in which tails are wings. Either way, the usage of the orthographic string 'tail' in a world will be irrelevant in evaluating the primary intension of 'tails are wings' in that world.

Yablo himself endorses a mixed view, on which it is a priori that 'sister' refers to sisters (like the semantic view), but on which it is not a priori that 'sister' refers to female siblings (like the orthographic view), even though it is a priori that sisters are female siblings. A mixed view like this cannot be accommodated in the current framework: the framework requires that apriority is preserved under a priori entailment, but Yablo's view violates this. (For the relevant A, B, C, it is a priori that A, that B, that if A and B then C, but not that C). But it can plausibly be argued that this violation of closure is reason enough to reject Yablo's mixed view. (The view seems to be grounded in an idiosyncratic conception of a priori knowledge, on which a priori knowledge that S depends on metalinguistic knowledge concerning 'S'. I think that such a view should clearly be rejected.) In any case, it seems that any residual problems here arise from Yablo's somewhat idiosyncratic view of these metalinguistic cases, and not from the cases themselves.

For his own view of the epistemic evaluation of statements in worlds, Yablo endorses a "could have turned out" heuristic: "If it had turned out that W, would it have turned out that S?". Although I have occasionally used this heuristic myself in earlier work, I am less comfortable with it than with the "turns out" heuristic, as the subjunctive conditional here can easily be read non-epistemically, and it is too close to the subjunctive "If it had been that W, it would have been that S" for comfort. (I am also worried that Yablo's paper has the wrong title - most uses of "coulda", "woulda", and "shoulda" go with secondary intensions (!), as characterized below.) Still, it may be that there is at least a reading of this locution that gives approximately correct results in most cases. (End of sideline.)

(3) Positive conceivability is a better guide to possibility than negative conceivability.

We have already seen that prima facie negative conceivability is a relatively weak guide to possibility. The canonical case here is the prima facie negative conceivability of both Goldbach's conjecture and its negation. It should be noted that neither of these cases is backed by a corresponding prima facie positive conceivability. (There is a "positive" case in which mathematicians announce the proof, but this yields at best a very tenuous prima facie positive conceivability judgment, and raises separate issues).

So at least where prima facie conceivability is concerned, positive conceivability is a much better guide to possibility than negative conceivability. This fits the usual practice in philosophy, where the conceivability judgments that are usually taken as evidence of possibility are almost always positive conceivability judgments. (For just this reason, the Goldbach case was never a very compelling...
counterexample to this practice.)

With ideal conceivability, things are less clear. Certainly ideal positive conceivability is at least as good a guide to possibility as ideal negative conceivability, since the former entails the latter. What is less clear is whether there are cases of the latter without the former, and if so, whether those cases correspond to possibilities.

The most obvious potential case here is an extension of the Goldbach case above. If either Goldbach's conjecture or its negation is provable, or otherwise knowable a priori, then only one will be ideally negatively conceivable. But perhaps (as noted earlier) there are some true or false mathematical statements whose truth-value cannot be settled even by ideal rational reflection? If so, we would have cases of ideal negative conceivability without ideal positive conceivability and without possibility. It is not at all clear that cases of this type exist, however. I will discuss this and other potential counterexamples to a link between ideal negative conceivability and possibility later. It seems that there are at least no clear counterexamples, so a link between ideal negative conceivability and possibility remains tenable.

Overall, we can say that both ideal positive conceivability and ideal negative conceivability are promising as guides to possibility, but that the former is in a slightly better position to be a perfect guide than the latter, due to its added strength.

CONCEIVABILITY/POSSIBILITY THESES

To summarize: if any variety of a priori conceivability entails possibility, it must be a variety of ideal primary conceivability, and the variety of possibility that is entailed must be primary possibility. And positive conceivability is always at least a good a guide to possibility as negative conceivability. This leaves us with the following as the most plausible entailment between conceivability and possibility:

(1) Ideal primary positive conceivability entails primary possibility.

That is, if S is ideally primarily positively conceivable, then there is some metaphysically possible centered world satisfying S's primary intension (or that satisfies S when considered as actual).

We have also left open the status of the following:

(2) Ideal primary negative conceivability entails primary possibility.

For completeness, I note that the following two theses also remain plausible, although neither suffices for a thoroughgoing modal rationalism.

(3) Secunda facie primary positive conceivability is an extremely good guide to primary possibility.
Does Conceivability Entail Possibility?

(4) Ideal secondary (positive/negative) conceivability entails secondary possibility.

We have seen that the first thesis is compatible with the standard clear counterexamples to a link between conceivability and possibility, as is the second (although there are some unclear counterexamples that may threaten the second). So if there are any counterexamples to these two theses, they must come from a different source, and their existence will gain no support from the standard cases.

For my part, I think that thesis (1) is almost certainly true, and that thesis (2) is very likely true. In most of the rest of the paper, I will discuss what counterexamples to these theses would involve, and give a quick sketch of reasons to think the theses true.

Note that because the conceivability and possibility of a statement is speaker relative, the conceivability-possibility theses above must be interpreted in a speaker-relative way: if S is conceivable for a speaker, S is possible for that speaker. There are two main sources of speaker-relativity here: variation in cognitive capacity, which affects prima facie conceivability, and variation in primary and secondary intensions of terms, which affects primary conceivability/possibility and secondary conceivability/possibility respectively.

For the central theses (1) and (2), only the second sort of variation is relevant. This variation manifests itself in phenomena such as the following: "Neptune does not perturb the orbit of Uranus" may be ideally primarily conceivable for Leverrier's acquaintances but not for Leverrier himself; it will also be primarily possible for Leverrier's acquaintances, but not for Leverrier himself. In a similar way, "I am not David Chalmers" may be ideally secondarily conceivable for you but not for me; it is also secondarily possible for you but not for me. Because the variation here affects conceivability and possibility equally, it does not threaten an inference from conceivability to possibility. It suggests at most that in cases where this variation is present, the inference must be speaker-relative.

One might worry that because the notion of ideal conceivability itself involves the notion of possibility (for example, in claims about what some possible being could conceive, or about what is defeatable), there is a danger of circularity. There are a few different issues here. First, one might worry that this rules out a reduction of possibility to conceivability. But I am not trying to give such a reduction, but am simply investigating the connection between the two notions. Second, one might worry that circularity will make the conceivability-possibility thesis trivial. But the notion of possibility enters into the definition of conceivability in such a roundabout way that the thesis clearly remains substantive. Finally, one might worry that defining conceivability in terms of possibility renders conceivability toothless as an epistemic guide to possibility, and so defeats modal rationalism. But this is not so: modal rationalism holds that modality is a priori accessible, and so invokes the notion of possibility in a precisely parallel manner. If ideal conceivability tracks possibility, then modal facts are rationally accessible, as required.

(If one wanted to give a reductive account of possibility in terms of conceivability, there is one strategy that is worth trying. Instead of invoking possible beings in the definition of conceivability, one could invoke conceivable beings. There might then be a sort of bootstrapping definition. First, the notion of
conceivability would be grounded in our own prima facie conceivings. Second, we can conceive of beings who are better reasoners than us, with fewer cognitive limitations. Third, those beings could presumably conceive of better reasoners still. And so on. It is not out of the question that this process might lead to some sort of limit or fixed point. If so, one might obtain a recursive (not noncircular) definition of possibility in terms of conceivability. I cannot pretend that this matter is entirely clear, however.)

Does this account leave room for modal error? If theses (1) and (2) are correct, then modal errors arising from conceivability judgments will stem either from the difference between prima facie and ideal conceivability or from the difference between primary and secondary conceivability (and possibility). These modal errors will fall into one or more of the following classes:

(i) Prima facie negative conceivability judgments can go wrong in cases where a "deep" a priori contradiction is not revealed by prima facie reasoning.

(ii) Prima facie positive conceivability judgments can go wrong when (a) an imagined situation that is taken to verify P does not in fact verify S, upon rational reflection; or when (b) an imagined situation is not coherently imagined, because of the failure to notice a deep contradiction, or because of the inability to fill in crucial details.

(iii) Primary conceivability judgments can go wrong if a subject mistakenly expects them to be a guide to secondary possibility.

(iv) Prima facie secondary conceivability judgments can go wrong as a guide to secondary possibility when a subject is misinformed about relevant nonmodal empirical facts, and perhaps when an incautious subject is merely ignorant of those facts.

FROM NEGATIVE TO POSITIVE CONCEIVABILITY

In the remainder of the paper, I will focus on the status of the central conceivability-possibility theses (1) and (2), discussing what is required in order for them to be true, what form counterexamples must take, whether there are any plausible counterexamples, and what might ground the truth of the theses. Given space limitations, this discussion will only scratch the surface, but I hope to convey at least a broad view of the terrain. In discussing these theses, we can restrict our attention mostly to ideal primary positive conceivability and ideal primary negative conceivability, and to primary possibility. "Ideal primary" should be understood throughout, in references to positive and negative conceivability, and "possibility" should always be read as primary possibility. The speaker-relativity of the relevant claims should also be understood throughout.

I will first address the question of whether (ideal primary) negative conceivability entails (primary) possibility. Here I will factor out the question (addressed later) of whether positive conceivability entails possibility, and address the question of whether negative conceivability entails positive conceivability.
I call the (empty or nonempty) class of statements that are negatively conceivable but not positively conceivable the *twilight zone*. Potential members of the twilight zone come from two sources: inscrutabilities and open inconceivabilities.

**INSCRUTABILITIES:**

The class of inscrutabilities can be introduced by considering an attractive thesis about truth and reference.

**SCRUTABILITY OF TRUTH AND REFERENCE:** Once we know how the world is qualitatively, we are in a position to know what our terms refer to and whether our statements are true.

Take the case of reference first. Often we do not know what our terms refer to, but this knowledge is usually grounded in some qualitative ignorance of the way the world is. Given enough qualitative information (typically information about physical and mental states, although more on this later), we are in a position to know what our terms refer to. This reflects common practice in the theory of reference: in thinking about reference of a term in actual and hypothetical situations (considered as actual), it suffices to give a complete enough qualitative description of relevant features of those situations. From here, reference can be determined.

There are a few difficulties with the thesis of scrutability of reference. The first is that it is not entirely obvious what it means to "know what a term refers to". Presumably this is to be able to give some sort of alternative description of the referent; but just which alternative descriptions qualify? The second is that there may be a degree of indeterminacy in the reference of our terms over and above what is present in the truth-values of our statements. Examples might include terms like "number" and "symphony", or Quine's examples of mass-nouns and count-nouns in Japanese (see Benacerraf 1965, Horgan 1986, and Quine 1961 respectively). In these cases, it seems that there are multiple ways to assign referents to our terms, each of which capture our intuitions about the truth-values of our statements, insofar as these truth-values are determinate. In these cases it is not at all clear that there is a fact of the matter between these assignments of reference.

For both of these reasons it is easier to focus on the scrutability of truth. On the first issue, there is no analogous problem making sense of what it is to know the truth-value of a statement. On the second issue, almost all of the indeterminacies discussed above drop out when it comes to the truth-values of statements. (The exception may be such statements as "the number two is a set of sets", and the like, but now we are at least down to an isolated problem in the metaphysical domain, as opposed to a problem that arises with every use of the word "two".) And most of the intuitive backing behind the scrutability of reference (e.g. that given enough qualitative information, we can know who Jack the Ripper is) is reflected in the scrutability of truth (e.g. that given enough qualitative information, we can know whether Jack the Ripper was Prince Albert Victor).

The scrutability of truth can be formulated somewhat more precisely as follows:
SCRUTABILITY OF TRUTH (second pass): If D is a complete qualitative description of the world, then for all T, T -> (D implies T).

Here and elsewhere, 'A -> B' is a material conditional, and A implies B iff 'A -> B' is a priori. So the scrutability thesis says, in effect, that all truths are derivable through a priori reasoning from a complete qualitative description of the world. The thesis can also be weakened somewhat to hold that all truths are derivable from a complete enough qualitative description, thus avoiding the need to invoke a description of the whole world for every truth, but I will use the simpler if less practical formulation in what follows.

This way of putting things is not only more precise than "Once we know A, we're in a position to know B"; it also overcomes a problem posed by the paradox of knowability. Let P be a truth that I don't currently know, and let Q be "P and I don't know that P". Then Q is true but unknowable. (To know Q, I would have to know P; but once I know P, then Q is false). So Q is in danger of coming out inscrutable on the first formulation - it is a truth such that having full qualitative information about the world doesn't suffice to know it. But for all this it may remain the case that Q is implied by a full qualitative description of the world. The "paradox" gives no special reason to deny that given such a complete qualitative description D, I can know a priori that if D, then Q.

We can also put the scrutability thesis in terms of epistemic completeness, where an epistemically complete statement is one that, roughly speaking, epistemically settles everything that could be settled. More precisely, let us say as before that a statement D is epistemically possible (in the broad sense) when D is not ruled out a priori: i.e. when it is not a priori that ~D (or that ~det(D), to cover cases of indeterminacy), i.e., when D is ideally negatively conceivable. Then

A statement D is epistemically complete iff (i) D is epistemically possible, and (ii) for all F, if D&F is epistemically possible, then D implies F.

Then the scrutability thesis, reformulated, says that a complete qualitative description of the world is epistemically complete. The second formulation implies the first, since if D is a complete qualitative description of the world and T is the case, then D&T is true, so D&T is epistemically possible, so (by the second formulation) D implies T. In the other direction: if D&F is epistemically possible, then D does not imply ~F, so (by the contrapositive of the first formulation) ~~F, so F, so (by the first formulation) D implies F. (Worries about indeterminacy are handled by the observation that if D&F is epistemically possible, D does not imply ~det(F), so the indeterminacy of F is excluded.)

The residual unclarity, of course, is in the notion of a "complete qualitative description of the world"? What counts as a complete qualitative description? One idea is that a complete enough qualitative description is one that specifies all truths; but this will not do for our purposes, since it renders the scrutability thesis trivial. Intuitively, a qualitative description of the world is a "neutral" description from which many other truths might be derived.
A second and promising idea says that a complete qualitative description is a complete description in terms of fundamental natural properties (plus indexical information). That is, it involves a description in terms of fundamental microphysical properties (perhaps such as mass, charge, position, and spin), and perhaps also in terms of those fundamental properties (if any) that are not microphysical (on some nonmaterialist views, phenomenal or protophenomenal properties). So understood, the scrutability thesis would come to the claim that the fundamental natural truth about the world, in conjunction with indexical truths, implies (a priori) all truths.

We might formalize this by understanding this sort of description of the world as an ontologically complete description of the world: roughly speaking, one that metaphysically necessitates all truths about the world. In order a resulting scrutability thesis to be tenable, the relevant sort of metaphysical necessitation must be 1-necessitation (recalling that a statement is 1-necessary if its primary intension is true in all centered metaphysically possible worlds). More precisely, we can say:

A statement D is ontologically complete if (i) D is 1-possible, and (ii) if D&F is 1-possible, then D->F is 1-necessary.

The resulting scrutability thesis is:

**STRONG SCRUTABILITY**: If D is an ontologically complete truth, then D is epistemically complete.

The strong scrutability thesis is interesting and not obviously false, and is closely related to thesis (2) connecting ideal negative conceivability and possibility (in fact it is a consequence of that thesis). But it does not cut things quite finely enough for our purposes here. The thesis would be denied by a materialist who holds that it is positively conceivable that there be zombies (or other worlds physically identical to ours and phenomenally distinct), but that zombies are not metaphysically possible. (I have elsewhere called this view type-B materialism, as opposed to type-A materialism on which zombies are not even conceivable.) According to such a materialist, phenomenal truths about the world are not implied by the complete fundamental truth about the world, which is microphysical, so strong scrutability is false. This sort of denial of strong scrutability raises issues somewhat distinct from those I am concerned with here. For now, I am concerned with potential gaps between negative and positive conceivability, but this denial is best assimilated to a potential gap between positive conceivability and possibility. So it is useful to factor out a weaker scrutability thesis which this denial does not contravene.

The weaker scrutability thesis requires a sense of "complete qualitative description" such that on the type-B materialist view, a microphysical description is not a complete qualitative description. Intuitively, the microphysical description seems incomplete (in a sense) as a qualitative description precisely because it does not specify the phenomenal truths, and the phenomenal truths seem to be (in a sense) qualitative truths. And the sense in which these are qualitative truths seems to correspond to the fact that such truths will be required for a fully clear and distinct conception of what the world is qualitatively like. That is, they are required for a description of the world to the limits of positive conceivability.
A qualitatively complete description of the world, then, should be understood as a description to the limits of positive conceivable. That is, it is a description which specifies a unique positively conceivable situation. We can define this more precisely as follows:

A statement $D$ is qualitatively complete if (i) $D$ is positively conceivable, and (ii) if $D\&F$ is positively conceivable, then $D$ implies $F$.

On the type-B materialist view, a complete microphysical description of the world will not be qualitatively complete. For various phenomenal truths $F$, $D\&F$ will be positively conceivable, as will $D\&\neg F$, but $D$ will imply neither $F$ nor $\neg F$. On this view, a complete qualitative description of the world will require at least something akin to a full microphysical and phenomenal description.

With the notion of qualitative completeness in hand, we can now formulate our final version of the scrutability thesis.

SCRUTABILITY: If $D$ is a qualitatively complete truth, then for all $S$, $S \rightarrow (D \implies S)$.

Or equivalently:

SCRUTABILITY If $D$ is a qualitatively complete truth, then $D$ is epistemically complete.

We can say that $S$ is an inscrutable truth if $S$ is true and some qualitatively complete truth $D$ does not imply $S$. The scrutability thesis above says that there are no inscrutable truths.

It is easy to see that if $S$ is inscrutable, then both $D\&S$ and $D\&\neg S$ (for a relevant $D$) are in the twilight zone. $D\&S$ and $D\&\neg S$ are negatively conceivable since their negations ($D\rightarrow \neg S$, $D\rightarrow S$) are not a priori. But they are not positively conceivable: if they were, then $D$ could not be qualitatively complete. So if there are inscrutable truths, there are inhabitants of the twilight zone, and negative conceivable implies neither positive conceivable nor possibility.

Are there any likely candidates to be inscrutable truths? To assess this, it helps to have an idea of what a qualitatively complete truth will involve. It presumably will require at least microphysical information, including microphysical laws. It may or may not require phenomenal information (a type-A materialist view will deny this), but it cannot hurt to include it (specified in the sort of "pure phenomenal" vocabulary discussed by Chalmers 2002). On any of the type-A materialist, type-B materialist, and property dualist views, a qualitatively complete truth will imply the complete microphysical and phenomenal truth, so anything not implied by the former will not be implied by the latter. Indexical information is required, since more than one conjunction of complete objective truths with indexical claims will be positively conceivable. Finally, in order to rule out situations containing extra nonphysical, nonphenomenal goings-on, qualitative completeness requires a "totality" claim, holding that the world is a minimal world that satisfies the physical, phenomenal, and indexical claims specify.
Elsewhere (Chalmers and Jackson forthcoming), this conjunction of microphysical, phenomenal, indexical, and totality claims is referred to as PQTI. It is not entirely implausible that PQTI is itself a complete qualitative description of the world: for the most part, even where there are candidates M for truths not implied by PQTI, these do not seem to be associated with intuitions of distinct positively conceivable situations (verifying PQTI&M and PQTI&~M) analogous to the intuitions in the zombie case. In any case, even if PQTI is not itself qualitatively complete, we can at least say that any inscrutable truth will be a truth not implied by PQTI.

Possible candidates might fall into a number of classes.

(i) *Ordinary macroscopic truths*. One might first question whether ordinary macroscopic truths about the natural world, such as "grass is green" and "there is water in my pool" can be derived by a priori reasoning from PQTI. I have argued elsewhere (Chalmers 1996; Chalmers and Jackson forthcoming) that they can be, and I will not repeat that case here. But the basic idea is that straightforward a priori reasoning from PQTI puts one in a position to know all about the physical composition, the phenomenal appearance, the spatial structure, and the dynamic behavior of macroscopic systems, along with facts about their relation to oneself and their distribution in space and time; and this information in turns puts one in a position to know all ordinary macroscopic truths S about such systems, as long as one possesses the concepts involved in S. The information will include all the information on which ordinary perceptual or theoretical knowledge that S might be based, along with sufficient information to conclusively rule out skeptical counterpossibilities to S. If so, it is very plausible that PQTI implies S.

One worry arises with names and natural kind terms: someone might object that truths involving these terms cannot be a priori entailed by PQTI, as the relevant a priori connections are not built into the semantic content of these terms. In response, recall that we are working with a speaker-relative conception of apriority and primary intension. It may be in cases such as 'Neptune' or even 'water', the primary intension and a priori connections of a term varies between speakers, so that if "semantic content" must be common to all speakers, primary intensions and a priori connections are not determined by semantic content. But all that is required here is that the conditional "PQTI->S" be a priori for any given speaker. This thesis is quite compatible with the variation in primary intension, and it can be argued for straightforwardly along the lines of the previous paragraph.

(It might be thought that Kripke's epistemological arguments tell against even speaker-relative a priori entailments, but it is easy to see they have no power against the sort of specific entailment at issue here. At most, they suggest that a term's primary intension cannot be captured by a description. Special issues come up for expressions that are used with semantic deference, as when a speaker defers to other speakers in fixing a term's reference. I think that even these expressions can be accommodated on this framework, but for present purposes it is easiest to stipulate that we are concerned only with nondeferential uses.)

(ii) *Certain mathematical truths*. Someone might suggest that there are true mathematical statements that are not a priori, i.e. that are not knowable even on ideal rational reflection. For example, one might suppose that certain Gödelian statements in arithmetic (the Gödel sentence of the finite human brain?), or certain statements of higher set theory (the continuum hypothesis or its negation?) may be determinately

true without being ideally knowable. If such truths exist, they will plausibly not be implied by a qualitatively complete description of the world, so they will be inscrutable.

However, it is not at all clear that such statements exist. In any given case, one can argue that either (i) the statements in question are knowable under some idealization of rational reasoning, or (ii) that the statements are not determinately true or false. In the arithmetical case, one can argue that for any statement S there is some better reasoner than us that could know S a priori. Our inability to know a given Gödel sentence plausibly results from a contingent cognitive limitation: perhaps our limitations in the ordinal counting required for repeated Gödelization (which can be shown to settle all truths of arithmetic), or even our contingent inability to evaluate a predicate of all integers simultaneously (Russell's "mere medical impossibility"). In the case of unprovable statements of set theory, it is not at all clear that truth or falsity is determinate. Most set theorists seem to hold that the relevant cases are indeterminate (although see Lavine 1999 for an argument for determinacy); and even if they are determinate in some cases, it is not out of the question that possible beings could know the truth of further axioms that settle the determinate truths.

There is more to say about this issue. I think that the mathematical case is the most significant challenge to scrutability, and even if it fails, it clearly raises important questions about just what sorts of idealizations are allowed in our rational notions. For now, however, it suffices to note that there is no strong positive reason to hold that cases of mathematical determinacy without apriority exist.

(iii) Vague statements. It is plausible that some statements involving vague predicates (e.g., "person X is bald") cannot be known a priori to be true or false, even given complete qualitative information. Complete qualitative information will tell us how much hair a person has, but may leave the question of tallness unsettled. On the standard view of vagueness, this will not be a case of inscrutability, since the statements themselves will be neither true nor false. On the epistemic theory of vagueness, however, such statements are determinate even if we cannot know their truth-values: there is a precise border between the bald and the nonbald, but we cannot know where it is. Some versions of the epistemic theory may hold that this is due to rational limitations on our part (so that more intelligent creatures might be able to locate the border between baldness and nonbaldness); but we can consider a version on which even this epistemic connection fails. On such a view, some statements involving vague predicates will be inscrutable truths.

For example, let us assume for simplicity that baldness supervenes on number of hairs. On this version of the epistemic theory, some truths of the form "X is bald" will not be implied by truths of the form "X has n hairs". Here, "X has n hairs and is not bald" will be ideally negatively conceivable, but impossible. Here, the two statements "X has n hairs and is not bald" nor "X has n hairs and is bald" are negatively but not positively conceivable. When we consider any imagined situation in the vicinity - one in which X has n hairs of a specified nature and has further qualitative properties that are inessential here - it verifies neither "X is bald" nor "X is not bald". So these statements fall into the twilight zone.

(Contrast the zombie case in the philosophy of mind, where it seems that "physical structure P and conscious" and "physical structure P and not conscious" are each positively conceivable, verified by two different modally imaginable situations. In the baldness case, and other cases of vagueness, there are no
two such distinct modally imaginable situations: at best, there are two coherently entertainable descriptions. So in these cases, unlike the zombie case, there is no call to include information about baldness explicitly in a qualitatively complete description of the world; the existing description was already qualitatively complete, at least as far as the matters here are concerned. So the truths about baldness fall into the gap between negative and positive conceivability (yielding inscrutability), whereas truths about consciousness do not.)

Of course all this is contingent on the truth of the epistemic theory of vagueness, and the epistemic theory is widely regarded as very implausible. In fact one might trace the implausibility of the epistemic theory at least in part to the way it denies inscrutability. In these cases, it seems that a subject has all the qualitative information that could possibly be relevant, and it seems almost obvious that given that information, the subject is in a position to know all there is to know about baldness here. So it might be argued that the intuitive implausibility of the epistemic theory is grounded in an intuitive endorsement of scrutability, at least in this domain.

One might worry about the status of vague statements even when the epistemic theory is rejected. Here the answer depends on one's view of vagueness. If one accepts the law of the excluded middle (Sv~S), then one must also accept (PQTI implies S)v(PQTI implies ~S). If one rejects the law of the excluded middle (the best option, on my view), then one will reject the corresponding claim about implication. If there are determinacy operators "det" and "indet", and cases in which indet(S), then PQTI must imply indet(S). But I do not think there are any fatal problems for scrutability here, over and above the problems that arise in analyzing vagueness in general.

(4) Moral claims.

Many philosophers hold that the truth or falsity of moral claims, such as "eating animals is bad", is not determined a priori by natural truths. This can be argued by a generalization of Moore's open question argument, suggesting that two people possessing full natural information might disagree on the truth of a claim like this, without either displaying incapacities of reasoning or failing to grasp moral concepts. This view is often combined with the view that moral claims are not strictly true or false at all; but some philosophers holds that moral claims are true or false despite being epistemically underdetermined by the natural truth in this way. On this view, moral truths are not implied by PQTI. As in the case of vagueness, there do not seem to be distinct positively conceivable situations verifying PQTI&M and PQTI&~M, where M is a moral claim. If so, then moral truths are inscrutable truths.

As in the case of vagueness, this view of morality is controversial, so it certainly does not provide a clear case for inscrutable truths. Proponents of this sort of view often argue for the view by appealing to Kripke's distinction between the a priori and the necessary, but there are strong disanalogies: Kripke's cases are compatible with an entailment from (negative) conceivability to possibility, and with the scrutability of truth, whereas this view is not. And I think that there are good arguments against the view, based on considerations related to scrutability (Horgan and Tienson 19xx give some related arguments). But in any case, the view helps to illustrate what an inscrutable truth might be.
(A related issue: Yablo (this volume) worries that in the moral case, given the nonapriority of PQTI→M and PQTI→~M and a principle connecting nonapriority of ~S with primary possibility of S, one could infer the primary possibility of both PQTI&M and PQTI&~M, which seems wrong. In response: if one denies the apriority of the conditionals and also rules out the position above, then the most plausible position remaining is that moral claims are not strictly true or false but are indeterminate; and it is plausible that if this view is true, it is a priori. If so, then it is a priori that ~det(PQTI&M) and that ~det(PQTI&~M). If so, then (given the official characterization of ideal negative conceivability) PQTI&M and PQTI&~M are not ideally negatively conceivable, so they will not be primarily possible.)

(5) Metaphysical claims.

Many issues within philosophy are such that it is not obvious that they can be conclusively settled by rationally reasoning from the information in PQTI. This applies especially to questions at issue within metaphysics: Do mereological sums exist? Do all dispositions have categorical bases? Are properties universals or tropes? What is required for identity over time? Do numbers exist? Is an A-theory or a B-theory of time correct? And even: does conceivability suffice for possibility?

There is no space here to consider these issues separately. But in general, an advocate of scrutability can take one of three strategies any given one of these issues. (1) Argue that sufficient rational reflection - perhaps more than has been done to date - can conclusively settle the issue (perhaps the issues about numbers and conceivability fall here). (2) Argue that the issue is positively conceivable either way, so that PQTI needs to be supplemented by further information to yield a qualitatively complete description of the world (perhaps the issues about categorical bases and about time fall here). (3) Argue that there is no fact of the matter about the issue, or that it can only be settled by terminological refinement (perhaps the issues about mereological sums and identity over time fall here). In each case, there is room for argument, but it certainly seems that there are no clear cases where all three of these strategies fail.

Overall: It seems that there is no clear counterexample to scrutability. At best there are some unclear potential counterexamples, none of which carries enormous antecedent plausibility, although some deserve further investigation.

Stepping back for a moment, why should we accept the scrutability thesis? One way to argue for it is to suggest that any reasonable candidate for an inscrutable truth will be an unknown and unknowable truth, since what we know is limited to information gained through perception (and so present in or implied by PQTI), plus that derived from rational reflection (and so implied by PQTI). One can also argue that all unknown truths stem from either ignorance of the qualitative nature of the world, or from insufficient a priori reasoning; and that the only unknowable truths stem from ignorance of the qualitative nature of the world. If this is so in general, then there are no inscrutable truths.

None of this yields a knockdown argument, but it does give reason to take the scrutability thesis very seriously.

Sideline: Modal Rationalism and Logical Empiricism
As Yablo (this volume) notes, the scrutability thesis has something in common with some versions of logical empiricism. A common logical empiricist thesis was that phenomenal truths analytically entail all truths. The main differences between the theses are (1) in appealing to a qualitatively complete truth, the scrutability thesis allows much more in its entailment base than just phenomenal truths (in particular, it allows the complete microphysical truth); and (2) scrutability as I have characterized appeals not to analyticity but to apriority, which I think is a more basic notion.

Yablo suggests that the problems of logical empiricism may infect the modal rationalism that I advocate. The problem on which Yablo focuses is the underdetermination of theory by evidence. Underdetermination of theory by local evidence is no problem for a sufficiently holistic logical empiricist, but underdetermination of theory by total evidence is a real problem. It seems easily conceivable that different states-of-affairs might provide the same evidence, or that some truths might leave no trace on our evidence; and there are even pairs of real-life scientific theories (as in quantum mechanics) that save all appearances while making different microphysical claims. These considerations are all tied to the limitations of observation, however: they suggest that phenomenal truths or observational truths underdetermine theory. They do nothing at all to suggest that the complete qualitative truth (including microphysical truths) underdetermines theory. So the most common worries about underdetermination do nothing to threaten the scrutability thesis.

To make a stronger parallel argument, Yablo appeals to a different worry, about the role played by a posteriori considerations of "reasonableness" and "sensibility" in moving from evidence to theory. There seem to be a number of separate arguments here, although I am not certain that Yablo intended all of them.

First: considerations of reasonableness cannot be reduced to a set of a priori rules (as in "the dream of an a priori inductive logic"). Response: there is no reason to suppose that a priori truths, or a priori entailments, must be reducible to some basic set of explicit formal principles. So this is a red herring. (See Chalmers and Jackson forthcoming for more on this.) At best, this point might affect a thesis cast in terms of analyticity, if analyticity is defined in terms of logic plus definitions.

Second: the modal rationalist requires too much of our "grasp of meaning", by requiring knowledge of the relevant conditionals. Response: On the rationalist view, knowledge of the relevant conditionals need not be built into grasp of meaning, and need not be possessed by every subject who possesses the relevant concepts. Where present, the knowledge is usually a product of substantive reasoning, grounded both in possession of the relevant concepts and in rational reflection.

Third: there are cases where rational reflection on qualitative information underdetermines theoretical truth, which is settled only by pragmatic factors. Response: if the pragmatic factors are rationally underdetermined, then these are cases where originally indeterminate statements become determinately true or false because of terminological evolution. (See Chalmers and Jackson forthcoming.) So there is no point in the process at which there are inscrutable truths.
Fourth: the inference from PQTI to macroscopic truths may depend on "peeking", as when one perceptually imagines the appearance of a situation. Response: This point might threaten a scrutability thesis based on PTI, as information about appearances may be crucial but disallowed. But given the phenomenal information Q about appearances (in a pure phenomenal vocabulary), peeking comes for free. Knowledge of PQTI yields knowledge of the phenomenology of the appearances, and this puts one in as good a position to reason from those appearances to macroscopic truths as if one had experienced the appearances directly. (See also the further discussion below.)

Fifth: the general exercise of "sensibility" is a posteriori, since it involves introspective knowledge of concept application in one's own mind. Response: No introspective knowledge is needed to know the entailment from PQTI to S. One merely needs to deploy the concepts involved in S; one does not need to observe their deployment.

There is more to say here, but it seems that at least on a first look, the scrutability thesis is unthreatened by its parallels with logical empiricism. Still, the parallels certainly exist, both with logical empiricism and other broadly phenomenalist and anti-realist views. These anti-realist views hold (in a sense) that when it comes to truth, nothing is hidden. The scrutability thesis does not suggest this, and is perfectly compatible with a realist view. But it suggests a weaker thesis: given complete qualitative knowledge (and ideal reflection), nothing is hidden. There is perhaps a tiny residue of anti-realism here: if a claim cannot be settled by a priori reasoning on the basic qualitative facts, then there is no fact of the matter about that claim. But one does not have to be a logical positivist to find this thesis attractive. (After all, there are some things that it is perfectly reasonable to be anti-realist about.) Indeed, in almost all cases where a claim cannot be settled in this way, as we have seen, it is independently plausible that the claim is indeterminate. So the scrutability thesis may well embody a principle that is tacit in our reasoning.

THE STRUCTURE OF THE TWILIGHT ZONE

We have seen that if there are inscrutable truths, then there are inhabitants of the "twilight zone" between negative and positive conceivability. We have also seen that there is no clear reason to accept that there are inscrutable truths. Where does this leave us on the relation between negative and positive conceivability more generally? Are there other inhabitants of the twilight zone?

To address this, it is useful to generalize the scrutability thesis slightly, so that it applies not only to complete qualitative descriptions of the actual world and to actual truths, but to any complete qualitative descriptions and to any truths. The generalized thesis is that a complete enough qualitative description of any world leaves no truth about that world epistemically open. After all, it would be odd if scrutability turned out to be true in this world but not in others; the thesis seems to have a much more general source than that.

GENERALIZED SCRUTABILITY: If D is qualitatively complete, then D is epistemically complete.
Does Conceivability Entail Possibility?

Clearly generalized scrutability implies scrutability: the earlier scrutability thesis is the special case where D is a qualitatively complete truth. Scrutability does not logically imply generalized scrutability, but it is natural to think that if scrutability is true, generalized scrutability is probably true. If scrutability holds, it seems unlikely that it holds accidentally, because of the character of the actual world. Rather, its truth would seem to reflect something deep about concepts, truth, and reason. If this is right, then the two theses are likely to stand and fall together.

OPEN INCONCEIVABILITIES:

The second potential source of a gap between negative and positive conceivability arises from states of affairs that are inconceivable, but that are nevertheless not ruled out a priori.

There are quite likely many prima facie inconceivabilities: a rich source is provided by statements about phenomenal properties quite distinct from our own. For example, the claim that there are creatures with 12-dimensional phenomenal color spaces cannot be ruled out a priori, but it may be beyond our capacity to conceive of a situation verifying this claim. Such a conception might require phenomenal concepts (and ultimately phenomenal experiences to ground those concepts) that we simply lack. If so, such a claim is prima facie negatively conceivable, but not prima facie positively conceivable. This is not obviously a case of ideal inconceivability, however. We have already seen that the inconceivability here stems from a lack in our repertoire of phenomenal concepts, and this limitation is contingent. If we idealize away from this conceptual lack, then the situation in question will plausibly turn out to be conceivable after all. Presumably there are possible creatures with the relevant concepts, and such creatures would have no difficulty in conceiving of the situations in question.

Still, perhaps there are some features of the world, or of some world, that simply cannot be positively conceived at all. One example might be provided by intrinsic properties that are not phenomenal properties, and are not conceptually related to them. One might argue that the only way to form a conception of an intrinsic property is by direct acquaintance, as in the phenomenal case, or perhaps by a priori reasoning from concepts of intrinsic properties one has direct acquaintance with; think of the missing shade of phenomenal blue. (Of course one might form an extrinsic conception of an intrinsic property, such as "the property that is causally responsible for such-and-such", but this is not good enough here, as such a conception leaves open multiple epistemic possibilities as to the nature of the property.) And one might argue that the only intrinsic properties any subject can be directly acquainted with are phenomenal properties. If so, then any intrinsic properties that are not phenomenal properties will be in the relevant sense inconceivable.

Of course all the assumptions going into the case above are highly contestable, but the possibility of inconceivable features of the world does not seem easy to rule out. This can be exploited to yield perhaps the most plausible example of an open inconceivability: namely, "there are inconceivable features of the world". This statement is by its nature verified by no positively conceivable situation, but it is also not easy to rule out a priori. Unless some way can be found to rule out this statement a priori, it will be (ideally) negatively conceivable but not positively conceivable, and hence will be in the twilight zone.
More precisely:

S is an **OPEN INCONCEIVABILITY** if S is negatively conceivable, but for all qualitatively complete D, D implies ~S.

(Note: to handle indeterminacies, the last clause should hold that for all D, D implies ~det(S). If S is negatively conceivable, det(S) is not ruled out a priori; if nevertheless for all D, D implies that S is indeterminate, then S should be an open inconceivability.)

We have seen that "There are no inconceivable features of the world" is one potential open inconceivability. Another is "There is no PC-complete description of the world". At a more specific level, the case of nonphenomenal intrinsic properties, on the assumptions above, will provide examples of open inconceivabilities insofar as there are ways to express relevant inconceivable truths (e.g., "There are nonphenomenal intrinsic properties", if nothing else). Still, none of these yield clear cases, so we can at least formulate a relevant thesis opposed to them:

**NOINCONCEIVABILITY**: No S is an open inconceivability.

It is not clear how best to argue for this thesis. One might argue for any property, there is some creature than can form a conception of it - perhaps any intrinsic property can be known by acquaintance, and any non-intrinsic property by description. And one might argue that this principle is itself a priori. If that is so, then it plausibly follows that there are no open inconceivabilities. But the central claim here is far from obvious.

Like inscrutabilities, open inconceivabilities (if they exist) provide a gap between negative and positive conceivability. They differ, however, in that they may not provide a gap between negative conceivability and possibility. That gap depends on whether the open inconceivabilities in question correspond to real possibilities (e.g. properties we can't form a conception of), or whether they correspond to impossibilities that we cannot rule out a priori (perhaps all properties are conceivable, but we can't rule out the alternative a priori). If all open inconceivabilities are of the former sort, then negative conceivability might still be a guide to possibility - it is just that the possible will outstrip the positively conceivable. If some are of the latter sort, then negative conceivability will be an imperfect guide to possibility.

**TWILIGHT ZONE SUMMARY**:

We have seen that potential members of the twilight zone stem from at least two classes: inscrutabilities and open inconceivabilities. In fact is is not hard to see that all members of the twilight zone stem from these two classes.

**NEGPOS**: Ideal negative conceivability entails ideal primary positive conceivability.

The negpos principle says that there are no members of the twilight zone. Then
Claim: NEGPOS <-> GENERALIZED SCRUTABILITY & NOINCONCEIVABILITY

Proof: Left-to-right: Given negpos, any qualitatively complete statement will be epistemically complete, so generalized scrutability will be true. Given negpos, any negatively conceivable statement will be positively conceivable, so will be entailed by some qualitatively complete D, so noinconceivability will be true. Note that the second part requires the principle that any positively conceivable statement is implied by some qualitatively complete statement. This seems reasonable, as it encapsulates the idea that a statement verified only by "uncompletable" situations will not be ideally positively conceivable.

Right-to-left: Let S be negatively conceivable. Noinconceivability implies that there is a D such that ~(D implies ~det(S))). Generalized scrutability implies that D settles S's truth-value, so D implies S. (Note that the determinacy operator in the definition of open inconceivability is needed here, in order to exclude the possibility that D implies neither S nor ~S, due to indeterminacy.)

So in order to close a potential gap between (ideal primary) negative and positive conceivability, it is necessary and sufficient to rule out generalized inscrutabilities and open inconceivabilities.

In order to close a potential gap between negative conceivability and possibility, it is necessary to rule out generalized inscrutabilities (if S is a generalized inscrutability, then both D->S and D->~S will be negatively conceivable for a relevant D, but both cannot be possible). It is not necessary to rule out all open inconceivabilities, but one must rule out all impossible open inconceivabilities. If some open inconceivabilities are also impossibilities, then negative conceivability does not entail possibility. But if all open inconceivabilities are possibilities (which is not entirely implausible), then an entailment between negative conceivability and possibility is not threatened.

FROM POSITIVE CONCEIVABILITY TO POSSIBILITY

Does (ideal primary) conceivability imply (primary) possibility? A counterexample to this principle must involve what I have elsewhere called a strong necessity: a statement that is falsified by some positively conceivable situation (considered as actual), but which nevertheless true in all possible worlds (considered as actual). For such necessities to exist, the space of positively conceivable situations must outstrip the space of possible worlds.

There are certainly no clear examples of strong necessities, and the only candidates are highly tendentious. I have discussed this matter at some length elsewhere (Chalmers 1999), so I will say only a little about some possible candidates here.

(i) The existence of God. On many theist views, a god exists necessarily, so that every possible world contains a god. But a theist may hold that it is not a priori that a god exists, and that a godless world is positively conceivable, even on rational reflection. On this view, it is natural to hold that "no god exists" is primarily positively conceivable, but not primarily possible. So if this view is correct, then "a god exists" is a strong necessity. Of course, the theist thesis here is highly controversial, so this is not a strong
Does Conceivability Entail Possibility?

counterexample, but it illustrates what a counterexample must involve.

One further worry: if god does not exist necessarily, then "A necessary god exists" is impossible. But it may seem that a necessary god is at least conceivable (see Yablo 1999). In response, I deny that a necessarily existing god is ideally conceivable. A god's existence may be conceivable, but to conceive of a god's necessary existence is much harder, especially given its conceivable nonexistence. In effect, one must conceive (metamodally!) that conceivability does not imply possibility. But it is not clear that this is more than prima facie negatively conceivable. On my view, it is a priori (if non-obvious) that conceivability entails possibility (see below for the sketch of an a priori argument). If so, then the denial of the entailment is not ideally conceivable, and so neither is the necessary existence of a god.

(2) Laws of nature. Some philosophers hold that the laws of nature are metaphysically necessary. On some views of this sort (e.g. those discussed by Fine and Sidelle in this volume), this necessity arises for broadly Kripkean reasons: the reference of terms such as "mass" is fixed a posteriori to a certain very specific property, so that worlds with different laws do not contain mass. I think this view is implausible, but in any case it is compatible with an entailment from primary conceivability to primary possibility. If G' is a counternomic statement (say, an adjusted statement of gravitational laws with a different constant), then G' is both primarily conceivable and primarily possible. G' is verified by a metaphysically possible world W considered as actual, although not by W considered as counterfactual. (Considered as counterfactual, W contains "schmass", not mass.) So there are no strong necessities here.

There is a stronger view on which the laws of every world are the laws of our world, governing properties instantiated in our world. On this sort of view, even "schmass" worlds are metaphysically impossible: G' will be primarily conceivable but not even primarily possible. So on this view, laws of nature are strong necessities. There is no reason to accept this view, however. (It is notable that Fine and Sidelle quickly dismiss such a view as too extreme to be plausible.) Proponents of necessary laws usually appeal to Kripke's necessary a posteriori for support, but the Kripkean cases support at best the weak view in the previous paragraph. Nothing here gives reason to suppose that worlds with different laws are impossible; at best, it suggests that they are misdescribed as breaking our laws. So there is no good reason here to deny the conceivability-possibility thesis.

(3) Response-enabled concepts. Yablo (this volume) considers a class of response-enabled concepts whose extension, and whose meaning, is fixed by our responses. He suggests that "oval" is in this class: the reference of "oval" is fixed by picking out whatever looks oval-shaped to us, irrespective of any pure geometric description of their shape. I think the example is unfortunate, since "oval" is arguably a pure geometric concept, picking out certain geometric shapes regardless of the responses they cause in us. But there may be other terms that function as Yablo suggests, so I will play along with his suggestion that "oval" works this way.

Following Yablo, let "cassini" be a term for a certain class of mathematically defined geometric figures, of a sort that actually cause "oval"-responses. Then (given Yablo's view of "oval"), it is not a priori that cassinis are ovals. So "cassinis are not ovals" is ideally negatively conceivable. "Cassinis are not ovals" is also plausibly ideally positively conceivable, since it is verified by a situation in which cassinis are not the
sort of object that cause "oval"-responses. But Yablo suggests that "cassinis are ovals" is nevertheless true in all worlds considered as actual: in all such worlds, cassinis fall under the extension of "oval". If this is correct, then ideal (negative or positive) primary conceivability does not entail primary possibility.

In response: As I have characterized considering-as-actual, it is clear that "cassinis are oval" is true of some worlds considered as actual. Let W be a world in which cassinis cause oval-responses. Let us grant that it is a priori that if W is actual, cassinis cause oval-responses. (Yablo raises no objection to this.) We can also note that if "oval" functions as described, then a material conditional such as "if Hs cause oval responses, then Hs are ovals" is pretty clearly a priori. (Yablo himself allows that there may be an apriori connection here.) It follows that the material conditional "if W is actual, cassinis are ovals" is a priori. So as I have defined things, "cassinis are ovals" is true in W considered as actual, and is primarily possible.

Why does Yablo resist this straightforward conclusion? It seems to me that he is operating with a different conception of how statements are evaluated in considering a world as actual, one tied to the "if it had turned out" location and to certain claims about "conceptual necessity". I am not sure that I fully grasp this conception, but for present purposes I need not deny that it is coherent or that it captures some feature of our concepts. But it is clearly distinct from the conception I am operating with, on which considering as actual involves a priori reasoning about epistemic possibilities. Yablo gives no reason to deny that this conception is coherent, or that it yields the results I have suggested. So the conceivability-possibility link that I have advocated is unthreatened by Yablo's discussion.

Something similar applies to other claims that Yablo discusses, including "unless we are greatly misled about the circumstances of visual perception, what looks green is green". If this (or something like it) is a priori, then like all a priori statements, it will automatically hold in all worlds considered as actual, at least on my conception of considering as actual (though perhaps not on Yablo's). And the statement "Fs are not red", where "F" involves a complete intrinsic characterization of something that is actually red, will be a posteriori, primarily positively conceivable, and primarily possible on my conception: it will be straightforwardly true in a world (considered as actual) where Fs do not look red.

At one point Yablo raises another worry about response-dependent concepts: physical and phenomenal truths may not imply truths about yellowness (say), since an characterization of the relevant phenomenology may not enable one to identify the "yellow" responses a priori. I think this is not a problem. The relevant responses are phenomenal kinds, characterized by what it is like to have them. In particular, knowledge of what it is like to experience an object (in normal circumstances) enables knowledge of whether the object is yellow, with no further empirical justification required. Further, physical and phenomenal knowledge enable knowledge of what it is like to experience the relevant objects (in normal circumstances), with no further empirical justification required. It follows that the physical and phenomenal truths imply the truths about yellowness.

(4) Psychophysical laws. A final example is given by some type-B materialist views, on which there is an epistemic gap between the physical and the phenomenal, but no ontological gap. On such a view, zombies (and the like) are positively conceivable but not possible. Type-B materialists often appeal to Kripkean cases for support, but it is not hard to see that these do not help, since those cases are compatible with the
primary conceivability-possibility link, and even the primary possibility of zombies causes problems for materialism. In response, some type-B materialists deny that zombies are even primarily possible. On such a view, psychophysical laws (of the form "if P, then Q" for physical P and phenomenal Q) are strong necessities.

Again, this view is highly controversial, so it does not provide any clear counterexample. This view is usually put forward on the grounds that it is the only tenable way to preserve materialism, given the epistemic gap; but of course that falls well short of a positive argument for the view, especially when the truth of materialism is at issue. Indeed, one can suggest that the conceivability-possibility link that holds elsewhere itself provides a strong argument against this view. Given the discussion above, it seems that the strong necessities required here will be unique. (Even if one thinks that God and laws of nature provide partners in crime, it is notable that the sort of strong necessity at issue there cannot save materialism: in those cases, strong necessities connect ontologically distinct existences!) Some type-B materialists (e.g. Loar 1997 and Hill 1998) have bitten this bullet and tried to give an explanation of why strong necessities should uniquely arise in the phenomenal domain. I have argued elsewhere (Chalmers 1999) that these explanations fail.

In summary: in each case, the claim that there are strong necessities rests on very controversial assumptions. One might more plausibly argue in reverse: in each of these cases, the elsewhere unbroken link between conceivability and possibility provides an argument against the assumptions in question. In any case, there is no strong threat to the conceivability-possibility thesis here.

Still, all this at best makes a negative case for the conceivability-possibility thesis, by defeating potential counterexamples and explanations. It remains to make a positive case for the thesis, giving reasons why we should expect it to be true. I make a start on this case in Chalmers (1999). I hope to expand on this further elsewhere, but here I will just recapitulate the case briefly.

The argument involves locating the roots of our modal concepts in the rational domain. When one looks at the purposes to which modality is put (e.g. in the first chapter of Lewis 1986), it is striking that many of these purposes are tied closely to the rational and the psychological: analyzing the contents of thoughts and the semantics of language, giving an account of counterfactual thought, analyzing rational inference. It can be argued that for a concept of possibility and necessity to be truly useful in analyzing these domains, it must be a rational modal concept, tied constitutively to consistency, rational inference, or conceivability.

It is not difficult to argue that even if not all conceivable worlds are metaphysically possible worlds, we need a rational modal concept -- call it logical possibility - to best analyze the phenomena in question. For example, even if all counternomic worlds are metaphysically impossible, it will still be tremendously useful to have a wider space of worlds (or world-like entities) to help analyze and explain the hypotheses and inferences of a scientist investigating the laws of nature. Further, there is no bar to a space of such worlds. If one does not want simply to postulate them, one can easily construct them in an "ersatz" way - via equivalence classes of qualitatively complete (or epistemically complete) descriptions, for example - and introduce means of semantic evaluations such that the worlds in question are perfectly well-behaved.
One can then argue that this space of worlds suffices to account for all modal phenomena that we have reason to believe in. Such a space will analyze such rational and psychological matters as counterfactual thought, rational inference, and the contents of thought and language as well as any other modal can. And with the help of a little two-dimensional semantics, it can account for such "metaphysical" modal phenomena as the concept/property distinction, a posteriori necessities, and so on. The two-dimensional semantics in question will be grounded in a priori conceptual analysis plus nonmodal facts about the actual world. So one modal space plus conceptual analysis plus nonmodal facts gives us everything, as long as this modal space is tied constitutively to the rational domain. If this modal space is all, we have modal monism.

The believer in strong necessities, by contrast, must embrace a modal dualism, with distinct primitive modalities of logical and metaphysical possibility, neither of which is reducible to the other. There is no good reason to accept such a modal dualism, when modal monism can explain all the untendentious phenomena. One can argue further that there is no distinct concept of metaphysical possibility for the second modality to answer to. The momentary impression of such a concept stems from a confused understanding of such ontic/epistemic distinctions such as that between apriority and necessity, and that between concept and property, all of which are easily subsumed under a modal monism with the help of some two-dimensional semantics.

Ultimately, there is just one circle of modal concepts, including both the rational modal concepts (validity, rational entailment, a priority, conceivability) and the metaphysical modal concepts (possibility, necessity, property). The result we are left with is modal rationalism in more senses than one: a priori access to modality, and constitutive ties between the modal and rational domains.

**CONCLUSIONS**

We can sum up the lay of the land by labeling some varieties of modal rationalism:

**WEAK MODAL RATIONALISM**: (Ideal primary) positive conceivability entails (primary) possibility.

**STRONG MODAL RATIONALISM**: Negative conceivability entails possibility.

**PURE MODAL RATIONALISM**: Positive conceivability $\leftrightarrow$ negative conceivability $\leftrightarrow$ possibility.

Then

**PURE MODAL RATIONALISM $\leftrightarrow$ WEAK MODAL RATIONALISM & NEGPOS**

The left-to-right direction here is obvious, and the right-to-left direction follows from the observation that
Does Conceivability Entail Possibility?

possibility entails negative conceivability (no primary possibility is ruled out a priori). Combining this with the previous result about the nature of the twilight zone, we can say:

**PURE MODAL RATIONALISM <-> WEAK MODAL RATIONALISM & GENERALIZED SCRUTABILITY & NOINCONCEIVABILITY.**

It follows that to establish pure modal rationalism, we must rule out strong necessities, generalized inscrutabilities, and open inconceivabilities. Here I am most confident about the first, reasonably confident about the second, and unsure about the third. I have outlined a case against strong necessities here, and given tentative reasons to be doubtful about inscrutabilities, while the status of open inconceivabilities is unclear. In any case, it seems to me that each of these three is a distinct and substantial philosophical project, and that the investigation of each raises deep philosophical questions and promises significant philosophical rewards.

If weak modal rationalism is the best we can establish, then we will have done enough to support conceivability arguments as traditionally used, although the overall picture of modality and of modal epistemology will remain somewhat messy. We will have distinct notions of positive and negative conceivability, and thus a mild dualism within the rational modal sphere (though of course it will be a dualism that is forced on us by the phenomena). If there are generalized inscrutabilities, then although conceivability will guarantee access to a possible world, it may not yield access to all truths in that world. And if there are open inconceivabilities, there will be worlds that conceivability offers no access to.

Pure modal rationalism yields a simpler picture of modal space, and a correspondingly elegant epistemology. Looking at its three components in turn: the first says that positive conceivability gives us access to only possible worlds, the third says that it gives us access to all the possible worlds, and the second says that we can know all the truths about these possible worlds. In effect, we have a telescope that gives us access to all and only the stars, and that tells us the exact composition of every star. If this thesis is true, the epistemology of modality, at least when idealized, will be simple and beautiful.

**APPENDIX: THE MIND-BODY PROBLEM**

With these conceivability-possibility theses in hand, it is interesting to apply them to various conceivability arguments against materialism in the philosophy of mind.

Historically, the most important such argument has been Descartes' conceivability argument. This argues from the conceivability of my existing without a body to the possibility of my existence without a body, and so to the claim that I am not physical. The soundness of this argument is often doubted, and the standard reasons for doubt can be expressed straightforwardly in the current framework. The sense in which it is clearly conceivable that I am disembodied is primary positive conceivability, from which the 1-possibility of disembodiment follows. The sense in which physical things are essentially physical involves 2-necessity (as do all claims of de re necessity). But the 1-possibility of disembodiment is quite compatible with the 2-impossibility of disembodiment, so the claim that I am physical is not threatened by Descartes' argument.

http://www.u.arizona.edu/~chalmers/papers/conceivability.html (41 of 47) [4/7/2002 1:43:32 PM]
Does Conceivability Entail Possibility?

More recently, the knowledge argument and the zombie argument against materialism have been widely discussed. Here, let \( P \) be the conjunction of physical truths about the world, and let \( Q \) be a phenomenal truth. The zombie argument claims that zombies, and therefore \( P \& \neg Q \), are primarily positively conceivable. (Here, \( Q \) might be "someone is conscious".) The knowledge argument claims that \( Q \) cannot be derived a priori from \( P \), so that \( P \& \neg Q \) is primarily negatively conceivable. (Here, \( Q \) might be "someone is having a such-and-such experience".) From here, both step to the denial of materialism. If we use the current framework to analyze these arguments, a first pass might yield something like the following:

1. \( P \& \neg Q \) is ideally primarily positively (negatively) conceivable.
2. If \( P \& \neg Q \) is ideally primarily positively (negatively) conceivable, then \( P \& \neg Q \) is primarily possible.
3. If \( P \& \neg Q \) is primarily possible, materialism is false.

Here, premise (2) is a special case of one of the two main conceivability-possibility theses already outlined. It is notable that the zombie argument requires a weaker epistemic-modal premise here: the thesis connecting positive conceivability to possibility is weaker than the thesis connecting negative conceivability to possibility. (It requires excluding only strong necessities, not inscrutabilities.) This is offset to some extent by the fact that the knowledge argument requires a weaker epistemic premise: the claim that \( P \& \neg Q \) is negatively conceivable is weaker than the claim that it is positively conceivable.

What of the epistemic premise (1)? This is widely although not universally accepted in the knowledge argument case, and to a somewhat lesser extent in the zombie case. A materialist might deny it in two ways: either by denying even the prima facie conceivability of \( P \& \neg Q \), or by accepting prima facie conceivability but denying ideal conceivability. Some type-A materialists will deny even prima facie conceivability, but this denial is not easy to defend, since it runs counter to a very strong intuition. Others accept prima facie conceivability but deny ideal conceivability, holding that there may be a deep epistemic connection between \( P \) and \( Q \), and a deep a priori contradiction in the notion of a zombie.

The second position, exploiting the gap between prima facie and ideal conceivability, may seem particularly promising, especially in the "type-C materialist" view that holds that there is a deep connection that we have not found yet (or perhaps cannot find). But there are two problems. First, this materialist will concede that zombies are not just prima facie but secunda facie positively conceivable, and we have seen that secunda facie conceivability is an extremely good guide to possibility. Second, defeating ideal conceivability will require an a priori entailment from physical to phenomenal, which will require an analysis of phenomenal concepts that can support that entailment. Given the structural-dispositional nature of the physical concepts in \( P \), this could only be a structural or functional analysis. But there is good reason to believe that any such analysis of phenomenal concepts is a misanalysis. So while type-C strategy is an interesting strategy that deserves investigation, I think we have reason to believe that it will not succeed.
Does Conceivability Entail Possibility?

That leaves premise (3). Here, one runs up against the same problem as in the Cartesian argument. Materialism requires that the physical truths secondarily necessitate all truths, and so requires that P&~Q is secondarily possible. But there is no clear inference from the primary possibility of P&~Q to its secondary possibility. So the argument seems to be unsound as it stands. (An eliminativist who denies Q might deny (3) for different reasons, but I will set that position aside here.)

In this case, unlike the Cartesian case, the argument can be rescued. First, one can observe that if P and Q both had identical primary and secondary intensions (up to centering), then premise (3) would be straightforwardly true. Further, it is very plausible that the most important phenomenal concepts do indeed have the same primary and secondary intensions (see Chalmers forthcoming), so that Q at least can be accommodated here. And even if this is false, Q's primary intension can be seen as the secondary intension of some other truth Q', which stands to Q roughly as "watery stuff" stands to "water". As long as P has the same primary and secondary intension, then the primary possibility of P&~Q will entail the secondary possibility of P&~Q', which will itself entail the falsity of materialism.

A loophole emerges: it is not clear that P has the same primary and secondary intension. It can reasonably be argued that physical concepts have their reference fixed by some dispositional role, but refer to an underlying categorical property. If so, their primary intensions pick out whatever plays a certain role in the world (irrespective of categorical nature), while their secondary intensions pick out instances of a certain categorical property (irrespective of its role). If so, the purported "zombie world" in which the primary intension of P&~Q holds may be a world in which the secondary intension of P is false, so we cannot infer the secondary possibility of P&~Q (or P&~Q').

However, this loophole opens up only a small space for the materialist. Consider the conceived world W, in which the primary intension of P&~Q holds. Because the primary intension of P holds, this world must be structurally-dispositionally isomorphic to the actual world, with the same patterns of microphysical causal roles being played. If P's secondary intension fails, it can only be because these microphysical causal roles have different categorical bases in W (or just possibly, no categorical bases at all). This difference is the only microphysical difference between our world and W. If physicalism is true, it is this difference that is responsible for the presence of consciousness in our world and its absence in W.

What results is a view on which the existence of consciousness is not necessitated by the structural or dispositional aspects of the microphysics of our world, but is necessitated by the categorical aspects of microphysics (the underlying categorical basis of microphysical dispositions), perhaps in combination with structural/dispositional aspects. This is an important view: it is the view put forward by Russell (1926) and discussed in recent years by Maxwell (1978), Lockwood (1989), and others. In effect, the view holds that consciousness stems from the underlying categorical aspect of microphysics. On this view, the nature of the categorical aspect is left open by physical theory, but it turns out to involve special properties that are collectively responsible for constituting consciousness. We can call these special properties protophenomenal: they might not themselves be phenomenal properties, but they stand in a constitutive relation to phenomenal properties. We can call the view as a whole panprotopsychism.
It is not clear whether this sort of panprotopsychism qualifies as a version of physicalism. That question turns on whether the underlying protophenomenal properties are best counted as physical properties, or not. We need not settle that question here: We need only note that if it is a sort of physicalism, it is a quite unusual sort, and one that many physicalists do not accept. In many ways, it has more in common with nonmaterialist views, in virtue of its postulation of fundamental protophenomenal properties whose nature is not revealed to us by physical theory.

In any case, we are now in a position to reformulate the relevant argument:

1. P&~Q is ideally primarily positively (negatively) conceivable.
2. If P&~Q is ideally primarily positively (negatively) conceivable, then P&~Q is primarily possible.
3. If P&~Q is primarily possible but not secondarily possible, then panprotopsychism is true.
4. If P&~Q is secondarily possible, materialism is false.

---

5. Materialism is false or panprotopsychism is true.

The argument (in both versions) is valid, and I have given reasons to accept all of the premises. Note that one can substitute the secondary possibility of P&Q' for the secondary possibility of P&Q in the third and fourth premises, if necessary. Note also that I have said nothing about the role of indexicals and centering. One might think that these raise another loophole in the argument (around premise (3)), by opening another gap between primary and secondary possibility. It is not hard to give a fuller version that takes this role into account (see Chalmers 1998), but I omit the details here for reasons of space.

Finally, a note on Stalnaker's paper in this volume, concerning the zombie argument. Stalnaker (through his character "Anne") questions the argument, by questioning the inference from conceivability to possibility. He invokes a notion of conceivability distinct from those discussed here, which we might call 1-2-conceivability. It is 1-2-conceivable that S if it is primarily conceivable that S is secondarily possible, or more precisely, if "possibly S" is 1-conceivable, where the modal operator here represents 2-possibility. Stalnaker accepts that zombies are 1-2-conceivable (property dualism is not a priori false, and if property dualism is true, then zombies are 2-possible). But he notes that the 1-2-conceivability of S does not entail the possibility of S: the epistemic possibility of property dualism is compatible with the truth of materialism, and with the 2-impossibility (and 1-impossibility) of zombies.

I agree that the conceivability of zombies, in this sense, does not directly entail the falsity of materialism. But this sort of conceivability plays no role in the arguments I have given. What is relevant is simply the 1-conceivability of P&~Q. In the knowledge argument, the argument aims to directly establish the non-apriority of P->~Q, and so the prima negative conceivability of P&~Q. In the zombie argument itself, the claim is that it is conceivable that in the actual world, P holds but no-one is conscious. (Of course I know that I am conscious, but this is a posteriori knowledge; that issue can also be bypassed by considering only the epistemic possibility that P holds while others in the actual world are zombies.) That is, the claim is that P&~Q is primarily positively conceivable. Stalnaker says nothing to cast doubt on this claim (or the
analogous claim about negative conceivability), and he says nothing to cast doubt on the inference from primary conceivability to primary possibility. So his discussion leaves this argument untouched.

ACKNOWLEDGMENTS: I have presented this material at Arizona State University, Princeton University, and the Mighty Midwestern Metaphysical Mayhem conference at Notre Dame in summer 1999. Thanks to many on those occasions and elsewhere for discussion of these issues. Special thanks to Tamar Gendler, John Hawthorne, Bernie Kobes, and David Sosa for comments on the paper, and to Steve Yablo for discussion and correspondence.

Conceptual Analysis and Reductive Explanation

David J. Chalmers & Frank Jackson

[[Forthcoming in the Philosophical Review. This is in part a reply to Block and Stalnaker's "Conceptual Analysis, Dualism, and the Explanatory Gap".]]

1 Introduction

Is conceptual analysis required for reductive explanation? If there is no a priori entailment from microphysical truths to phenomenal truths, does reductive explanation of the phenomenal fail? We say yes (Chalmers 1996; Jackson 1994, 1998). Ned Block and Robert Stalnaker say no (Block and Stalnaker 1999).

A number of issues can be distinguished:

(1) Is there an a priori entailment from microphysical truths to ordinary macroscopic truths?

(2) If there is no a priori entailment from microphysical truths to phenomenal truths, does reductive explanation of the phenomenal fail?

(3) If there is no a priori entailment from microphysical truths to phenomenal truths, is physicalism about the phenomenal false?

(4) Is there an a priori entailment from microphysical truths to phenomenal truths?

We hold that the first three questions should be answered positively (with some qualifications to be outlined). Block and Stalnaker hold that the first three questions should be answered negatively. Their central strategy is to argue for a negative answer to the first question, and to use this conclusion to argue for a negative answer to the second and third. They argue that truths about water and about life, for example, are not entailed a priori by microphysical truths, but that this is no bar to the reductive explanation and physical constitution of water and of life.

In this paper, we will address Block and Stalnaker's arguments for a negative answer to the first three questions, while remaining neutral on the fourth. We will proceed by first giving an independent defence of a positive answer to the first question. This makes the ensuing reply to Block and Stalnaker more straightforward, and also makes the discussion accessible to those unfamiliar with the literature.

2 Clarifying the thesis
Conceptual Analysis and Reductive Explanation

The initial thesis at issue is whether there is an a priori entailment from microphysical truths to ordinary macrophysical truths. Before proceeding, this thesis needs to be clarified and qualified to meet some obvious objections.

[Horgan (1984) puts forward a version of this thesis under the name "cosmic hermeneutics", although he qualifies the thesis to allow a role for a posteriori identities involving rigid designators in inferring macroscopic truths from microscopic truths. Chalmers (1996), Jackson (1994; 1998), and Lewis (1994) argue for versions of the thesis.]

On our usage, \( P \) entails \( Q \) when the material conditional \( P \rightarrow Q \) is true; that is, when it is not the case that \( P \) is true and \( Q \) is false. An a priori entailment is just an a priori material conditional. For ease of usage, we will speak of a priori entailment as implication. On this usage, \( P \) implies \( Q \) when the material conditional \( P \rightarrow Q \) is a priori; that is, when it is possible to know that \( P \) entails \( Q \) with justification independent of experience. On this usage, entailment is a nonmodal notion, while implication involves an epistemic modality. We will assume that there are some a priori truths; general skepticism about the a priori is beyond the scope of this paper.

Let \( P \) be the conjunction of microphysical truths about the world. Microphysical truths are truths about the fundamental entities and properties of physics, in the language of a completed physics. We can also stipulate that \( P \) includes the conjunction of the fundamental laws of physics. We will not engage the issue of what counts as "physics", but will stipulate that if there are any fundamental mental entities or properties, they are not part of physics. (This begs no important questions: if the mental is fundamental, it cannot be reductively explained.) We also will not engage issues arising specifically from the foundations of quantum mechanics, and will take it for granted that microphysical truths include or imply truths about the spatiotemporal position, velocity, and mass of microscopic entities. So \( P \) will likely include or imply truths about the distribution of fundamental entities (perhaps particles, waves, and/or fields) in space-time, truths about their fundamental properties, and truths about the fundamental laws that govern them.

[To simplify, we can assume something like a Bohmian interpretation of quantum mechanics. The central claim can also be defended under other interpretations, but further complexities are involved.]

Let \( M \) be a typical macroscopic truth concerning natural phenomena, such as water or life, outside the psychological, social, and evaluative domains. Some such truths include: 'Water boils at 100 degrees Centigrade'; 'water is H2O'; 'water covers much of this planet'; 'life propagates through the replication of DNA'; 'there are many living beings'; and so on. The initial thesis at issue is that for this sort of \( M \), \( P \) implies \( M \). This thesis needs to be immediately qualified to handle some obvious loopholes.

(1) Negative truths. As described, \( P \) is compatible with the claim that there are further nonphysical entities or properties in the world: angels, perhaps, or epiphenomenal ectoplasm. So \( P \) does not imply such negative truths (if they are truths) as the truth that there are no angels, or that there is no epiphenomenal ectoplasm. For similar reasons, \( P \) does not imply such universally quantified truths as the truth (if it is a truth) that all living beings contain DNA molecules.
This loophole can be closed by conjoining to $P$ a "that's-all" statement $T$, asserting that our world is a *minimal* world satisfying $P$. Intuitively, this statement says that our world contains what is implied by $P$, and *only* what is implied by $P$. More formally, we can say that world $W1$ *outstrips* world $W2$ if $W1$ contains a qualitative duplicate of $W2$ as a proper part and the reverse is not the case. Then a minimal $P$-world is a $P$-world that outstrips no other $P$-world.[*] It is plausible that no world containing angels is a minimal $P$-world: for any $P$-world containing angels, there is an angel-free $P$-world that it outstrips. So $P&T$ implies that there are no angels. For similar reasons, $P&T$ implies the other negative and universally quantified statements mentioned above. So the thesis at issue should be that for the relevant macroscopic truths $M$, $P&T$ implies $M$. (From now on we will abbreviate 'P&T' as 'PT', and similarly for other conjunctions among the four statements discussed in this section.)

[It is well-known that (just as in the case of defining intrinsic properties), some notion in this circle has to be taken as primitive: perhaps the notion of minimality, or of outstripping, or of containing a qualitative duplicate. One also might invoke the notion of intrinsic property itself, e.g. to say that world $W1$ outstrips if all the intrinsic properties and relations in $W2$ are correspondingly instantiated in $W1$, and if the reverse is not the case.

There is a complication that arises in characterizing the that's-all claim in terms of minimality where a priori entailment, rather than necessitation, is concerned. The relevant claim must hold that the actual world is minimal among the class of *epistemic* possibilities satisfying $P$, where an epistemic possibility corresponds intuitively to a maximally specific hypothesis that is not ruled out a priori. On some philosophical views, this might come apart from a definition in terms of minimality among the class of metaphysical possibilities. For example, on a view on which it is necessary but not a priori that God exists, 'God exists' might be entailed by $P$ conjoined with an assertion of metaphysical minimality, but not conjoined with an assertion of epistemic minimality. This can be handled straightforwardly by formalizing the notion of epistemic possibility (e.g. Chalmers forthcoming c). Alternatively, where this sort of case is concerned, one can retain the intuitive characterization of the that's-all statement.]

(2) *Indexical truths.* As described, the information contained in $PT$ specifies a world objectively. For this reason, it does not imply any indexical truths: truths such as 'I am Australian', or 'life evolved in the past', or 'there is water on this planet'. It also may not imply such truths as 'water is made of H2O'. If the universe contains an inhabited planet where there is a superficially identical liquid made of XYZ, then the information in $PT$ alone will not allow us to decide whether we live on the H2O planet or on the XYZ planet, so $PT$ is at least epistemically compatible with the claim that water is made of XYZ.

This loophole can be closed by conjoining to $PT$ some *locating* information (or *indexical* information) $I$. $I$ can be thought of as a "you are here" marker added to the objective map given by $PT$. $I$ can consist of the conjunction of any two truths 'I am A' and 'now is B', where $A$ is an identifying description of myself (or the subject in question) and $B$ is an identifying description of the current time. (An identifying description is a description such that $PT$ implies that there is a unique individual or time satisfying the description.) As long as $PT$ implies all relevant objective information, then $I$ will enable the subject to "locate" himself or herself, and $PTI$ will imply all indexical truths.[*] So the thesis at issue should be that for the relevant macroscopic truths $M$, $PTI$ implies $M$.

[Strictly speaking, to handle some cases (e.g. the "Two Tubes" case discussed in Austin 1990), $I$ needs to contain further indexical information, such as information about the referent of certain special demonstratives (see Chalmers forthcoming...]

http://www.u.arizona.edu/~chalmers/papers/analysis.html (3 of 34) [4/7/2002 1:43:38 PM]
(3) *Phenomenal truths.* One of the questions at issue is whether phenomenal truths - truths concerning states of phenomenal consciousness - are implied by microphysical truths. Many hold that they are not, and hold that adding indexical and that's-all information does not close the gap. We will not adjudicate that issue here. But we note that if phenomenal truths are not implied by $PTI$, then it is likely that many other macroscopic truths are not so implied either. For example, knowing whether an object is red arguably requires knowing whether it is the sort of object that causes a certain sort of color experience, and knowing whether an object is hot arguably requires knowing whether it is the sort of object that causes experiences of heat. If so, then if truths about color experience and heat experience are not implied by $PTI$, truths about color and heat are not implied either.

This loophole can be closed while remaining neutral on the important issues, by conjoining $Q$, the conjunction of all phenomenal truths, to $PTI$. $Q$ will specify the phenomenal states and properties instantiated by every subject bearing such states and properties, at every time. That is, for every subject who is phenomenally conscious at a given time, $Q$ will specify precisely what it is like to be that subject at that time. We can also stipulate that $Q$ includes any fundamental principles that lawfully govern phenomenal states, or that connect phenomenal states with physical states. The thesis at issue is then whether $PQTI$ implies the relevant macroscopic truths $M$, which we can now understand to include truths about color and heat, as well as phenomenal truths.

To see that this is a neutral way of posing the issue, note that if $PQTI$ implies all such $M$ (as we shall argue), then either (i) $PTI$ alone implies all such $M$, or (ii) $PQTI$ implies all such $M$, but $PTI$ does not. In the first case, the original thesis involving $PTI$ will be upheld. (In this case, phenomenal truths will themselves be implied by $PTI$.) In the second case, all failures of $PTI$ to imply a relevant $M$ will be associated with the failure of $PTI$ to imply $Q$, in the sense that adding $Q$ will close any epistemic gaps. Putting these cases together, the thesis concerning $PQTI$ entails the crucial claim that if phenomenal truths are not implied by $PTI$, then there is a special epistemic gap in the phenomenal case.

(If we combine these alternatives with the thesis that reductive explanation goes along with a priori entailment, then the first alternative above leads to the view that all the relevant macroscopic truths, including phenomenal truths, are reductively explainable. The second alternative leads to the view that phenomenal truths are not reductively explainable, and that other macroscopic truths are reductively explainable "modulo phenomenology" - that is, that we can reductively explain those aspects of them for which the phenomenal plays no conceptually constitutive role. This would fit nicely with the view (articulated by Nagel 1974 and Searle 1991, among others) that the actual reductive explanation of phenomena such as color and heat has proceeded by explaining their objective aspects while leaving their subjective aspects untouched.)
Note that the addition of $Q$ to the conjunction changes the way that we define $T$ and $I$. $T$ will now hold that the actual world is a minimal world satisfying $PQ$, and $I$ will involve identifying descriptions of a subject and a time relative to the information in $PQ$. (In fact, if $P$ does not imply $Q$ and $Q$ is true, then the original version of $PTI$ is false.) So the crucial thesis is that $PQTI$, understood as the conjunction of $P$ and $Q$ with $T$ and $I$ so understood, implies $M$, for the relevant $M$. Note also that the information in $I$ depends on the specification of a subject and a time, so that strictly speaking, $PQTI$ will vary between subjects, and the thesis will be that $PQTI$ implies $M$ for any given subject and time in our community. In what follows, we will assume that an arbitrary subject and time have been selected.

3 A Priori Entailment and Conceptual Analysis

It is sometimes claimed that for $A \rightarrow B$ to be a priori, the terms in $B$ must be definable using the terms of $A$. On this view, a priori entailment requires definitions, or explicit conceptual analyses: that is, finite expressions in the relevant language that are a priori equivalent to the original terms, yielding counterexample-free analyses of those terms. This is not our view. The falsity of the claim can be seen from the following.

Let $G$ be the conjunction of the statements in the following passage: 'Smith believes with justification that Jones owns a Ford. Smith initially has no beliefs about Brown's whereabouts. Smith forms a belief that Jones owns a Ford or Brown is in Barcelona, based solely on a valid inference from his belief that Jones owns a Ford. Jones does not own a Ford, but as it happens, Brown is in Barcelona.' Let $K$ be the statement 'John does not know that Jones owns a Ford or Brown is in Barcelona'.

It is plausible that $G \rightarrow K$ is a priori. But it is also plausible that there is no explicit analysis of the concept of knowledge using the terms involved in $G$. If so, a priori entailment does not require explicit analyses of the terms in the consequent using the terms in the antecedent. It is also somewhat plausible that there is no explicit analysis of the concept of knowledge at all. If so, a priori entailment does not require explicit analyses of the terms in the consequent.

The two important features of the case are the apriority of the conditional $G \rightarrow K$ and the absence of explicit analyses of the concept of knowledge. On the first point: once general skepticism about the a priori is set aside, this conditional seems to be a typical example of an a priori truth. Someone who knows that $G$ is true and who possesses the concepts involved in $K$ (in particular the concept of knowledge) is thereby in a position to know that $K$ is true, even if they lack any further relevant empirical information. That is, a grasp of the concept of knowledge (along with a grasp of the other concepts involved) and rational reflection suffices to eliminate the possibility that $G$ is true and $K$ is false.

This conditional plays an essential role in Gettier's argument for the conclusion that knowledge is not justified true belief. Gettier's argument was an a priori argument, in which empirical information played no essential role, and its conclusion is a paradigmatic example of a non-obvious a priori truth. The argument proceeds by presenting the possibility that $G$ holds, and appealing to the reader's concept of knowledge to make the case that if $G$ holds, $K$ holds (and $J$ holds, where $J$ is a corresponding positive
claim about John's justified true belief). Empirical information plays no essential role in justifying belief in this conditional, so the conditional is a priori. The a priori conditional itself plays an essential role in deriving the a priori conclusion.

On the absence of explicit analyses of knowledge: We take it that this is a reasonable conclusion to draw from four decades of failed attempts to produce explicit analyses. Certainly no explicit analysis has met with widespread approval, and proposed analyses are always confronted quickly by plausible counterexamples. Of course it could be that there is a correct explicit analysis that has not yet been produced, or that has been produced but overlooked. But even if so, it seems clear that the a priori entailment from $G$ to $K$ is not hostage to an explicit analysis of knowledge that would support the entailment. Whether or not there is such an analysis, the entailment is a priori all the same.

So a priori entailment does not require explicit analysis. If anything, the moral of the Gettier discussion is that the reverse is often true: explicit analyses are themselves dependent on a priori intuitions concerning specific cases, or equivalently, on a priori intuitions about certain conditionals. The Gettier literature shows repeatedly that explicit analyses are hostage to specific counterexamples, where these counterexamples involve a priori intuitions about hypothetical cases. So a priori conditionals seem to be prior to explicit analyses at least in matters of explicit justification; and in general there is no reason to hold that a priori conditionals need explicit analyses to underwrite them.

It could be argued that while these a priori entailments are not underwritten by explicit analyses, they are underwritten by explicit sufficient conditions for knowledge or its absence: for example, the condition that a belief solely based on inference from a false belief is not knowledge. Of course it is trivial that there is a sufficient condition in the vicinity of such an entailment (the antecedent provides one such), so the claim will be interesting only if the complete set of sufficient conditions for knowledge is not indefinite and open-ended. But the Gettier literature suggests precisely that the set of sufficient conditions for knowledge is open-ended in this way; if it were not, we would have a satisfactory explicit analysis. And as before, the a priori entailments are not hostage to the proposed sufficient conditions; if anything, proposed sufficient conditions are hostage to a priori intuitions about specific cases.

Once an essential role for explicit definitions is eschewed, the model of conceptual analysis that emerges is something like the following. When given sufficient information about a hypothetical scenario, subjects are frequently in a position to identify the extension of a given concept, on reflection, under the hypothesis that the scenario in question obtains. Analysis of a concept proceeds at least in part through consideration of a concept's extension within hypothetical scenarios, and noting regularities that emerge. This sort of analysis can reveal that certain features of the world are highly relevant to determining the extension of a concept, and that other features are irrelevant.

What emerges as a result of this process may or may not be an explicit definition, but it will at least give useful information about the features in virtue of which a concept applies to the world. It will usually be the case that one can find complex expressions whose conditions of application approximate those of the original concept to some degree, where one finds increasingly good approximations through increasingly complex expressions. In this way we can elucidate at least many important aspects of how a concept's
extension depends on the world. But in general, there is no reason to suppose that a finite expression yielding a counterexample-free analysis of a concept must result from this process.[*] This pattern, whereby a conditional ability to evaluate a concept's extension yields elucidation of a concept without a finite counterexample-free analysis, is illustrated very clearly in the case of 'knowledge'.

[[FJ is somewhat more optimistic than DJC about the possibility of satisfactory finite analyses, especially if one recognizes that conceptual analysis can accommodate an element of conceptual revision to clear up confusions in a folk concept. See Jackson, Pettit, and Smith 2000 for some reasons for optimism.]]

The possibility of this sort of analysis is grounded in the following general feature of our concepts. If a subject possesses a concept and has unimpaired rational processes, then sufficient empirical information about the actual world puts a subject in a position to identify the concept's extension. For example, if a subject possesses the concept 'water',[*] then sufficient information about the distribution, behavior, and appearance of clusters of H2O molecules enables the subject to know that water is H2O, to know where water is and is not, and so on. This conditional knowledge requires only possession of the concept and rational reflection, and so requires no further a posteriori knowledge.

[[We will use quoted expressions for both concepts and terms in this article, and will slide between the levels of thought and language for ease of discussion; nothing turns on this.]]

Of course this claim is trivial if the empirical information in question is allowed to include information directly involving the concept at issue (e.g. 'water'). But as this case and the case of knowledge suggests, the claim is often true even when that sort of information is excluded: a 'water'-free description of the world can enable one to identify the referent of 'water', and a 'knowledge'-free description of the world can enable one to decide whether a given belief is an instance of knowledge. In these cases, we can say that nontrivially sufficient information enables identification of a concept's extension. We will not try to give a precise account of what counts as nontrivially sufficient information (presumably one should also exclude near-synonymous expressions, such as 'aqueous' or 'epistemic'), but will leave the notion intuitive. Note that there is no requirement at this point that the information in question be microphysical, or that it be about perceptual evidence, or that it be the information in PQTI.

This ability to identify a concept's extension is not restricted to true empirical information about the actual world. If the world had turned out differently, we could still have identified the concept's extension. Correspondingly, we can evaluate the concept's extension given hypothetical information about ways the actual world might be. Let us say that a hypothesis is epistemically possible (in the broad sense) when it is not ruled out a priori. Let us say that an epistemically possible hypothesis characterizing the total state of the world corresponds to an epistemic possibility: intuitively, a specific way the actual world might turn out to be, for all one can know a priori.[*] Then sufficient information about an epistemic possibility enables a subject to know what a concept's extension will be, under the hypothesis that the epistemic possibility in question is actual. For example, in the Gettier case, it is irrelevant whether or not John's case is actual: a subject can know that if John's case as described is actual, then John does not know that someone owns a Ford. Or in the case of water, given appropriate information about the distribution, behavior, and appearance of clusters of XYZ molecules (information analogous to the information we
have about H2O in the actual world), a subject is in a position to conclude that if the information is correct, then water is XYZ.

*[[See Chalmers (forthcoming c) for a formalization of this notion. The informal characterization suffices for present purposes.]]

If something like this is right, then possession of a concept such as 'knowledge' or 'water' bestows a conditional ability to identify the concept's extension under a hypothetical epistemic possibility, given sufficient information about that epistemic possibility and sufficient reasoning. That is, possession of these concepts in a sufficiently rational subject bestows an ability to evaluate certain conditionals of the form $E \rightarrow C$, where $E$ contains sufficient information about an epistemic possibility and where $C$ is an statement using the concept and characterizing its extension, for arbitrary epistemic possibilities.[*] And conceptual analysis often proceeds precisely by evaluating conditionals like these.

*[[Determinate application of these conditionals may be restricted to epistemic possibilities that are not too far from home. When epistemic possibilities deviate greatly from our presuppositions about the actual world, some of our concepts will lose determinate application.]]

In the most important cases, these conditionals will be a priori. Certainly there will be related cases in which $E \rightarrow C$ is a posteriori: for example, it is a posteriori that if a glass contains H2O, it contains water. But these will be cases in which the antecedent $E$ does not contain sufficient empirical information to identify the concept's extension given possession of the concept alone. The a posteriority of these conditionals reflects the fact that further empirical information is required for their justification. But then all we need to do is conjoin $E$ with the relevant further empirical information $F$, and we will obtain a conditional $E' \rightarrow C$ that is knowable a priori, where $E'$ is the conjunction of $E$ and $F$. For example, in the case of 'water', identification of the concept's extension requires a great deal of further information about the distribution, behavior, and appearance of clusters of H2O molecules in the world. But once this information $F$ is conjoined with the original information $E$, we obtain a more complex conditional of the form $E' \rightarrow C$ that is plausibly a priori.

Given sufficient empirical information in the antecedent, there is good reason to believe that the resulting conditionals will be a priori. These a priori conditionals will reflect the way in which we can identify a concept's referent. If we possess a concept, then sufficient empirical information $E$ enables us to conclusively identify the concept's extension and to know associated truths $C$, and we are in a position to do this whether the information in $E$ is actual or hypothetical. Because all the relevant empirical information is present in the antecedent of the conditional, empirical information plays no essential role in justifying belief in the conditional. So $E \rightarrow C$ is a priori. We can call this sort of conditional an application conditional.

We do not claim that application conditionals with nontrivially sufficient information in the antecedent exist for all concepts. For example, it may be that there is no way to know truths about time without having empirical information that more or less explicitly invokes the concept of time. If so, there will be no antecedents with nontrivially sufficient information to imply consequents about time. Some other
primitive concepts (space? cause? consciousness?) may also be like this. But for many or most concepts, there will exist application conditionals (corresponding to arbitrary epistemic possibilities) whose antecedents contain nontrivially sufficient information.

It should be noted that nothing here conflicts with the conclusions of Kripke (1972) about names and natural kind terms. On Kripke's picture, it is an a posteriori necessity that water is H2O. But this is entirely compatible with there being an a priori conditional from certain (false) statements about the distribution, behavior, and role of XYZ to 'water is XYZ'. Kripke allows that a conditional can be a priori even when it is not necessary. For example, his view allows that claims such as 'heat (if it exists) is the dominant cause of heat sensations' is a priori, although not necessary. The same goes for many claims with similar form, such as claims about the length of the meter stick in Paris. If so, then many conditionals of the same form as 'if X is such-and-such, then X is heat' are a priori, even where it is an a posteriori necessity that heat is not X.[*]

*[[Some contemporary philosophers (e.g. Salmon 1986) go beyond Kripke's view, holding that statements such as 'heat (if it exists) is the dominant cause of heat sensations' (and the like) are not a priori, and that many apparently empirical identities of the form 'X is Y' are a priori. This counterintuitive view is usually held for theory-dependent reasons. For example, if a philosophical theory holds that statements like these express singular propositions (so that 'X is Y' expresses the same singular proposition as 'Y is Y'), and that the apriority of a statement is a function of the proposition it expresses, then given certain assumptions about the apriority of singular propositions the theory will be committed to these counterintuitive claims. We think that this is itself a good reason to reject the theories in question, and that there are also strong independent reasons to reject such theories, but we cannot go into that matter here. For present purposes, we will simply assume that the intuitive claims about apriority are correct.]]

One can put this by making the familiar observation that even if it is not metaphysically possible that water is XYZ, it is epistemically possible that water is XYZ, in the broad sense that it is not ruled out a priori that water is XYZ. It is also epistemically possible that XYZ has a certain specific distribution, behavior, and appearance (of a sort that is characteristic of water). A subject possessing the concept of 'water' can reason straightforwardly that if the second hypothesis obtains (in the actual world), then the first hypothesis obtains. This sort of a priori relationship among epistemic possibilities is entirely compatible with different necessary relationships among metaphysical possibilities.

There is also nothing here that contravenes Kripke's epistemological arguments against certain descriptive views of reference-fixing. Indeed, these arguments can be seen as invoking just this sort of reasoning about epistemic possibilities. In considering whether the term 'Gödel' is a priori equivalent to 'the prover of the incompleteness of arithmetic', Kripke considers a certain epistemically possible hypothesis on which the incompleteness of arithmetic was proved by a man named 'Schmidt' and was then stolen and promulgated by a friend named 'Gödel'. Kripke suggests that if this hypothesis is actual, then our term 'Gödel' refers not to Schmidt, who proved incompleteness, but to his friend. If so, it is not a priori that Gödel (if he existed) proved the incompleteness of arithmetic. This is a straightforward example of armchair reasoning about how the extension of a concept depends on how the actual world turns out.

One observation must be made in the case of names. It is possible that two people who use a given name might use it with different a priori application conditionals. For example, if Leverrier uses 'Neptune' as a
name for whatever planet perturbs the orbit of Uranus, then conditionals of the form 'If X is the planet that perturbs the orbit of Uranus, X is Neptune' will be knowable a priori by him. But if Leverrier's wife uses 'Neptune' knowing only that it is an astronomical object for which her husband is searching, then the conditional just mentioned will not be knowable a priori by her. She will still have an ability to know the term's extension given sufficient information about the actual world, but for her, the antecedent information will crucially require information about her husband's intentions. So possession of 'Neptune' gives the wife and the husband conditional abilities to apply the term that are somewhat different from each other: they yield different application conditionals, and they yield a different pattern of application across epistemic possibilities.

This sort of epistemic variability suggests that at least in the case of names, we should take the apriority of a sentence to be subject-relative. For example, we can say that a sentence S is a priori for a speaker when the belief that S would express for the speaker can be justified independently of experience, yielding a priori knowledge.[*] So above, 'Neptune (if it exists) perturbs the orbit of Uranus' is a priori for Leverrier but not for his wife. The relevant class of a priori conditionals will then be subject-relative in a similar way. But it remains the case that when a subject possesses a name, the subject will have a conditional ability to identify its extension given sufficient empirical information about the actual world, and the relevant conditionals will be a priori for the subject.

*[[Or we might say: a sentence S is a priori for a subject when a assertion of S by that subject would express an a priori justifiable thought, where thoughts are the sort of propositional attitude tokens apt to be directly expressed by an assertion, including beliefs and belief-like attitudes such as entertainings. The move from beliefs to thoughts accommodates the possibility that the subject does not believe what he or she asserts. An a priori justifiable thought is a thought that can be justified independently of experience, on idealized rational reflection, yielding a priori knowledge.]]

The case of names is incidental to our central purposes, but it is arguable that something similar can occur for a natural kind term such as 'water'. The most obvious cases of this will occur when a subject uses the term with deference to others in a linguistic community. Such cases will be not unlike the case of Leverrier's wife above. For present purposes, it is probably best to take it that we are stipulating that the terms in question are used nondeferentially. Deference raises issues that are orthogonal to the central issues here about reductive explanation here. Nothing important to those issues would change if we were dealing with a community of one speaker, or with only "expert" subjects.

It may be that a natural-kind term can be epistemically variable for reasons independent of deference. For example, perhaps a city-dweller might use 'water' nondeferentially for the liquid that comes out of faucets (knowing nothing of oceans), and a beach-dweller might use 'water' nondeferentially for the liquid in the oceans (knowing nothing of faucets). This sort of case can be treated as we suggested that cases involving names be treated: the subjects have different conditional abilities, and different associated conditionals will be knowable a priori for each of them. But as before, this epistemic variability gives no reasons to deny that the a priori conditionals exist. In what follows, we will usually abstract away from this sort of cross-subject variability, as the central issues about reductive explanation are largely orthogonal to these questions about variable use within a community. But when necessary, all of the claims about apriority in the following can be put in subject-relative terms.
4 On the Entailment of Macroscopic Truths

We can now address the crucial question: for the relevant macroscopic truths \( M \), does \( PQTI \) imply \( M \)?

We have already made the case that for many such truths \( M \), there is some nontrivially sufficient empirical information \( E \) such that \( E \) implies \( M \). The question now is whether the specific empirical truth \( PQTI \) is such an \( E \); that is, whether \( PQTI \) contains sufficient information to imply \( M \).

A conclusive argument for this thesis would require very detailed discussion, but here we will present some reasons for finding the thesis plausible. The basic argument has a two-step structure. First, \( PQTI \) implies complete information (in the language of physics) about the structure, dynamics, composition, and distribution of macroscopic systems, as well as about the actual and potential perceptual appearances that they present. Second, this information about macroscopic structure, dynamics, composition, distribution, and appearance (along with residual information from \( PQTI \)) implies ordinary macroscopic truths such as \( M \). But we can take things a little more slowly. To address the question, it is useful to start by imagining that one starts with only the empirical information specified by \( PQTI \), and by asking: could one thereby come to know the truth of \( M \)?

To start with, one can get some distance using \( Q \) alone. On a phenomenalist view, \( Q \) alone (construed as the complete truth about actual and counterfactual experiences) implies all truths. Even if phenomenalism is rejected, \( Q \) still gives a significant epistemic foothold on the world. Combining the complete phenomenal information in \( Q \) with the indexical information in \( I \) puts me in a position to determine the phenomenal character of my current experiences, and of my experiences throughout my lifetime. This will include in particular the phenomenal character of a lifetime of perceptual experiences. This information serves as at least an epistemic guide to many macroscopic truths, just as it does in ordinary life. If \( V \) is a specific phenomenal character of a visual experience as of a large object in front of me, then if I know that I am now having an experience with phenomenal character \( V \), then I might reasonably infer that there is a large object in front of me.[*] The same goes for many other perceptual experiences.

[*][Note that as before, \( Q \) will characterize the experience according to its phenomenal character alone, leaving causal relationships to the environment unspecified. So \( Q \) will not characterize \( V \) as the phenomenal character of visual experiences caused by large objects, and knowledge of \( Q \) will not build in this sort of causal knowledge. Rather, knowledge of \( Q \) will build in knowledge of phenomenal character: that is, knowledge of what it is like to have the relevant experiences. The relevant point here is that knowledge of phenomenal character alone plausibly gives some epistemic guidance about the nature of the environment, even if it leaves open many skeptical hypotheses.]

Of course this information does not remotely suffice to imply all the relevant macroscopic truths \( M \). First, there is a vast class of truths about which my perceptual experience give no guidance: truths concerning unperceived objects, for example. Second, for those truths \( M \) about which my perceptual experience gives guidance, it remains epistemically possible (in the broad sense) that I have these perceptual states but that \( M \) is false. Such epistemic possibilities range from traditional skeptical scenarios concerning the nonexistence of the external world to a wide range of scenarios involving perceptual illusions, false
testimony, false abductive or inductive inferences, and so on.

Nevertheless, truths about which my perceptual experience gives no guidance can often be settled by further information; and skeptical scenarios can often be ruled out by further information. Starting with the further information in \( Q \), information about others' experiences and about counterfactual experiences will give guidance about many unperceived objects. Of course numerous skeptical scenarios will still be left open, at least if phenomenalism and related views are rejected. But once the information in \( P \) (and \( T \) and \( I \)) is admitted, many such scenarios are immediately ruled out: those in which the physical world does not exist, for example. The residual question is whether the information in \( PQTI \) suffices to derive knowledge of the unknown truths, and to rule out all the skeptical scenarios.

The information in \( P \) will play a crucial role. This includes complete information about the structure and dynamics of the world at the microphysical level: in particular, it includes or implies the complete truth about the spatiotemporal position, velocity, and mass of microphysical entities. This information suffices in turn to imply information about the structure and dynamics of the world at the macroscopic level, at least insofar as this structure and dynamics can be captured in terms of spatiotemporal structure (position, velocity, shape, etc) and mass distribution. For example, for any given region of space at a time, the information in \( P \) implies information about the mass density in the region, the mass density in various subregions, the causal connections among various complex configurations of matter in the region, and the extent to which the matter in the region behaves or is disposed to behave as a coherent system. This information suffices to determine which regions are occupied wholly by causally integrated systems that are disposed to behave coherently. So the information plausibly suffices for at least a geometric characterization - in terms of shape, position, mass, composition, and dynamics - of systems in the macroscopic world.

The central point here is that a macroscopic description of the world in the language of physics is implied by a microscopic description of the world in the language of physics. Such a thesis is extremely plausible: it is not subject to any worries about translation between vocabularies, and involves only a change of scale. The only worry might concern the status of bridging principles within physical vocabulary: for example, is it a priori that the mass of a complex system is the sum of the masses of its parts? If there are any concerns here, however, they can be bypassed by stipulating that the relevant physical principles are built into \( P \). [\^] \( P \) also implies information about systems' microstructural composition, and about their distribution of systems across space and time, including the relations between systems (characterized in macrophysical terms) and about any given system's history (characterized in macrophysical terms).

[\[^\] In fact, for present purposes one could even stipulate that \( P \) contains a complete description of the world, both microscopic and macroscopic, in the language of physics. The central issues about consciousness, and the central issues that divide us from Block and Stalnaker, arise equally whether one starts with microphysics or macrophysics, and so are unaffected by such a stipulation. Still, on our view such a stipulation is unnecessary.]]

Further, the information in \( P \) and \( Q \) together will imply truths about regularities connecting the physical and phenomenal domains. \( PQTI \) will include or imply all truths about lawful covariation between the world's physical and phenomenal states. If my own phenomenal states depend directly on associated
Conceptual Analysis and Reductive Explanation

physical states, then $P$ and $Q$ in conjunction with $I$ will imply information about the dependence. If there are certain regularities by which other physical systems in the world indirectly affect my perceptual phenomenal states, then $P$, $Q$, and $I$ will imply information about those regularities. So although information about the external causes of perceptual phenomenal states is not built in to $Q$, $PQTI$ will imply information about these causes. It will also imply information about the perceptual phenomenal states that various external systems are disposed to cause when appropriately situated: that is, about the perceptual appearance of these systems.

Overall, $PQTI$ implies complete information about the (geometrically characterized) structure and dynamics of macroscopic systems and objects in the world, their spatiotemporal distribution and microstructural composition, and their actual and potential perceptual appearances. This information puts a subject in a position to conclusively know (on rational reflection) the truth or otherwise of any ordinary macroscopic claim $M$. Complete knowledge of perceptual appearances yields the information that members of our community rely on in coming to know macroscopic truths; and complete structural, dynamic, distributional, and compositional information contains all the information that we need to settle the truth of claims that perceptual information does not settle.

For example, knowledge of the appearance, behavior, and composition of a certain body of matter in one's environment, along with complete knowledge of the appearance, behavior, and composition of other bodies of matter in the environment, and knowledge of their relationships to oneself, puts one in a position to know (on rational reflection) whether or not the original system is a body of water. The same goes for knowledge of whether or not the system is gold, whether or not it is alive, whether or not it boils at a certain temperature, or whether or not it is found in the oceans. And the same applies to ordinary macroscopic truths $M$ in general: complete knowledge of structure, dynamics, composition, distribution, and appearance puts one in a position to know whether or not $M$ is true.

Further, the information in $PQTI$ serves to conclusively eliminate arbitrary skeptical hypotheses under which $M$ might be false. Hypotheses involving perceptual illusions or hallucinations are eliminated by full structural and dynamical information. Hypotheses concerning differences in the past and the future are eliminated by full distributional information. Hypotheses concerning differences in underlying causal or compositional structure are eliminated by full compositional information. Even skeptical hypotheses concerning differences in others' minds are plausibly eliminated by full phenomenal information. Further skeptical hypotheses about the subject's own relation to these systems, or about their exhaustiveness, are removed by the indexical and that's-all information in $PQTI$. A relevant skeptical hypothesis would have to be one in which the structure, dynamics, distribution, composition, and appearance of objects and systems across space and time is preserved (along with indexical and that's-all information), but on which $M$ is false. There do not seem to be any such: the knowledge outlined above suffices for conclusive knowledge of $M$.

Importantly, no other empirical information is required to justify the inference from $PQTI$ to $M$: $PQTI$ contains all the information that is needed to know $M$. We can imagine a subject engaged in a Cartesian suspension of all empirical belief, and then given the information that $PQTI$. Given this information alone, the subject would be in a position to reconstruct knowledge of the structure, dynamics, distribution,
composition, and appearance of external systems by the reasoning above, and from there to ascertain the truth of macroscopic claims such as $M$ and to eliminate any relevant skeptical hypotheses. All that is required here is possession of the concepts in $M$, the information in $PQTI$, and rational reflection.

So knowledge of $PQTI$ suffices in principle for conclusive knowledge of $M$, with no other empirical information required. The same reasoning applies hypothetically: so even without knowing $PQTI$, a subject is in a position to know that if $PQTI$ is true, then $M$ is true, and to rule out any hypothesis on which $PQTI$ is true but $M$ is not. So the subject is in a position to know the truth of the material conditional $PQTI \rightarrow M$. As before, empirical information plays no essential role in justifying knowledge of this conditional (all the information required is present in the antecedent), so the subject in a position to know the conditional a priori. It follows that $PQTI$ implies $M$.

[[One might worry: if $M$ involves a natural kind term, might belief in truths involving the term (even conditional truths) require acquaintance with the relevant kind? In response: even if acquaintance is required for possession of the concept and so for the relevant belief, it does not enter essentially into the belief's justification, for the reasons above. Whatever one says about acquaintance, it is plausible that a subject competent with the terms can in principle use 'PQTI $\rightarrow$ M' to express a belief, such that the belief is true, justified, and constitutes knowledge, and such that empirical information does not enter essentially into the justification of this knowledge. So $PQTI \rightarrow M$ will be a priori for the subject.]]

[[A more detailed argument against empirical justification is given in section 5, part (6).]]

As before, a priori knowledge of $PQTI \rightarrow M$ does not rely on any explicit analysis of the concepts involved in $M$, or on any explicit bridging principles connecting the vocabulary of $PQTI$ with the vocabulary of $M$. Just as a 'knowledge'-free description of a Gettier situation implies relevant claims about knowledge without requiring an explicit bridge between the vocabularies, $PQTI$ implies the truth of $M$ without requiring an explicit bridge between the vocabularies. Rather, $PQTI$ serves as sufficient information for determining the truth of $M$, in the sense described earlier. In effect, this breaks down into two stages: $PQTI$ serves as sufficient information for determining complete information about structure, dynamics, distribution, composition, and appearance, and this information serves in turn as sufficient information for determining the truth of $M$. So $PQTI \rightarrow M$ is an a priori application conditional.

It might be objected that we do not yet have a completed physics, so that we do not yet know what $P$ says, so we cannot know whether $PQTI$ implies $M$. But for present purposes, we do not need to know what $P$ says. All we have needed here is that $P$ implies truths about the structure and dynamics of macroscopic objects in spatiotemporal terms, along with truths about mass and about microphysical composition. And that implication is likely to be robust over physical theories. (If a physical theory does not yield this implication, we are unlikely to count it as a complete physical theory.) In any case, we stipulated earlier that we are assuming a physical theory that implies truths about the position, velocity, and mass of all microscopic entities. Given this assumption, the step to an analogous characterization of macroscopic systems proceeds as outlined above.

[[Byrne (1998) makes this sort of objection against an argument for a priori entailment in Chalmers (1996). Byrne's objections in this paper pass over the two-step character of the entailment, from microphysical structure and dynamics to...]]
It might also be objected that no human could grasp all the information in \( PQTI \), so that no human could grasp the truth of the relevant conditional. This is surely true, but it is no bar to the apriority of the conditional. Apriority concerns what is knowable in principle, not in practice, and in assessing apriority, we idealize away from contingent cognitive limitations concerning memory, attention, reasoning, and the like. Once we idealize away from human memory and processing limitations, the problem here is removed.

We can summarize the argument in a way that makes clear the role of the idealization, by appeal to a fanciful thought-experiment. Imagine a human augmented by a "virtual world" machine. This is a machine containing (i) a supercomputer to store the physical information in \( P \) and to make the a priori calculations required to move from microscopic structure to macroscopic structure, (ii) a virtual reality device to produce direct knowledge of the phenomenal states described in \( Q \), and (iii) tools that use these devices to focus on arbitrary regions of the world, and to deliver information about the macroscopic structure, dynamics, composition, and perceptual appearance of systems in those regions. Using such a machine, a human with no other empirical information could straightforwardly ascertain the truth of the relevant claims \( M \). The virtual world does no more than give access to the information contained in \( PQTI \) and process this information on a priori grounds. So if a human using such a device can ascertain the truth of \( M \), it is plausible that \( PQTI \rightarrow M \) is a priori.

One might ask: given that \( PQTI \) implies ordinary macroscopic truths, does similar reasoning suggest that \( PTI \) alone implies many such truths? Such reasoning may work for truths concerning the objective spatiotemporal structure of macroscopic systems. But for many or most macroscopic concepts (most obviously concepts such as 'green' and 'hot', but plausibly also concepts such as 'water' and 'tiger'), our application of the concepts relies essentially on associated perceptual appearances. For a typical truth \( M \) involving such a concept, \( PTI \) will imply \( M \) only if \( PTI \) implies truths about the associated perceptual appearances. And this will plausibly require that \( PTI \) implies the relevant phenomenal truths in \( Q \).

One can then ask: could reasoning such as the above establish that \( PTI \) implies the truths in \( Q \)? It seems not. There are familiar reasons (e.g. Jackson 1982) to hold that information about the structure, dynamics, and composition of physical systems does not suffice for information about the character of conscious experiences. And there are familiar reasons (e.g. Chalmers 1996) to hold that there are conceptually coherent alternative possibilities on things are physically just as in \( PTI \), but in which different sorts of experiences are present, or in which there are no experiences at all.[*] Whether or not these reasons are sound, their existence makes it clear that there is no direct argument that \( PTI \) implies \( Q \) analogous to the argument concerning \( PQTI \) above. Any argument that \( PTI \) implies \( Q \) must rest on quite different considerations.[*]

[[A reviewer asks whether this be squared with knowledge of other minds. Yes: just as the information in \( Q \) can be an epistemic guide to truths about the external world without implying those truths, the information in \( P \) (and information

http://www.u.arizona.edu/~chalmers/papers/analysis.html (15 of 34) [4/7/2002 1:43:38 PM]
about one's own mind) might be a epistemic guide to truths about other minds without implying those truths.

*[[FJ articulates considerations of this sort in forthcoming work.]]

Note that we have not argued here that \textit{PQTI} implies every truth in every domain (although we are inclined to accept this claim). Given what we have said here, it could be that certain truths in special domains - perhaps concerning mathematics, metaphysics, morality, or mentality? - are not implied by \textit{PQTI}.\[*\] Presumably this will be because these truths are not conclusively knowable even given full information about structure, dynamics, appearance, distribution, composition and so on. Perhaps these truths are knowable only through different means, or perhaps they are not conclusively knowable at all. But we hope we have said enough to make it plausible that ordinary macroscopic truths concerning everyday macroscopic natural phenomena are implied by \textit{PQTI}.

*[[One might worry in particular about mental truths concerning subjects' propositional attitudes. If these truths are not implied by \textit{PQTI}, then it is likely that many other truths will not be: for example, truths involving social concepts (e.g. 'money') or involving terms used deferentially (e.g. 'arthritis', used by an non-expert). For a more general thesis that applies to such truths, one would need to argue that \textit{PQTI} implies these mental truths (as we hold), or to expand \textit{PQTI} to include mental truths of a more general sort. This question does not affect the present discussion, as truths involving ordinary macroscopic concepts of the natural world (such as 'water' or 'gold', used nondeferentially) do not seem to be tied to propositional attitudes in this way.]]

5 Block and Stalnaker on A Priori Entailment

Block and Stalnaker give a number of arguments against a priori entailments from microphysical truths to macroscopic truths. They do not always cast things in these terms: their discussion often suggests that the issue is whether there is an analysis of macroscopic concepts "in microphysical terms", and whether principles that cross the bridge from microphysical to macroscopic are themselves "microphysical claims". This way of putting things is unfortunate, as on a natural reading these theses are implausible and much stronger than what is needed. But it is clear from the context of Block and Stalnaker's discussion that a priori entailment is the real issue, and many of their arguments are naturally seen as arguments against a priori entailments.

\begin{enumerate}
  \item \textit{Explicit analyses}. One aspect of the global structure of Block and Stalnaker's article can be seen as follows. In the first part of their article (especially sections 4-9), they argue there are no explicit analyses of typical macroscopic concepts (such as 'water' and 'life') of a sort that could support an a priori entailment from microphysical to macroscopic truths. In the second part of their article (the long section 10), they discuss the use of the two-dimensional semantic framework as an alternative to explicit analyses, and argue that the existence of the framework does not support the a priori entailments in question. The intended upshot is that the existence of these a priori entailments is doubtful, and that reductive explanation does not require a priori entailment.
  
  An argument with this structure cannot successfully make a case against a priori entailments. To see this, it suffices to note that if this sort of argument succeeds, it succeeds equally in making a case against the a
priori Gettier entailments discussed earlier. It is at least as plausible for 'knowledge' as for 'water' and for 'life' that there is no explicit analysis to support the entailments. And the general criticisms of this use of the two-dimensional framework presumably apply equally to its use in the case of 'knowledge'. But nevertheless, the a priori Gettier entailments discussed earlier exist; or at least, it is clear that this sort of argument does little to make a case against them. So by parity, this sort of argument does little to make a case against the a priori entailments we are concerned with.

We can agree with Block and Stalnaker that there are plausibly no precise explicit conceptual analyses of concepts such as 'water' and 'life' (or at least, no precise analyses of a manageable length). But as we made clear earlier (and as is also made clear in Chalmers 1996 and Jackson 1998), such explicit analyses are not required for a priori entailment.[*]

*[[As part of their argument, Block And Stalnaker suggest the most plausible conceptual analyses are restricted to connections within the same "family" of terms (as with the analysis of 'bachelor' as 'unmarried man'), so that analyses of macroscopic concepts in microphysical terms are implausible. Ned Block has suggested in correspondence that this point extends to a priori entailments, so that the only plausible a priori entailments involve connections within a family. The reasons for accepting this thesis are unclear, however. The main evidence for it seems to lie in the fact that the most familiar and uncontroversial a priori entailments involve intrafamily connections. On the view we are advocating, however, this evidence is easily explained by the fact that there are few short crossfamily a priori entailments, since crossfamily entailments will usually have detailed and unwieldy antecedents.]]

We can also agree with Block and Stalnaker that the mere existence of the two-dimensional semantic framework does not imply that the a priori entailments in question exist. As Block and Stalnaker say, the two-dimensional framework provides a good way to capture a priori connections when they exist, but the framework alone does not demonstrate specific a priori connections. But the two-dimensional framework plays no essential role in our arguments for a priori entailments.[*] It played no role in the arguments given here. In the arguments given in Chalmers (1996) and Jackson (1998), it plays only a clarifying role, in removing certain confusions that may arise from the presence of a posteriori necessary connections, and in providing a convenient shorthand for discussing the patterns by which a concept applies to the world. The core of the argument for a priori entailments proceeds independently of these semantic details, just as it does in the Gettier case.

*[[For this reason, we will not address Block and Stalnaker's discussion of the two-dimensional framework in this paper. On our use of the two-dimensional framework, the primary intension (or A-intension) of a concept reflects the a priori conditionals that capture the way a concept applies within various epistemic possibilities, in the manner suggested in section 3 of this paper. This understanding of the framework in epistemic terms differs subtly from Block and Stalnaker's understanding in terms of context-dependence; for discussion, see Chalmers (forthcoming d).]]

Insofar as it is captured by this global structure, then, Block and Stalnaker's discussion does not engage the first-order issue of whether the a priori entailments in question exist. But Block and Stalnaker's article also contains numerous arguments that go beyond what is suggested by this structure. We will discuss these in what follows.

(2) Conceivability. In a discussion about conceivability, Block and Stalnaker discuss the issue (raised by
Levine 1993) of whether it is conceivable that $P$ holds without $W$ holding, where $P$ is the complete microphysical truth and $W$ is 'water is boiling'. They discuss two senses of conceivability. In the first sense, conceivability is tied closely to a posteriori possibility and necessity, so that $P&\neg W$ is inconceivable; but this sense of conceivability is clearly irrelevant to the issue of a priori entailment. In the second sense, $P$ without $Q$ is conceivable if $Q$ cannot be deduced from $P$ using logic and conceptual truths. This sense is more clearly relevant to the issue; we would prefer that the notion be cast in the more general terms of a priori reasoning rather than explicit deduction, but this does not matter to Block and Stalnaker's discussion.[*]

They say:

[[Block and Stalnaker's first sense of conceivability is a version of what Chalmers (forthcoming b) calls "secondary conceivability". Their second sense is a version of "primary conceivability", and in particular is close to Chalmers' "ideal primary negative conceivability". Block and Stalnaker note that this notion is a purely negative notion, so that the name "conceivability" is misleading. It is worth noting that there is also a closely related positive notion in the vicinity, which Chalmers calls "ideal primary positive conceivability".]]

Let $C$ be a complete description, in microphysical terms, of a situation in which water (H2O) is boiling, and let $T$ be a complete theory of physics. Can one deduce from $T$, supplemented with analytic definitions, that H2O would boil in circumstances $C$? To see that one cannot, suppose that the deduction is taking place on Twin Earth. The stuff they call 'water' is XYZ, and the process they call 'boiling' is a process that superficially resembles boiling, but that involves a different physical process. Just as they would say (truly) 'water is XYZ, and not H2O (and if there were H2O, it wouldn't be water),' so they would say, truly, 'If there were H2O, and it were behaving like that, it wouldn't be boiling.' They could hardly deduce `H2O would boil in circumstances C' if on their meaning of `boil', H2O can't boil at all. (We assume that boiling is a natural kind concept. If you don't agree, substitute some other process term that does express a natural kind concept.)

We can agree with Block and Stalnaker that if there are residents of Twin Earth, they might truly say 'If there were H2O, and it were behaving like that, it wouldn't be boiling'. But this is irrelevant to the issue of whether there is an a priori entailment from 'H2O is behaving like that' to 'H2O is boiling'. The first is a subjunctive conditional about an explicitly counterfactual scenario, and as such is relevant to issues concerning necessity, not apriority.

Compare the following: There is plausibly an a priori entailment from something like 'molecular motion is the dominant cause of our heat sensations' ($M1$) to 'molecular motion is heat' ($M2$). But on a Twin Earth, where heat sensations are caused by something very different, residents might truly say 'if molecular motion were the dominant cause of our heat sensations, it wouldn't be heat'. The latter is a subjunctive claim about an explicitly counterfactual scenario, so at best its truth reflects negatively on the necessity of an entailment from $M1$ to $M2$. Its truth clearly has no bearing on the apriority of the entailment (which remains plausible for everything said here). The same goes for microphysics and the boiling of water.

(In fact, the thought experiment does not even bear directly on the necessity of the entailment, since presumably the necessity of an utterance in English does not entail the necessity of the homophonically.

http://www.u.arizona.edu/~chalmers/papers/analysis.html (18 of 34) [4/7/2002 1:43:38 PM]
utterance in Twin English (witness 'water is H2O'). If anything, the thought experiment bears on whether it is a priori that the entailment is necessary.)

Block and Stalnaker also say:

We don't really need a Twin Earth story to make our point. Consider a person on actual Earth, who does not know the story about how water boils - perhaps she doesn't even know that water is made up of molecules. One presents her with the theory $T$, and a description (in microphysical terms) of a water boiling situation. Can she then deduce that if $T$ is true and a situation met conditions $C$, then the H2O would be boiling? No, since for all she knows the actual situation is like the one on Twin Earth. Perhaps, if she were told, or could figure out, that the theory was actually true of the relevant stuff in her environment, she could then conclude (using her knowledge of the observable behavior of the things in her environment) that H2O is water, and that the relevant microphysical description is a description of boiling, but the additional information is of course not a priori, and the inference from her experience would be inductive.

This example is simply an illustration of the general phenomenon whereby physical information must be supplemented by locating information ("you are here") to imply relevant conclusions. The subject needs locating information to know that the theory describes her own environment and not a very different environment. So while this example may show that there is no implication from $P$ (the complete physical truth) to $W$, it does nothing to show that there is no implication from $PI$ (physical truth supplemented by locating information) to $W$. Of course (as is made clear in Chalmers 1996 and Jackson 1998) the latter is the more relevant claim.

(3) Uniqueness

In discussing the possibility of conceptual analyses of terms 'water', Block and Stalnaker spend a considerable amount of time discussing the possibility of analyzing this term as something like 'the waterish stuff around here', where 'waterish' abbreviates a cluster of descriptions of familiar macroscopic properties of water (such as clarity, liquidity, drinkability, and so on). They argue that no such analysis can succeed. The argument proceeds by considering various possible cases where there is more than one sort of stuff in the environment that satisfies the relevant descriptions. Given that we hold that explicit analysis is not required for a priori entailment, we could simply set this discussion aside as irrelevant, but there are some points that are worth discussing.

Block and Stalnaker suggest at one point that for an a priori entailment to go through, water must be analyzed as something like 'the unique waterish stuff in our environment'. This seems clearly false. First, it seems obviously epistemically possible (in the broad sense) that there could turn out to be two sorts of stuff with the relevant properties filling the oceans and lakes in our environment, in roughly equal distributions. In such a case, it seems clear that we would say that there are two sorts of water (i.e. this epistemically possible hypothesis is an instance of the epistemically possible hypothesis that there are two sorts of water). So any a priori analysis requiring uniqueness would clearly be incorrect.
Second, the falsity of an analysis involving uniqueness does nothing to rule out a priori entailment. The thought experiment above itself involves largely a priori consideration of an epistemically possible hypothesis. A priori consideration of that hypothesis suggested that it counts as an instance of the epistemically possible hypothesis that there are two sorts of water. So the thought experiment is entirely compatible with an a priori entailment from specific details concerning the hypothesis (in 'water'-free terms) to a conclusion involving water, and indeed may even positively suggest the existence of such an entailment.

If one wanted to come up with an explicit analysis that handles these cases directly, one might start simply with 'the watery stuff in our environment', which handles them well (where the phrase is naturally interpreted to cover all instances of watery stuff in our environment). There will be cases where this analysis does not work: perhaps if there is a single dominant watery stuff and small pockets of different stuff, we might count only the dominant stuff as 'water'. We could then move to something like 'the dominant watery stuff in our environment, if there is one; or any watery stuff in our environment, if there is not'. But no doubt this analysis would itself need to be refined to handle more complex cases, just as in the case of knowledge. It is probably easier, then, to give up the aim of producing a perfect explicit analysis, and to content ourselves with the observation that we have an a priori grasp of how our concepts apply to specific epistemic possibilities, when these are described in sufficient detail. Nothing about these cases contravenes this observation.

(4) Ghost heat. In the course of their discussion of uniqueness, Block and Stalnaker discuss a hypothetical epistemic possibility in which it turns out that there is "ghost heat". In this epistemic possibility, things are microphysically just as normal \((P)\) is true, so the causal role associated with heat is filled by molecular motion. But the causal role is also filled by a nonphysical substance, which we can call 'ghost heat', in a case of causal overdetermination. Block and Stalnaker say that under this epistemic possibility, it turns out that there are two sorts of heat (molecular motion and ghost heat), so that 'heat = molecular motion' turns out to be false. So \(P\) does not imply that heat is molecular motion.

We are not certain that this sort of causal overdetermination is coherent, and we are not certain that if it is coherent, then the epistemic possibility in question should be interpreted as one in which there are two kinds of heat. But even if so, the conclusion is simply an instance of the failure of the microphysical facts \(P\) to rule out epistemic possibilities in which there are further nonphysical facts. As before, ruling out these epistemic possibilities requires conjoining a "that's-all" statement \(T\), holding that the actual world is a minimal \(P\)-world to \(P\). Once \(T\) is conjoined to \(P\) (yielding \(PT\)), the hypothesis involving ghost heat is ruled out, as a world with ghost heat is clearly not a minimal \(P\)-world. So the example shows at best that \(P\) does not imply \(H\) (where \(H\) is 'heat is molecular motion'); it does not show that \(PT\) does not imply \(H\). And (as is clear in Chalmers 1996 and Jackson 1998), the latter is the more relevant claim.

Block and Stalnaker anticipate this sort of response, and reply:

Recall that Jackson's definition of physicalism recognized the possibility of a world that is a microphysical duplicate of the actual world, while also containing some additional
Conceptual Analysis and Reductive Explanation

nonphysical substances and properties. In response, a "nothing but" condition is built into the definition of physicalism by requiring for the truth of physicalism only that minimal physical duplicates of the actual world be duplicates simpliciter. But the need for this qualification presupposes that the "nothing but" condition is not something that is entailed by microphysics itself; that is, it is not a claim of microphysics that our world is a minimal physical duplicate of itself. To take the "nothing but" condition to be an implicit claim of microphysics would be to build the thesis of physicalism into microphysics, which philosophers such as Jackson and Chalmers, who reject physicalism, should be reluctant to do. They reject physicalism, not microphysics. The truth of what physicists write in textbooks does not depend on the mind-body problem. Even if it is a microphysical fact that H2O is a waterish stuff around here, it is not a microphysical fact that it is the waterish stuff around here.

The objection here seems to be that the "that's-all" statement $T$ is not itself implied by $P$. This is correct but irrelevant. The thesis is not that $T$ is part of microphysics. The theses are rather that (i) $PT$ (perhaps in conjunction with $QI$) imply the relevant macroscopic truths; that (ii) this sort of implication is required for reductive explanation; and that (iii) an analogous claim (that $PT$ necessitates all truths) is required for physicalism. Nothing that Block and Stalnaker say here gives any reason to reject these claims.

(5) Methodology and simplicity. In the background of Block and Stalnaker's specific arguments about uniqueness, there lie some more general worries about the role of a posteriori methodological considerations, such as simplicity, in determining the extension of our terms. These worries are not elaborated at length in Block and Stalnaker's discussion, but they come up in a number of places and in a number of different ways.

For example, in the discussion of ghost heat, Block and Stalnaker suggest that it is by using considerations of simplicity that we rule out the possibility of ghost heat. That seems roughly correct. Our observations are compatible with two hypotheses: $P&T$ and $P&G$, where $P$ contains the relevant physical truths, $T$ is a "that's-all" statement, and $G$ is a claim about ghost heat. We do not decide between these hypotheses purely through observation, or through deduction, but through the use of simplicity considerations such as Ockham's razor. Something similar goes on in inductive inference, and in abductive inference, and so on. These considerations play a common role in moving from partial information about the world to more complete information about the world.

All this is quite compatible with our position. It is no part of our position that a posteriori methods are never used in determining our concepts' extensions. They are used all the time: in particular, it is by using a posteriori methods that we form empirical hypotheses about how the world is. The information in $PQTI$ itself is knowable only a posteriori; and simplicity considerations play a central role in our coming to know aspects of this information. But nothing here bears on the claim that given the information about $PQTI$ (which rules out the $P&G$ hypothesis), the application of our concepts is determined a priori.

There is one passage that may bear directly on the question above. After considering our intuitions about how the term 'water' might apply to various epistemic possibilities, including possibilities in which there...
are multiple substances that play the relevant role, Block and Stalnaker write:

It is a part of the semantics of natural kind terms that they are natural kinds, but it may also
be part of the semantics of these terms that this is a defeasible condition. What is not
plausibly part of the semantics, something we all know in virtue of knowing our language
alone, is what to say in all the myriad cases in which the defeasible condition is defeated. In
these cases, what we should say will no doubt be dictated by principles of "simplicity",
conservativeness, etc.

Block and Stalnaker do not say anything to back up these claims directly, or to argue against an opponent
who holds that these conditions of application to various epistemic possibilities are as much a (tacit) part
of the concept of 'water' as the conditions of application brought out in the Gettier literature are a (tacit)
part of the concept of 'knowledge'. It should also be noted that even if these conditions of application are
not part of the semantics of 'water' in English, this does not entail that a subject's application of the term to
epistemic possibilities is not justified a priori. As we saw above in the case of 'Neptune', it may be the
case that the relevant conditionals involving a term may vary between users of a term (so that the
corresponding conditions of application are not built in to the term's semantics in English), but that each
user's knowledge of the conditionals is justified a priori all the same. So Block and Stalnaker need to give
substantive arguments against the a priori knowability of the conditionals in question.

Block and Stalnaker go on to discuss the case of 'rheumatism', in which as scientists acquired more
empirical informations about various diseases underlying a central syndrome, the term began to be used
for the syndrome rather than the diseases. And they discuss the case of 'jade', in which we discovered two
underlying substances and decided that there are two sorts of jade. Nothing here contravenes the claim
that these decisions manifested a tacit grasp of a priori conditions of application of the terms in question,
and that the relevant conditionals (from a full specification of the empirical details to conclusions about
jade and rheumatism) are a priori.

Of course the claim should not be made too strong. There is almost certainly a high degree of
indeterminacy in our concepts, in their application both to the actual world and to hypothetical epistemic
possibilities. It can sometimes happens that when an epistemic possibility is found to be actual, no clear
decision about the concept's application is dictated. In such a case there often ensues (explicit or implicit)
terminological stipulation or refinement, influenced by various sociological and pragmatic factors. It may
be that in the 'rheumatism' case, for example, the initial extension of the concept was indeterminate
between applying to the syndrome in general, and applying to the most common underlying disease. If so,
there is an equally rational possible history in which the term comes to be applied to the disease; but in
our world, it came to be applied to the syndrome.

Such cases can naturally be seen as cases of mild conceptual change, or of conceptual refinement. In these
cases, a term that formerly expressed one concept comes to express a slightly different concept, so that (i)
the term's extension becomes more determinate, (ii) certain sentences whose truth-values were previously
indeterminate come to express truths, and (iii) certain conditionals that were not a priori come to be a
priori. But these changes happen in parallel, and there is no time at which a concept's extension is not
determined a priori by truths about the underlying state of the world.

Conceptual change is the exception rather than the rule. Most of the time, decision concerning a concept's extension in response to empirical developments are dictated rationally rather than arbitrarily. Cases of this sort pose no threat to the a priori entailment thesis. To see this, note that in these cases, the relevant empirical developments could be presented in advance as an epistemically possible hypothesis, and decisions concerning the concept's extension under that hypothesis will themselves rationally accessible in principle. So the empirical knowledge in question plays no essential role in justifying the conditional from the empirical developments so a conclusion about the concept's extension. So in these cases we have no argument against a priori entailment.

(6) A priori knowledge vs. armchair knowledge.

A more general worry may be lurking in the background. It may be that Block and Stalnaker are prepared to concede that in many cases, a conditional from a sufficiently complete description of an epistemic possibility to a conclusion about a concept's extension is knowable "from the armchair", but they may deny that it is a priori. This view is suggested by the following passage (p. 43):

This seems to be armchair reasoning, reflection that does not include any obvious reference to real experiments, so it is tempting to conclude that this reflection just unfolds our concepts in a totally a priori way. But what this conclusion misses is that our reasoning about the proper epistemic response in various counterfactual situations is informed not only by our concepts, but by implicit and explicit theories and general methodological principles that we have absorbed through our scientific culture - by everything that the "we" who are performing these thought experiments believe. What people should rationally say in response to various hypothesized discoveries will vary depending on their experience, commitments and epistemic priorities.

On this view, armchair knowledge of application conditionals depends in part on general empirical background knowledge. For example, the empirical background knowledge that the world is simple may play a role in our requiring that the extension of a concept be as simple as possible. Or perhaps the knowledge that the world contains numerous natural kinds may make us more inclined to apply terms in the manner typical of natural kinds. The view can be put as follows. For relevant truths $M$: (i) a subject can know an application conditional $PQTI \rightarrow M$ from the armchair; (ii) there is some general empirical information $E$, acquired at some time in the past, that plays a role in justifying the subject's knowledge of the conditional; and (iii) empirical knowledge such as $E$ plays an essential role in justifying knowledge of the conditional. If (i) and (ii) are correct, the conditional is not known a priori; if (iii) is also correct, the conditional is not knowable a priori.

We argued in section 4 that empirical knowledge $E$ does not play this sort of justificatory role. But it is useful to further examine the roles that empirical information might play in knowledge of application conditionals. There is no question that empirical information can play a causal role in acquiring this knowledge. Empirical knowledge often plays a causal role in the acquisition of concepts with certain a
priori connections, and it sometimes play a role in triggering changes in the a priori connections associated with a term, as in the cases above. There is also no question that $E$ could play a *mediating* role in our knowledge of an application conditional. In some cases, $E$ might itself be implied by $PQTI$, and one could then straightforwardly use $E$ in combination with $PQTI$ to deduce $M$. But neither of these possibilities entails that $E$ plays an essential role in *justifying* knowledge of the relevant conditionals. We suspect that the cases in which Block and Stalnaker think that empirical information has a justifactory role are in fact cases where the information has a causal or mediating role.

To examine this matter in the context of the current objection, we will take it for granted that considerations earlier in the paper establish that for empirical truths $M$, the conditional $PQTI \rightarrow M$ is at least knowable from the armchair. The same considerations suggest that the truth or falsity of conditionals of the form $X \rightarrow M$ will be knowable from the armchair, for (false) antecedents $X$ representing specific epistemic possibilities that are analogous to but distinct from $PQTI$. (Such possibilities might include different configurations of physical and phenomenal properties, and possibilities involving different laws of nature.) Further, the earlier considerations suggest that the relevant armchair knowledge is sufficient to justify hypothetical reasoning from the hypothetical acceptance of $X$ to the conclusion that $M$. (Note that this entails that our knowledge of these conditionals is not essentially grounded, uninterestingly, in armchair knowledge that $X$ is false.) We can call the relevant conditionals *armchair conditionals*. Now the question is: insofar as an empirical claim $E$ plays a role in knowledge of armchair conditionals such as $PQTI \rightarrow M$, does it play a justificatory role or merely a causal or mediating role?

To adjudicate this issue, we can focus on the status of $E$ itself. By the usual reasoning, knowledge of $PQTI$ will enables a subject to know from the armchair whether or not $E$ is true. For example, the information in $PQTI$ puts us in a position to know that the world is reasonably simple.*[4] So there will be corresponding armchair conditionals of the form $PQTI \rightarrow E$. Further, since $E$ is a posteriori, there will also be epistemic possibilities (in the broad sense) under which $E$ is *false*: e.g., epistemic possibilities under which the world is not simple. So there will be antecedents $X$ (e.g. describing a non-simple world) such that $X \rightarrow \neg E$ is an armchair conditional. Although the epistemic possibility specified by $X$ falsifies $E$, we can nevertheless evaluate it using various ordinary concepts, yielding corresponding armchair conditionals $X \rightarrow C$.

*[[An opponent might try to avoid this line of argument by holding the truth or falsity of $E$ cannot be settled even by armchair reasoning from antecedents such as $PQTI$ and $X$. This position would require a very different sort of argument, however, arguing directly against the considerations in favor of armchair knowledge in section 4. The position is also implausible in Block and Stalnaker's favored case of simplicity.]]

We can then ask: does the role played by $E$ in knowledge of armchair conditionals $PQTI \rightarrow M$ extend to a role in knowledge of armchair conditionals $X \rightarrow C$ where $X$ falsifies $E$? (E.g., does our knowledge that the world is simple play a role in our application of concepts to a non-simple epistemic possibility?) If $E$ plays a causal role in knowledge of application conditionals, we would expect the answer to be yes. If $E$ plays a mediating role, we would expect the answer to be no. If $E$ plays a justifying role, it is not clear what we would expect the answer to be. In fact, one can argue that whether the answer is yes or no, $E$ plays no essential role in justifying the application conditionals.
If the answer is yes: then for such an $X$ and $C$, $X \rightarrow C$ and $X \rightarrow \neg E$ are armchair conditionals, so the subject can reason hypothetically from the information that $X$ to the conclusion that $C$ and $\neg E$. So if the subject were to discover that $X$ were actual (assuming rationality), the subject would come to know that $C$ and $\neg E$. $E$ would then play no essential role in justifying the subject's knowledge that $C$, as the justification for items of knowledge cannot be essentially grounded in a falsehood. A subject who rationally evaluates $X$ as a hypothetical can come to conclude $C$ (under that hypothesis) by the same rational process; so $E$ plays no essential role in justifying acceptance of the conditional from $X$ to $C$. So in this application of the concepts involved in $C$, $E$ plays no essential justificatory role. At most, $E$ plays a causal role in the subject's acquiring a concept with this pattern of application.

If the answer is no: then the justificatory role of $E$ extends at most to armchair conditionals $Y \rightarrow C$ such that there is armchair justification for $Y \rightarrow E$. Further: if there is armchair justification for $Y \rightarrow E$, then if $E$ justifies $Y \rightarrow C$, $Y \rightarrow E$ will also justify $Y \rightarrow C$ without antecedently assuming $E$ (by hypothetical reasoning from $Y$ to $E$ to $C$). So justification of $Y \rightarrow E$ is required for $E$-involving knowledge of $Y \rightarrow C$, and given this justification, $E$ plays no further essential role in justifying $Y \rightarrow C$. In particular, justification of $PQTI \rightarrow E$ is required for $E$-involving knowledge of $PQTI \rightarrow C$, and given this justification, $E$ plays no further essential role in justifying $PQTI \rightarrow C$. This suggests strongly that in these cases, $E$ plays only a mediating role in knowledge of $PQTI \rightarrow C$.

The only residual question about this second class of cases is what justifies the armchair conditional $PQTI \rightarrow E$. Knowledge of this conditional is not essentially justified by $E$ itself. To see this, note that a subject who is given the information in $PQTI$ and who antecedently suspends judgment about $E$ will nevertheless be in a position to conclude that $E$ holds. Further, the same sort of factors are plausibly relevant in justifying $PQTI \rightarrow E$ and in justifying $X \rightarrow \neg E$ for those $X$ that falsify $E$; but $E$ cannot justify the latter, for the reasons given above. Alternatively, $PQTI \rightarrow E$ might be justified by some other empirical factor $F$; but then knowledge of $E$ does not play an essential role in justifying $PQTI \rightarrow C$, contrary to the original hypothesis. Knowledge that $F$ is all that is required; and we can run the same argument for $F$. The same goes for the disjunction of $E$ and $F$, and indeed for any empirical claim. So no empirical claim plays an essential role in justifying knowledge of armchair conditionals of the form $PQTI \rightarrow C$. At most, such claims play a mediating role.

To illustrate the situation, we can take the case of simplicity, and the example of $PQTI \rightarrow M$. On both alternatives described here, a posteriori simplicity considerations might play some role in adjudicating the status of $M$. On the first alternative, this is because these considerations have played a causal role in the subject's possessing a concept whose a priori conditions of application across all epistemic possibilities involve simplicity. On the second alternative, it is because the information that the world is simple is itself derivable from $PQTI$, and thereby plays a role in the a priori process of reasoning from antecedent to consequent. Either way, the a posteriori considerations play no role in justifying the conditional itself, and are therefore no bar to its apriority.

It might be objected that if empirical considerations can play a role in affecting what is a priori involving a concept (as in the first alternative above regarding simplicity, and also on the version of the
'rheumatism' case involving terminological stipulation), then the notion of apriority is being watered down. But this seems wrong: apriority is a matter of non-empirical justification. Concept acquisition is usually empirically driven, and conceptual drift can occur in response to empirical factors, but neither of these is any bar to to the apriority of resulting claims involving the concepts.

A related objection notes that if the apriority of various sentences can be affected by empirical developments, then there is no guarantee that claims we now regard as a priori will turn out to be a priori; as a result, any metaphysical and explanatory conclusions that rest on claims about apriority are suspect. But this is wrong. Even where the sort of conceptual drift described here occurs, the relevant claims at the first stage are still a priori; it is just that later, the same sentence is used to express something different that is not a priori. The change here is merely terminological. Whether people use 'rheumatism' for the syndrome or the disease, the substantive issues concerning the phenomenon itself are the same; and whether people choose to use terms in a way that requires simplicity or not, the substantive issues concerning the phenomena are the same. The change in language simply means that we express things differently.

It may even be that in the future, people may come to use a term such as 'consciousness' or 'life' with a priori application conditions that differ from ours, due to sociological or pragmatic factors, or terminological stipulation, or terminological drift. But this sort of future terminological change has no bearing on the truth or the apriority of claims that we currently make using the term, and has no bearing on any metaphysical or explanatory conclusions that might follow. For example, it could turn out that due to this sort of drift, what someone later calls 'consciousness' can be reductively explained; but that does not imply that consciousness can be reductively explained.

We conclude that none of Block and Stalnaker's arguments against a priori entailment are compelling.

We conclude that none of Block and Stalnaker's arguments against a priori entailment are compelling.

6 Does Reductive Explanation Require A Priori Entailment?

Block and Stalnaker hold that reductive explanation does not require a priori entailment. In arguing for this thesis, their main strategy involves arguing that in paradigm cases of reductive explanation, no a
priori entailment exists. We have already rebutted these arguments. But they also offer a positive model of reductive explanation with some arguments in support. So it is worth saying something here about what reductive explanation involves. We start by examining a clear way in which reductive explanation can succeed and a clear way in which it can fail.

*A close tie between reductive explanation and a priori entailment is suggested by Chalmers 1996, Levine 1993, and Loar 1997.]*

When a concept of some natural phenomenon supports a priori entailments from the microphysical, there is a clear sense in which the phenomenon can be reductively explained. These a priori entailments might not support a reduction of the phenomenon in question to a microphysical phenomenon (at least in some senses of this term), perhaps because such entailments are compatible with multiple realizability. But nevertheless, in showing how any instance of the phenomenon is itself implied by microphysical phenomena, we show that there is a sort of transparent epistemic connection between the microphysical and macroscopic phenomena. Both the microphysical and the macroscopic phenomena are epistemically contingent, in that they involve the actualization of just one of a host of coherent epistemic possibilities. But where this sort of transparent entailment is present, the epistemic contingency in the macroscopic phenomena is reduced to the epistemic contingency in the microphysical phenomena: there is no further epistemic contingency in the connection.

When a phenomenon is entailed a priori by $PQTI$ rather than by just $P$, something similar applies. To be sure, there may be some further epistemic contingency in $T$, $I$, and possibly $Q$, so that these truths themselves may not be reductively explained. But we generally count reductive explanation "modulo totality, indexicality, and consciousness" - that is, reduction of the epistemic contingency of a phenomenon to the epistemic contingency in $PQTI$ - to be reductive explanation enough. $T$ and $I$ are sufficiently minor additions to the reduction base that they do not change much; and while $Q$ is a larger addition, scientists are prepared to put the explanation of the subjective aspects of a phenomenon (such as color and heat) on hold and settle for an explanation of the objective aspects. This "carving off" strategy arguably does not yield a complete reductive explanation of these phenomena; but at least we know just what we are not explaining.

So in a reductive explanation of a phenomenon such as water or life, we find that a low-level account of the physical processes involved will in principle imply and explain truths about the macroscopic structure, dynamics, behavior, and (in conjunction with $Q$) appearance of relevant systems. And our concepts of 'water' or 'life' dictate that systems with appropriate sorts of structure, dynamics, behavior, and appearance automatically qualify as water or as alive (at least if they are appropriately situated in our environment, or are relevantly related to systems in our environment). So the relevant microphysical truths (perhaps in conjunction with $Q$, $T$, and $I$) imply the existence of water or of life, and their existence is reductively explained. The same applies to various specific features of water and of life, which can be implied and explained in similar ways.

The corresponding view on the problem of consciousness is what Chalmers (1996; 1999) has called "type-A materialism": the view that there is an a priori entailment from $PTI$ to the phenomenal truths $Q$ (perhaps...
because phenomenal concepts are functional concepts). It is clear that if type-A materialism is true, then
the phenomenal can be reductively explained in terms of the physical, for much the same reason as above.
In this case, there will be a transparent epistemic connection from the physical to the phenomenal, and
any epistemic contingency in the phenomenal truths will be reduced to epistemic contingency in physical
truths. (And consequently, all those other macroscopic truths that are reductively explainable "modulo
consciousness" will be reductively explainable simpliciter.) As above, a priori entailment supports
reductive explanation.

Next consider a clear case of a failure of reductive explanation. Let us say that the property dualist is right
about consciousness, and that consciousness is connected to the physical only by contingent laws, perhaps
ultimately by fundamental psychophysical laws. These laws might be inferred, in principle, from
psychophysical regularities in the actual world. Given the presence of these laws, we can still arguably
have some sort of explanation of consciousness and its properties, in terms of physical processes and the
psychophysical laws. From PTI plus psychophysical laws, the various specific phenomena of
consciousness will be implied. But this will not be a case of reductive explanation, precisely because of
the need for principles in our explanatory base over and above what is present in P. The laws themselves
are not explained: they are epistemically primitive, in that they are not implied by more basic truths. [*]
And these substantive, epistemically primitive principles play a central role in the explanation of the
phenomena. So there is no transparent explanation of the phenomena in physical terms alone, and
reductive explanation fails.

[*[That is: they are not implied by truths that do not themselves involve phenomenal states. On a Humean view of laws,
fundamental psychophysical laws will be implied by truths about the distribution of physical and phenomenal states; but
this sort of implication is irrelevant to reductive explanation, as phenomenal states are what we are aiming to explain. On a
non-Humean view of laws, fundamental psychophysical laws will be straightforwardly epistemically primitive.]]

Now let us consider a third sort of case, which corresponds to the way Block and Stalnaker envisage the
situation with respect to consciousness, and to the way they envisage reductive explanation in general.
Here, as in the case above, we observe numerous psychophysical regularities between brain states and
states of consciousness. We are led to infer an underlying identity between various brain states and
phenomenal states. These identities are not entailed a priori by PTI; and correspondingly, the truths about
consciousness are not entailed a priori by PTI. But the truths about consciousness are entailed a priori by
PTI plus the identities (at least if truths about brain states are entailed a priori by PTI). So we still have a
sort of explanation of consciousness and its properties, in terms of physical processes and psychophysical
identities.

This third case is a version of what Chalmers calls "type-B materialism", on which physical truths
necessitate phenomenal truths without entailing them a priori. We think that this sort of case cannot occur,
but we will set that worry aside for the moment, and pretend that it can occur. Assuming that it can occur,
is the third case more akin to the first case or to the second case? There are different respects in which it
resembles each. Ontologically, it is more akin to the first case, involving type-A materialism, since it is
compatible with a materialist ontology on which the explained phenomenon is ultimately physical. But
epistemically, it is more akin to the second case, involving property dualism.
Like the second case, the third case yields no transparent explanation of consciousness in terms of physical processes. At best, there is an explanation in terms of physical processes plus psychophysical identities. And epistemically, the psychophysical identities play exactly the same role as psychophysical laws. They are inferred from regularities between brain processes and consciousness, in order to systematize and explain those regularities. And most importantly, the identities are not themselves explained, but are epistemically primitive. As with the second case, it is precisely because we need these epistemically primitive psychophysical principles to explain the phenomenon that transparent reductive explanation fails.

Ontologically, these identities may differ from laws. But epistemically, they are just like laws. They are epistemically primitive psychophysical "bridging" principles that are not themselves explained, but that combine with physical truths to explain phenomenal truths. An explanation of the phenomenal will have two epistemically irreducible components: a physical component and a psychophysical component. By calling the bridging principles identities rather than laws, this view may preserve the ontological structure of materialism. But the explanatory structure of this materialist view is just like the explanatory structure of property dualism.

Identities play a role in reductive explanation in other domains, of course. Identities involving heat, or temperature, or genes all have some explanatory work to do. But in these cases, the identities are not epistemically primitive. The identities between heat and the motion of molecules and the identity between genes and DNA, for example, are themselves implied by $PQTI$ (at least insofar as they are true), for the reasons canvassed earlier in this paper. So in these cases, both macroscopic truths about the phenomena and the identities themselves are transparently explained.

It is sometimes held that "identities do not need to be explained" (e.g. Papineau 1993). Block and Stalnaker say something similar ("Identities don't have explanations"). But this seems to conflate ontological and epistemological matters. Identities are ontologically primitive, but they are not epistemically primitive. Identities are typically implied by underlying truths that do not involve identities. The identity between genes and DNA, or between water and H₂O, is implied by the underlying truths in $PQTI$, for example. Once a subject knows all the truths about DNA and its role in reproduction and development, for example, the subject will be in a position to deduce that genes are DNA. So this identity is not epistemically primitive.

Of course like other truths involving macroscopic phenomena, subjects do not typically come to know these identities by deducing them from microscopic truths. But the identities are so deducible all the same, and their deducibility is what makes the phenomena in question reductively explainable. If the identities in question were epistemically primitive, then explanations of the macroscopic phenomena in terms of microscopic phenomena would have a primitive "vertical" element, and science would have established a far weaker explanatory connection between the microscopic and the macroscopic than it actually has. [*]

[*] [One could plausibly go further, and argue that a scientist's warrant to accept a micro-macro identity in the first place
Conceptual Analysis and Reductive Explanation depends on a warrant to accept in-principle deducibility of the macroscopic phenomena from underlying processes. In the absence of warrant to accept such deducibility, scientists will only be warranted in accepting correlation, not identity.]

Something similar applies even to the case of "Mark Twain is Samuel Clemens", which Block and Stalnaker discuss. A subject who knows all the qualitative truths in question - physical, mental, social - and who possesses the concepts of 'Mark Twain' and 'Samuel Clemens' will be in a position to deduce that the identity is true, even if the subject is initially ignorant of it. The subject will be in a position to know that there was an individual who was known to his parents as 'Samuel Clemens', who wrote books such as Huckleberry Finn and the like under the name of 'Mark Twain', whose deeds were causally responsible for the current discussion involving 'Mark Twain' and involving 'Samuel Clemens', and so on. From all this information, the subject will be able to easily deduce that Mark Twain was Samuel Clemens, and the deduction will be a priori in the sense that it will not rely on any empirical information outside the information specified in the base. So this identity is not epistemically primitive.

We might imagine that there are eliminativists who deny the existence of Mark Twain. They accept the existence of Samuel Clemens, and the description of his exploits: that he went under the name 'Mark Twain', that he published many of the works that we know of under that name, and so on. But they deny that Clemens was Twain: Clemens used the name, but Twain never really existed. The response to such an eliminativist seems clear. Once the eliminativist concedes the full description of Clemens' exploits and of his connection to our current use of the name 'Mark Twain', we should say: if you grant all that, you grant that Clemens was Twain. Once the qualitative description is given, there is no further fact about Twain's existence of which we are ignorant. There is at most a terminological decision to make, and the terminological decision seems clear. So the identity of Twain with Clemens is itself deducible from underlying truths.

It may be that there is a way in which it sounds odd to ask for an explanation of why Mark Twain is Samuel Clemens, or of why water is H2O. This is partly because we naturally interpret these phrases as asking for a causal or historical explanation. When asked why Mark Twain lived in Missouri, we will give a causal explanation of the factors that led him to be there and to stay there. It is not so easily to causally explain why H2O is water, or why Samuel Clemens is Mark Twain (although even here, historical explanation might do at least some work).

Setting aside causal/historical explanation, it seems no harder and no easier to reductively explain the identities that Mark Twain is Samuel Clemens or that water is H2O than it is to reductively explain the non-identities that Mark Twain lived in Missouri or that there is water in the Pacific Ocean. The slight sense of linguistic oddness is equally present all these cases, so there is nothing special about identities here. What matters is that in all these cases, the relevant truths are not epistemically primitive: they are implied by various underlying truths, and none of them are needed to deduce truths that cannot be deduced without them. So there is nothing here that gives support to the sort of epistemically primitive micro-macro identities that Block and Stalnaker need.

We have argued that (1) there is no reason to believe that there are epistemically primitive micro-macro identities; and (2) even if there were any epistemically primitive micro-macro identities, they would not
support transparent reductive explanation of the macroscopic phenomena, of the sort found in most cases of reductive explanation.

Of course an opponent could hold that such identities (if they existed) would support "reductive explanation" in some sense - e.g., a sense wherein a reductive explanation is simply an explanation that involves an ontological reduction. Nothing rests on the terminological issue, however. The significant points are (1) that this sort of explanation would be very much unlike most paradigmatic cases of reductive explanation, and (2) that by invoking an epistemically primitive bridging structure, the explanatory structure of this theory would be more akin to that of property dualism rather than that of standard materialism. We might say that this sort of theory would be ontologically reductive, but epistemically nonreductive. With this sort of theory, as with a property dualist theory, the explanatory gap between physical and phenomenal might be bridged, but it would not be closed.

7 Does Materialism Require A Priori Entailment?

We have argued elsewhere that if there are phenomenal truths that are not implied by $PTI$, then materialism is false.[*] Block and Stalnaker deny this, endorsing a version of type-B materialism, with a conceptual gap between physical and phenomenal but no ontological gap. They spend much less time on materialism than they do on reductive explanation, however. Their main counterargument again proceeds via the claim that there are no such a priori entailments for most macroscopic phenomena (which are nevertheless clearly physical). We have already addressed these arguments.

We will not discuss the tenability of type-B materialist views in depth, as there is a large recent literature on the topic.[*] But it may be worthwhile to use what has gone already to outline one way of seeing what we think is wrong with the view.

[*][Balog 1999; Chalmers 1999; Hill and McLaughlin 1999; Loar 1997; Levine 1998; Perry 2000; Yablo 2000; and many others.]

The standard form of type-B materialism invokes identities to cross the explanatory gap, between phenomenal states and physical or functional states. The identities are epistemically primitive, for reasons discussed above. Of course if we are right about what has gone before, this makes the physical-phenomenal identity unlike any other micro-macro identity, in which there is no analogous epistemic gap. And indeed, it makes the physical-phenomenal identity unlike any other identities, none of which are epistemically primitive in the same way.

A type-B materialist might bite the bullet on these things and hold that psychophysical identities are sui generis. In response, one can argue that identities between natural phenomena cannot be epistemically primitive. The point where one finds objective (non-indexical) epistemically primitive regularities among natural phenomena is precisely the point at which one finds fundamental natural laws. And one can argue
that what it is to be a fundamental law of nature is precisely to be an objective, epistemically primitive counterfactual-supporting regularity. If this is right, then if there are epistemically primitive psychophysical regularities, they must be regarded as fundamental natural laws.

A more general version of type-B materialism holds that the physical truths necessitate the phenomenal truths, whether or not there are any psychophysical identities. One can argue against this view in a similar way. The view requires that there are epistemically primitive necessities connecting natural phenomena; but one can argue that all necessities connecting natural phenomena are implied by PQT. Even Kripkean a posteriori necessities can be seen to be derivable by a priori reasoning from nonmodal empirical truths. So these necessities will be unsupported by analogies with any other clear cases of necessities.

Again, an opponent can bite the bullet and hold that these necessities are sui generis. And again, one can respond by arguing that necessities cannot be epistemically primitive in this way, and that the only epistemically primitive necessities connecting natural phenomena are natural (or nomological) necessities.

[[Among type-B materialists, Balog 1999 and Loar 1997 (and possibly others) accept that psychophysical necessities may be sui generis in this way. Balog 1999 argues that reasoning from an epistemic gap to an ontological gap is invalid, since a zombie (a physical duplicate of a conscious being, without consciousness) could engage in similar reasoning with true premises and a false conclusion. Balog's argument crucially requires the premise that a zombie's utterance of 'I am phenomenally conscious' is true. But there are good reasons to hold that such an utterance would be false or truth-valueless. (In an argument between a zombie realist and a zombie eliminativist, the eliminativist would be closer to the truth.) This conclusion is supported on independent grounds in Chalmers (forthcoming a).]]

A more detailed treatment of the arguments here requires invoking the two-dimensional semantic framework. We will not go into those details here. Note that it is only at this point that the two-dimensional framework enters our arguments in an essential way, and not earlier, as Block and Stalnaker suggest.

[[Very briefly: When the two-dimensional framework is used to argue against type-B materialism, the crucial thesis is that every a posteriori necessity has a metaphysically contingent primary intension. A posteriori necessities of the Kripkean variety all appear to have a metaphysically contingent primary intension, and are therefore compatible with the thesis. But it can straightforwardly be shown that if the thesis is true, type-B materialism is false. The only way out for the type-B materialist is to deny the thesis, accepting "strong necessities" that do not have a metaphysically contingent primary intension. The upshot is that on this view, (1) psychophysical necessities are sui generis, and that (2) one is committed to an underlying very strong modal dualism, with two distinct modal primitives (corresponding to spaces of conceptually possible and metaphysically possible worlds). Chalmers (1999) argues that this modal dualism is unacceptable.]]

8 Conclusions

We have argued that ordinary truths about macroscopic natural phenomena are entailed a priori by the combination of physical truths, phenomenal truths, indexical truths, and a that's-all statement. We have argued that reductive explanation requires a priori entailment, and (more briefly) that physicalism requires a priori entailment. If that is right, then if the phenomenal is reductively explainable in terms of the physical, then there is an a priori entailment from physical truths, indexical truths, and a that's-all
statement to phenomenal truths. Contrapositively, if there is no such entailment, then the phenomenal is not reductively explainable in terms of the physical.

This appeared in Philosophy and Phenomenological Research 59:473-93, as a response to four papers in a symposium on my book The Conscious Mind. Most of it should be comprehensible without having read the papers in question. This paper is for an audience of philosophers and so is relatively technical. It will probably also help to have read some of the book. (There is a corresponding precis of the book, written for the symposium.) The papers I'm responding to are:

- Chris Hill & Brian McLaughlin, There are fewer things in reality than are dreamt of in Chalmers' philosophy
- Brian Loar, David Chalmers' The Conscious Mind
- Sydney Shoemaker, On David Chalmers' The Conscious Mind
- Stephen Yablo, Concepts and consciousness

Contents:

- 1 Introduction
- 2 Logical supervenience (Shoemaker)
- 3 Type-B materialism
  - 3.1 The form of the argument (Hill/McLaughlin, Loar)
  - 3.2 Are there logically possible zombie worlds? (Yablo, Loar)
  - 3.3 Are there strong necessities? I. Examples (Yablo)
  - 3.4 Are there strong necessities? II. Explanations (Hill/McLaughlin, Loar)
  - 3.5 Modal rationalism
  - 3.6 Type-B materialism: Loose ends (Hill/McLaughlin, Loar)
- 4 Epiphenomenalism and the paradox of phenomenal judgment (Hill/McLaughlin, Shoemaker)
- 5 Dancing qualia (Shoemaker)

1 Introduction

The argument against materialism in The Conscious Mind has two parts. The first part, in Chapter 3 of the book, argues that facts about consciousness are not necessitated a priori by physical facts. The second part, in Chapter 4 of the book, argues that facts about consciousness are not necessitated a posteriori by physical facts. Either part of the argument might be resisted. Corresponding to these paths of resistance,
there are two very different brands of materialism, which I call type-A and type-B materialism.

Type-A materialists hold that phenomenal facts (insofar as there are such facts) are necessitated \( \textit{a priori} \) by physical facts. Such a materialist denies that physically identical zombie worlds or inverted-qualia worlds are coherently conceivable, denies that Mary (of the black-and-white room) gains any factual knowledge on seeing red for the first time, and typically embraces a functional (or eliminative) analysis of consciousness.

Type-B materialists accept that phenomenal facts are not necessitated \( \textit{a priori} \) by physical facts, but hold that they are necessitated \( \textit{a posteriori} \) by physical facts. Such a materialist accepts that zombie worlds or inverted-qualia worlds (often both) are coherently conceivable but denies that such worlds are metaphysically possible, holds that the factual knowledge that Mary gains is knowledge of an old fact in a new way, and typically embraces an \( \textit{a posteriori} \) identification of consciousness with a physical or functional property.

All of the commentators in this symposium are type-B materialists, and three of the commentaries focus on my argument against an \( \textit{a posteriori} \) necessary entailment. This makes for a focused and productive discussion. I would like to thank all the commentators for their detailed, sophisticated, and generous commentaries, which in all cases significantly advance the discussion of important issues.

I will organize my replies to parallel the discussion in the book. In order, I will discuss issues relevant to the argument against \( \textit{a priori} \) entailment (Chapter 3), then those relevant to the argument against \( \textit{a posteriori} \) entailment (Chapter 4, backed by Chapter 2), then those relevant to epiphenomenalism and the paradox of phenomenal judgment (Chapter 5), and finally those relevant to the fading and dancing qualia arguments for nonreductive functionalism (Chapter 7). The first, third, and fourth of these parts mostly revolve around Shoemaker's commentary. The second part, and by far the longest, mostly revolves around the commentaries by Hill & McLaughlin, Loar, and Yablo.

## 2 Logical supervenience

All of the commentators are type-B materialists, holding that the phenomenal facts are not entailed \( \textit{a priori} \) by the physical facts, or do not logically supervene on those facts, as I put in in the book. Unlike the others, Shoemaker endorses one element of the type-A materialist position, in that he denies that zombies are conceivable. He allows that inverted spectra are conceivable, which is enough to defeat logical supervenience in general. In effect, he holds that \textit{some} phenomenal facts (facts concerning the existence of consciousness in a system, and facts about qualitative similarity) logically supervene on physical facts, but others (facts about the specific nature of experiences) do not. Facts in the second class are entailed only \( \textit{a posteriori} \) by physical facts.

Shoemaker does not argue directly for his position here. But he says that its coherence threatens my arguments in two places. First, he says it shows how there could be a necessary entailment from physical to phenomenal even without an \( \textit{a priori} \) entailment. Second, he says it shows that I am not "entitled"
the claim that zombies are conceivable.

Taking the second point first: Shoemaker is correct to say that the conceivability of zombies is not implied by the failure of *a priori* entailment. But he is incorrect in saying that I suppose that it is so implied, and in suggesting that my entitlement to the former rests on my entitlement to the latter. The direction of support is the other way around: the conceivability of zombies is used as one argument for the failure of logical supervenience. (There are other arguments for the failure of logical supervenience, and I note (p. 101) that one might endorse this failure without endorsing the conceivability of zombies.) The argument for the conceivability of zombies rests on quite distinct considerations.

Shoemaker may be misled by the sentence he quotes from Chapter 1 (p. 23): "If there were a functional analysis of the notion of experience or of phenomenal quality, then the analysis in question would yield functional analyses of specific phenomenal properties." I take the blame for misleading him here, as the sentence is ambiguous. If "the analysis in question" is taken to refer to the analysis in the first part of the sentence, this claim might be questionable. But the expression was in fact intended to refer to a quite different analysis under discussion earlier in that paragraph. The "analysis in question" is the analysis of specific phenomenal properties as "the sort of conscious experience that tends to accompany [functional property] P". If there were a functional analysis of the concept of conscious experience, one could plug it into the quoted analysis to yield a functional analysis of the specific phenomenal properties in question, as I asserted. I apologize for the misleading ambiguity.

Shoemaker also suggests that his position shows how a psychophysical entailment can be necessary without being *a priori*. I don't think this is quite right, however. Even the conceivability of inverted worlds is enough for my arguments against a necessary connection (in Chapter 4) to go through. If we combine the conceivability of such worlds with the two-dimensional analysis of *a posteriori* necessity, it turns out that there can be *no* *a posteriori* necessary connection from physical facts to specific phenomenal facts (essentially because specific phenomenal concepts will have primary intensions that do not supervene on the physical), and Shoemaker's position will be ruled out. Of course Shoemaker may hold that there are *a posteriori* necessities that do not fit the two-dimensional model; but that point needs independent argument, and it is that argument that will do all the work. Merely exhibiting the position does no work, as my argument in Chapter 4 is itself an argument against the position.

Of course I disagree with Shoemaker's position on independent grounds. In particular I don't think that qualitative similarity and difference are functionally definable (partly because of the conceivability of zombies, and partly because I think that qualitative similarity depends only on intrinsic properties of experiences). Shoemaker says his claim should be "no more controversial" than my claim that judgment, memory, and other psychological states are functionally definable; but the claim about "judgment" and "psychological states" involve stipulative uses of those terms and are therefore trivial, while the claim about memory is not made in any definitive way and plays no role in my arguments. Even if one accepts his claim, I don't think it implies that specific qualia are fixed by physical facts, as he suggests. Shoemaker's discussion of "realizing" functional definitions seems to suggest that specific qualia should be rigidly defined as the occupiers of the relevant functional role; but that definition would be incompatible with the failure of *a priori* entailment. And without such a definition, there is no reason to
think that fixing qualitative similarity fixes qualia. In any case, the failure of \textit{a priori} entailment (which Shoemaker concedes) is all that my central arguments require.

This touches on a minor misrepresentation of my argument in Chapter 3 that occurs repeatedly. Loar says my argument against \textit{a priori} entailment is "grounded" in the conceivability of zombies, and Yablo says "everything turns on" the claim that there are zombie worlds. In fact the zombie argument is just one of five arguments against \textit{a priori} entailment, and is not obviously the most important. First, the inverted spectrum and Mary arguments make claims that do not imply the zombie claim, so someone (like Shoemaker) who rejects zombies may still accept the first two. Second, it may be more correct to say the zombie argument is grounded in the argument from absence of structural/functional analysis than vice versa. Finally, at least from a rhetorical standpoint, the Mary argument works better than the zombie argument against a type-A materialist (a conceivability claim is easy to deny, a new-knowledge claim much harder). So I would not like to give the impression that everything depends on zombies here.

\section*{3 Type-B materialism}

Type-B materialism has been perhaps the most popular position on consciousness in recent years. It simultaneously promises to take consciousness seriously (avoiding the deflationary excesses of type-A materialists) and to save materialism (avoiding the ontological excesses of the property dualist). For these purposes, Kripke's introduction of \textit{a posteriori} necessities has seemed a godsend. In recent years, almost every type-B materialist (Loar is a notable exception) has appealed to Kripkean examples in support of their position. On such a view, the relationship between consciousness and physical processes is supposed to be like that between water and H2O, or between Hesperus and Phosphorus.

In \textit{The Conscious Mind} I argue that this does not work. These (and other) standard examples of \textit{a posteriori} necessity give no support to a type-B materialist. Kripke's \textit{a posteriori} necessities can all be seen to fall under a two-dimensional framework, which has just one space of worlds (the conceivable worlds) and two intensions (primary and secondary) for terms and statements over those worlds. On this framework, the distinction between conceivability and possibility, and between epistemic and metaphysical necessity, falls at the level of statements, not worlds. In particular, \textit{a posteriori} necessities are statements with a contingent primary intension and a necessary secondary intension. It is relatively easy to see that necessities of this sort cannot save the materialist. So if \textit{a posteriori} necessity is to save the materialist, it must be a radically new form of \textit{a posteriori} necessity, a form not explicable by the two-dimensional framework, and not supportable by appeal to the Kripkean examples.

Little of this is disputed by the current commentators. Instead most of them bite the bullet and argue that psychophysical necessities are different in kind from the Kripkean examples, and not explicable by the two-dimensional framework. Let us call these \textit{a posteriori} necessities not explicable by the 2-D framework \textit{strong necessities}. I argue in the book that there is no reason to believe in strong necessities, and that they are highly problematic. In response, Hill \& McLaughlin and Loar offer what they take to be accounts of the roots of these strong necessities; and Yablo gives reasons why he thinks strong necessities must exist. Before discussing these crucial counterarguments, I will first clarify some issues concerning
my argument.

3.1 The form of the argument

Hill & McLaughlin and Loar focus on the four-step argument at the beginning of Chapter 4. This formulation does not really engage the type-B materialist, however, as it was intended to be accessible to readers ignorant of the purported distinction between conceptual and metaphysical necessity. The material most relevant to a type-B materialist can instead be found in section 2 of chapter 4, on objections from a posteriori necessity, and also in section 4 of chapter 2, which outlines the 2-D framework.

As far as the four-step argument is concerned, Loar is correct that the jump from (2) to (3) is the part that a type-B materialist should dispute. Hill & McLaughlin dispute (2) instead, but this rests on a misunderstanding of my use of "logical possibility". On my usage (as Loar and Yablo note), "logically possible" is near enough to interchangeable with "conceptually possible" (not "metaphysically possible"), and is tied by stipulation to conceivability.[*] Without noting this usage, many passages and arguments will seem nonsensical.

*[Throughout this discussion, "conceivability" should be understood as ideal conceivability, or conceivability on ideal rational reflection.]]

Here is a crucial passage from p. 68 of the book:

Most importantly, none of the cases we have seen give reason to believe that any conceivable worlds are impossible. Any worries about the gap between conceivability and possibility apply at the level of statements, not worlds: either we use a statement to misdescribe a conceived world (as in the Kripkean case, and the second Goldbach case mentioned), or we claim that a statement is conceivable without conceiving of a world at all (as in the first Goldbach case). So there seems to be no reason to deny that conceivability of a world implies possibility. I will henceforth take this for granted as a claim about logical possibility; any variety of possibility for which conceivability does not imply possibility will then be a narrower class. Someone might hold that there is a narrower variety of "metaphysically possible worlds"; but any reason for believing in such a class would have to be quite independent of the standard reasons I have considered here.

Perhaps it was not clear enough that "taking for granted" here is stipulative. I note, though, that the notion of logical possibility is introduced on p. 35 with a tie to conceivability, and the quoted passage (and much of the rest of the book) does not really make sense otherwise. I also don't think my usage is unusual; it's typical in philosophy for the adjective "logical" to be tied to matters of conceptual truth and rational inference. I don't use "conceptual possibility" as the term doesn't seem quite right to me: it downplays the role of modal intuition (as opposed to mere semantic intuition); and while mathematical truths are certainly logically necessary on my usage, it is widely held that many of them are not conceptually necessary. But if a reader wants to substitute "conceptual" for "logical" on every occurrence, she will not
be led too badly astray.

Of course, I hold that conceptual possibility = logical possibility = metaphysical possibility (at the level of worlds). But when we are discussing a potential distinction between conceptual and metaphysical possibility, "logical possibility" always goes with the former and not with the latter. Hill & McLaughlin read it as going with the latter, hence the confusion.[*]

[Hill's commentary on my book in *Analysis* (Hill 1998) rests largely on this misunderstanding. Hill says that my claim that we have a priori access to the space of logically possible worlds "begs the question"; but when "logical possibility" is understood appropriately, the claim becomes relatively uncontroversial.]

(Two further clarifications: Hill & McLaughlin locate my "argument" for premise (2) in an incidental passage on p. 131, but in fact it is given in detail in Chapter 3. And they say that I hardly discuss the view that phenomenal states are a posteriori identical with neurobiological states, but in fact it is a special case of the type-B materialist view that I discuss at considerable length.)

With this matter clarified, the step that a type-B materialist must question is certainly the step from the failure of logical supervenience to the failure of metaphysical supervenience (and hence the falsity of materialism). My argument for this step has three parts. The first part (section 4 of chapter 2) outlines the two-dimensional account of a posteriori necessity and argues that it handles all standard a posteriori necessities without a gap between conceivable and possible worlds. The second part (section 2 of chapter 4) applies the 2-D account to argue that a posteriori necessities of the usual variety cannot save materialism. The third part (later in the same section) argues that there is no reason to believe in "strong necessities" which escape the 2-D account.[*]

[Yablo calls the view that all a posteriori necessities fall under the two-dimensional account "textbook Kripkeanism". I think this may be the wrong term, partly because it is not clear that Kripke accepts the view himself, and partly because many textbook uses of a posteriori necessity are incompatible with it. If one needs a name for the position, I might suggest "two-dimensionalism" or perhaps "modal rationalism".]

The first two parts of the argument are straightforward, and none of the commentators dispute them. But a point of clarification. Hill & McLaughlin and Loar say that (in the second part) I rely on the Kripke-style observation that when it comes to phenomenal concepts, primary intension and secondary intension are the same. In fact (as Yablo notes), while I accept this observation, it is inessential to the argument. Even if primary and secondary intensions of phenomenal concepts differ, the argument against materialism goes through, although things have to be put slightly differently.

It is easy to see how, if we accept the 2-D account of a posteriori necessity, any apparent "holes" in my argument are filled in.[*] Loar's question about the step from distinct primary intensions to distinct properties is answered straightforwardly, for example: such intensions will provide different functions from worlds to extensions (remember, there is just one space of worlds), and therefore distinct properties (wrinkles about centering aside). Hill & McLaughlin question the same move, but get into unnecessary difficulties. The passage that they quote and criticize from p. 373 in fact ends as follows:
if the subject cannot know that \( R \) is \( P \) \textit{a priori}, then reference to \( R \) and \( P \) is fixed in different ways and the reference-fixing intensions can come apart in certain conceivable situations. Unless we invoke the additional machinery of strong metaphysical necessity, the difference in primary intensions will correspond to a difference in reference-fixing properties.

Nothing Hill & McLaughlin say provides any reason to deny this. They change "reference-fixing intensions" in their quotation to "[properties]", but the change is not innocent. The claim in the first sentence involves primary intensions across conceivable worlds, and is relatively uncontroversial; even Loar accepts it. And the claim in the second sentence is that this difference in intensions yields a difference in properties \textit{unless} one accepts strong necessities (i.e., unless one holds that there are \textit{a posteriori} necessities that escape the 2-D framework). Again, there is little reason to deny this.[*]

The residual question, then, is whether there are strong psychophysical necessities. Standard \textit{a posteriori} necessities have a necessary secondary intension but a contingent primary intension. A strong necessity, by contrast, is an \textit{a posteriori} necessity with a necessary primary intension. (This should be taken as the defining property of a strong necessity.) The primary intension of a strong necessity (unlike that of a standard \textit{a posteriori} necessities) will be false in no metaphysically possible world. Of course the primary intension will be false in some conceivable world, because the statement is \textit{a posteriori}. Hence the crucial feature of strong necessities, which is that they require a distinction between conceivability and possibility at the level of worlds.

In the book (p. 136), I call these "strong metaphysical necessities", and characterize them by the view that there are fewer metaphysically possible worlds than logically possible worlds. Not all of the commentators recognize their view in this description. Hill and McLaughlin's resistance is explained by their misreading of my use of "logically possible". (They also reject my characterization of the view as requiring that such necessities stem from factors independent of the semantics of the terms involved; I should have said "from the two-dimensionality of the semantics of the terms involved"). Yablo resists by denying that zombie scenarios involve "worlds" at all. Before addressing the question of whether there are strong necessities, I will address this point of Yablo's.

3.2 Are there logically possible zombie worlds?
In an interesting line of resistance, Yablo accepts that it is logically (or conceptually) possible that there are zombies, but denies that there are logically possible zombie worlds. One way to make this denial would be to stipulate that "world" means "metaphysically possible world". This would make the denial a mere terminological variant of the usual core issue: instead of discussing a gap between conceptually possible and metaphysically possible worlds, we would have to discuss a gap between conceptually possible "scenarios" and metaphysically possible worlds, where scenarios are world-like except that they are metaphysically impossible. But I think Yablo is making a deeper point, questioning whether there are any world-like objects that correspond to "zombie worlds" at all.

I think the answer to this question is clearly yes: if zombies are ideally conceivable, we need logically possible zombie worlds.[*]

*[[The same goes for inverted worlds. Here and in what follows, I use zombie worlds to stand in for any world physically the same as and phenomenally different from our own. If we allow that the primary and secondary intensions of phenomenal concepts may differ, this should be taken to include worlds in which the primary intensions of our phenomenal concepts yield different results.]]

To consider the issue, pretend for a moment that zombies are conceivable but not metaphysically possible. Even better, take another "strong necessity" view, on which the only possible worlds are those whose laws of nature are our laws. (This view differs from a weaker view on which apparently counternomic worlds should be redescribed as not containing "mass" and such at all. The latter view also endorses the metaphysical necessity of laws, but is compatible with the 2-D framework.) On such a view, counternomic scenarios, although conceivable, are reflected in no metaphysically possible worlds at all. But we still need logically possible worlds with different laws, for all sorts of reasons.

Think of the reasons why "possible worlds" talk is introduced into philosophy in the first place. Possible worlds are introduced to deal with counterfactual thought, the semantics of counterfactual language, rational inference, and the contents of belief, among other reasons. A scientist can think counterfactually (and rationally) about scenarios with different laws, and can make true utterances about these scenarios. If we are to use possible-worlds talk to characterize the contents of her beliefs in discovering laws, we will need to appeal to counternomic worlds. Without counternomic worlds, we will not be able to use worlds to make sense of her inference processes. And so on. Ruling out counternomic worlds will make possible worlds useless for many or most standard purposes. Even if someone insists that such worlds are not metaphysically possible, we need logically possible counternomic worlds.

Something similar applies to zombie worlds. Even on a type-B materialist view, we can think counterfactually (and rationally) about the possibility of a different distribution of phenomenal properties with the same physical properties. We need worlds corresponding to these possibilities to make sense of counterfactual thought, of the semantics of counterfactual utterances, of rational inferences involving consciousness, of the contents of rational beliefs about consciousness, and so on. We can write coherent science fiction about zombies, and speak coherently about the truth in such fictions. Talk of logically possible zombie worlds is justified in the usual way by their role in these uses.
I suppose one might resist by holding an extreme modal-realist view (even stronger than David Lewis's) on which possible worlds are simply "out there" and on which their connection to the rational uses in question is neither here nor there. But even on such a view, we would end up having to postulate worldlike objects ("ersatz" worlds, at the very least) for the rational purposes. And on the dominant view on which all counterfactual worlds are regarded as ersatz abstract objects, there seems no ground for resistance. It is easy to construct an ersatz object that behaves in just the way that a zombie world should. The obvious strategy is to use maximal consistent worldbooks, where "consistent" is understood in the a priori sense. One has to tread carefully in handling two-dimensional phenomena and centering, but the matter is straightforward.

Another line of resistance might liken zombie worlds to supposed "impossible worlds" with all their problems, but the analogy doesn't work. Impossible worlds simply don't behave as worlds should: statements are both true and false there, for example. In zombie worlds, statements can be semantically evaluated with ease, and they never come out both true and false. Zombie worlds can even be considered both as actual and as counterfactual, as a world should be, and statements will be well-behaved on both methods of evaluation.

Loar suggests a concern: if zombie worlds are logically possible but not metaphysically possible, such worlds won't satisfy the necessity of identity. I think this is a better argument against strong necessities than against zombie worlds: what causes problems is not the zombie worlds themselves but the postulation of strong necessities and the associated problematic identities. But if one does hold the strong necessity view, I think the right thing to say is that the necessity of identity applies only across metaphysically possible worlds, not logically possible worlds. At worst, if someone insists both on strong necessities and that worlds must satisfy the necessity of identity, we'll just have to call the zombie situation a "scenario" or some such instead. Nothing crucial changes.

So, it seems that there are overwhelming grounds for admitting something like zombie worlds into our ontology, at least given that zombies are ideally conceivable and that we have worlds in our ontology at all. More generally, there are overwhelming grounds for admitting a logically possible world for every ideally conceivable scenario: we need to do so in order to make sense of most of the things that possible worlds are supposed to make sense of. The only question is whether we also need to stipulate a distinct modality of metaphysical possibility, holding that only some of these worlds are metaphysically possible. I think not, but more on this shortly.

I have in effect just argued for Yablo's CP: we need a logically possible world for every ideally conceivable scenario if we are to make sense of the various rational notions in question. Yablo's (1)-(7) argument for CP is not my argument: on my reading, his (2) is weaker than his (1) and his (5), for example. Yablo is right, though, that I need to be able to move from de dicto to de re possibility where logically possible worlds are concerned, and that I need to exclude opacity phenomena. The conception of logically possible worlds I am using does just that. With a world for every ideally conceivable scenario, it follows that whenever it is conceivable that $P$, there will be a logically possible world in which $P$ (according to primary intension). And whenever two conceived-of scenarios are not identifiable even
under ideal rational reflection, they will correspond to distinct logically possible worlds.

Yablo asks how we conceive of worlds in order to evaluate them under primary intensions. I take Yablo's first option: we conceive of them under descriptions. I certainly don't endorse the "immaculate conception" option. Perhaps a couple of my remarks suggest the "what I would say if plopped down in W" option; this may be a useful heuristic but it is not my considered view, partly for the reasons Yablo mentions. Instead, I take a (centered) world - always under a description, of course - and consider it as an epistemic possibility, asking "what is the correct thing to say if this world is actual".

I avoid opacity phenomena not by conceiving under canonical descriptions (as Yablo suggests in his discussion of the first option), but simply because rationally inequivalent descriptions will pick out inequivalent worlds, by definition of logically possible worlds. Of course a world can be described in many different ways, but such descriptions will always yield the same results when primary intensions are evaluated, as the equivalence between the descriptions will be revealed on ideal rational reflection.

(This applies at least when the descriptions under which we conceive of worlds are intended as "primary" descriptions. We can also conceive of worlds under "secondary" descriptions, if we like, but then all bets are off. (This is more or less the distinction between 1-conceivability and 2-conceivability outlined in the book, or Yablo's distinction between conceiving of an E-verifying world and an E-satisfying world.). When worlds are conceived of in the secondary way, opacity phenomena can arise: we won't in general know whether two descriptions describe the same world (unless we have relevant empirical knowledge of the actual world, or unless the concepts' primary and secondary intensions coincide), and we can't always know whether we have conceived of a world. When worlds are conceived of in the primary way, however, no such problems arise.)

### 3.3 Are there strong necessities? I. Examples

The discussion of strong necessities in my book is relatively brief, as few people in the literature had embraced them; the great majority of type-B materialists appealed to the Kripkean examples instead. (Loar is an exception.) But I argue against strong necessities (pp. 136-38), saying there is no reason to believe in them. In particular, I say that (a) they cannot be supported by analogy with other \textit{a posteriori} necessities; (b) they involve a far more radical sort of \textit{a posteriori} necessity than Kripke's, requiring a distinction between logical and metaphysical possibility at the level of worlds; (c) they lead to an \textit{ad hoc} proliferation of modalities, (d) they raise deep questions of coherence, (e) strong necessities will be brute and inexplicable, and (f) the only motivation to postulate such necessities is the desire to save materialism. I stand by these points, but there is more to say about all of them, and each of the commentaries raises interesting questions.

The first part of the argument is the absence of analogy: there are no other counterexamples to the two-dimensional account of \textit{a posteriori} necessity. I think it is relatively uncontroversial that \textit{most a posteriori} necessities fall under the 2-D model, and certainly that the most commonly accepted examples do. Loar accepts explicitly that there are no other counterexamples to the 2-D model: he thinks that psychophysical
necessities are *sui generis*. Hill & McLaughlin appear to accept the same thing. Shoemaker touches on one source of counterexamples, though, and Yablo discusses a potential counterexample in detail.

Shoemaker mentions his view that the laws of nature are metaphysically necessary. As we have seen, this view can be interpreted as requiring that laws are strong necessities. These purported necessities are at least as tendentious as psychophysical necessities (and far less widely accepted), however, and I would use the 2-D framework to argue equally against them.

The same goes for the claim that God exists necessarily, which would also provide a strong necessity if true. Yablo adapts the God example to provide an ingenious argument for strong necessities, however. In effect, he notes that one of the following statements must be necessary: "a necessarily existing god exists", and "a necessarily existing god does not exist". But each of these statements is conceivably false (he suggests), and therefore *a posteriori*; and the necessary *a posteriori* status of either statement is not plausibly explicable by the 2-D framework. So one of these statements is a strong necessity.

I deny this, because I deny that a necessarily existing god is conceivable. Such a god may be conceivable in the sense of "not obviously inconceivable", but in no stronger sense. I certainly can form no clear and distinct conception of such a god (like many, I was suspicious of the idea the moment I heard about it as a student), and continued rational reflection reveals all sorts of problems with the idea. One thing that rational reflection reveals is the conceivability of a world *without* a god. If such an intuition is accepted, it causes grave difficulty for the coherence of the idea of a necessarily existing god. (Ideal reflection allows us to use one modal intuition in evaluating others, of course.)

The problematic issues here arise because of the double modality: we are conceiving not just of worlds "in themselves", but also of what is possible or necessary within those worlds. Conceiving of a god (an omnipotent, omniscient, and benevolent being, say) is arguably not too hard; but to conceive in addition that the being exists necessarily, we have to conceive that the space of possible worlds is such that this god exists in each of them, *despite* the conceivability of a godless world. That is, we have to conceive that the conceivability/possibility thesis (CPT: all conceivable worlds are possible worlds) is itself false. This is what does all the work in the example: if it is conceivable that CPT is false, then (by CPT!) it is possible that CPT is false, and CPT is therefore false (as it is surely necessarily true, if true).

A natural response to this sort of argument is to restrict the conceivability/possibility thesis to claims about the distribution of (nonmodal) properties within worlds, leaving double modals outside its scope. I think this response would be defensible, and not entirely *ad hoc* (CPT might still apply to worlds in themselves, although not to "cosmoses" of possible worlds; all that changes is that one can't make Yablo's "*de dicto* to *de re*" step for double modals). But I prefer to hold onto the stronger thesis, by denying that it is conceivable that CPT is false. I hold that CPT is *a priori*, although highly nontrivial, like many theses in philosophy. In fact I will sketch an *a priori* argument for CPT later in this paper. If this is correct, then CPT is not conceivably false on ideal rational reflection, and it is not ideally conceivable that a necessarily existing god exists.

One might resist the conclusion by stripping down one's conception of a god so that a god's nonexistence
becomes inconceivable. If we conceive of a god (nonrigidly) as "all there is", for example, then a god exists necessarily. (My discussion above assumes that a god is required to have contingent-seeming properties such as omnipotence.) The case of numbers and sets, which Yablo raises, is something like this. I think it is a priori that numbers exist, so inconceivable that they do not exist. Of course this depends on one's conception of numbers. There are alternative conceptions on which it is a posteriori that numbers exist, or on which it is a priori that numbers do not exist. What matters is that there is no tenable conception of numbers on which (a) there is a conceivable world in which numbers exist, (b) there is a conceivable world in which numbers do not exist, and (c) if numbers exist, they exist necessarily. I think there is no reason to deny this.[*]

*[[Another class of candidates for strong necessities might include mathematical statements that are necessarily true (even by primary intension) but not knowable a priori. It is far from clear that such statements exist (idealizing away from our cognitive limitations), but even if they exist, I do not count them as strong necessities. Unlike strong necessities, such statements open no gap between the conceivability and possibility of worlds, as opposed to statements; there is no conceivable world (considered as actual) in which these statements are false. I think such statements, if they exist, are best regarded as neither a priori nor a posteriori, but as a third category, "inscrutable". (The epistemic theory of vagueness, if true, would supply further inscrutable truths.) The existence of inscrutable truths would not help the type-B materialist, who accepts that zombie scenarios are clearly conceivable, so I set them aside here. I discuss this topic in more depth in forthcoming work.]]

3.4 Are there strong necessities? II. Explanations

If I am right so far, there are no good reasons to believe in strong necessities outside the psychophysical case. But Hill & McLaughlin and Loar both provide interesting potential explanations of why there should be strong necessities in the psychophysical case. If this worked, it would be as good as a resolution of the mind-body problem as any. Unfortunately, I don't think the proffered explanations work. Below I explain why.

Hill & McLaughlin offer a psychological explanation of why we can conceive of zombies, in terms of the independent cognitive processes by which we conceive of physical processes and by which we conceive of experiences. There are some questions about the details of this explanation; and I should note that it is not obviously a purely physical/functional explanation, as it helps itself to the unreduced notion of a sensory concept. But let me grant that some explanation along these lines can be given. The question is whether it provides any explanation of strong necessities. On the face of it, it seems not. After all, one can also give a psychological explanation of why we can conceive of red squares, in terms of the distinct cognitive processes and epistemic constraints involved in conceiving of color and shape. One can give a psychological explanation of why we can conceive of five-horned animals, or of silicon-based life. But no-one would infer that there are strong necessities denying the metaphysical possibility of red squares or five-horned animals or silicon-based life.

The form of Hill & McLaughlin's argument is far from unique to the psychophysical domain. The precise details (concerning sensory concepts and recognitional concepts) may be unique, but these details are inessential. What does the work in their argument is the distinctness of the "faculties" or the "epistemic
Materialism and the Metaphysics of Modality

constraints" that these concepts involve. One could make an argument with the same form about shape concepts and color concepts, an argument that should then be just as compelling. And one could make a very similar argument concerning any two pairs of concepts with different cognitive roles, thus "explaining away" any conceivable intuition at all. (There will always be a cognitive explanation of a modal intuition!) If this account tells us that Cartesian modal intuitions are unreliable, the same will go for all modal intuitions.

(Worse: a similar account might tell us that all of our mathematical beliefs are unreliable. There will presumably be cognitive explanations of these beliefs, too.)

The trouble is that an explanation of a strong necessity has to do two things: it has to show us why a state-of-affairs should be conceivable while at the same time being impossible. To put matters differently, it should explain why conceivability is an unreliable guide to possibility of such states-of-affairs (Hill & McLaughlin put it this way themselves). But Hill & McLaughlin have discharged only half of the burden, and the easy half: they have explained why zombies might be conceivable. But they have done nothing to explain why we should take this conceivability to be unreliable.

Hill (1997) likens his strategy to Kripke's "explaining away" of modal intuitions about heat and molecular motion, but I think it is crucially different. Kripke's strategy explains why necessity and apparent contingency are co-present: if we mistakenly describe a conceived situation by considering it as actual rather than as counterfactual, we should expect that certain necessary statements will falsely appear to be contingent. By contrast, Hill's strategy merely explains the appearance of contingency; why this appearance is co-present with necessity is not explained at all. At most, Hill tacks the hypothesis of necessity onto the end of his explanation of contingency, so it remains an unexplained explainer.

The closest Hill & McLaughlin come to addressing this burden is saying: "Given these differences between sensory concepts and physical concepts, a sensory state and its nomologically correlated brain state would seem contingently connected even if they were necessarily one" (my italics). But this may well be a deeply "per impossibile" counterfactual ("given mathematical concepts, 1+1 would seem to be 2 even if it were 3"). What we need is an explanation of how the two states could be necessarily one. Or ascending to the level of concepts, we need an explanation of how two such distinct concepts could pick out the same property, and indeed have the same property as a reference-fixer.

That is just what Loar attempts to provide. Some parts of Loar's discussion appeal only to the distinctness of cognitive role of the two sorts of concepts; as an "explanation", this has the same problems as Hill & McLaughlin's. But other parts attempt something more. In effect, they attempt to explain strong necessities by explaining how it is that physical and phenomenal concepts could pick out the same property and have the same property as their reference-fixer, despite their cognitive distinctness. The details of Loar's account here are somewhat vague, but they are spelled out in much more detail in Loar (1997), which I rely on below.

Loar appeals to two facts about phenomenal concepts: they are (a) recognitional concepts[*] that (b) express the same property that they refer to. (In Loar's terminology, the property a concept "expresses" is
Materialism and the Metaphysics of Modality

its reference-fixer, or the property corresponding to its primary intension across possible worlds.) The significance of (a) is that recognitional concepts and physical-theoretical concepts are generally cognitively distinct even when they refer to the same property. But this is not enough to save materialism: other recognitional concepts conceive of their referents under contingent modes of presentation (i.e., they have distinct primary and secondary intensions across possible worlds), so they express a property quite distinct from that expressed by the corresponding theoretical property. So Loar adds (b), noting that in the phenomenal case, uniquely, we have recognitional concepts that express the property they refer to. He appeals here to Kripke's observation about pain, in effect noting that phenomenal concepts have the same primary and secondary intension, and do not conceive of their referents under contingent modes of presentation. Granting all this, we deduce that the two concepts are cognitively distinct and coreferential (because of (a)), and that each concept expresses the property it refers to (because of (b)), from which it follows that the two concepts have the same reference-fixing property.[*] So strong psychophysical necessities are explained.

*I am not sure that phenomenal concepts should be thought of as recognitional concepts, but I will go along with Loar on this point here. In his paper in this symposium, Loar sometimes says "experiential" rather than "recognitional", but he means something similar. "Experiential concept" has a different meaning for me (it is more or less synonymous with "phenomenal concept"), so I will use "recognitional" here.]

*I require the assumption (implicit in Loar's discussion) that a physical-theoretical concept expresses the same property that it refers to. I think this is arguable, but I will go along with it to keep things simple. If this assumption is retracted, related versions of Loar's point and my reply can still be given.]

The problem with this is straightforward. The introduction of point (b) undercuts the value of point (a). The significance of point (a) for Loar lies not just in the cognitive distinctness but also the coreference of recognitional and theoretical concepts. But this coreference is explained by the two-dimensional nature of such recognitional concepts: they typically conceive of their referent as "the cause of such-and-such experience", or under some similar contingent mode of presentation. If we remove this feature of recognitional concepts (as we do in accepting (b)), we no longer have any reason to believe that recognitional concepts and distinct theoretical concepts should corefer.

As things stand, in accepting (a) and (b) we are left with the observation that phenomenal concepts and physical concepts (i) are cognitively distinct, and (ii) both express the property that they refer to. It's clear that nothing here begins to justify the coreference of phenomenal and physical concepts. In fact the situation is the opposite: in every other case of concepts satisfying (i) and (ii), they have distinct referents. One might suppose that recognitionality is doing some extra work here (thus distinguishing this case from other cases involving nonrecognitional concepts), but the only work it does for Loar is in explaining (i) and in providing cases of coreference when (ii) is false. So once (i) and (ii) are granted, there is nothing in Loar's account to justify coreference, and his explanation of strong necessity fails.

Loar slides over this point repeatedly. His argument often seems to have the form (1) Given that phenomenal concepts and physical-theoretical concepts corefer (as is typical with recognitional concepts), and (2) given that phenomenal concepts express the property that they refer to (as is unusual
with recognitional concepts), then (3) phenomenal concepts will express physical-theoretical properties. This argument is valid, but Loar fails to note that premise (2) undercuts the support for premise (1).

A final way to put the problem. Loar's account requires, and rests on the claim, that a phenomenal concept ("feels like this") might conceive of a physical property under a necessary mode of presentation. This in turn rests on the claim that a physical property might have this mode of presentation necessarily; that is, it rests on the claim that there might be a necessary connection between a physical property and a phenomenal feel. But this is just the sort of strong necessity that was in question and that we were trying to explain. So rather than explaining strong psychophysical necessities, Loar's account presupposes strong psychophysical necessities.

We see, then, that neither Hill & McLaughlin's nor Loar's account can explain strong psychophysical necessities. Instead, both accounts *assume* such necessities at a key point, as a kind of primitive. Such necessities remain as mysterious and problematic as ever.

### 3.5 Modal rationalism

Hill & McLaughlin suggest that defeating all other candidates for strong necessities doesn't count for much; all that it does is remove a few "counterexamples" to the two-dimensional analysis, or to the conceivability/possibility thesis. I think this analysis gets the dialectic wrong: most type-B materialists (even Hill 1991) support their case by appealing to these examples; and the reason that many are skeptical that conceivability implies possibility is that they think there are clear counterexamples to the thesis. So removing these counterexamples removes the central plank of support from the type-B position. And the failure of any apparent explanation of strong necessities weakens the position further.

Still, the position remains at least formally open. An opponent *could* hold that there are strong psychophysical necessities quite unlike the usual *a posteriori* necessities, that the space of metaphysically possible worlds is smaller than the space of logically possible (or conceivable) worlds, and that zombie worlds are excluded. If my arguments have been successful so far, I have removed many of the positive reasons for believing this. But perhaps Hill and McLaughlin's point is that I have not shown why it *couldn't* be true. So, why must it be false?

That is a deep and interesting question on which I hope to write at length in the future, but here I will say just a few words. Of course there are the further considerations against strong necessities that I raise in the book: they they will be brute and inexplicable, that they lead to an *ad hoc* proliferation of modalities, and that they will be epistemically just like fundamental laws. And their introduction would lead to a philosophical revolution far more radical than Kripke's. But an opponent might bite the bullet on all these points. What is fundamentally *wrong* with the idea?

The fundamental problem with the idea, I think, is that it rests on a false conception of modality. It is widely acknowledged that there is a circle of modal notions: possibility, consistency, and rational entailment, for example. Some of these, and perhaps the most grounded of all, are clearly *rational*
notions, such as consistency and rational entailment. The framework of possible worlds is tremendously valuable in making sense of these notions; and as I suggested earlier, the space of worlds that we need here is the space of logically possible worlds, with one world for every ideally conceivable scenario. A narrower class of worlds is no help in making sense of these notions; breaking the tie between conceivability and possibility breaks the tie between rationality and modality.

Some might think that we cannot "break out of the circle" from rational notions to such "metaphysical" matters as \textit{a posteriori} necessity and the concept/property distinction, but that is wrong. The point of the two-dimensional analysis of \textit{a posteriori} necessity is that it allows us to explain such matters with only one modal primitive (the space of logically possible worlds). Given this primitive, we need only the two-dimensional intensional structure of our concepts (an \textit{a priori} matter of conceptual analysis) along with nonmodal facts about the actual world to ground all these matters of metaphysical modality.

So one modal primitive (plus conceptual analysis plus nonmodal fundamentals) gives us everything. And it must be a primitive tied constitutively to such rational notions as consistency, entailment, and ideal conceivability. For if it is not tied constitutively to those notions, we will not be able to explain those notions (nonmodal facts certainly won't help us here), and such notions are part of what a theory of modality needs to handle. If our choice of primitive is a space of worlds, it is clearly the logically possible worlds that we need; and if our choice if primitive is not a space of worlds, it will be some other notion in the rational/modal circle.

Advocate of strong necessities must reject this picture. They cannot reject a rational modality altogether, as they use such modal notions as consistency, rational entailment, and conceivability themselves (their position is partly defined with respect to these notions). So they must accept something akin to the space of logically possible worlds, although they might use another name. But they think there is a further metaphysical modality, and that not every logically possible world is a metaphysically possible world. This modality is not to be defined in terms of the rational modality, or even in terms of the rational modality plus nonmodal facts; it is a further primitive, part of a different circle entirely.

This picture is \textit{modal dualism}. It requires two modal primitives: there is a space of logically possible worlds, and then (as a further primitive fact) a smaller space of these picked out as "metaphysically possible". The primitives need not be cast in these terms, but we know that two primitives will be needed, as we need one to account for the rational modalities, and we need another in turn to account for the "metaphysical".

Once we get this far, it is clear that something has gone wrong. There is no reason to believe in any more than one modal primitive, and there is no reason to postulate a second "metaphysical" primitive at all. The second primitive is an \textit{invention}; nothing in our conceptual system requires it. In particular, we need it to account for none of our existing modal notions. So it is a primitive that answers to no-one and does no work.

It seems to me that we do not even have a distinct \textit{concept} of metaphysical necessity to which the second primitive can answer. The momentary impression of such a concept may be a residue from initial
impressions of the Kripkean distinction between epistemic and metaphysical modality. But once we recognize that this distinction can be explained with one modal primitive, and that there are constitutive ties between the Kripkean modalities, the grounds for this impression disappears. The only concept of a "metaphysical possible world" that we have is that of a logically possible world. If someone thinks they have a distinct concept here, there is no reason to believe that anything answers to it.[*]

*[[One sometimes hears phrases such as "ways the world really could have been", or "worlds that God could have created" as a way of trying to draw a distinction, but I cannot see any real content in these phrases over and above the invocation of logical possibility. (Of course a theist could take the second phrase literally, and perhaps call the resulting modality "metaphysical necessity". This way we would use God to ground a modal dualism. Even so, it's not clear why God's powers should prevent him from creating any logically possible world, except perhaps for those worlds not created by a God. So it may be that only strong necessity that this modal dualism would support is the existence of God!)]]

I think there is overwhelming reason to reject modal dualism and accept only one modal primitive. If so, strong necessities are ruled out, and type-B materialism is false.

## 3.6 Type-B materialism: Loose ends

(1) Hill & McLaughlin say at one point that the counterintuitive nature of my conclusion is itself a flaw in my treatment of modality. I think this is making the counterintuitivity do double duty. To be sure, the conclusions give reasons to resist the argument, and to look long and hard at it, but they are doing that already. But the argument itself must be assessed on its merits. Hill & McLaughlin also suggest that my view is "wishful thinking", but I think the situation is precisely the opposite. If it were not that the antecedent impulse to believe materialism were so strong (I share it, too), and my conclusions so hard to accept, I think the arguments would be relatively uncontroversial. As things stand we are in the situation where we scratch around for a materialist "way out", and the existence of any potential loophole in the argument, no matter how ad hoc, is seized upon. I don't say this is a bad strategy, given one's initial subjective probabilities, but I think it is clear where the wishful thinking lies.

(2) Loar mentions the explanatory gap. I think this is indeed a problem for the type-B materialist view (how could a physical process necessitate conscious experience? why couldn't God have created a zombie world?) and I think Loar's answer doesn't work, for the reasons I've given. But even if a type-B materialism is accepted, the explanatory gap is still a major issue. Loar treats the explanatory gap as if the only issue is whether it threatens materialism, and here he is like a lot of philosophers who take the truth of materialism to be the major question in this whole area; but this is not my view. There are questions about explanation, and there are questions about ontology, and the former are as at least as important as the latter. In the book, I devote at least as much space to the explanatory issues, and in the end they may matter more in developing a theory of consciousness.

Although a type-B materialism will reject my conclusions about ontology, it will (in effect) accept my conclusions about explanation. It remains the case that crossing the gap requires epistemically primitive bridging principles. These principles will be called "identities" or "necessities" rather than "laws", but their role in a theory will be much the same. A theory of consciousness will still need to have a primitive
vertical structure, not derivable from the horizontal structure of physical theory. No matter how we interpret the ontology, the shape of a theory of consciousness will be entirely different from theories in other domains.

So even if one saves the letter of materialism, it is not clear that one saves the spirit. The materialist dream of a seamless explanatory web from physics on up will fail, and we will need to search for a theoretically independent bridge. We will eventually want to systematize and simplify this bridge until we are left with a set of simple (fundamental?) identities or necessities from which all the others follow. The result will be something much like the sort of psychophysical theory that I advocate in my book (and the specific suggestions I make in the second half of the book may apply equally well or badly here). In a way, the type-B materialist ought to be as concerned with the search for a "fundamental theory" as I am.

4 Epiphenomenalism and the paradox of phenomenal judgment

Hill & McLaughlin say that I endorse epiphenomenalism, and that my anti-materialist argument implies epiphenomenalism. This is not strictly true. In fact perhaps my favorite position on the mind-body problem (as Yablo in effect notes) is not epiphenomenalism but the "panprotopsychist" (or "Russellian") position on which basic physical dispositions are grounded in basic phenomenal or protophenomenal properties. Far from making experience causally irrelevant, this view holds that experience will be part of the categorical grounds of causation.

I think there is also more to say about interactionism than I said in my book. In particular, I think there is no knockdown argument against a quantum interactionism on which consciousness is the categorical basis of wave-function collapse. I don't favor this view myself, but it needs to be taken seriously.

Both the panprotopsychist view and the quantum interactionist views are counterintuitive, but both are elegant and appealing and not obviously false. In both cases there are questions about whether they can really be made to work, but those issues remain open. So the conclusion of my anti-materialist argument ought not to be taken as epiphenomenalism. Rather, it is the disjunction of panprotopsychism, epiphenomenalism, and interactionism. The question between these three views is really a distinct issue, as it can only be decided by considerations further to the argument against materialism. For my part, I rank the options in roughly the order given, but it is a deep question on which I have no settled opinion.

On none of these positions is it true that we need "an independent swarming mass of fundamental psychophysical laws", as Hill & McLaughlin suggest. We need fundamental psychophysical laws (or in the panprotopsychist case, we need principles associating physical dispositions with (proto)phenomenal bases), but there might be very few of them, perhaps only one. (Or two, in the interactionist case: one in each direction.) It is not unreasonable to suppose that there might be a single basic psychophysical principle (some sort of transformation operator, for example) that when applied to a specific complex physical system yields a specific complex phenomenal state.

It is true that I say that phenomenal states are in a sense explanatorily irrelevant to behavior; and I think
that remains true on each of these views, as well as on the type-B materialist view. In each case, the very conceptual possibility of varying phenomenal states while preserving patterns of causal interaction suggests that explanations of behavior can be given in a way that makes no deep appeal to the phenomenal states in question. But that is not to say that they are causally irrelevant, except on the epiphenomenalist view.

I note also that Hill & McLaughlin are wrong in suggesting that I think sensory states are explanatorily irrelevant to our beliefs that we are in them. I do say that they are explanatorily irrelevant to the judgments we make about them, but this is in a stipulative functional sense of judgment, on which it comes to not much more than a disposition to report. I am quite clear, though, that experiences are not explanatorily irrelevant to our beliefs about them, and in fact often directly constitute aspects of those beliefs (see especially the last section of Chapter 5).

Shoemaker is right that my response to the paradox of phenomenal judgment is one of the weaker parts of the book. If I were writing Chapter 5 now, I would stress much more strongly the feature I have just mentioned: the role that phenomenal states play in constituting our phenomenal beliefs. While I noted this feature in the book, I tried to give an answer to the paradox that did not rely on it. I now think this was a mistake, as the constitutive relation between phenomenal states and associated phenomenal beliefs is crucial to the epistemology of phenomenal belief. (In effect, I would expand on the points in the last section of the chapter, particularly the parenthetical suggestion on pp. 207-8.) It is true that the paradox still applies to (functionally individuated) judgments and reports; but it is beliefs that are crucial in epistemology.

Shoemaker raises two very interesting issues related to the paradox. First, he suggests that a zombie's phenomenal judgments will be causally related to physical states in a way that is sufficient for reference and knowledge; so a zombie's judgments will refer to those states and will express knowledge of them; so my phenomenal judgments refer to physical states, too, as everything going on in the zombie is going on in me.

I deny the first step here. I think that for phenomenal concepts, no mere causal relation suffices for reference; and the same goes for a zombie's analog of a phenomenal concept. As I say in the book, the causal theory of reference is by no means universal. In particular, the concepts to which it applies are generally causal concepts; at some level, their referents are conceived as the cause of something or other, if only implicitly. This is reflected that in the fact that for most of our concepts (e.g. "atom" or "dog"), the notion that the referent of the concept is wholly epiphenomenal is epistemically impossible (it is epistemically impossible that all atoms or dogs are epiphenomenal). But phenomenal concepts are not causal concepts, as witnessed by the fact that epiphenomenalism about experience is epistemically possible, if counterintuitive. The same goes for a zombie's analog of a phenomenal concept. So there is no reason to believe that a causal relation suffices for reference here, and in fact there is good reason to believe that a zombie's phenomenal concepts do not refer. (In the zombie world, zombie eliminativists are right!)

In his ingenious second point, Shoemaker notes that on my account, a zombie's phenomenal judgments
are false and unjustified, but the zombie does not seem to display any failure of rationality. But if the zombie's judgment is both rational and unjustified, then the concept of justification is cut loose from its rational moorings. Thus a conceptual incoherence seems to threaten. This is a potential problem for any view on which zombies are conceptually possible, including not only my view but also those of Hill & McLaughlin, Loar, and Yablo. What should we say?

I think the best thing to say is that the zombie's judgment is (a) unjustified (or at least not as justified as a conscious being's corresponding judgment), but (b) at least negatively rational in the sense that the zombie makes no invalid inferences and other such errors of reasoning. Justification and negative rationality often go together, but not always; this is a case where justification and negative rationality come apart. (Other such cases might be provided by an externalist view of justification, where justification is not always grounded in rationality. This is not to say that the zombie case involves externalist justification: my analysis holds onto the internalist idea that justification is a matter of having evidence.) I think it is plausible that where truly basic evidence is concerned, as with the relation between an experience and the associated phenomenal belief, the justification relation is something tighter than any cognitive relation involving mere negative rationality. This fits with the idea mentioned above, that the justification comes from the constitutive relation between experience and belief. If this is so, we should not expect the justification to be a wholly rational matter.

The zombie lacks evidence for its judgment (so it is unjustified), but it does not know that it lacks this evidence, and it is not culpable for this lack of knowledge (it is negatively rational). Shoemaker's "rational moorings" for justification may still be preserved in a link between justification and positive rationality, which requires sufficient reasons and evidence for a judgment. But justification (especially basic justification) and positive rationality involve more than a mere absence of mistakes, so negative rationality does not in general suffice.

One could also take a more extreme line, and deny that notions such as rationality and justification apply to zombies at all. I have gradually become more sympathetic with the idea that phenomenology plays a role in constituting intentionality, so that a zombie has intentional states in at best a weak sense. But I do not want to rely on that point here.

5 Dancing qualia

Shoemaker also comments on the dancing qualia case. I think he is certainly right that qualitative beliefs will change when qualia change. This follows from the constitutive relation between experience and belief mentioned above; and it is how things must go, in order that the post-flip state not be incoherent. I did not mean to deny that beliefs would change in this sort of way. I was instead focusing on the absence of a belief about the change.

The surprising part of the dancing qualia case is not that the subject (after the flip) has false beliefs about past qualia, or even that he does not introspectively realize that his qualia are different. These things hold for any case of inverted qualia. The surprising part of the dancing qualia case is that the flip should go
unnoticed when it happens. To have one's qualia change massively before one's eyes will be a major
phenomenal event; but it will be a phenomenal event to which we have no access. Of course Shoemaker
is right that if inverted qualia are possible, we should expect unnoticed changes in this scenario (because
beliefs and memories will change too). But I don't think this diminishes the implausibility of the
consequent here; rather, it indirectly adds to the implausibility of the antecedent.

Shoemaker thinks the surprisingness can be explained away in this case, because there is an "unnatural
tampering with cognitive dynamics". I am not sure that it is all that unnatural. In future years, we might
end up performing this sort of substitution with some regularity; and on a lower level, physiological
changes with little impact on function may already be happening all the time. It's true that if we assume
that qualia are changing massively, then there is a sense in which the change in "unnatural", but the
question of whether qualia change massively is precisely what is at issue. Characterized in neutral terms,
the change to one's underlying processes does not seem especially unnatural; so it is surprising that it
should produce such a massive, unnoticed change.

In any case the dancing qualia case was never intended as a knockdown argument, and there are certainly
ways in which it can be resisted. On balance of intuition, I have come to think that in some ways the
fading qualia argument is stronger than the dancing qualia argument: the idea of a system continually and
completely out of touch with its "faded" qualia is even stranger than the idea of a system momentarily out
of touch with its massively changing qualia. (Of course this is a conclusion Shoemaker would be happy
with, as he thinks that absent and fading qualia are logically impossible, while inverted and dancing
qualia may be naturally possible.) But at the end of the day these arguments are really intended as thought-
experiments that any theory must face up to and make sense out of. Proponents of a different view might
bite the bullet on any of them, as long as they are aware of the costs. I think that other things being equal,
the conclusion that qualia do not fade and dance unnoticed is more plausible than the alternatives, but as
with all of these matters, there is probably more to be said.[*]

Studies 87:61-85.

The Nature of Consciousness: Philosophical Debates. MIT Press.
Chapter 1: *Two Concepts of Mind*. I distinguish the phenomenal and psychological (functional) concepts of mind. I argue that every mental state is a phenomenal state, a psychological state, or a hybrid of the two. I discuss the two mind-body problems corresponding to the two concepts of mind, and discuss the various senses of the term "consciousness".

Chapter 2: *Supervenience and Explanation*. I distinguish varieties of supervenience, especially logical and natural supervenience, where supervening properties covary with base properties across either logically possible (conceivable) or naturally possible worlds. (One can also define a distinct notion of metaphysical supervenience, if one believes that the classes of logically possible and metaphysically possible worlds are distinct; I hold that the two classes coincide.) *Materialism* is the thesis that all positive properties globally metaphysically supervene on microphysical properties. A property is *reductively explainable* in terms of physical properties if it globally logically supervenes on those properties.

I defend the notion of conceptual truth against various objections, and outline a two-dimensional intensional framework for handling *a posteriori* necessity. Every concept has two intensions, a primary intension and a secondary intension. The primary intension delivers a concept's referent in a centered world when the world is considered as actual (i.e., considered as an epistemic possibility); the secondary intension delivers a concept's referent in a world when it is considered as counterfactual. (The primary intension of "water" picks out the "watery stuff" in a world; the secondary intension picks out H2O.) A statement is *a priori* when it has a necessary primary intension; a statement is necessary when it has a necessary secondary intensions. *A posteriori* necessities (such as "water is H2O") have a necessary secondary intension but a contingent primary intension. A statement is conceivable (or logically possible) when its primary intension is true in some world; a statement is possible (metaphysically possible) when its secondary intension is true in some world. So the Kripkean gap between conceivability and possibility is explained at the level of statements, without appealing to a distinction between conceivable and possible worlds. The class of worlds in question is always that of the ideally conceivable (or logically possible) worlds.
I use arguments from conceivability, epistemology, and analysis to argue that almost all properties logically supervene on the physical, except perhaps for phenomenal properties and other properties depending on them.

Chapter 3: Can Consciousness be Reductively Explained? I use arguments from conceivability, epistemology, and analysis to argue that phenomenal properties do not logically supervene on (are not a priori entailed by) physical properties. These include arguments from the conceivability of zombies and inverted spectra, arguments from incomplete knowledge and from epistemic asymmetry, and arguments from the absence of structural/functional analysis. It follows that there is no reductive explanation of consciousness. I apply this to potential explanations in neuroscience, cognitive science, and physics.

Chapter 4: Naturalistic Dualism. I argue that phenomenal properties are not necessitated by physical properties, so that materialism is false. The arguments of Chapter 3 are supplemented by an argument that there is no a posteriori necessary entailment from physical to phenomenal. I use the two-dimensional analysis of a posteriori necessity to argue that no such necessity can save materialism if a priori entailment fails. And I argue that there is no reason to believe in "strong" metaphysical necessities that escape the two-dimensional account. I also discuss and argue against the possibility that there is an a priori connection that we cannot grasp due to cognitive limitations.

I compare this argument to related arguments for dualism and discuss the position that results. Materialist ontology must be expanded by new fundamental properties (phenomenal or protophenomenal properties) and new fundamental psychophysical laws. The resulting position may be epiphenomenalism, interactionism (although I argue against this), or a Russellian monism on which (proto)phenomenal properties serve as the categorical grounds of basic physical dispositions. I sketch the logical geography of the issues and defend my "naturalistic dualism" from objections.

Chapter 5: The Paradox of Phenomenal Judgment. On my position, even if consciousness cannot be physically explained, behavior and functioning can be. So it seems that consciousness is explanatorily (although perhaps not causally) irrelevant to behavior. In particular it is explanatorily irrelevant to claims such as "I am conscious" and related phenomenal judgments (where judgments are defined in functional terms). I call this the "paradox of phenomenal judgment". I argue that this paradox is counterintuitive but poses no fatal flaws. I address the objections that it implies that we are unable to know about, refer to, or remember our phenomenal states. I argue that these objections rest on causal theories of knowledge and of reference that we have independent reason to reject in the phenomenal case. Knowledge of and reference to phenomenal states is based on something tighter than a causal relation; it is based on a relation of acquaintance. I discuss the content of phenomenal beliefs and the constitutive relation between experience and phenomenal belief.
Chapter 6: On the Coherence between Consciousness and Cognition. I outline the program of searching for a theory of consciousness in terms of psychophysical laws: first nonfundamental, then fundamental laws. Data is hard to come by, but first-person data plus plausibility assumptions in the third-person case can do much work. I discuss some candidates for nonfundamental psychophysical laws, involving the "coherence" between consciousness and "awareness", a functional state defined in terms of direct availability for global control. I argue that consciousness and awareness covary, as do their structures. I apply this to some methodological questions about the empirical study of consciousness.

Chapter 7: Absent Qualia, Fading Qualia, Dancing Qualia. I argue for a principle of organizational invariance: systems with the same fine-grained functional organization will have the same sort of phenomenal states (with natural necessity). I argue against the empirical possibility of "absent" and "inverted" qualia, using thought-experiments involving replacement of neurons by silicon chips. If absent qualia are possible, then "fading" qualia are possible, and if absent or inverted qualia are possible, then "dancing" qualia are possible; but I argue that it is very implausible that fading or dancing qualia are possible.

Chapter 8: Consciousness and Information: Some Speculation. I speculate on the form of a fundamental theory of consciousness, suggesting that it may involve a dual-aspect view of information (information realized both physically and phenomenally). I argue that this would cohere well with the other principles, and with the relation between consciousness and phenomenal claims. One version of this view implies a sort of panpsychism; this need not follow, but I argue that it is not as implausible as is often supposed. I suggest that such a metaphysics of information may fit well with the Russellian monism discussed earlier, and discuss some open questions for such a theory.

Chapter 9: Strong Artificial Intelligence. I apply previous conclusions to argue that strong artificial intelligence is true: there is a class of programs such that any implementation of a program in that class is conscious. I give an account of computation and implementation to support this conclusion, and I argue against Searle's "Chinese room" arguments and other objections to strong artificial intelligence.

Chapter 10: The Interpretation of Quantum Mechanics. I discuss some relations between a theory of consciousness and the interpretation of quantum mechanics. After discussing the measurement problem and various interpretations, I defend a version of the Everett interpretation on which wavefunctions never
collapse. A major question for this view is why, given that the physical world is superposed, we experience it as discrete. I suggest that this is a question for a theory of consciousness, and argue that the principles I have developed predict that there will be discrete experiences in a superposed world. I defend the Everett interpretation from some objections, although I am ultimately agnostic about its truth.
What follows are compressed versions of three lectures on the subject of "Mind and Modality", given at Princeton University the week of October 12-16, 1998. The first two form a series; the third stands alone to some extent. All are philosophically technical, and probably of interest mainly to philosophers. I hope that they make sense, at least to those familiar with my book *The Conscious Mind*.

Lecture 1 recapitulates some of the material in the book in a somewhat different form, and adds some further material on conditionals and on Kripke. Note that section 5 has a more or less definitive formalization of the anti-materialist argument from the book (lots of people have asked for this). Lecture 2 pushes deeper into the heart of modality, further investigating the conceivability/possibility relationship and the epistemology of modality (with some material on the scrutability of truth in general), and arguing for a sort of modal rationalism. Lecture 3 gives an analysis of the content of beliefs about experiences, and applies this to a number of epistemological issues, including incorrigibility and the dialectic on "The Myth of the Given".

Much of this material is being further developed in work in progress, so comments are very welcome. The material in the first two lectures may see the light of day either as a series of papers or as a book. For an earlier, non-outline version of a few of these ideas, see my response ("Materialism and the Metaphysics of Modality") in the *Philosophy and Phenomenological Research* symposium on my book. Many of the ideas in lecture two are elaborated in much more detail in my newer (summer 1999) paper "Does Conceivability Entail Possibility?". The ideas in lecture three now form the basis for a separate long paper, "The Content and Epistemology of Phenomenal Belief".

My Arizona graduate seminar (spring 1999) on "Mind and Modality" largely followed the content of these lectures. The web page for that seminar has links to a lot of e-mail discussion in which I and others discussed many of these ideas in more depth.

- **Lecture 1:** Consciousness, Conceivability, and Conditionals
- **Lecture 2:** Modal Rationalism and the Scrutability of Truth
- **Lecture 3:** The Content and Epistemology of Phenomenal Belief
1: CONSCIOUSNESS, CONCEIVABILITY, AND CONDITIONALS

(1) EPISTEMIC ARGUMENTS AGAINST MATERIALISM

The phenomenal facts are not entailed a priori by the physical facts. (See *The Conscious Mind*, chapter 3.)

- (a) Conceivability of zombies
- (b) Conceivability of inverted spectra and other phenomenal variants
- (c) Knowledge argument
- (d) Epistemic asymmetry
- (e) Absence of structural/functional analysis of phenomenal concepts

(2) MATERIALIST RESPONSES

(i) **Type-A materialism**: Deny the epistemic intuitions, and assert *a priori* entailment (eliminativism, analytic functionalism, ...). Not considered here.

(ii) **Type-B materialism**: Accept the epistemic intuitions, but hold that there is an *a posteriori* necessary entailment from physical to phenomenal. Physical:phenomenal as water:H2O or Hesperus:Phosphorus. Conceivability doesn't imply possibility.

(3) TWO-DIMENSIONAL ANALYSIS OF A POSTERIORI NECESSITY

This framework analyzes *a posteriori* necessity in terms of two-dimensional semantic evaluation over one space of possible worlds. Every statement S (as used by a given speaker on a given occasion) has two intensions, a primary and secondary intension. (See *The Conscious Mind*, section 2.4, and *The Components of Content*.)

**Primary intension** of S: (or *epistemic profile* of S). Evaluate at a centered world W.

\[ W \rightarrow \text{truth-value of } S \text{ in } W \text{ when } W \text{ is considered as actual (i.e., considered the way we consider epistemic possibilities).} \]

Heuristic: If W is the case, is S the case? [Indicative conditional.]

- "water is H2O": the set of worlds in which watery stuff is H2O-structured
- "Hesperus is Phosphorus": worlds in which morning star is evening star

**Secondary intension** of S: (or *modal profile* of S). Evaluate at an uncentered world W.
W -> truth-value of S un W when W is considered as counterfactual.

Heuristic: If W were the case, would S be the case? [Subjunctive conditional.]

- "water is H2O": the set of worlds in which H2O is H2O
- "Hesperus is Phosphorus": the set of worlds in which Venus is Venus

S is "necessary" -> S has a necessary secondary intension.

S is a priori -> S has a necessary primary intension

S is a posteriori necessary -> S has a contingent primary intension and a necessary secondary intension.

Supports modal rationalism: when S is conceivable (approx: not-S is not a priori), S describes a possible world, at least according to its primary intension (although perhaps not according to its secondary intension). We retain a priori access to the space of possible worlds.

(4) DIVERSION: THE TYRANNY OF THE SUBJUNCTIVE?

An important difference between indicative and subjunctive conditionals:

(1a) "If Prince Albert killed those people, he is Jack the Ripper."
(1b) "If Prince Albert had killed those people, Jack the Ripper wouldn't have".

(2a) "If XYZ is the liquid in the oceans and lakes, water is XYZ."
(2b) "If XYZ were the liquid in the oceans and lakes, water wouldn't be in the oceans and lakes".

These conditionals give what is at least the intuitively correct thing to say about the consequent, given the antecedent. General moral: (At least on an intuitive reading) indicatives consider the antecedent as actual; subjunctives consider the antecedent as counterfactual. Indicatives track primary intensions; subjunctives track secondary intensions.

The analysis of necessity and possibility:

S is necessary <-> S is true in all possible worlds.
S is possible <-> S is true in some possible world.

QUESTION: How to evaluate "S is true in W"?

SUBJUNCTIVE READING: "S is true in W" iff
If W were the case, S would be the case.

**INDICATIVE READING**: "S is true in W" iff

If W is the case, S is the case.

There are two resulting sorts of "necessity": *subjunctive necessity* and *indicative necessity*. And two sorts of "possibility", etc. Indicative necessity is necessity according to primary intensions; subjunctive necessity is necessity according to secondary intensions.

In contemporary philosophy (at least since Kripke), "necessity" (simpliciter) is always read as subjunctive necessity, and "P is true in W" is always evaluated by the subjunctive reading.

In fact: subjunctive conditionals ground the contemporary evaluation of statements in worlds, and the consequent analysis of necessity. Kripke's ultimate court of appeals in *Naming and Necessity* is always a subjunctive.

**QUESTIONS**: Why is this? Is it an arbitrary choice? Is the choice argued or stipulated?

One might propose a **SYMMEtRY THESIS**: Indicative necessity is as good a candidate for "necessity" as subjunctive necessity. Is this viable?

[If so, it would be just as reasonable to say that "Hesperus is visible in the evening (if it exists)" is necessary; that "water is H2O" is contingent; that "I am here now (if I exist)" is necessary; that "the meter stick in Paris is a meter long (if it exists)" is necessary; that the necessity of identity doesn't hold; etc.

Imagine an alternative universe in which Kripke used indicatives instead of subjunctives. The resulting book, *Naming and Non-Necessity*, might have defended a strong link between the a priori and the necessary, have argued against the necessity of identity and de re necessities, and so on. Direct reference theory, singular propositions, and externalism have a much harder time getting off the ground. The theory of content that ensues has much less trouble meshing with a theory of cognition. And so on.

Or imagine a symmetrical universe, a history in which the notion of necessity is seen to divide into two sorts, indicative and subjunctive necessity. The former tracks epistemic notions more closely than the latter. One can do quantified modal logic with the latter but not the former (thus a split decision in the debate between the likes of Quine and the likes of Kripke)? Whenever one speaks of truth in a possible worlds, one has to be explicit about the means of evaluation, rather than presupposing the subjunctive evaluation. Subjunctive necessity gives a nice metaphysics of essentialism and a semantics for counterfactuals, but indicative necessity yields a more powerful theory of content. A more balanced 30 years of philosophy?]

**SIX POSSIBLE REASONS FOR FAVORING THE SUBJUNCTIVE**

- (a) "Could not have been otherwise".
- (b) Indicative necessity is "merely epistemic".
(c) Indicative necessity requires centered worlds.
(d) Subjunctive necessity supports quantified modal logic, etc.
(e) The relevant indicative conditionals aren't true/false, just assertible, due to epistemic relativity.
(f) Indicative "necessities" will vary in truth-value between users, since primary intensions can vary.

[The first four clearly don't carry much weight against the symmetry thesis. The last two carry a little, but not an overwhelming amount. The epistemic relativity in (e) applies only to incomplete antecedents - how one fleshes out an incomplete antecedent into a world depends on what one believes - but the underlying evaluation in a world is unaffected. The variability in (f) is present in reverse, for secondary intensions and subjunctive necessities, with terms such as indexicals and demonstratives, but that isn't taken to undermine claims of necessity of utterances here; so the same should arguably go for indicative necessity. So the symmetry thesis is still tempting.]

(5) APPLICATION OF 2-D ANALYSIS TO THE ARGUMENT AGAINST MATERIALISM

[This is a crisper version of the argument in The Conscious Mind, section 4.2]

Premise 1: The physical truths don't a priori entail the phenomenal truths.

Premise 2: When S is a posteriori, S has a contingent primary intension.

Premise 3: If materialism is true, the physical facts necessitate all true propositions.

4: P->Q is a posteriori. [P = physical truths, Q = a phenomenal truth] (from 1)

5: P->Q has a contingent primary intension (from 2, 4)

6: Exists W: P' is true in W, Q' is false in W [P',Q' = PI's of P,Q] (from 5)

7: Exists W: P is true in W, Q' is false in W [from 6; see loophole 2]

8: Materialism is false [from 3, 7; see loophole 1]

Loophole 1: Primary intensions are indexical; Q' is a centered proposition. Materialism requires only that P necessitates all true uncentered propositions.
Response 1: Adding "locating" information I (an identifying description picking out an individual at a
time within a world) to P doesn't help. Revised premise 1: P&I -> Q is not a priori. So (P' at I) -> (Q' at I)
is contingent. And (Q' at I) is an uncentered proposition.

[N.B. We can understand the physical facts to include a "that's-all" fact without changing anything essential.]

Loophole 2: Maybe microphysical facts have different PI/SI, so P necessitates phenomenal facts but P'
or (P' at I)] does not.

Response 2: This is a valid point, but when cashed out it leads to "panprotopsychism", with fundamental
protophenomenal properties as the categorical basis of microphysical dispositions. An important
position, but more in the spirit of dualism than materialism.

UPSHOT: A posteriori necessity (at least of the usual variety) can't save materialism.

Essential point: If it is ideally conceivable that there are zombies, then the primary intension of "There
are zombies" describes at least one possible world, and that suffices to ensure that materialism is false.
(Conceivability implies possibility at the level of worlds, if not at the level of statements.)

(6) Kripke's Argument

There is a natural mapping between this argument and Kripke's argument against materialism. Some
differences and correspondences:

(i) I'm arguing against upward necessitation, not type or token identity.

[Token and type identity arguably aren't required for materialism. E.g. consider the statue and the lump of clay (re
token identity), or the possibility of disembodied life (re type identity). What matters is upward necessitation.]

(ii) I appeal to physical-without-mental scenarios, but not mental-without-physical scenarios.

[The possibility of mental-without-physical doesn't falsify materialism. Again, witness the possibility of
disembodied life.]

(iii) Premise 2 is somewhat akin to Kripke's two strategies for explaining away apparent contingency.

[Kripke's strategy 1: "a qualitatively analogous statement would be false in a qualitatively identical epistemic
situation". The "qualitatively analogous statement" is more or less a statement with the same primary intension.
But the criterion is too strong.

Consider "Bill", stipulated to be a name for the quality in the center of my visual field. Then "Bill = blue" is an
"apparently contingent" necessity in the usual way. But in any qualitatively identical epistemic situation, a
qualitatively analogous statement is true. Moral: drop the "qualitatively identical epistemic situation" clause,
which is unnecessary (the epistemic situation plays no special role).

Consider also "Fred", a name stipulated to pick out 1 if there is at least one statement in the world, otherwise 0. Then "Fred = 1" is another "apparently contingent" necessity. But a qualitatively analogous statement will always be true. Moral: drop the idea of evaluating a statement present at the center of a given alternative world, and instead evaluate the actual statement in that world considered as actual. The result of these two changes will be more or less my premise 2. (N.B. The primary intension of "Fred = 1" is false in an empty world, even though there is no statement to evaluate there. Indicatively: if the empty world is actual, then Fred = 0.)

Kripke's strategy 2, "contingently coinciding reference-fixers for an identity", can be seen to be a special case of premise 2.

(iv) Kripke's premise "pain = felt-as-pain" is not required.

[Maps to: primary intension = secondary intension for phenomenal concepts. This is plausible but unnecessary for the argument to go through.]

(v) One needs to handle primary/secondary gap for physical concepts.

[Kripke only discusses the gap, in effect, for phenomenal concepts. This gap leads to the "panprotopsychohist" escape route, discussed e.g. in Maxwell's paper on Kripke.]

(7) WHITHER TYPE-B MATERIALISM?

To resist, a type-B materialist must deny the 2-D analysis of a posteriori psychophysical necessities. Psychophysical necessities are different in kind from standard a posteriori necessities.

Must deny premise 2. Psychophysical necessities, although a posteriori, have a metaphysically necessary primary intension.

Must deny modal rationalism: Zombies, although conceivable, are strongly metaphysically impossible: there is no possible world satisfying even the primary intension of "There are zombies". The conceivable world corresponds to no possible world at all.

More on this in lecture 2.

(8) CONCLUSION

If the anti-materialism argument is accepted (so type-A and type-B materialism are rejected), we're left with about three positions to choose from. All might be called versions of "phenomenal fundamentalism". The conclusion of the argument should best be seen as a disjunction of these.

(i) Epiphenomenalism: Causally closed physical world, naturally supervenient phenomenal properties.
[No knockdown arguments against this, although counterintuitive and more importantly inelegant.]

(ii) Interactionism: No causal closure, two-way psychophysical laws.

[Compatible with one natural interpretation of quantum mechanics.]

(iii) Panprotopsychism: Fundamental protophenomenal properties serve as the categorical basis for microphysical dispositions in a causally closed physical world.

[Might be seen as materialism, or as non-Berkeleyan idealism, or (perhaps best) as a dual-aspect view with an underlying neutral monism. Deeply attractive, if the constitution relations can be figured out.]

2: MODAL RATIONALISM AND THE SCRUTABILITY OF TRUTH

[Much of the material in this lecture is elaborated in detail in my paper "Does Conceivability Entail Possibility".]

(1) YESTERDAY

(a) Epistemic arguments against materialism. The phenomenal facts are not entailed a priori by the physical facts. (Zombies, inverted spectra, knowledge argument, etc.)

(b) Type-B materialism: There is an a posteriori necessary entailment from physical to phenomenal.

(c) Two-dimensional analysis of a posteriori necessity. Every statement S (as used by an individual) has two intensions, a primary and a secondary intension. Primary intension evaluates S in a (centered) world when the world is considered as actual; secondary intension evaluates S in a world when the world is considered as counterfactual. S is "necessary" when it has a necessary secondary intension. If S is a priori, it has a necessary primary intension. A posteriori necessities have contingent primary intension and necessary secondary intension.

(d) Argument against materialism. Premise 1: The physical facts don't a priori entail the phenomenal facts. Premise 2: An a posteriori statement has a contingent primary intension. Conclusion: Materialism is false.

(e) To resist: a type-B materialist must deny premise 2, and deny the 2-D analysis of a posteriori
psychophysical necessities. These necessities, unlike standard a posteriori necessities, do not have a contingent primary intension. Must deny modal rationalism: Zombies, although conceivable, are strongly metaphysically impossible: there is no possible world satisfying even the primary intension of "There are zombies". The conceivable world corresponds to no possible world at all.

(2) STRONG NECESSITIES

Crucial issue: Are there strong a posteriori necessities? ["Strong metaphysical necessities", in _The Conscious Mind_.]

**Strong necessity** = an a posteriori necessity with a metaphysically necessary primary intension.

Intuitively: If S is a posteriori, there is some conceivable "world" W such that if W is actual, S turns out to be true. If S is a standard a posteriori necessity, W is possible. If S is a strong necessity, W is not possible.

(3) DOES CONCEIVABILITY IMPLY POSSIBILITY?

Distinguish three independent dimensions in notions of conceivability (of a statement S):

Positive vs. **negative** conceivability (clear and distinct conceivability of a situation verifying S, vs. absence of any apparent contradiction in S).

**Prima facie** vs. **ideal** conceivability (conceivability on first appearances, vs. on ideal rational reflection).

Primary vs. **secondary** conceivability (conceivability when considered as actual vs. when considered as counterfactual).

Standard worries about conceivability vs. possibility, translated:

1. **Prima facie** conceivability is an imperfect guide to possibility (but mainly insofar as it's an imperfect guide to ideal conceivability).
2. Secondary conceivability is a posteriori (so set it aside).
3. **Primary** conceivability is a poor guide to standard (secondary) possibility of S (but may be a good guide to the primary possibility of S, i.e. the possibility of a world satisfying S's primary intension).

So ideal primary conceivability is the sort that counts.
**THESIS:** ideal primary positive conceivability of S implies primary possibility (i.e., possibility of a world satisfying S's primary intension).

And just maybe: ideal primary negative conceivability of S (i.e., ~S is not a priori) implies primary possibility.

["Ideal primary" is tacit henceforth.]

**(4) VARIETIES OF MODAL RATIONALISM**

S is **a priori** if it is rationally knowable (justifiable independently of experience).

S is **a posteriori** if there is a positively conceivable scenario (considered as actual) which verifies ~S.

S is in the **twilight zone** if it is neither a priori nor a posteriori (as above): not rationally knowable, but not positively conceivable otherwise. i.e., ~S is negatively conceivable, but not positively conceivable.

*Deep issue:* are there any twilight-zone truths? i.e., is there a gap between positive conceivability and negative conceivability?

Candidates (more on these below):

- (i) Certain mathematical statements, e.g. continuum hypothesis?
- (ii) Conditionals about (e.g.) tallness, on epistemic view of vagueness?

**STRONG MODAL RATIONALISM:** S is a priori iff it has a necessary primary intension

or: if S is negatively conceivable, it is possible.

**WEAK MODAL RATIONALISM:** If S is a posteriori, it has a contingent primary intension

or: if S is positively conceivable, it is possible.

**NEGPOS PRINCIPLE:** If S is negatively conceivable, it is positively conceivable.

Weak modal rationalism denies the existence of strong necessities. The negpos principle denies the existence of twilight-zone truths. Strong modal rationalism (roughly) denies both.

Here, I'll argue only for weak modal rationalism, not strong modal rationalism (though I am inclined to accept both). What matters for the mind-body issue are strong necessities, not twilight-zone truths (as zombies are positively conceivable).
(5) DIVERSION: THE SCRUTABILITY OF TRUTH

(Or: on the deep philosophical importance of the twilight zone.)

**SCRUTABILITY PRINCIPLE** (first pass): Once we know how the world is qualitatively, we're in a position to know what our terms refer to and whether our statements are true.

**SCRUTABILITY OF REFERENCE** is problematic due to (i) unclarity of "know what terms refer to", (ii) indeterminacy due to varying reference while preserving truth-value across worlds. (cf. Quine, Benacerraf, Putnam, etc). So work with truth.

**SCRUTABILITY OF TRUTH** (second pass): A complete enough qualitative description of the world implies all true statements. ["A implies B" means "\`A->B' is a priori" throughout.]

**QUESTION**: What counts as a "complete enough qualitative description"?

- (i) Explicitly specifies all the facts? No, that makes the claim trivial.
- (ii) A description in terms of fundamental natural properties? Not bad, but will be denied by a type-B materialist. I want to keep issue of scrutability separate from the issue of strong necessities.

But note: point of fundamental-property description is to specify the world uniquely within the space of metaphysically possible worlds. So a "complete enough qualitative description" should specify a unique positively conceivable scenario.

D is **PC-complete** if (i) D is positively conceivable; (ii) if E is positively conceivable and E implies D, D implies E.

[For a type-A materialist, a complete microphysical description of the world will be PC-complete. For a type-B materialist or a phenomenal fundamentalist, a complete physical and phenomenal description of the world will probably be PC-complete.]

**SCRUTABILITY OF TRUTH**: If D is a PC-complete truth and S is true, D->S is a priori.

S is an **inscrutable truth** if S is true and some PC-complete truth D doesn't imply S. [N.B. If S is inscrutable, D->S is in the twilight zone.]

Deep question: are there any inscrutable truths? Candidates:

- (i) Some mathematical statements, e.g. continuum hypothesis?
- (ii) Statements about e.g. tallness, on epistemic theory of vagueness?
[But: one can argue that all mathematical truths are a priori (our inability to know them is merely due to cognitive limitation, and disappears on idealization), and that any that are not a priori are not determinate at all. And the epistemic theory of vagueness is generally regarded as implausible.]

Generalization of scrutability: a complete qualitative description of any world (not just the actual world) leaves nothing epistemically open (except indeterminacies).

D is **NC-complete** if (i) D is negatively conceivable, (ii) if E is negatively conceivable and E implies D, then D implies E.

**GENERALIZED SCRUTABILITY**: If D is PC-complete, D is NC-complete.

[I am inclined to believe both scrutability and generalized scrutability, but I think this is one of the deepest issues in philosophy and requires an extended treatment in its own right. It connects not just to the theory of truth and reference but to issues of realism and anti-realism (one might think of scrutability as a watered-down "realist" version of the anti-realist "nothing is hidden" thesis: nothing is hidden given enough qualitative information). And if true it has application throughout metaphysics, ethics, philosophy of mind, etc.]

(6) **DIVERSION CONTINUED: PURE MODAL RATIONALISM**

S is an **open inconceivability** if S is negatively conceivable, but for all PC-complete D, D implies ¬S. (e.g., S = "There are inconceivable features of the world").

**NOINCONCEIVABILITY**: No S is an open inconceivability.

Then: **NEGPOS <-> GENERALIZED SCRUTABILITY & NOINCONCEIVABILITY**.

**PURE MODAL RATIONALISM**: S is positively conceivable <-> S is negatively conceivable <-> S is possible.

Pure modal rationalism <-> weak modal rationalism & negpos <-> weak modal rationalism & generalized scrutability & noinconceivability.

This requires ruling out (i) strong necessities (ii) generalized inscrutabilities (iii) open inconceivabilities. [Weak modal rationalism rules out (i), strong modal rationalism rules out (i) and (ii).]

[I'd like to believe pure modal rationalism. If true, it gives a beautifully elegant view of our epistemic access to modality. I am very confident about ruling out (i), fairly confident about ruling out (ii), and somewhat unsure about ruling out (iii), but I can at least see a case for it.]

(7) **ARE THERE STRONG NECESSITIES? I. COUNTEREXAMPLES**
Back to making the case for weak modal rationalism and against strong necessities, which is what's relevant to the mind-body issue.

Possible examples of strong necessities:

- (i) Standard a posteriori necessities - no good.
- (ii) Psychophysical necessities (on type-B view) - tendentious.
- (iii) Laws of nature (on some "strong law" views) - tendentious.
- (iv) God's existence (on some theist views) - tendentious.

[For more discussion see my PPR response, section 3.3.]

(8) ARE THERE STRONG NECESSITIES? II. EXPLANATIONS

In The Conscious Mind, I say that strong necessities will be brute facts and inexplicable. (And are thus better seen as contingent laws.) Some "explanations" have been offered in response:

(i) Hill: Explain "illusion of possibility" in psychological terms.

[Response: this doesn't explain the unreliability of modal intuition, i.e. the co-presence of necessity and apparent contingency; so needs to assume strong necessities as an additional part of the explanation; also, this strategy would analogously "explain away" all mathematical/modal knowledge. See PPR response, section 3.4.]

(ii) Loar: Because phenomenal concepts are recognitional concepts with primary = secondary intension.

[Response: this doesn't work unless it presupposes strong necessities to start with, as it presupposes that physical properties have a necessary phenomenal mode of presentation. Also, the recognitionality argument doesn't work. See PPR response, section 3.4.]

(iii) Levine, Melnyk: We don't always have a priori access to primary intensions.

[Response: This is hard to support and in any case would yield inscrutable truths rather than strong necessities. See responses to Levine and Melnyk.]

(9) ARE THERE STRONG NECESSITIES? III. WHY NOT?

Materialist might say: I still haven't ruled out the possibility that strong necessities exist. Perhaps strong necessities are sui generis and inexplicable? Or perhaps an explanation is waiting to be found?

Q: How to argue positively for (weak) modal rationalism? (So far, we've argued negatively by defeating counterexamples and arguments against it.)
This raises the deepest philosophical issues in the vicinity. Here is an argument sketch.

Step by step...

(i) We need the modality of ideally conceivable worlds (= logically possible worlds). EVEN IF some of these worlds aren't "metaphysically possible", we need these worlds for most of the purposes that we need possible worlds in the first place.

- To make sense of counterfactual thought.
- To give an account of the contents of thought.
- To give an account of the semantics of language.
- To systematize rational inference.
- Etc.

Imagine that a "strong laws" view is true, and counternomic worlds are metaphysically impossible. (Or that a type-B materialist view is true, and zombie worlds are metaphysically impossible.) Still, we will need counternomic worlds and zombie worlds in some strong sense for the above purposes: to make sense of a scientist's thought processes, counterfactuals concerning counternomic scenarios, the differing meanings of nomically coextensive terms, and so on. Same for zombie worlds. (See my PPR response, section 3.2.)

(ii) There is no bar to the existence of logically possible worlds. If one doesn't want to just postulate them, they are easy to construct (to "ersatz" into existence), e.g. in terms of equivalence classes of PC-complete descriptions. (With small twists to handle centering and two-dimensional semantics. Th construction is an instructive enterprise.). They behave just as possible worlds should: one can tell coherent science fiction about them, one can semantically evaluate all our terms and statements in them, and one can consider them both as actual and counterfactual.

(iii) So: we need the logical modality and there is no bar to it. So insofar as there is reason to believe in modality at all, there is reason to believe in this modality.

(iv) From the logical modality, we can recover all modal phenomena in which we have reason to believe; and we can use it to explain everything which modality can plausibly explain. We can use it in explaining counterfactuals, the contents of thought, rational inference, the semantics of language, and so on. And with the help of two-dimensional semantics (plus nonmodal facts), we can use it to explain such "metaphysical" phenomena as a posteriori necessity, the concept/property distinction, and so on.

(v) So: one modal primitive (plus conceptual analysis plus nonmodal facts) gives us everything we have reason to believe in. And this modal primitive is tied constitutively to the rational notions (if it's not, we won't be able to explain them): hence, constitutive ties between rational and modal notions.

(vi) The believer in strong necessities, by contrast, must embrace a modal dualism: there are distinct
primitive modalities of logical and metaphysical possibility. The metaphysically possible worlds are a
subset of the logically possible worlds, and neither class is reducible to the other. One modality handles "rational" modal concepts, the other handles "metaphysical" modal concepts.

(vii) There is no reason to believe in such a distinct "metaphysical" modality. (There is a metaphysical modality, but it is just the logical modality.) There is nothing for a distinct metaphysical modality to explain; what is plausibly explainable is already explained. The only reason to believe in it is to justify certain antecedently held theoretical views (e.g. materialism); but this justification is circular in this context. The distinct modality is a frictionless wheel.

(viii) We do not even have a distinct concept of metaphysical modality for the second primitive to answer to. The momentary impression of such a concept stems from a false and confused understanding of such ontic/epistemic distinctions as that between apriority and necessity, and that between concept and property. But all that is easily subsumed under modal monism with the help of two-dimensional semantics.

(ix) Ultimately, there is just one circle of modal concepts, including both the rational modal concepts (validity, rational entailment, a priority, conceivability) and the metaphysical modal concepts (possibility, necessity, property). The relation between these is subtle, but it's a confusion to postulate a new primitive modality: all our reasons for believing in the metaphysical modality are grounded in the rational modality in the first place. (Witness the use of conceivability arguments in establishing a posteriori necessity.)

10) LOOSE ENDS

To establish pure modal rationalism, we need to cross the bridge from a priority to necessity. This requires ruling out intermediate truths. If we can't rule out such truths, we have distinct circles of "positive" and "negative" rational modal concepts; so close yet so far! This isn't so crucial for the mind-body issue, but it's an important project in its own right.

3: THE CONTENT AND EPISTEMOLOGY OF PHENOMENAL BELIEF

[The material in this lecture now exists as a (much revised and expanded) full paper, "The Content and Epistemology of Phenomenal Belief".]

1) INTRODUCTION
PHENOMENAL BELIEF = a belief about an experience (or about experiences in general). I'll concentrate on first-person phenomenal beliefs. E.g.

- "I am having a red experience now".
- "I am in pain".

PROJECT: Try to understand the content of such beliefs. And try to understand their first-person epistemology.

STARTING POINT: I assume "phenomenal realism". Roughly: that phenomenal properties (or qualia) exist - properties capturing what it is like to be in a given mental state - and that the phenomenal isn't conceptually reducible to the functional. On this view, when Mary learns what it is like to see something red, she learns something factual; and it's coherently conceivable that there be a functional (and environmental) duplicate of a conscious being with qualitatively different experiences.

[Includes: e.g. property dualism, qualia-friendly (type-B) materialism. Excludes e.g. eliminativism, analytic functionalism (type-A materialism).]

Q: Does this conceptual irreducibility of the phenomenal to the functional "spread" to other aspects of mentality, e.g. belief content?

A: (to be justified): Yes, at least for phenomenal beliefs.

(2) THE CONTENT OF PHENOMENAL CONCEPTS AND PHENOMENAL BELIEFS

I look at a tomato, have a red experience, and think: "I'm having an experience of such-and-such quality". There are various concepts of the quality in question that might yield a true belief.

THE COMMUNITY RELATIONAL CONCEPT: red_C = "the quality caused in normal observers in my community by red things" (i.e. by paradigms X, Y)

THE INDIVIDUAL RELATIONAL CONCEPT: red_I = "the quality normally caused in me by red things"

THE INDEXICAL CONCEPT: E = "the quality I'm experiencing now" (or: I'm ostending now)

THE QUALITATIVE CONCEPT: R = [red splotch]

The qualitative concept is the one that captures Mary's new knowledge: her new knowledge that certain experiences have such-and-such quality is knowledge that those experiences are R. This concept differs
from all the others: witness the *nontriviality* of:

- \( \text{red}_C = R \)
- \( \text{red}_I = R \)
- \( E = R \)

The knowledge Mary *gains* is that e.g.

- tomatoes look \( R \) to her (and probably to others)
- red things look \( R \) to her
- she is now having an \( R \) experience.

[Technically: \( \text{red}_C, \text{red}_I, E, \) and \( R \), all have different primary intensions (across conceptually possible worlds), as witnessed by the aposteriority of these identities. They have the same secondary intensions.]

Contrast Inverted Mary, who has green experiences where Mary has red experiences. Her new knowledge differs from Mary's. She learns that tomatoes look \( G \) to her, that red things look \( G \) to her, and so on.

**UPSHOT:** If experience isn't conceptually supervenient on the functional, phenomenal belief isn't, either. (Mary and Inverted Mary are functional twins but have different beliefs.)

**TEMPTATION:** Handle the Mary/Inverted Mary difference analogously to standard externalism, e.g. the water/twin water case. (Oscar believes he's seeing water, Twin Oscar believes he's seeing twin water.) Roughly, similar "cognitive" or "notional" content ("the watery stuff around here"), different "relational content" (\( \text{H}_2\text{O} \) vs. \( \text{XYZ} \)).

BUT: This doesn't work. The "water" analogy works for \( \text{red}_C, \text{red}_I, \text{E} \), or \( R \). E.g. Mary and Twin Mary might both have concepts with the notional content of \( \text{red}_C \) but different relational content. But their \( R \) and \( G \) concepts differ in their notional content, not just their relational content.

**Crucial factor:** When Mary confidently believes that tomatoes look \( R \), she can thereby rule out all epistemic possibilities (all centered worlds) in which tomatoes look \( G \). When Oscar confidently believes that the class contains water, he cannot thereby rule out epistemic possibilities in which the glass contains \( \text{XYZ} \) (unless he has some other knowledge, e.g. that water = \( \text{H}_2\text{O} \)). \( R \) is more analogous to a lucid concept of "\( \text{H}_2\text{O} \)" here, not the concept of "water". (Hence the disanalogy: one doesn't find twins with respective concepts of \( \text{H}_2\text{O} \) and \( \text{XYZ} \)).

[Technically: Primary intension of "water" picks out the watery stuff near the center of a centered world. Primary intensions of \( \text{red}_C \) and \( \text{red}_I \) pick out the qualities satisfying the relevant descriptions near the center, and \( E \) picks out whatever quality is experienced or ostended by the center. But primary intension of \( R \) picks out (red splotch) in all worlds, and primary intension of \( G \) picks out (green splotch) in all worlds.]
In these cases: the quality of the experiences "gets inside" the notional content of the concept, and of the corresponding belief. The reference is somehow inside the sense, in a way much stronger than the usual "direct reference". I.e. the quality doesn't just determine secondary intension (as usual), but primary intension. (The only true "direct reference"? cf. Russell.) A strange and interesting phenomenon!

**MORAL:** Experience plays a role in constituting our phenomenal concepts and phenomenal beliefs. Mary's phenomenal concept/belief content supervenes not on her functioning but on her functioning plus phenomenology. Call this sort of concept an experience-constituted phenomenal concept. In the crucial cases (like Mary's), the phenomenal contribution to the content of a concept may be constituted by the quality of a single experience one is having right now. Call this a single-case experience-constituted phenomenal concept, or a direct phenomenal concept for short.

A direct phenomenal concept need not accompany every experience, but they are common when one attends to one's experiences. One has an experience with a certain quality, and forms a concept of this sort of quality (N.B. not the mere indexical "this", as in E). The quality is "taken up" into the concept, such that the (primary intension of the) concept picks out experiences of that quality in any centered world.

A direct phenomenal belief arises when one forms a direct phenomenal concept based on a certain experience, and predicates that concept of the experience in question. E.g. one has a red experience, uses it to form the direct phenomenal concept R, and believes "this experience is R".

Note 1: LIMITATIONS: Most phenomenal beliefs are still corrigible, as most phenomenal beliefs are not direct phenomenal beliefs. E.g. applications of a pre-existing phenomenal concept to a new situation ("I am having a red experience now", "I am in pain", etc.) are corrigible, as are applications of a direct phenomenal concept to an experience other than the one that constitutes it. All the standard

(3) THE EPISTEMOLOGY OF PHENOMENAL BELIEF

(3.1) LIMITED INCORRIGIBILITY THESIS

Direct phenomenal beliefs are incorrigible; i.e., they cannot be false. If a direct phenomenal concept R is constituted by a quality Q of experience E, R applies truly to any experience with Q. In a direct phenomenal belief, R is predicated of E, which has Q, so the belief is true. The role of the experience in constituting both concept and object ensures this. [cf. Pollock.]

Note 1: LIMITATIONS: Most phenomenal beliefs are still corrigible, as most phenomenal beliefs are not direct phenomenal beliefs. E.g. applications of a pre-existing phenomenal concept to a new situation ("I am having a red experience now", "I am in pain", etc.) are corrigible, as are applications of a direct phenomenal concept to an experience other than the one that constitutes it. All the standard
counterexamples fall into classes like these, so none are counterexamples to the limited incorrigibility thesis here. But I suggest that this thesis captures the plausible core of standard incorrigibility theses.

Other limitations: (a) Direct phenomenal beliefs are incorrigible, but subjects may be corrigible (at least in some circumstances) about whether they are having a direct phenomenal belief. (b) Most (token) experiences do not have corresponding direct phenomenal concepts, so are not incorrigibly known. (c) It may be that some experiences (e.g. fleeting or background experiences) cannot be taken up into a direct phenomenal concept, so are not incorrigibly knowable.

Note 2: NONTRIVIALITY: It might be thought that this incorrigible knowledge is trivial, like "this is this", or "I am here". But this is not so. The belief in question is cognitively significant: it heavily constrains the subject's space of epistemic possibilities, unlike the trivial beliefs in question. Technically: the belief in question has a conceptually contingent primary intension (false in many centered worlds), whereas the trivial beliefs have a conceptually necessary primary intension (true in all centered worlds, omitting a wrinkle or two).

(3.2) EPISTEMOLOGICAL PROBLEMS FOR PHENOMENAL REALISM

Phenomenal realism, especially property dualism, is often thought to face epistemological problems centering on the relation between experience and beliefs about experience. E.g. Shoemaker, "Functionalism and qualia", and "The paradox of phenomenal judgment", in The Conscious Mind, Chapter 5.

Starkest argument (for the epiphenomenalist): if experience is causally irrelevant, then experiences are not causally related to beliefs about experiences, so beliefs about experiences are not knowledge. Reply: The relation between experience and phenomenal belief is tighter than any causal relation; it is constitution. And it is the constitutive relation that qualifies a phenomenal belief as knowledge.

Related argument: A zombie would have the same beliefs as me, caused by the same mechanisms, but its beliefs are not justified, so my beliefs are not justified. Reply: The premise is false. My zombie twin's relevant beliefs are not the same as mine, because of the constitutive role of experience in phenomenal belief. (His "direct" phenomenal concepts are arguably empty, or close to empty, if he has concepts at all.)

[In The Conscious Mind I handled these problems differently, relying mostly on our "acquaintance" with experience, and relegating the constitutive relation to a minor role. I now think the constitutive relation is central in answering the arguments. Acquaintance still has an important role to play, but this is a further story.]

(3.3) "THE MYTH OF THE GIVEN"

Presumably this view accepts some sort of "given". Question: Are the arguments that have been put
forward against the "myth of the given" good arguments against this view?

(I) Sellars' inconsistent triad.

- (A) "S senses red sense-content s" entails "S non-inferentially knows that s is red";
- (B) The ability to sense sense-contents is unacquired.
- (C) The ability to know facts of the form "x is phi" is acquired.

My view denies (A). An experience need not be accompanied by a phenomenal belief, and most experiences are not. Phenomenal beliefs are more cognitively sophisticated than experiences. The belief involves concepts; the experience does not, or need not. Knowledge requires belief, so experience does not entail phenomenal knowledge.

Sellars notes that denying (A) entails that a sensing doesn't constitute an item of knowledge. I think this is correct (although it can partly constitute an item of knowledge). Sellars associates the "given" most strongly with (A), so doesn't explicitly argue further against (A)-denying views here.

But such a view leads into

(II) The justification dilemma. If experience is nonconceptual, how can it play a role in justifying something conceptual? (Davidson, Bonjour, McDowell.)

- (1) There can be no inferential relation between an experience and a belief, as inference requires connections within the conceptual domain.
- (2) But a mere causal relation between experience and belief cannot justify the belief. (McDowell: "This offers exculpation where we wanted justification.")
- (3) So: experience cannot play any foundational role in the justification of belief?

REPLY: An option has been missed. The relation between experience and belief is not inference, not causation, not identity, but (partial) constitution. It is the role an experience plays in constituting a direct phenomenal belief that makes that belief incorrigible, and indeed incorrigible in virtue of its phenomenological structure, and so justified.

In any case, the view avoids Sellars' central version of the "given" (i.e., (A)) and McDowell's central version (i.e. a mere causal relation), and the arguments against those versions. Are there further arguments?

FURTHER QUESTIONS:

(1) Does the experience-dependence and functional irreducibility of phenomenal concepts and beliefs extend to other concepts and beliefs?
[Suggestive, at least for perceptual concepts and those based on them.]

(2) Does the limited foundationalism for direct phenomenal beliefs support a wider foundationalism, for a wider class of beliefs?

[At least the gap between experience and belief - often taken to the the greatest problem for foundationalism - has been bridged. The gap between direct phenomenal beliefs and other phenomenal beliefs is bridgeable, by invoking "standing phenomenal concepts" (the sort of coarse-grained qualitative concept we can have of a quality when that quality isn't present). The other major gap, between phenomenal beliefs and beliefs about the external world, still remains.]
The Content and Epistemology of Phenomenal Belief

chalmers@arizona.edu

1 Introduction

Experiences and beliefs are different sorts of mental states, and are often taken to belong to very different domains. Experiences are paradigmatically phenomenal, characterized by what it is like to have them. Beliefs are paradigmatically intentional, characterized by their propositional content. But there are a number of crucial points where these domains intersect. One central locus of intersection arises from the existence of phenomenal beliefs: beliefs that are about experiences.

The most important phenomenal beliefs are first-person phenomenal beliefs: a subject's beliefs about his or her own experiences, and especially, about the phenomenal character of the experiences that he or she is currently having. Examples include the belief that one is now having a red experience, or that one is experiencing pain.

These phenomenal beliefs raise important issues in metaphysics, in the theory of content, and in epistemology. In metaphysics, the relationship between phenomenal states and phenomenal beliefs is sometimes taken to put strong constraints on the metaphysics of mind. In the theory of content, analyzing the content of phenomenal beliefs raises special issues for a general theory of content to handle, and the content of such beliefs has sometimes been taken to be at the foundations of a theory of content more generally. In epistemology, phenomenal beliefs are often taken to have a special epistemic status, and are sometimes taken to be the central epistemic nexus between cognition and the external world.

My project here is to analyze phenomenal beliefs in a way that sheds some light on these issues. I will start by focusing on the content of these beliefs, and will use the analysis developed there to discuss the underlying factors in virtue of which this content is constituted. I will then apply this framework to the central epistemological issues in the vicinity: incorrigibility, justification, and the dialectic over the "Myth of the Given".

1.1 Phenomenal realism
The discussion that follows is premised upon what I call "phenomenal realism": the view that there are phenomenal properties (or phenomenal qualities, or qualia), properties that type mental states by what it is like to have them, and that phenomenal properties are not conceptually reducible to physical or functional properties (or equivalently, that phenomenal concepts are not reducible to physical or functional concepts). On this view, there are truths about what it is like to be a subject that are not entailed a priori by the physical and functional truth (including the environmental truth) about that subject.

The phenomenal realist view is most easily illustrated with some familiar thought-experiments. Consider Frank Jackson's case of Mary, the neuroscientist who knows all relevant physical truths about color processing, but whose visual experience has been entirely monochromatic. On the phenomenal realist view, Mary lacks factual knowledge concerning what it is like to see red. Views that deny this deny phenomenal realism. Or consider cases in which a hypothetical being has the same physical, functional and environmental properties as an existing conscious being, but does not have the same phenomenal properties. Such a being might be a zombie, lacking experiences altogether, or it might be an inverted being, with experiences of a different character. On the phenomenal realist view, some such duplicates are coherently conceivable, in the sense that there is no a priori contradiction in the hypothesis in question. Views that deny this deny phenomenal realism.

(What if someone holds that functional duplicates without consciousness are coherently conceivable, but that physical duplicates without consciousness are not? Such a view would be in the spirit of phenomenal realism. This suggests that we could define phenomenal realism more weakly as the thesis that the phenomenal is not conceptually reducible to the functional, omitting mention of the physical. I do not define it this way, for two reasons. First, I think if functional duplicates without consciousness are conceivable, physical duplicates without consciousness must be conceivable too, as there is no reasonable possibility of a conceptual entailment from microphysical to phenomenal that does not proceed via the functional. Second, it is not easy to give a precise account of what functional duplication consists in, and stipulating physical identity finesses that question. But if someone disagrees, everything that I say in this paper will apply, with appropriate changes, on the weaker view.)

Phenomenal realism subsumes most varieties of dualism about the phenomenal. It also subsumes many varieties of materialism. In particular it subsumes what I have called "type-B" materialism (see Chalmers 2002a): views that hold that there is an a posteriori necessary entailment from the physical to the phenomenal, so that there is an epistemic or conceptual gap between the physical and phenomenal domains, but no ontological gap. Views of this sort typically allow that Mary gains factual knowledge when she sees red for the first time, but hold that it is knowledge of an old fact known in a new way; and they typically hold that the duplication cases mentioned above are conceptually coherent but not metaphysically possible.

Phenomenal realism excludes what I have called "type-A" materialism: views that hold that all phenomenal truths are entailed a priori by physical truths. Such views include eliminativism about the phenomenal, as well as analytical functionalism and logical behaviorism, and certain forms of analytic
The Content and Epistemology of Phenomenal Belief

representationalism. Views of this sort typically deny that Mary gains any knowledge when she sees red for the first time, or hold that she gains only new abilities; and they typically deny that the duplication cases mentioned above are coherently conceivable.

Those who are not phenomenal realists might want to stop reading now, but there are two reasons why they might continue. First, although the arguments I will give for my view of phenomenal beliefs will presuppose phenomenal realism, it is possible that some aspects of the view itself may be tenable even on some views that deny phenomenal realism. Second, some of the most important arguments against phenomenal realism are epistemological arguments that center on the connection between experience and belief. I will be using my analysis to help rebut those arguments, and thus indirectly to support phenomenal realism against its opponents.

A note on modality: Because I am assuming phenomenal realism but not property dualism in this paper, all references to necessity and possibility should be taken as invoking conceptual necessity and possibility. Similarly, talk of possible worlds can be taken as invoking conceivable worlds (corresponding to the epistemically constructed scenarios of Chalmers (forthcoming); see also the appendix), and talk of constitutive relations should be taken as invoking conceptually necessary connections. If one accepts a certain sort of link between conceptual and metaphysical possibility (e.g. the thesis that ideal primary conceivability entails primary possibility), then these references can equally be taken as invoking metaphysical possibility and necessity.

A note on phenomenal properties: It is natural to speak as if phenomenal properties are instantiated by mental states, and as if there are entities, experiences, that bear their phenomenal properties essentially. But one can also speak as if phenomenal properties are directly instantiated by conscious subjects, typing subjects by aspects of what it is like to be them at the time of instantiation. These ways of speaking do not commit one to corresponding ontologies, but they at least suggest such ontologies. In a quality-based ontology, the subject-property relation is fundamental. From this one can derive a subject-experience-property structure, by identifying experiences with phenomenal states (instantiations of phenomenal properties), and attributing phenomenal properties to these states in a derivative sense. In a more complex experience-based ontology, a subject-experience-property structure is fundamental (where experiences are phenomenal individuals, or at least something more than property instantiations), and the subject-property relation is derivative. In what follows, I will sometimes use both sorts of language, and will be neutral between the ontological frameworks.

2 The Content of Phenomenal Concepts and Phenomenal Beliefs

2.1 Relational, demonstrative, and pure phenomenal concepts

Phenomenal beliefs involve the attribution of phenomenal properties. These properties are attributed under phenomenal concepts. To understand the content of phenomenal beliefs, we need to understand the nature and content of phenomenal concepts.
I look at a red apple, and visually experience its color. This experience instantiates a phenomenal quality \( R \), which we might call phenomenal redness. It is natural to say that I am having a red experience, even though of course experiences are not red in the same sense in which apples are red. Phenomenal redness (a property of experiences, or of subjects of experience) is a different property from external redness (a property of external objects), but both are respectable properties in their own right.

I attend to my visual experience, and think *I am having an experience of such-and-such quality*, referring to the quality of phenomenal redness. There are various concepts of the quality in question that might yield a true belief.[*]

*[[I take concepts to be mental entities on a par with beliefs: they are constituents of beliefs (and other propositional attitudes) in a manner loosely analogous to the way in which words are constituents of sentences. Like beliefs, concepts are tokens rather than types in the first instance. But they also fall under types, some of which I explore in what follows. In such cases it is natural to use singular expressions such as 'the concept' for a concept-type, just as one sometimes uses expressions such as 'the belief' for a belief-type, or 'the word' for a word-type.]]

We can first consider the concept expressed by 'red' in the public-language expression 'red experience', or the concept expressed by the public-language expression 'phenomenal redness'. The reference of these expressions is fixed via a relation to red things in the external world, and ultimately via a relation to certain paradigmatic red objects that are ostended in learning the public-language term 'red'. A language learner learns to call the experiences typically brought about by these objects 'red' (in the phenomenal sense), and to call the objects that typically bring about those experiences 'red' (in the external sense). So the phenomenal concept involved here is *relational*, in that it has its reference fixed by a relation to external objects. The property that is referred to need not be relational, however. The phenomenal concept plausibly designates an intrinsic property rigidly, so that there are counterfactual worlds in which red experiences are never caused by red things.

One can distinguish at least two relational phenomenal concepts, depending on whether reference is fixed by relations across a whole community of subjects, or by relations restricted to the subject in question. The first is what we can call the community relational concept, or \( red_C \). This can be glossed roughly as the phenomenal quality typically caused in normal subjects within my community by paradigmatic red things. The second is what we can call the individual relational concept, or \( red_I \). This can be glossed roughly as the phenomenal quality typically caused in me by paradigmatic red things. The two concepts \( red_C \) and \( red_I \) will corefer for normal subjects, but for abnormal subjects they may yield different results. For example, a red/green-inverted subject's concept \( red_C \) will refer to (what others call) phenomenal redness, but his or her concept \( red_I \) will refer to (what others call) phenomenal greenness.

The public-language term 'red' as a predicate of experiences can arguably be read as expressing either \( red_C \) or \( red_I \). The community reading of 'red' guarantees a sort of shared meaning within the community, in that all uses of the term are guaranteed to corefer, and in that tokens of sentences such as 'X has a red experience at time t' will have the same truth-value whether uttered by normal or abnormal subjects. On the other hand, the individual reading allows a subject better access to the term's referent. On this reading, an unknowingly inverted subject's term 'red' will refer to what she think it refers to
(unless the inversion was recent), while on the community reading, her term 'red' may refer to something quite different, and her utterance 'I have had red experiences' may even be unknowingly quite false.[*] In any case, we need not settle here just what is expressed by phenomenal predicates in public language. All that matters is that both concepts are available.

[*][These cases may not be entirely hypothetical. Nida-Rumelin (1996) gives reasons, based on the neurobiological and genetic bases of colorblindness, to believe that a small fraction of the population may actually be spectrum-inverted with respect to the rest of us. If so, it is natural to wonder just what their phenomenal expressions refer to.]]

Phenomenal properties can also be picked out by demonstratives. When seeing the tomato, I can refer demonstratively to a visual quality associated with it, using a concept I might express by saying 'this quality' or 'this sort of experience'. The relevant concept here is the phenomenal demonstrative that we might call $E$, which functions roughly by picking out whatever quality the subject is currently ostending. Like other demonstratives, it has a "character", which fixes reference in a context roughly by picking out whatever quality is ostended in that context; and it has a distinct "content", corresponding to the quality that is actually ostended - in this case, phenomenal redness. The demonstrative concept $E$ rigidly designates its referent, so that it picks out the quality in question even in counterfactual worlds in which no-one is ostending the quality.

The three concepts $red_C$, $red_I$, and $E$ may all refer to the same quality, phenomenal redness. All of them fix reference to phenomenal redness relationally, characterizing it in terms of its relations to external objects or acts of ostension. There is another crucial phenomenal concept in the vicinity, one that does not pick out phenomenal redness relationally, but rather picks it out directly, in terms of its intrinsic phenomenal nature. This is what we might call a pure phenomenal concept.

To see the need for the pure phenomenal concept, consider the knowledge that Mary gains when she learns for the first time what it is like to see red. She learns that seeing red has such-and-such quality. Mary learns (or reasonably comes to believe) that red things will typically cause experiences of such-and-such quality in her, and in other members of her community. She learns (or gains the cognitively significant belief) that the experience she is now having has such-and-such quality, and that the quality she is now ostending is such-and-such. Call Mary's "such-and-such" concept here $R$.

Mary's concept $R$ picks out phenomenal redness, but it is quite distinct from the concepts $red_C$, $red_I$, and $E$. We can see this by using cognitive significance as a test for difference between concepts. Mary gains the belief $red_C=R$ - that the quality typically caused in her community by red things is such-and-such - and this belief is cognitively significant knowledge. She gains the cognitively significant belief $red_I = R$ in a similar way. And she gains the belief $E=R$ - roughly, that the quality she is now ostending is such-and-such.

Mary's belief $E=R$ is as cognitively significant as any other belief in which the object of a demonstrative is independently characterized: e.g. my belief I am David Chalmers, or my belief that object is tall, or my belief that shape is roundness. For Mary, $E=R$ is not a priori. No a priori reasoning can rule out the hypothesis that she is now ostending some other quality entirely, just as no a priori reasoning can rule out
the hypothesis that I am David Hume, or that the object I am pointing to is short. Indeed, nothing known a priori entails that R is ever instantiated in the actual world.

So the concept R is quite distinct from red_C, red_I, and E. Unlike the other concepts, the pure phenomenal concept characterizes the phenomenal quality as the phenomenal quality that it is.

The concept R is difficult to express directly in language, since the most natural terms, such as 'phenomenal redness' and 'this experience', arguably express other concepts such as red_C and E. Still, one can arguably discern uses of these terms that express pure phenomenal concepts; or if not, one can stipulate such uses. For example, Chisholm suggests that there is a "noncomparative" sense of expressions such as 'looks red'; this sense seems to express a pure phenomenal concept, whereas his "comparative sense" seems to express a relational phenomenal concept.[*] And at least informally, demonstratives are sometimes used to express pure phenomenal concepts. For example, the belief that E=R might be informally expressed by saying something like "this quality is this quality".

[*][The distinction also roughly tracks Nida-Rumelin's (1995; 1997) distinction between "phenomenal" and "nonphenomenal" readings of belief attributions concerning phenomenal states. "Phenomenal" belief attributions seem to require that the subject satisfies the attribution by virtue of a belief involving a pure phenomenal concept, while "nonphenomenal" attributions allow that the subject can satisfy the attribution by virtue of a belief involving a relational phenomenal concept.]

It may be that there is a sense in which R can be regarded as a "demonstrative" concept. I will not regard it this way: I take it that demonstrative concepts work roughly as analyzed by Kaplan (1977), so that they have an epistemic reference-fixing "character" that leaves their referent open. This is how E behaves: its content might be expressed roughly as "this quality, whatever it happens to be". R, on the other hand, is a substantive concept that is tied a priori to a specific sort of quality, so it does not behave the way that Kaplan suggests that a demonstrative should. Still, there is an intimate relationship between pure and demonstrative phenomenal concepts that I will discuss later in the paper; and if someone wants to count pure phenomenal concepts as "demonstrative" in a broad sense, there is no great harm in doing so, as long as the relevant distinctions are kept clear. What matters for my purposes is not the terminological point, but the more basic point that the distinct concepts E and R exist. For a phenomenal realist, there can be no doubt about this.[*]

The relations among these concepts can be analyzed straightforwardly using the two-dimensional framework for representing the content of concepts. A quick introduction to this framework is given in an appendix; more details can be found in Chalmers (2002c). The central points of this paper should be comprehensible if matters involving the two-dimensional framework are skipped, but the framework makes the analysis of some crucial points much clearer.

According to the two-dimensional framework, when an identity A=B is a posteriori, the concepts A and B have different epistemic (or primary) intensions. If A and B are rigid concepts and the identity is true, A and B have the same subjunctive (or secondary) intension. So we should expect that the concepts red_C, red_I, E, and R have different epistemic intensions, but the same subjunctive intension. And this is what
we find. The subjunctive intension of each picks out phenomenal redness in all worlds. The epistemic intension of \textit{red\_C} picks out, in a given centered world, roughly the quality typically caused by certain paradigmatic objects in the community of the subject at the center of the world. The epistemic intension of \textit{red\_I} picks out roughly the quality typically caused by those objects in the subject at the center.

As for the demonstrative concept \textit{E}: to a first approximation, one might hold that its epistemic intension picks out the quality that is ostended by the subject at the center. This characterization is good enough for most of our purposes, but it is not quite correct. It is possible to ostend two experiences simultaneously and invoke two distinct demonstrative concepts, as when one thinks \textit{that quality differs from that quality}, ostending two different parts of a symmetrical visual field (see Austin 1990). Here no descriptive characterization such as the one above will capture the difference between the two concepts. It is better to see \textit{E} as a sort of indexical, like \textit{I} or \textit{now}. To characterize the epistemic possibilities relevant to demonstrative phenomenal concepts, we need centered worlds whose centers contain not only a "marked" subject and time, but also one or more marked experiences; in the general case, a sequence of such experiences.\[*\] Then a concept such as \textit{E} will map a centered world to the quality of the "marked" experience (if any) in that world. Where two demonstrative concepts \textit{E1} and \textit{E2} are involved, as above, the relevant epistemic possibilities will contain at least two marked experiences, and we can see \textit{E1} as picking out the quality of the first marked experience in a centered world, and \textit{E2} as picking out the quality of the second. Then the belief above will endorse all worlds at which the quality of the first marked experience differs from the quality of the second. This subtlety will not be central for the purposes of this paper.

\[*[In the experience-based framework: if experiences do not map one-to-one to instances of phenomenal properties, then instances of phenomenal properties should be marked instead.]]*

The epistemic intension of \textit{R} is quite distinct from all of these. It picks out phenomenal redness in all worlds. I will analyze this matter in more depth shortly; but one can see intuitively why this is plausible. When Mary believes \textit{roses cause R experiences}, or \textit{I am currently having an R experience}, she thereby excludes all epistemic possibilities in which roses cause some other quality (such as \textit{G}, phenomenal greenness), or in which she is experiencing some other quality: only epistemic possibilities involving phenomenal redness remain.

The cognitive significance of identities such as \textit{red\_C=R}, \textit{red\_I=R}, and \textit{E=R} is reflected in the differences between the concept's epistemic intensions. The first two identities endorse all epistemic possibilities in which paradigmatic objects stand in the right relation to experiences of \textit{R}; these are only a subset of the epistemic possibilities available a priori. The third identity endorses all epistemic possibilities in which the marked experience at the center (or the ostended experience, on the rough characterization) is \textit{R}. Again, there are many epistemic possibilities (a priori) that are not like this: centered worlds in which the marked experience is \textit{G}, for example. Once again, this epistemic contingency reflects the cognitive significance of the identity.\[*\]

(Phenomenal realists (e.g. Loar 1997, Hawthorne 2001) analyzing what Mary learns have occasionally suggested that her phenomenal concept is a demonstrative concept. This is particularly popular as a way
of resisting anti-materialist arguments, as it is tempting to invoke the distinctive epistemic and referential behavior of demonstrative concepts in explaining why an epistemic gap does not reflect an ontological gap. But on a closer look it is clear that Mary's central phenomenal concept $R$ (the one that captures what she learns) is distinct from her central demonstrative concept $E$, as witnessed by the nontrivial identity $E=R$, and is not a demonstrative concept in the usual sense. This is not just a terminological point. Those who use these analyses to rebut anti-materialist arguments typically rely on analogies with the epistemic and referential behavior of ordinary (Kaplan-style) demonstratives. Insofar as these analyses rely on such analogies, they fail. Something similar applies to analyses that liken phenomenal concepts to indexical concepts (e.g. Ismael 1999, Perry 2001). If my analysis is correct, then pure phenomenal concepts (unlike demonstrative phenomenal concepts) are not indexical concepts at all.)

2.2 Inverted Mary

We can now complicate the situation by introducing another thought-experiment on top of the first one. Consider the case of Inverted Mary, who is physically, functionally, and environmentally just like Mary, except that her phenomenal color vision is red/green inverted. (I will assume for simplicity that Inverted Mary lives in a community of inverted observers.) Like Mary, Inverted Mary learns something new when she sees red things for the first time. But Inverted Mary learns something different from what Mary learns. Where Mary learns that tomatoes cause experiences of (what we call) phenomenal redness, Inverted Mary learns that they cause experiences of (what we call) phenomenal greenness. In the terms given earlier, Mary acquires beliefs $\text{red}_C=R$, $\text{red}_I=R$, and $E=R$, while Inverted Mary acquires beliefs $\text{red}_C=G$, $\text{red}_I=G$, and $E=G$ (where $G$ is the obvious analog of $R$). So Mary and Inverted Mary acquire beliefs with quite different contents.

This is already enough to draw a strong conclusion about the irreducibility of content. Recall that Mary and Inverted Mary are physical/functional and environmental twins, even after they see red things for the first time. Nevertheless, they have beliefs with different contents. It follows that belief content does not supervene conceptually on physical/functional properties. And it follows from this that intentional properties are not conceptually supervenient on physical/functional properties, in the general case.

This is a nontrivial conclusion. Phenomenal realists often hold that while the phenomenal is conceptually irreducible to the physical and functional, the intentional can be analyzed in functional terms. But if what I have said here is correct, then this irreducibility cannot be quarantined in this way. If the phenomenal is conceptually irreducible to the physical and functional, so too is at least one aspect of the intentional: the content of phenomenal beliefs.

At this point, there is a natural temptation to downplay this phenomenon by reducing it to a sort of dependence of belief content on reference that is found in many other cases: in particular in the cases that are central to externalism about the content of belief. Take Putnam's case of Twin Earth. Oscar and Twin Oscar are functional duplicates, but they inhabit different environments: Oscar's contains H2O as the clear liquid in the oceans and lakes, while Twin Oscar's contains XYZ (which we count not as water but as twin water). As a consequence, Oscar's water concept refers to water (H2O), while Twin Oscar's
The Content and Epistemology of Phenomenal Belief

analogous concept refers to twin water (XYZ). Because of this difference in reference, Oscar and Twin Oscar seem to have different beliefs: Oscar believes that water is wet, while Twin Oscar believes that twin water is wet. Perhaps the case of Mary and Inverted Mary is just like this?[*]

*[[This sort of treatment of phenomenal belief is suggested by Francescotti (1994).]]

The analogy does not go through, however. Or rather, it goes through only to a limited extent. Oscar and Twin Oscar's *water* concepts here are analogous to Mary and Inverted Mary's relational phenomenal concepts (*red_C* or *red_I*), or perhaps to their demonstrative concepts. For example, the relational concepts that they express with their public-language expressions 'red experience' will refer to two different properties, phenomenal redness and phenomenal greenness. Mary and Inverted Mary can deploy these concepts in certain beliefs, such as the beliefs that they express by saying 'Tomatoes cause red experiences', even before they leave their monochromatic rooms for the first time. Because of the distinct referents of their concepts, there is a natural sense (Nida-Rumelin's "nonphenomenal" sense) in which we can say that Mary believed that tomatoes caused red experiences, while Inverted Mary did not; she believed that tomatoes caused green experiences. Here the analogy goes through straightforwardly.

The pure phenomenal concepts *R* and *G*, however, are less analogous to the two *water* concepts than to the chemical concepts *H2O* and *XYZ*. When Oscar learns the true nature of water, he acquires the new belief *water = H2O*, while Twin Oscar acquires an analogous belief involving *XYZ*. When Mary learns the true nature of red experiences, she acquires a new belief *red_C = R*, while Inverted Mary acquires an analogous belief involving *G*. That is, Mary and Inverted Mary's later knowledge involving *R* and *G* is fully lucid knowledge of the referents of the concepts in question, analogous to Oscar and Twin Oscar's knowledge involving the chemical concepts *H2O* and *XYZ*.

But here we see the strong disanalogy. Once Oscar acquires the chemical concept *H2O* and Twin Oscar acquires *XYZ*, they will no longer be twins: their functional properties will differ significantly. By contrast, at the corresponding point Mary and Inverted Mary are still twins. Even though Mary has the pure phenomenal concept *R* and Inverted Mary has *G*, their functional properties are just the same. So the difference between the concepts *R* and *G* across functional twins is something that has no counterpart in the standard Twin Earth story.

All this reflects the fact that in standard externalist cases, the pairs of corresponding concepts may differ in reference, but they have the same or similar *epistemic* or *notional* contents. Oscar and Twin Oscar's *water* concepts have different referents (*H2O* vs. *XYZ*), but they have the same epistemic contents: both intend to refer to roughly the liquid around them with certain superficial properties. Something like this applies to Mary's and Inverted Mary's relational phenomenal concepts, which have different referents but the same epistemic content (which picks out whatever quality stands in a certain relation), and to their demonstrative concepts (which pick out roughly whatever quality happens to be ostended).

In terms of the two-dimensional framework, where epistemic contents correspond to epistemic intensions: Oscar's and Twin Oscar's *water* concepts have the same epistemic intension but different
subjunctive intensions. A similar pattern holds in all the cases characteristic of standard externalism. The pattern also holds for Mary's and Inverted Mary's relational phenomenal concepts, and their demonstrative phenomenal concepts.

But Mary's concept $R$ and Twin Mary's concept $G$ have different epistemic contents. In this way they are analogous to Oscar's concept $H2O$ and Twin Oscar's concept $XYZ$. But again, the disanalogy is that $R$ and $G$ are possessed by twins, and $H2O$ and $XYZ$ are not. So the case of Inverted Mary yields an entirely different phenomenon: a case in which epistemic content differs between twins.

This can be illustrated by seeing how the concepts in question are used to constrain epistemic possibilities. When Oscar confidently believes that there is water in the glass, he is not thereby in a position to rule out the epistemic possibility that there is $XYZ$ in the glass (unless he has some further knowledge, such as the knowledge that water is $H2O$). The same goes for Twin Oscar's corresponding belief. For both of them, it is equally epistemically possible that the glass contains $H2O$ and that it contains $XYZ$. Any epistemic possibility compatible with Oscar's belief is also compatible with Twin Oscar's belief: in both cases, these will be roughly those epistemic possibilities in which a sample of the dominant watery stuff in the environment is in the glass.

Epistemic content reflects the way that a belief constrains the space of epistemic possibilities, so Oscar's and Twin Oscar's epistemic contents are the same. Something similar applies to Mary and Inverted Mary, at least where their pairwise relational and demonstrative phenomenal concepts are concerned. When Mary confidently believes (under her relational concept) that her mother is having a red experience, for example, she is not thereby in a position to rule out the epistemic possibility that her mother is having an experience with the quality $G$. Both Mary's and Inverted Mary's beliefs are compatible with any epistemic possibility in which the subject's mother is having the sort of experience typically caused in the community by paradigmatic red objects. So their beliefs have the same epistemic contents.

But Mary's and Inverted Mary's pure phenomenal concepts do not work like this. Mary's concept $R$ and Inverted Mary's concept $G$ differ not just in their referents but in their epistemic contents. When Mary leaves the monochromatic room and acquires the confident belief (under her pure phenomenal concept) that tomatoes cause red experiences, she is thereby in a position to rule out the epistemic possibility that tomatoes cause experiences with quality $G$. The only epistemic possibilities compatible with her belief are those in which tomatoes cause $R$ experiences. For Inverted Mary, things are reversed: the only epistemic possibilities compatible with her belief are those in which tomatoes cause $G$ experiences. So their epistemic contents are quite different.

Again, the epistemic situation with $R$ and $G$ is analogous to the epistemic situation with the concepts $H2O$ and $XYZ$. When Oscar believes (under a fully lucid chemical concept) that the glass contains $H2O$, he is thereby in a position to rule out all epistemic possibilities in which the glass contains $XYZ$. For Twin Oscar, things are reversed: this is to say that $H2O$ and $XYZ$ have different epistemic contents. The same goes for $R$ and $G$. 

http://www.u.arizona.edu/~chalmers/papers/belief.html (10 of 45) [4/7/2002 1:44:00 PM]
So in the case of the pure phenomenal concepts, uniquely, we have a situation in which two concepts differ in their epistemic content despite the subjects being physically identical. So phenomenal concepts seem to give a case in which even epistemic content is not conceptually supervenient on the physical.

Using the two-dimensional framework: the epistemic intension of a concept reflects the way it applies to epistemic possibilities. We saw above that the epistemic intensions of Oscar's and Twin Oscar's water concepts are the same, as are the epistemic intensions of Mary's and Inverted Mary's relational and demonstrative phenomenal concepts. But R and G differ in the way they apply to epistemic possibilities, and their epistemic intensions differ accordingly: the epistemic intension of R picks out phenomenal redness in all worlds, and the epistemic intension of G picks out phenomenal greenness in all worlds. When Mary thinks I am having an R experience now, the epistemic intension of her thought is true at all and only those worlds in which the being at the center is having an R experience.

Something very unusual is going on here. In standard externalism, and in standard cases of so-called "direct reference", a referent plays a role in constituting the subjunctive content (subjunctive intension) of concepts and beliefs, while leaving the epistemic content (epistemic intension) unaffected. In the pure phenomenal case, by contrast, the quality of the experiences plays a role in constituting the epistemic content of the concept and of the corresponding belief. One might say very loosely that in this case, the referent of the concept is somehow present inside the concept's sense, in a way much stronger than in the usual cases of "direct reference".[*]

[[Martine Nida-Rumelin suggests in a forthcoming paper that we can call this sort of concept a super-rigid concept. A rigid concept is one whose subjunctive intension picks out the same referent at all worlds; a super-rigid concept is a rigid concept whose epistemic intension picks out the same referent at all worlds.]]

One might see here some justification for Russell's claim that we have a special capacity for direct reference to our experiences.[*] Contemporary direct reference theorists hold that Russell's view was too restrictive, and that we can make direct reference to a much broader class of entities. But the cases they invoke are "direct" only in the weak sense outlined above: the subjunctive content depends on the referent, but the epistemic content of the concept does not. In the phenomenal case, the epistemic content itself seems to be constituted by the referent. It is not hard to imagine that some such epistemic requirement on direct reference is what Russell had in mind.

[[Russell also held that direct reference is possible to universals, and perhaps to the self. It is arguable that for at least some universals (in the domains of causation, space, time, or mathematics, perhaps), one can form a concept whose epistemic content picks out instances of that universal in all worlds. So there is at least a limited analogy here, though it seems unlikely that the content of such a (token) concept is directly constituted by an underlying instance of the universal, in the manner suggested below.

There is no analogous phenomenon with the self. There may, however, be a different sense in which we can make "direct reference" to the self, to the current time, and to particular experiences: this is the sort of direct indexical reference that corresponds to the need to build these entities into the center of a centered world. We can refer to these "directly" (in a certain sense) under indexical concepts; but we cannot form concepts whose epistemic content reflect the referents in question. This suggests that direct reference to particulars and direct reference to properties are quite different]
3 The Constitution of Phenomenal Beliefs

3.1 Direct phenomenal concepts and beliefs

We have seen that the content of phenomenal concepts and phenomenal beliefs does not supervene conceptually on physical properties. Does this content supervene conceptually on some broader class of properties, and if so, on which? I will offer an analysis of how the content of pure phenomenal concepts is constituted. I will not give a knockdown argument for this analysis by decisively refuting all alternatives, but I will offer it as perhaps the most natural and elegant account of the phenomena, and as an account which can in turn do further explanatory work.

To start with, it is natural to hold that the content of phenomenal concepts and beliefs supervenes conceptually on the combination of physical and phenomenal properties. Mary and Inverted Mary are physical twins, but they are phenomenally distinct, and this phenomenal distinctness (Mary experiences phenomenal redness, Inverted Mary experiences phenomenal greenness) precisely mirrors their intentional distinctness (Mary believes that tomatoes cause R experiences, Inverted Mary believes that tomatoes cause G experiences). It is very plausible to suppose that their intentional distinctness holds in virtue of their phenomenal distinctness.

The alternative is that the intentional content of the phenomenal concept is conceptually independent of both physical and phenomenal properties. If that is so, it should be conceivable that two subjects have the same physical and phenomenal properties, while having phenomenal beliefs that differ in content. Such a case might involve Mary and Mary' as physical and phenomenal twins, who are both experiencing phenomenal redness for the first time (while being phenomenally identical in all other respects), with Mary acquiring the belief that tomatoes cause R experiences while Mary' acquires the belief that tomatoes cause G experiences. It is not at all clear that such a case is conceivable.

Another possibility is that the intentional content of Mary's phenomenal concept in question might be determined by phenomenal states other than the phenomenal redness that Mary is visually experiencing. For example, maybe Mary's belief content is determined by a faint phenomenal "idea" that goes along with her phenomenal "impression", where the former is not conceptually determined by the latter, and neither is conceptually determined by the physical. In that case, it should once again be conceivable that twins Mary and Mary' both visually experience phenomenal redness upon leaving the room, with Mary acquiring the belief that tomatoes cause R experiences while Mary' acquires the belief that tomatoes cause G experiences, this time because of a difference in their associated phenomenal ideas. But again, it is far from clear that this is conceivable.

There is a very strong intuition that the content of Mary's phenomenal concept and phenomenal belief is determined by the phenomenal character of her visual experience, in that it will vary directly as a function of that character in cases where that character varies while physical and other phenomenal
properties are held fixed, and that it will not vary independently of that character in such cases. I will adopt this claim as a plausible working hypothesis.

In particular, I will take it that in cases like Mary's, the content of a phenomenal concept and a corresponding phenomenal belief, is partly \textit{constituted} by an underlying phenomenal quality, in that the content will mirror the quality (picking out instances of the quality in all epistemic possibilities), and in that across a wide range of nearby conceptually possible cases in which the underlying quality is varied while background properties are held constant, the content will covary to mirror the quality. Let us call this sort of phenomenal concept a \textit{direct phenomenal concept}.

Not all experiences are accompanied by corresponding direct phenomenal concepts. Many of our experiences appear to pass without our forming any beliefs about them, and without the sort of concept formation that occurs in the Mary case. The clearest cases of direct phenomenal concepts arise when a subject attends to the quality of an experience, and forms a concept wholly based on the attention to the quality, "taking up" the quality into the concept. This sort of concept formation can occur with visual experiences, as in the Mary case, but it can equally occur with all sorts of other experiences: auditory and other perceptual experiences, bodily sensations, emotional experiences, and so on. In each case we can imagine the analog of Mary having such an experience for the first time, attending to it, and coming to have a concept of what it is like to have it. There is no reason to suppose that this sort of concept formation is restricted to entirely novel experiences. I can experience a particular shade of phenomenal redness for the hundredth time, attend to it, and form a concept of what it is like to have that experience, a concept whose content is based entirely on the character of the experience.

Direct phenomenal concepts can be deployed in a wide variety of beliefs, and other propositional attitudes. When Mary attends to her phenomenally red experience and forms her direct phenomenal concept $R$, she is thereby in a position to believe that tomatoes cause $R$ experiences, to believe that others have $R$ experiences, to believe that she previously had no $R$ experiences, to desire more $R$ experiences, and so on.

Perhaps the most crucial sort of deployment of a direct phenomenal concept occurs when a subject predicates the concept of the very experience responsible for constituting its content. Mary has a phenomenally red experience, attends to it and forms the direct phenomenal concept $R$, and forms the belief \textit{This experience is $R$}, demonstrating the phenomenally red experience in question. We can call this special sort of belief a \textit{direct phenomenal belief}.

We can also cast this idea within an experience-free ontology of qualities. In this framework, we can say that a direct phenomenal concept is formed by attending to a quality and taking up that quality into a concept whose content mirrors the quality, picking out instances of the quality in all epistemic possibilities. A direct phenomenal belief is formed when the referent of this direct phenomenal concept is identified with the referent of a corresponding demonstrative phenomenal concept, e.g. when Mary forms the belief that \textit{This quality is $R$}. The general form of a direct phenomenal belief in this framework is $E=R$, where $E$ is a demonstrative phenomenal concept and $R$ is the corresponding direct phenomenal concept.
3.2 Some notes on direct phenomenal beliefs

(1) For a direct phenomenal belief, it is required that the demonstrative and direct concepts involved be appropriately "aligned". Say that Mary experiences phenomenal redness in both the left and right halves of her visual field, forms a direct phenomenal concept $R$ based on her attention to the left half, forms a demonstrative concept of phenomenal redness based on her attention to the right half, and identifies the two by a belief of the form $E=R$. Then this is not a direct phenomenal belief, even though the same quality (phenomenal redness) is referred to on both sides, since the concepts are grounded in different instances of that quality. The belief has the right sort of content, but it does not have the right sort of constitution.

To characterize the required alignment more carefully we can note that all direct phenomenal concepts, like all demonstrative phenomenal concepts, are based in acts of attention to instances of phenomenal qualities. A direct phenomenal concept such as $R$ does not characterize a quality as an object of attention, but it nevertheless requires attention to a quality for its formation. The same act of attention can also be used to form a demonstrative phenomenal concept $E$. A direct phenomenal belief (in the quality-based framework) will be a belief of the form $E=R$ where the demonstrative phenomenal concept $E$ and the direct phenomenal concept $R$ are aligned: that is, where they are based in the same act of attention.

One can simplify the language by regarding the act of attention as a demonstration. We can then say that both demonstrative and direct phenomenal concepts are based in demonstrations, and that a direct phenomenal belief is a belief of the form $E=R$ where the two concepts are based in the same demonstration.[*]

[*][Gertler (2001) has independently developed a related account of phenomenal introspection, according to which a phenomenal state is introspected when it is "embedded" in another state, and when the second state constitutes demonstrative attention to the relevant content by virtue of this embedding. On my account, things are the other way around: any "embedding" holds in virtue of demonstrative attention, rather than the reverse.]]

(2) As with all acts of demonstration and attention, phenomenal demonstration and attention involves a cognitive element. Reference to a phenomenal quality is determined in part by cognitive elements of a demonstration. These cognitive elements will also enter into determining the content of a corresponding direct phenomenal concept.

Consider two individuals with identical visual experiences. These individuals might engage in different acts of demonstration - e.g. one might demonstrate a red quality experienced in the right half of the visual field, and the other a green quality experienced in the left half of the visual field - and thus form distinct direct phenomenal concepts. Or they might attend to the same location in the visual field, but demonstrate distinct qualities associated with that location: e.g. one might demonstrate a highly specific shade of phenomenal redness, and the other a less specific shade, again resulting in distinct direct phenomenal concepts. These differences will be due to differences in the cognitive backgrounds of the
demonstrations in the two individuals. I will be neutral here about whether such cognitive differences are themselves constituted by underlying functioning, aspects of cognitive phenomenology, or both.

One can imagine varying the visual experiences and the cognitive background here independently. Varying visual experiences might yield a range of cases in which direct phenomenal concepts of phenomenal redness, greenness, and other hues are formed. Varying the cognitive background might yield a range of cases in which direct phenomenal concepts of different degrees of specificity (for example) are formed.

Along with this cognitive element comes the possibility of failed demonstration, if the cognitive element and the targeted experiential elements mismatch sufficiently. Take Nancy, who attends to a patch of phenomenal color, acting cognitively as if to demonstrate a highly specific phenomenal shade. Nancy has not attended sufficiently closely to notice that the patch has a nonuniform phenomenal color: let us say it is a veridical experience of a square colored with different shades of red on its left and right side.[*] In such a case, the demonstrative phenomenal concept will presumably refer to no quality at all: given its cognitive structure, it could refer only to a specific quality, but it would break symmetry for it to refer to either instantiated quality, and presumably uninstantiated qualities cannot be demonstrated.

*[[This sort of case was suggested to me by Delia Graff and Mark Johnston.]]

What of any associated direct phenomenal concept? It is not out of the question that the subject forms some substantive concept where a direct phenomenal concept would ordinarily be formed: perhaps a concept of an intermediate uninstantiated shade of phenomenal red, at least if the instantiated shades are not too different. Like a direct phenomenal concept, this concept will have a content that depends constitutively on associated qualities of experience (Inverted Nancy might form a concept of an intermediate phenomenal green), but it will not truly be a direct phenomenal concept, since its content will not directly mirror an underlying quality.

This possibility of cognitive mismatch affects the path from demonstration to a demonstrated phenomenal quality, but given that a phenomenal quality is truly demonstrated, it does not seem to affect the path from demonstrated phenomenal quality to a direct phenomenal concept. That is, as long as a phenomenal quality is demonstrated, and the cognitive act typical of forming a direct phenomenal concept based on such a demonstration is present, a direct phenomenal concept will be formed.

We might call a concept that shares the cognitive structure of a direct phenomenal concept a quasi-direct phenomenal concept; and we can call a belief with the same cognitive structure as a direct phenomenal belief a quasi-direct phenomenal belief. Like a direct phenomenal concept, a quasi-direct phenomenal concept arises from an act of (intended) demonstration, along with a characteristic sort of cognitive act. Unlike a direct phenomenal concept, a quasi-direct phenomenal concept is not required to have a content that is constituted by an underlying quality. Nancy's concept above is a quasi-direct phenomenal concept but not a direct phenomenal concept, for example.
We can call a quasi-direct phenomenal concept that is not a direct phenomenal concept a pseudo-direct phenomenal concept, and we can define a pseudo-direct phenomenal belief similarly. If the suggestion above is correct, then the only pseudo-direct phenomenal concepts are like Nancy's, in involving an unsuccessful demonstration. As long as a quasi-direct phenomenal concept is grounded in a successful demonstration, it will be a direct phenomenal concept. I will return to this claim later.

(3) All direct phenomenal concepts are pure phenomenal concepts, but not all pure phenomenal concepts are direct phenomenal concepts. To see this, note that Mary may well retain some knowledge of what it is like to see tomatoes even after she goes back into her black-and-white room, or while she shuts her eyes, or while she looks at green grass. She still has a concept of phenomenal redness than can be deployed in various beliefs, with the sort of epistemic relations to relational and demonstrative phenomenal concepts that is characteristic of pure phenomenal concepts. Inverted Mary (still Mary's physical twin) has a corresponding concept deployed in corresponding beliefs that differ in content from Mary's. And as before their corresponding beliefs differ in epistemic content, including and excluding different classes of epistemic possibilities. As before, Mary's concept is a concept of phenomenal redness as the quality it is, based on a lucid understanding of that quality, rather than on a mere relational or demonstrative identification. So as before, it is a pure phenomenal concept. But it is not a direct phenomenal concept, since there is no corresponding experience (or instantiated quality) that is being attended to or taken up into the concept. We can call this sort of concept a standing phenomenal concept, since it may persist in a way that direct phenomenal concepts do not.

There are some differences in character between direct and standing phenomenal concepts. Direct phenomenal concepts may be very fine-grained, picking out a very specific phenomenal quality (a highly specific shade of phenomenal redness, for example). Standing phenomenal concepts are usually more coarse-grained, picking out less specific qualities. One can note this phenomenologically from the difficulty of "holding" in mind specific qualities as opposed to coarser categories when relevant visual experiences are not present; and this is also brought out by empirical results showing the difficulty of reidentifying specific qualities over time.[*] It usually seems possible for a direct phenomenal concept to yield a corresponding standing phenomenal concept as a "successor" concept once the experience in question disappears, at the cost of some degree of coarse-graining.

[*][See Raffman 1995 for a discussion of these results in an argument for an antirepresentationalist "presentational" analysis of phenomenal concepts that is very much compatible with the analysis here.]

As with direct phenomenal concepts, the content of standing phenomenal concepts does not conceptually supervene on the physical (witness Mary and Inverted Mary, back in their rooms). A question arises as to what determines their content. I will not try to analyze that matter here, but I think it is plausible that their content is determined by some combination of (i) nonsensory phenomenal states of a cognitive sort, which bear a relevant relation to the original phenomenal quality in question - e.g. a faint Humean phenomenal "idea" that is relevantly related to the original "impression"; (ii) dispositions to have such states; and (iii) dispositions to recognize instances of the phenomenal quality in question. It is not implausible that Mary and Inverted Mary (back in their rooms) still differ in some or all of these respects, and that these respects are constitutively responsible for the difference in the content of their concepts.
One might be tempted to use the existence of standing phenomenal concepts to argue against the earlier analysis of direct phenomenal concepts (that is, of concepts akin to those Mary acquires on first experiencing phenomenal redness) as constituted by the quality of the relevant instantiated experience. Why not assimilate them to standing phenomenal concepts instead, giving a unified account of the two? In response, note first that it remains difficult to conceive of the content of direct phenomenal concepts varying independently of the phenomenal quality in question, whereas it does not seem so difficult to conceive of the content of standing phenomenal concepts varying independently. And second, note that the difference in specificity between direct and standing phenomenal concepts gives some reason to believe that they are constituted in different ways.

The lifetime of a direct phenomenal concept is limited to the lifetime of the experience (or the instantiated quality) that constitutes it. (In some cases a specific phenomenal concept might persist for a few moments due to the persistence of a vivid iconic memory, but even this will soon disappear.) Some might worry that this lack of persistence suggests that it is not a concept at all, since concepthood requires persistence. This seems misguided, however: it is surely possible for a concept to be formed moments before a subject dies. The concepts in question are still predicatable of any number of entities, during their limited lifetimes, and these predications can be true or false. (E.g., Mary may falsely believe that her sister is currently experiencing R.) This sort of predicability, with assessibility for truth or falsehood, seems sufficient for concepthood; at least it is sufficient for the uses of concepthood that will be required here.

(4) As with pure phenomenal concepts generally, we do not have public language expressions that distinctively express the content of direct phenomenal concepts. Public reference to phenomenal qualities is always fixed relationally, it seems: by virtue of a relation to certain external stimuli, or certain sorts of behavior, or certain demonstrations. (As Ryle said, there are no "neat" sensation words.) Of course Mary can express a pure phenomenal concept by introducing her own term, such as 'R', or by using an old term, such as 'red', with this stipulated meaning. But this use will not be public, at least in the limited sense that there is no method by which we can ensure that other members of the community will use the term with the same epistemic content. One can at best ensure that they pick out the same quality by picking it out under a different epistemic content (e.g. as the quality Mary is having at a certain time), or by referring through semantic deference (as the quality that Mary picks out with 'R'). In this sense it seems that any resulting language will be "private": it can be used with full competence by just one subject, and others can use it only deferentially.

(An exception may arguably be made for terms expressing structural pure phenomenal concepts - e.g. phenomenal similarity and difference and perhaps phenomenal spatial relations - which arguably do not rely on relational reference-fixing.)

Of course the view I have set out here is just the sort of view that Wittgenstein directed his "private language" argument against. The nature of the private language argument is contested, so in response I can say only that I have seen no reconstruction of it that provides a strong case against the view I have laid out. Some versions of the argument seem to fall prey to the mistake just outlined, that of requiring a
strong sort of "repeatability" for concept possession (and an exceptionally strong sort at that, requiring the recognizability of correct repeated application). A certain sort of repeatability is required for concept possession, but it is merely the "hypothetical repeatability" involved in present predicability of the concept to actual and hypothetical cases, with associated truth-conditions. Another reconstruction of the argument, Kripke's, provides no distinctive traction against my analysis of direct phenomenal concepts: any force that it has applies to concepts quite generally.

(One might even argue that Kripke's argument provides less traction in the case of direct phenomenal concepts, as this is precisely a case in which we can see how a determinate application-condition can be constituted by an underlying phenomenal quality. Kripke's remarks (pp. 41-51) about associated phenomenal qualities - e.g. a certain sort of "headache" - being irrelevant to the content of concepts such as addition apply much less strongly where phenomenal concepts are concerned. Of course there is more to say here, but in any case it is a curiosity of Kripke's reconstruction of the argument that it applies least obviously to the phenomena at which Wittgenstein's argument is often taken to be aimed.)

4 The Epistemology of Phenomenal Belief

4.1 Incorrigibility

A traditional thesis in the epistemology of mind is that first-person beliefs about phenomenal states are incorrigible, or infallible (I use these terms equivalently), in that they cannot be false. In recent years such a thesis has been widely rejected. This rejection stems from both general philosophical reasoning (e.g., the suggestion that if beliefs and experiences are distinct existences, there can be no necessary connection between them) and from apparent counterexamples (e.g. a case where someone, expecting to be burnt, momentarily misclassified a cold sensation as hot). In this light, it is interesting to note that the framework outlined in this paper so far supports an incorrigibility thesis, albeit a very limited one.

Incorrigibility Thesis: A direct phenomenal belief cannot be false.

The truth of this thesis is an immediate consequence of the definition of direct phenomenal belief. A direct phenomenal concept by its nature picks out instances of an underlying demonstrated phenomenal quality, and a direct phenomenal belief identifies the referent of that concept with the very demonstrated quality (or predicates the concept of the very experience that instantiated the quality), so its truth is guaranteed.

If we combine this thesis (which is more or less true by definition) with the substantive thesis that there are direct phenomenal beliefs (which is argued earlier in this paper), then we have a substantive incorrigibility thesis, one that applies to a significant range of actual beliefs.[*]

[[Pollock (1986, pp. 32-33) entertains a version of this sort of view as a way of supporting incorrigibility, discussing a "Containment Thesis" according to which experiences are constituents of beliefs about experiences. He rejects the view on the grounds that (1) it does not support incorrigibility of negative beliefs about experiences (e.g. the belief that one is not...]]
having a given experience), which he holds to be required for incorrigibility in general, and that (2) that having an experience does not suffice to have the relevant belief, so having the belief also requires thinking about the experience, which renders the incorrigibility thesis trivial. I discuss both of these points below.]

The thesis nevertheless has a number of significant limitations. The first is that most phenomenal beliefs are not direct phenomenal beliefs, so most phenomenal beliefs are still corrigible. The most common sort of phenomenal belief arguably involves the application of a pre-existing phenomenal concept (either a relational phenomenal concept or a standing pure phenomenal concept) to a new situation, as with the beliefs typically expressed by claims such as 'I am having a red experience' or 'I am in pain'. These are not direct phenomenal beliefs, and are almost certainly corrigible.

There are also cases in which a direct phenomenal concept is applied to a quality (or an experience) other than the one that constituted it, as when one forms a direct phenomenal concept $R$ based on a quality instantiated in the left half of one's visual field, and applies it to a quality instantiated in the right half. These are also not direct phenomenal beliefs, and are again almost certainly corrigible.

(The second sort of case brings out a further limitation in the incorrigibility thesis: it does not yield incorrigibility in virtue of content. If the left and right qualities in the case above are in fact the same, then the resulting nondirect phenomenal belief will arguably have the same content as the corresponding direct phenomenal belief, but the incorrigibility thesis will not apply to it. The domain of the incorrigibility thesis is constrained not just by content, but by underlying constitution.)

It is plausible that all the standard counterexamples to incorrigibility theses fall into classes like these, particularly the first. All the standard counterexamples appear to involve the application of pre-existing phenomenal concepts (pain, hot, red experience). So none of the standard counterexamples apply to the incorrigibility thesis articulated here.

There is a natural temptation to find further counterexamples to the incorrigibility thesis. For example, one might consider a case in which a subject's experience changes very rapidly, and argue that the corresponding direct phenomenal concept must lag behind. In response to these attempted counterexamples, the most obvious reply is that these cannot truly be counterexamples, since the truth of the incorrigibility thesis is guaranteed by the definition of direct phenomenal belief. If the cases work as described, they do not involve direct phenomenal beliefs: they either involve a concept that is not a direct phenomenal concept, or they involve a direct phenomenal concept predicated of a quality other than the one that constitutes it. At best, they involve what I earlier called pseudo-direct phenomenal beliefs: beliefs that share the cognitive structure of a direct phenomenal beliefs (and thus are quasi-direct phenomenal beliefs) but that are not direct phenomenal beliefs.

One need not let matters rest there, however. I think that these counterexamples can usually be analyzed away on their own terms, so that the purported pseudo-direct phenomenal beliefs in question can be seen as direct phenomenal beliefs, and as correct. In the case of a rapidly changing experience, one can plausibly hold that the content of a direct phenomenal concept covaries immediately with the underlying quality, so that there is no moment at which the belief is false. This is just what we would expect, given
the constitutive relation suggested earlier. We might picture this schematically by suggesting that the basis for a direct phenomenal concept contains within it a "slot" for an instantiated quality, such that the quality that fills the slot constitutes the content. In a case where experience changes rapidly, the filler of the slot changes rapidly, and so does the content.

Something similar goes for many other examples involving quasi-direct phenomenal beliefs. Take a case where a subject attends to two different visual qualities (demonstrating them as $E_1$ and $E_2$), and mistakenly accepts $E_1 = E_2$. In this case, someone might suggest that if the subject forms specific quasi-direct phenomenal concepts $R_1$ and $R_2$ based on the two acts of attention, these must have the same content, leading to false quasi-direct phenomenal beliefs (and thus to pseudo-direct phenomenal beliefs). But on my account, this case is better classified as one in which $R_1$ and $R_2$ are direct phenomenal concepts with different contents, yielding two correct direct phenomenal beliefs $E_1 = R_1$ and $E_2 = R_2$. The false beliefs here are of the form $E_1 = R_2$, $E_2 = R_1$, and $R_1 = R_2$. The last of these illustrates the important point that identities involving two direct phenomenal concepts, like identities involving two pure phenomenal concepts more generally, are not incorrigible.

Other cases of misclassification can be treated similarly. In the case in which a subject expecting to be burnt misclassifies a cold sensation as hot, someone might suggest that any quasi-direct phenomenal concept will be a concept of phenomenal hotness, not coldness. But one can plausibly hold that if a quasi-direct phenomenal concept is formed, it will be a concept of phenomenal coldness and will yield a correct direct phenomenal beliefs. The subject's mistake involves misclassifying the experience under standing phenomenal concepts, and perhaps a mistaken identity involving a direct and a standing phenomenal concept.

It is arguable that most cases involving quasi-direct phenomenal beliefs can be treated this way. The only clear exceptions are cases such as Nancy's, in which no phenomenal quality is demonstrated and so no substantive direct phenomenal concept is formed. It remains plausible that as long as a quality is demonstrated, the cognitive act in question will yield a direct phenomenal concept with the right content, and a true direct phenomenal belief. If that is correct, one can then accept a broader incorrigibility thesis applying to any quasi-direct phenomenal belief that is based in a successful demonstration of a phenomenal quality. I will not try to establish this thesis conclusively, since I will not need it, and since the incorrigibility thesis for direct phenomenal beliefs is unthreatened either way. But it is interesting to see that it can be defended.

One might suggest that the incorrigibility thesis articulated here (in either the narrower or the broader version) captures the *plausible core* of traditional incorrigibility theses. A number of philosophers have had the sense that there is something correct about the incorrigibility theses, which is not touched by the counterexamples. This is reflected, for example, in Chisholm's distinction between "comparative" and "noncomparative" uses of "appears" talk, where only the noncomparative uses are held to be incorrigible. I think that this is not quite the right distinction: even noncomparative uses can be corrigible, when they correspond to uses of pure phenomenal concepts outside direct phenomenal beliefs. But perhaps a thesis restricted to direct phenomenal beliefs might play this role.
Certainly the analysis of direct phenomenal beliefs shows why the most common general philosophical argument against incorrigibility does not apply across the board. In the case of direct phenomenal beliefs, beliefs and experiences are not entirely distinct existences. It is precisely because of the constitutive connection between experiential quality and belief that the two can be necessarily connected.

Another limitation: Sometimes incorrigibility theses are articulated in a "reverse" or bidirectional form, holding that all phenomenal states are incorrigibly known, or at least incorrigibly knowable. Such a thesis is not supported by the current discussion. Most phenomenal states are not attended to, are not taken up into direct phenomenal concepts, and so are not the subjects of direct phenomenal beliefs. And for all I have said, it may be that some phenomenal states, such as fleeting or background phenomenal states, cannot be taken up into a direct phenomenal concept, perhaps because they cannot be subject to the right sort of attention. If so, they are not even incorrigibly knowable, let alone incorrigibly known.

Incorrigibility theses are also sometimes articulated in a "negative" form, requiring that a subject cannot be mistaken in their belief that they are not having a given sort of experience. No direct phenomenal belief is a negative phenomenal belief, so the current framework does not support this thesis, and I think the thesis is false in general.

A final limitation: Although direct phenomenal beliefs are incorrigible, subjects are not incorrigible about whether they are having a direct phenomenal belief. For example, if I am not thinking clearly, I might misclassify a belief involving a standing phenomenal concept as a direct phenomenal belief. And in the Nancy case above, if Nancy is philosophically sophisticated she might well think that she is having a direct phenomenal belief, although she is not.

One could argue that this lack of higher-order incorrigibility prevents the first-order incorrigibility thesis from doing significant epistemological work. The matter is delicate: higher-order incorrigibility is probably too strong a requirement for an epistemologically useful incorrigibility thesis. But on the other side, some sort of further condition is required for a useful thesis. For example, any member of the class of true mathematical beliefs is incorrigible (since it is necessarily true), but this is of little epistemic use to a subject who cannot antecedently distinguish true and false mathematical beliefs. A natural suggestion is that some sort of higher-order accessibility is required.

Intermediate accessibility requirements might include something like the following. For the incorrigibility of a direct phenomenal belief to be epistemologically significant, a subject must know that it is a direct phenomenal belief, or at least be justified in so believing; or a subject must be capable of so knowing on reflection; or direct phenomenal beliefs must be cognitively or phenomenologically distinctive as a class relative to nondirect phenomenal beliefs.

I am sympathetic with the sufficiency of a thesis like the last, if properly articulated. Its truth seems to turn on questions about quasi-direct and pseudo-direct phenomenal beliefs. If there are many pseudo-direct phenomenal beliefs, and if there is nothing cognitively or phenomenologically distinctive about direct phenomenal beliefs by comparison, then direct phenomenal beliefs will simply be distinguished as
quasi-direct phenomenal beliefs with the right sort of content, and the incorrigibility claim will be relatively trivial. On the other hand, if pseudo-direct phenomenal beliefs are rare, or if direct phenomenal beliefs are a cognitively or phenomenologically distinctive subclass, then it is more likely that incorrigibility will be nontrivial and carry epistemological significance.

If pseudo-direct phenomenal beliefs are restricted to cases in which no phenomenal quality is demonstrated, like the case of Nancy (as I have suggested), then the incorrigibility thesis will hold of a class of beliefs that can be distinctively and independently characterized in cognitive and phenomenological terms: the class of quasi-direct phenomenal beliefs which are based in a successful demonstration. This would render the incorrigibility claim entirely nontrivial, and it would make it more likely that it could do epistemological work. But I will not try to settle this matter decisively here, and I will not put the incorrigibility thesis to any epistemological work in what follows.

It might be thought that the incorrigibility thesis suffers from another problem: that direct phenomenal beliefs are incorrigible because they are trivial. After all, beliefs such as I am here or This is this are (close to) incorrigible, but only because they are (almost) trivial. (The qualifications are present because of the the arguable nontriviality of my existence and spatial locatedness in one case, and because of the possibility of reference failure for the demonstrative in the other.)

The analogy fails, however. The trivial beliefs in question are (almost) cognitively insignificant: they are (almost) a priori, containing (almost) no cognitively significant knowledge about the world. This is reflected in the fact that they hardly constrain the class of a priori epistemic possibilities: they are true of (almost) all such possibilities, considered as hypotheses about the actual world. (Two-dimensionally: these beliefs have a epistemic intension that is (almost) conceptually necessary.) A direct phenomenal belief, by contrast, is cognitively significant: it heavily constrains the class of a priori epistemic possibilities, and is false in most of them (considered as actual). For example, Mary's direct phenomenal belief, on leaving her room, is false of all worlds (considered as actual) in which the subject is not experiencing phenomenal redness. (Two-dimensionally: The epistemic intension of a direct phenomenal belief is conceptually contingent.) So direct phenomenal beliefs, unlike the beliefs above, are entirely nontrivial.

So: the incorrigibility thesis articulated here has a number of limitations, but it nevertheless applies to a significant class of nontrivial phenomenal beliefs.

4.2 Acquaintance and justification

At this point is is natural to ask: if we can form this special class of incorrigible, distinctively constituted beliefs where phenomenal states and properties are concerned, why cannot we do so where other states and properties are concerned? Why cannot we form direct height concepts, for example, whose epistemic content is directly constituted by our height properties, and which can be deployed in incorrigible direct height beliefs? Or similarly for direct chemical beliefs, direct age beliefs, direct color beliefs, and so on?
At one level, the answer is that we simply cannot. If one tries to form a direct height concept - one whose content depends constitutively on an instantiated height - the best one can do is form a relational height concept (my height, the height of my house) or a demonstrative height concept. But these are not pure height concepts at all. They are analogous only to red_C or E, in that their subjunctive content may depend on the property in question but their epistemic content does not.

It is arguable whether pure height concepts exist at all: that it, whether there is any concept whose epistemic content picks out a certain height (say, two meters) in any epistemic possibility. But even if there are pure height concepts, they are not direct height concepts. Perhaps one can independently form a pure height concept of a given height (two meters), which might coincide with an instantiated height, but it will not depend constitutively on an instantiated height. The best one can do is attend to an object, have an experience or judgment concerning its height, and use this experience or judgment as the epistemic content of a "pure" height concept. But here the instantiated height property is not constitutively relevant to the concept's content, but only causally relevant: it is the height experience or judgment that is constitutively relevant, and the experience or judgment is only causally dependent on the height. In no case does the epistemic content of a height concept depend constitutively on a demonstrated height property, or on any instantiated height property at all.

Proponents of certain direct realist views may hold that it is possible to form a direct concept of a height property (or other perceivable external properties), by demonstrating it and taking it up into a concept in a manner analogous to the manner suggested for phenomenal properties. I think that this is implausible. In a case where an object is two meters tall but appears to be one meter tall, any "pure" height concept formed as a result will be a concept of one meter, not of two meters. There may be a demonstrative concept of two meters, but that is not enough. More generally, considering a range of cases in which height and experience are varied independently, we can see that any contribution of the height to a pure concept is "screened off" by the contribution of the experience. This suggests that if anything is playing a constitutive role in the concept's content, it is the experience and not the external property.[*]

[*][There may be further moves available to the direct realist. For example, a direct realist might hold that the constitutive role of external properties is restricted to cases of veridical perception, and that nonveridical perception must be treated differently. I think that this sort of restriction threatens to trivialize the constitution thesis, as any causal connection might be seen as a "constitutive" connection by a relevantly similar restriction. (If A causes B which necessitates C, then A is contingently connected to C; but if we restrict attention to cases where A causes B, then A necessitates C relative to this restriction.) And the case remains formally disanalogous to the case of direct phenomenal concepts, in which there is no factor distinct from the quality that even looks like it screens off the contribution of the quality to the concept. But there is undoubtedly more to say here. In what follows I will assume that the direct realist view is incorrect, but direct realists are free to hold that what I say about phenomenal properties applies equally to the relevant external properties.]

The same goes for chemical concepts, age concepts, and external color concepts. Although we can form many such concepts, in no case is it possible to form a direct concept: that is, a concept whose epistemic content depends constitutively on a demonstrated property. It seems that only phenomenal properties can support direct concepts.

This conclusion is apparently revealed by an examination of cases; but it would be preferable not to leave
it as a brute conclusion. In particular, it is natural to suggest that the conclusion holds because we bear a special relation to the phenomenal properties instantiated in our experience: a relation that we do not bear to the other instantiated properties in question, and a relation that is required in order to form a direct concept of a property in the manner described. This relation would seem to be a peculiarly intimate one, made possible by the fact that experiences lie at the heart of the mind rather than standing at a distance from it; and it seems to be a relation that carries the potential for conceptual and epistemic consequences. We might call this relation **acquaintance**.

As things stand, acquaintance has been characterized only as that relation between subjects and properties that makes possible the formation of direct phenomenal concepts; so it is not yet doing much explanatory work. But having inferred the relation of acquaintance, we can put it to work. As characterized, acquaintance is a relation that makes possible the formation of pure phenomenal concepts, and we have seen that pure phenomenal concepts embody a certain sort of lucid understanding of phenomenal properties. So acquaintance is a relation that makes this sort of lucid understanding possible. As such, it is natural to suppose that the relation can also do work in the epistemic domain. If so, the result will be an attractive picture in which the distinctive conceptual character and the distinctive epistemic character of the phenomenal domain have a common source.

It is independently plausible to hold that phenomenal properties and beliefs have a distinctive epistemic character. Many have held that phenomenal properties can (at least sometimes) be known with a distinctive sort of justification, or even with certainty; and many have held that phenomenal beliefs have a special epistemic status. Even those who explicitly deny this will often tacitly concede that there is at least a prima facie case for this status: for example, it is striking that those who construct skeptical scenarios almost always ensure that that phenomenal properties are preserved. So it is arguable that simply having a phenomenal property provides the potential for a strong sort of phenomenal knowledge. Something similar is suggested by the Mary case: Mary's experience of the phenomenal property R allows her to have not just a distinctive phenomenal belief, but also distinctive phenomenal knowledge. Some element of this distinctive epistemic character can be captured in the present framework.

One natural suggestion is the following: direct phenomenal beliefs are always justified. Certainly Mary's belief on leaving her room seems to be justified, and most other examples seem to fit this thesis. This thesis has to be modified slightly. There are presumably subjects who who are so irrational or confused that none of their beliefs qualify as justified, so that their direct phenomenal beliefs are not justified either. And perhaps there could be subjects who are so confused about phenomenology that they accept not just direct phenomenal beliefs but their negations, casting doubt on whether either belief is truly justified. To meet this sort of case, we might adjust the thesis to say that all direct phenomenal beliefs have some prima facie justification, where prima facie justification is an element of justification that can sometimes be overridden by other elements, rendering a belief below the threshold for "justification" simpliciter. Something similar presumably applies to other features of a belief that might seem to confer justification, such as being inferred from justified beliefs by a justified rule of inference.

Assuming that something like this is right: it is nevertheless one thing to make the case that direct phenomenal beliefs are (prima facie) justified, and another to give an account of what this justification
The Content and Epistemology of Phenomenal Belief consists in. It may be tempting to appeal to incorrigibility; but incorrigibility alone does not entail justification (as the mathematical case shows), and while certain higher-order accessibility theses might close the gap, it is not obvious that they are satisfied for direct phenomenal beliefs.

A better idea is to appeal to the acquaintance relation, thus unifying the distinctive conceptual and epistemic character of phenomenal beliefs. In particular, one might assert the following:

Justification Thesis: When a subject forms a direct phenomenal belief based on a phenomenal quality, then that belief is prima facie justified by virtue of the subject's acquaintance with that quality.

Certainly many philosophers, including especially sense-data theorists and more recent foundationalists, have appealed to a relation of acquaintance (or "direct awareness") in supporting the special epistemic status of phenomenal beliefs. The current account offers a more constrained version of such a thesis, suggesting that it holds for a special class of phenomenal beliefs (on which the epistemic content of a predicated concept is required to mirror and be constituted by the acquainted quality, to which it is applied), and on the basis of a relation whose existence we have made an independent case for.

Some philosophers (e.g. Russell 1910; Fumerton 1995) have held that we are "acquainted with acquaintance", and have made the case of its existence that way. I think there is something to the idea that our special epistemic relation to experience is revealed in our experience, but I note that the proponent of acquaintance is not forced to rely on such a thesis. It is equally possible to regard acquaintance as a theoretical notion, inferred to give a unified account of the distinctive conceptual and epistemic character that we have reason to believe is present in the phenomenal domain.

Acquaintance can be regarded as a basic sort of epistemic relation between a subject and a property. Most fundamentally, it might be seen as a relation between a subject and an instance of a property: I am most directly acquainted with this instance of phenomenal greenness. This acquaintance with an instance can then be seen to confer a derivative relation to the property itself. Or in the experience-based framework, one might regard acquaintance as most fundamentally a relation between a subject and an experience, which confers a derivative relation between the subject and the phenomenal properties of the experience. But I will usually abstract away from these fine details. What is central will be the shared feature that whenever a subject has a phenomenal property, the subject is acquainted with that phenomenal property.

Even if acquaintance is a theoretical notion, it clearly gains some pretheoretical support from the intuitive view that beliefs can be epistemically grounded in experiences, where experiences are not themselves beliefs but nevertheless have an epistemic status that can help justify a belief. One might view acquaintance as capturing that epistemic status.

In certain respects (though not in all respects), the justification of a direct phenomenal belief by an experience can be seen as analogous to the justification of an inferred belief by another belief. For an inferred belief to be prima facie justified, there are three central requirements: one concerning the content of the belief in relation to the justifying state, one concerning the natural connection between the belief
and the justifying state, and one concerning the epistemic status of the justifying state. First, the epistemic content of the belief must be appropriately related to that of the belief that it is inferred from. Second, the belief must be appropriately be caused by the justifying belief. Third, the justifying belief must itself be justified.

In the prima facie justification of a direct phenomenal belief by an experience, there are three factors of the same sort. First, content: the epistemic content of the direct phenomenal belief must mirror the quality of the experience. Second, a natural connection: the phenomenal belief must be appropriately constituted by the experience. And third, epistemic status: the subject must be acquainted with the justifying quality. The details of the requirements are different, as befits the difference between belief and experience, but the basic pattern is very similar.

It is plausible that a subject can have phenomenal properties without having corresponding concepts, or corresponding beliefs, or corresponding justification. If so, the same goes for acquaintance. Acquaintance is not itself a conceptual relation: rather, it makes certain sorts of concepts possible. And it is not itself a justificatory relation: rather, it makes certain sorts of justification possible. Phenomenal concepts and phenomenal knowledge require not just acquaintance, but acquaintance in the right cognitive background: a cognitive background that minimally involves a certain sort of attention to the phenomenal quality in question, a cognitive act of concept formation, the absence of certain sorts of confusion and other undermining factors (for full justification), and so on. But it is acquaintance with the quality or the experience itself that does the crucial justifying work.

Some philosophers hold that only a belief can justify another belief. It is unclear why this view should be accepted. The view has no pretheoretical support: pretheoretically, it is extremely plausible that experiences (e.g. a certain experience of phenomenal greenness) play a role in justifying beliefs (e.g. my belief that there is something green in front of me, or my belief that I am having a certain sort of experience), even though experiences are not themselves beliefs. And the view has no obvious theoretical support. Perhaps the central motivation for the view comes from the idea that inference is the only sort of justification that we understand and have a theoretical model for, and that we have no model for any other sort of justification. But this is obviously not a strong reason, and the account I have just sketched suggests a theoretical model of how experiences can justify beliefs that fits well with our pretheoretical
intuitions. So it seems that the cases of justification of beliefs by other beliefs and by experiences are on a par here.

Another motivation for the view comes from the thesis that for a state to justify another state, it must itself be justified (along with the claim that only beliefs can be justified. But again, it is unclear why this thesis should be accepted. Again, it is pretheoretically reasonable to accept that beliefs are justified by experiences, and that experiences are not themselves the sort of states that can be justified or unjustified. And there is no obvious theoretical reason to accept the thesis. It may be that for a state to justify, it must have some sort of epistemic status, but there is no clear reason why the status of acquaintance should be insufficient.

(BonJour (1978) suggests that the denial that justifying states must be justified is an ad hoc maneuver aimed at stopping the regress argument against foundationalism. But considerations about foundationalism and about regress arguments have played no role in my claims: the claims are independently supported by observations about the epistemic and conceptual relations between belief and experience. BonJour also claims that a justifying state must involve assertive content; but again, there is no clear pretheoretical or theoretical reason to accept this. Pretheoretically: experiences can justify beliefs without obviously involving assertive content. Theoretically: acquaintance with a property makes the property available to a subject in a manner that makes concepts and assertions involving the property possible, and that enables these assertions to be justified. There is no reason why this requires acquaintance to itself involve an assertion.)

A number of epistemological issues remain. One concerns the strength of the justification of phenomenal beliefs. It is often held that phenomenal beliefs are (or can be) certain, for example. Can the present framework deliver this? It can certainly deliver incorrigibility, but certainty requires something different. I think that the relevant sense of certainty involves something like knowledge beyond skepticism: intuitively, knowledge such that one's epistemic situation enables one to rule out all skeptical counterpossibilities. There is an intuition that phenomenal belief at least sometimes involves this sort of knowledge beyond skepticism, as the standard construction of skeptical scenarios suggests.

This epistemic status might be captured by a claim to the effect that acquaintance with a property enables one to eliminate all (a priori) epistemic possibilities in which the property is absent.[*] If so, then in the right cognitive background (with sufficient attention, concept formation, lack of confusion, and so on), the justification of a direct phenomenal belief $P$ by acquaintance with a property will sometimes enable a subject not just to know that $P$ by the usual standards of knowledge, but to eliminate all skeptical counterpossibilities in which $P$ is false. This matter requires further exploration, but one can see at least the beginnings of a reasonable picture.[*]

[*][I argued in The Conscious Mind that something like acquaintance is required to secure certainty, and that a mere causal connection or reliable connection cannot do the job. If the justification of a belief is based solely on a reliable or causal connection, the subject will not be in a position to rule out skeptical scenarios in which the connection is absent and the belief is false, so the belief will not be certain. In response, a number of philosophers, including Bayne (2001), have argued that acquaintance accounts can be criticized in a similar way. Bayne notes that acquaintance alone is compatible with the
absence of certainty (e.g. in conditions of inattention), so certainty requires background factors in addition to acquaintance; but we cannot be certain that these factors obtain, so we cannot rule out skeptical scenarios in which they fail to obtain, so a phenomenal belief cannot be certain.

This argument stems from a natural misreading of my argument against reliabilist accounts. The argument is not: certainty requires certainty about the factors that enable certainty, and a reliabilist account cannot deliver this sort of certainty. That argument would requires a strong version of a CJ thesis, that certain justification requires certainty about the basis of certain justification (analogous to the KJ thesis that justification requires knowledge of justification). I think such a thesis should clearly be rejected. The argument is rather: certainty about P requires (first-order) "knowledge beyond skepticism", or an epistemic state that enables a subject to rule out all skeptical scenarios in which P is false. Reliabilism by its nature cannot do this: there will always be skeptical scenarios in which the reliable connection fails and in which P is false.

Bayne's argument against acquaintance gives an analog of the invalid CJ argument. At most this establishes that we cannot rule out scenarios in which the belief is uncertain. Even this is unclear, as it is not obvious that certainty about certainty requires certainty about the factors enabling certainty. But even if this point is granted, the existence of skeptical scenarios in which the belief is uncertain does not entail the existence of skeptical scenarios in which P is false. Acquaintance yields certainty about experiences, not about beliefs: it enables one to directly rule out skeptical scenarios in which P is false, whether or not it enables one to rule out skeptical scenarios in which a belief is uncertain. In cases of justification by a reliable connection, there are separate reasons to hold that skeptical scenarios in which P is false cannot be ruled out, but in the case of acquaintance, these reasons do not apply. (Note: the published version of Bayne's article takes these points into account and offers some further considerations.)

A second further issue: Can the justification thesis be extended to all pure phenomenal concepts, including standing phenomenal concepts? There is some intuitive appeal in the idea that application of a standing phenomenal concept to an instantiated quality may also carry some justification by virtue of acquaintance with the quality (perhaps under the restriction that the content of the standing concept match the quality, and that there be an appropriate natural connection between the quality and the belief). If this belief were justified directly by acquaintance, however, we would need an account of justification by acquaintance that does not give a central role to constitution. Such an account is not out of the question, but it is worth noting that justification for beliefs involving standing phenomenal concepts can also be secured indirectly.

Indirect justification for such beliefs can be secured by virtue of the plausible claim that any belief of the form S=R is (prima facie) justified, where S and R are standing and direct phenomenal concepts with the same epistemic content. This is an instance of the more general claim that any belief of the form A=B is justified when A and B have the same epistemic content. (This thesis may need some restriction to handle cases of deep hyperintensionality, but it is plausibly applicable in this case.) Such beliefs are plausibly justified a priori: experience may enter into a grasp of the concepts involved in such a belief, but it does not enter into the belief's justification. If so, then beliefs involving standing phenomenal concepts will inherit justification by a priori inference from direct phenomenal beliefs, which will be justified in virtue of the Justification Thesis.

Finally, a note on ontology: Talk of acquaintance often brings sense-data theories to mind, so it may be worth noting that a commitment to phenomenal realism and to acquaintance does not entail a commitment to sense-data. First, the picture is entirely compatible with an "adverbial" subject-property
model, and with other quality-based ontologies on which there are phenomenal properties but not phenomenal individuals. Second, even if one accepts the existence of phenomenal individuals such as experiences, one might well reject a sense-data model of perception, on which one perceives the world by perceiving these entities.

It is also worth noting that one need not regard the acquaintance relation that a subject bears to a phenomenal property as something ontologically over and above the subject's instantiation of the property, requiring a subject-relation-quality ontology at the fundamental level. It is arguable that it is a conceptual truth that to have a phenomenal quality is to be acquainted with it (at least insofar as we have a concept of acquaintance that is not wholly theoretical). Certainly it is hard to conceive of a scenario in which a phenomenal quality is instantiated but no-one is acquainted with it. If so, then the picture I have sketched is combined with a simple subject-quality ontology, combined with this conceptual truth. The ontological ground of all this might lie in the nature of phenomenal qualities, rather than in some ontologically further relation.

4.3 Epistemological problems for phenomenal realism

Phenomenal realism, especially property dualism, is often thought to face epistemological problems. In particular, it is sometimes held that these views make it hard to see how phenomenal beliefs can be justified or can qualify as knowledge, since the views entail that phenomenal beliefs do not stand in the right sort of relationship to experiences. If what I have said so far is right, this cannot be correct. But it is worth looking at the arguments more closely.[*]

*[[I discussed these arguments at length in Chapter 5 of The Conscious Mind, on "The paradox of phenomenal judgment". I now think that discussion is at best suboptimal. The final section of the chapter (pp. 203-209) put forward a preliminary and sketchy version of the view of phenomenal concepts I have discussed in this paper, but I did not give it a central epistemological role (except in a tentative suggestion on pp. 207-8). I now think that this view of phenomenal concepts is central to the epistemology. So the discussion in this paper can be viewed in part as a replacement for that chapter.]]

The most influential arguments of this sort have been put forward by Sydney Shoemaker (1975). Shoemaker's arguments are intended as an argument against a view that admits the conceptual possibility of "absent qualia": a experience-free functional duplicate of an experiencing being. The view under attack is slightly stronger than phenomenal realism (a phenomenal realist could admit inverted qualia without absent qualia), is slightly weaker than a view on which zombies (experience-free physical duplicates) are conceptually possible, and is weaker than property dualism. But for the purposes of the argument, it will not hurt to assume a property dualist version of the view on which zombies are metaphysically possible. This has the effect of making Shoemaker's arguments harder to answer, not easier. The answers can easily be adapted to weaker versions of phenomenal realism.

The starkest version of Shoemaker's epistemological argument runs as follows:

(1) If phenomenal realism is true, experiences are causally irrelevant to phenomenal
beliefs;

(2) If experiences are causally irrelevant to phenomenal beliefs, phenomenal beliefs are not knowledge; so

(3) If phenomenal realism is true, phenomenal beliefs are not knowledge.

Some phenomenal realists might deny the first premise: a type-B materialist could hold that experiences have effects on beliefs by virtue of their identity with physical states, and a property dualist could hold that these effects proceed through a fundamental causal connection between the phenomenal and physical domains, or through a fundamental causal connection among nonphysical mental states. But for the purposes of the argument, I will assume the version of phenomenal realism that makes answering the argument as hard as possible, so I will rule out these responses. In particular, I will assume epiphenomenalism, according to which the phenomenal has no effects on the physical domain.[*]

*[I am not endorsing epiphenomenalism, but I regard it as one of the three serious options that remain once one accepts phenomenal realism and rules out type-B materialism and idealism. The other two are interactionism and a Russellian "panprotopsychism". See Chalmers 2002a.]

The view I have outlined makes it easy to see why this argument fails, even against an epiphenomenalist. Whatever the status of the first premise, the second premise is false. The second premise assumes that a causal connection between experience and phenomenal belief is required for the latter to count as knowledge. But if what I have said is correct, the connection between experience and phenomenal belief is tighter than any causal connection: it is constitution. And if a causal connection can underwrite knowledge, a constitutive connection can certainly underwrite knowledge too.

Even without appealing to constitution, the epiphenomenalist can respond reasonably to this argument by appealing to the notion of acquaintance, and arguing that a subject's acquaintance with experience can noncausally justify a phenomenal belief. (I used this strategy in The Conscious Mind.) But when the role of constitution is made clear, the reply becomes even stronger. Acquaintance and constitution together enable a theoretical model of the justification of phenomenal belief (as above), a model that is compatible with epiphenomenalism. And any residual worries about the lack of an appropriate connection between the experience and the belief are removed by the presence of a constitutive connection.

This first argument is only a subsidiary argument in Shoemaker's discussion. Shoemaker's main argument specifically concerns the possibility of absent qualia. His argument involves functional duplicates and conceptual possibility, but as before I will modify these details to involve physical duplicates and metaphysical possibility, thus making the argument harder to answer. The modified argument runs roughly as follows:

(1) If phenomenal realism is true, then every conscious being has a possible zombie twin.
(2) If zombies are possible, they have the same phenomenal beliefs as their conscious twins, formed by the same mechanisms.

(3) If zombies are possible, their phenomenal beliefs are false and unjustified.

(4) If it is possible that there are beings with the same phenomenal beliefs as a conscious being, formed by the same mechanism, where those phenomenal beliefs are false and unjustified, then the conscious being's phenomenal beliefs are unjustified; so

(5) If phenomenal realism is true, every conscious being's phenomenal beliefs are unjustified.

Some phenomenal realists could respond by denying premise 1 and holding that zombies are impossible. But even the conceptual possibility of functional duplicates with absent qualia is arguably enough to make an analogous argument go through, if there are no other problems. Premise 3 is relatively unproblematic. Perhaps one could argue that a zombie's phenomenal beliefs have some sort of justification, but the conclusion that our phenomenal beliefs are no more justified than a zombie's would be strong enough for an opponent. Disputing premise 4 holds more promise. If one accepts an acquaintance model of justification, one might hold that the justification of a phenomenal belief does not supervene on its mechanism of formation. (I used this strategy in *The Conscious Mind*.) But given what has gone before in this paper, by far the most obvious reply is to dispute premise 2. There is no reason to accept that zombies have the same phenomenal beliefs as their conscious twins, and every reason to believe that they do not.

It is by no means obvious that zombies have beliefs at all. The basis of intentionality is poorly understood, and one might plausibly hold that a capacity for consciousness is required for intentional states. But even if we allow that zombies have beliefs, it is clear that a zombie cannot share a conscious being's phenomenal beliefs. The content of a conscious being's direct phenomenal beliefs is partly constituted by underlying phenomenal qualities. A zombie lacks those qualities, so it cannot have a phenomenal belief with the same content.

Let us take the case of Zombie Mary, where we recombine thought-experiments in the obvious way. Assuming that Zombie Mary has a belief where Mary has a direct phenomenal belief, what sort of content does it have? Mary has a belief with the content $E=R$, and Inverted Mary has a belief with the content $E=G$. Let us focus on the direct phenomenal concepts $R$ and $G$, and their zombie counterpart. It is obvious that Zombie Mary's concept is neither $R$ nor $G$: if it has content at all, it has a different content entirely. I think that the most plausible view is that the zombie's concept is empty: it has no content. On the view I have been outlining, a phenomenal quality can be thought of as filling a slot that is left open in the content of a direct phenomenal concept, and thus contributing its content. If there is no phenomenal quality to fill the slot, as in Zombie Mary's case, the concept will have no content at all.

What about Zombie Mary's analog of Mary's direct phenomenal belief $E=R$? It is not obvious that a
zombie can possess a demonstrative phenomenal concept: a concept whose content is that of 'this experience' seems to require a concept of experience, which a zombie may lack. But even if a zombie could possess a demonstrative phenomenal concept, any such concept would fail to refer (like failed demonstratives in other domains). And more importantly, the other half of the identity (the zombie's analog of R) would be empty. So Zombie Mary's belief would be entirely different from Mary's belief.

It is natural to wonder about the truth-value of Zombie Mary's belief. Clearly her belief is not true. I would say that it is either false or empty, depending on one's view about beliefs involving empty concepts. The latter view is perhaps the most plausible, since it seems that Zombie Mary's belief has no propositional content to evaluate. As for Zombie Mary's "new knowledge": it is clear that she gains no propositional knowledge (though she may think that she does). One might see her as in the position that type-A materialists, and in particular proponents of the "ability hypothesis", hold that we are in in the actual world. When Zombie Mary first sees a flower, she may gain certain abilities to recognize and discriminate, although even these abilities will be severely constrained, since they cannot involve experiences.

This is enough to see that the epistemological argument against phenomenal realism does not get off the ground. A zombie clearly does not have the same phenomenal beliefs as its conscious twin in general; and its corresponding beliefs are not even formed by the same mechanism, since constitution by a phenomenal quality plays a central role in forming a direct phenomenal belief. So the second premise is false, and there is no bar to the justification of direct phenomenal beliefs.[*]

[[Conee (1985) and Francescotti (1994) also respond to Shoemaker's argument by denying the equivalent of premise 2, although for somewhat different reasons.]]

What about other phenomenal beliefs? We have seen that standing phenomenal concepts differ between twins, and that their content is plausibly constituted either by phenomenal properties or by dispositions involving those properties. A zombie lacks all phenomenal properties, so it is plausible that its analogs of standing phenomenal concepts will be empty, too. So beliefs involving standing phenomenal concepts are also immune from this argument.

What about the standing concept of experience (or qualia or phenomenal consciousness) generally? In this case there is no difference in content between conscious twins. But it remains plausible that phenomenal properties and the capacity to have them play a crucial role in constituting its content, just as they do for specific standing phenomenal concepts. And it is equally plausible that the zombie's analog of this standing concept is empty.[*] So beliefs involving the standing concept of experience (such as I am conscious) are equally unthreatened by this argument. The same goes for beliefs involving concepts in which the concept experience plays a part, such as relational phenomenal concepts, and perhaps demonstrative phenomenal concepts.

[[This is relevant to an argument against conceivability arguments for property dualism given by Balog (1999). Balog maintains that a zombie could make a conceivability argument with the same form, with true premises and a false conclusion, so the argument form must be invalid. Balog's argument requires as a premise the claim that a zombie's...]]
The assertion 'I am phenomenally conscious' (and the like) expresses a truth. But the discussion here suggests that it is much more plausible that the assertion is false or truth-valueless. This is plausible on independent grounds: in a zombie world, when a zombie realist asserts (an analog of) 'Qualia exist', and a zombie eliminativist asserts 'Qualia do not exist', it seems clear that the zombie eliminativist is closer to being correct. If so, Balog's argument fails.

Balog also discusses "Yogis", creatures that make a form of direct reference to brain states without this being mediated by phenomenology. I think it is clear that Yogis have at most a sort of demonstrative concept (roughly: "this inner state"), and do not have the analog of pure phenomenal concepts. For these concepts, no analogous epistemic gap arises. For example, given full physical and indexical information, Yogis will be in a position to know all truths involving the concepts in question.]

How are these beliefs justified? For beliefs involving standing phenomenal concepts, such as $E=S$, we have seen that one reasonable model involves inference from $E=R$ and $R=S$. Here, the former belief is justified by acquaintance and constitution, and the second belief is justified a priori by virtue of its content. These two beliefs combine by virtue of the common element $R$ to justify the belief $E=S$. (One can also hold that $E=S$ is justified directly by acquaintance, at cost of losing the special contribution of constitution.) One can justify general beliefs of the form $E$ is a phenomenal property in much the same way, given that $R$ is a phenomenal property is a priori.

From here, beliefs such as I am conscious are a short leap away. The leap is nontrivial, as there are distinctive problems about the epistemology of the self: witness Hume's skepticism about the self, and Lichtenberg's point that in the cogito, Descartes was entitled only to There is thought, not to I think. I have nothing special to say about these epistemological problems. But assuming that these problems can be solved, it is not implausible that a belief such as If $E$ exists, I have $E$ is justified (perhaps a priori). Then the whole range of first-person phenomenal beliefs lies within reach.

(If one takes direct phenomenal beliefs as truly foundational, one might even suggest that the cogito should have a three-stage structure: from $E=R$ (or some such), to I have $E$, to I exist!)

As for beliefs involving relational phenomenal concepts: presumably beliefs such as $S=red_I$, where $S$ is a standing pure concept of phenomenal redness, will be justified a posteriori, perhaps by inference from the observation that the relevant paradigmatic objects typically cause one to experience instances of $S$. And beliefs of the form $S=red_C$ will be justified at least insofar as red_I=red_C is justified. Of course for the first sort of belief to be justified, skeptical problems about the external world (and about the self) must be overcome, and for the second sort of belief to be justified, skeptical problems about other minds must be overcome. I have nothing special to say about these problems here. But assuming that these problems can be dealt with, then both general relational phenomenal beliefs (e.g. $S=red_C$) and particular relational phenomenal beliefs (e.g. $E=red_C$) will be justified straightforwardly.

It seems, then, that a wide range of phenomenal beliefs can be justified by inference from direct phenomenal beliefs (such as $E=R$), a priori phenomenal beliefs (such as $R=S$ and perhaps If $E$ exists, I have $E$), and a posteriori phenomenal beliefs such as ($S=red_I$ and $S=red_C$). I have given a model for the justification of direct phenomenal beliefs. Phenomenal realism, and even epiphenomenalism, seem to pose no particular problem for the justification of the a priori phenomenal beliefs (or at least no
distinctive problem that does not arise for a priori justification on any view). And the same goes for the justification of the a posteriori phenomenal beliefs. Even if experience plays no causal role, this does not matter. Experiences have no special role in justifying the a priori beliefs, and the justification of the a posteriori beliefs can be seen as derivative on beliefs of the form $E=S$ (which are already accounted for), plus general methods of external observation and inductive inference.

So all we need to justify all these beliefs is the justification of direct phenomenal beliefs, the justification of a priori beliefs in virtue of their content, and the justification involved in inference, observation, and induction. There are no special problems in any of these matters for the phenomenal realist. One might think that inference poses a problem for the epiphenomenalist: how do $E=R$ and $R=S$ justify $E=S$ if the content of $R$ is partly constituted by an epiphenomenal quality, and if inference requires causation? But this is no problem: $R$ acts as a middle term and its content is not required to play any special causal role. We can think of the inference in question as being $E$ is $R$, which is $S$, so $E$ is $S$. Here the content of $R$ is inessential to the validity of the inference: as long as the premises are justified, the conclusion will be justified.

Perhaps the only residual epistemological issue concerns the persistence of standing phenomenal concepts. One might worry if $S$ is partly constituted by an element that is epiphenomenal, then even if one acquires a justified belief - say of the form *roses* cause $S$ - at one time, it is not clear how this justification carries over to instances of a belief with that content at a later time. It is plausible that more than a match in content is required for justification: the later belief must be in some sense the "same" belief, or at least a "descendant" belief, involving the "same" (or "descendant") concepts. The same sort of issue arises with inference of the sort in the previous paragraph. Whether or not $E$ is $S$ is wholly distinct from the two premises, we certainly want later beliefs of the form *that was* $S$ to be justified, and to play a role in further inferences in turn. But this arguably requires that the later concept be a "descendant" of the earlier concept in a sense that allows beliefs involving the later concept to inherit justification from beliefs involving the earlier concepts.

In response: I have no good account of what it is for one token of a concept to be a "descendant" of another, in a manner that allows it to inherit justification. Nor, I think, does anyone. Clearly more than sameness in content is required: if a new concept with the same content were to be formed *de novo*, no justification would be inherited. So some sort of natural connection between concept tokens is required. But it is plausible that this sort of connection need only require an appropriate causal connection between the physical vehicles of the concept, along with an appropriate match in content: it is not required that the elements constituting the content of the initial concept do any distinctive causal work.

[[This sort of persistence relation among tokens is central to our use of concepts and beliefs, but has received less discussion than it might have. In effect, it introduces a "typing" of concepts and beliefs that is more fine-grained than a mere typing by content, but less fine-grained than a typing by numerical identity of tokens. This sort of typing was already tacit in my earlier discussion, when I said that direct phenomenal concepts do not persist beyond the lifetime of an experience, but that standing phenomenal concepts do.]]

To see this, consider the persistence of concepts on an externalist view, where content is constituted by
external factors that may lie in the distant past. Here, the factors that constitute the content of two tokens of the concept will play no distinctive role in causally connecting the tokens, since those factors lie in the distant past. The persistence will instead be supported by appropriate connections between the tokens' physical vehicles. It is plausible that the phenomenal realist, and the epiphenomenalist, can say something similar: conceptual persistence is underwritten by natural connections among vehicles, perhaps along with an appropriate match in content. Of course it would be desirable to have a full positive account of this sort of conceptual persistence, but it seems that there is no distinctive problem for the phenomenal realist here.

Further questions concern the justification of beliefs about the representational content of experiences, and the role phenomenal beliefs might play in justifying beliefs about the external world. I will not say anything about these issues here. But it is plausible that these issues pose mere challenges for the phenomenal realist to answer, rather than posing distinctive arguments against it. The distinctive epistemological problems for phenomenal realism have been removed.

4.4 "The Myth of the Given"

A traditional view in epistemology and the philosophy of mind holds that experiences have a special epistemic status that renders them "given" to a subject. This epistemic status is traditionally held to give phenomenal beliefs a special status, and sometimes to allow experiences to act as a foundation for all empirical knowledge. In recent years, this sort of view has often been rejected. The *locus classicus* for this rejection is Wilfrid Sellars' "Empiricism and the Philosophy of Mind" (1956), which criticized such views as involving "The Myth of the Given". Sellars' (deliberately abusive) term for the view has caught on, and today it is not uncommon for this label to be used in criticizing such views as if no further argument is necessary.

I do not know whether my view is one on which experiences are "given". It does not fit Sellars' official characterization of the given (as we will see), and there are other characterizations which it also does not fit. But the term "given" (and in particular "myth of the given") often shifts to encompass many different views, and it may well be that my view shares something of the spirit of the views that were originally criticized under this label. So rather than trying to adjudicate the terminological issue, we can simply ask: are any of the arguments that have been put forward against the "given" good arguments against the view I have put forward here?

Here one runs up against the problem that clear arguments against the "given" are surprisingly hard to find. There are many suggestive ideas in Sellars' paper, but few explicit arguments. When arguments appear, they often take the form of suggesting alternative views, rather than directly criticizing an existing view. But there is at least one clear argument against the "given" in Sellars' paper. This is his famous "inconsistent triad". This was intended as an argument against sense-datum theories, but it clearly applies to a wider class of views.

It is clear from the above analysis, therefore, that classical sense-datum theories [...] are
confronted by an inconsistent triad made up of the following three propositions:

A. $x$ senses red sense content $s$ entails $x$ non-inferentially knows that $s$ is red. B. The ability to sense sense contents is unacquired. C. The ability to know facts of the form $x$ is $\phi$ is acquired.

A and B together entail not-C; B and C entail not-A; A and C entail not-B. (Sellars 1956, section 6)

It is clear how the view I have put forward should deal with this inconsistent triad: by denying A. I have said nothing about just which mental capacities are acquired or unacquired, but on the view I have put forward, it is clearly possible to have experiences without having phenomenal beliefs, and therefore without having knowledge of phenomenal facts. On my view, phenomenal beliefs are formed only rarely, when a subject attends to his or her experiences and makes judgments about them. The rest of the time, the experiences pass unaccompanied by any phenomenal beliefs or phenomenal knowledge.

Underlying Sellars' critique is the idea that knowledge requires concepts, and that experiences do not require concepts, so that having experiences cannot entail having knowledge. The view I have put forward is compatible with all of this. On my view, experiences require little cognitive sophistication, and in particular do not require the possession of concepts. There may be some experiences that require concepts (for example, the experience of a spoon as a spoon), but not all experiences do. No concepts are required to experience phenomenal redness, for example. Knowledge of facts requires belief, however, and belief requires the possession of concepts. So experience does not entail knowledge.

Sellars associated the "given" most strongly with the acceptance of (A), and the denial of (A) is what he argues for himself. In discussing the possibility that a sense-datum theorist might deny (A), all he says is:

He can abandon A, in which case the sensing of sense contents becomes a noncognitive fact - a noncognitive fact, to be sure which may be a necessary condition, even a logically necessary condition, of non-inferential knowledge, but a fact, nevertheless, which cannot constitute this knowledge.

On my view, all this is correct. Experiences do not, on their own, constitute knowledge. They play a role in justifying knowledge, and they play a role in partly constituting the beliefs that qualify as knowledge, in combination with other cognitive elements. But experiences themselves are to be sharply separated from beliefs and from items of knowledge. So none of this provides any argument against my view.

(On my reading, a number of the sense-data theorists also deny (A), making clear distinctions between the sort of nonconceptual epistemic relation that one stands in by virtue of having an experience and the sort of conceptual epistemic relation that one has when one knows facts. Such theorists clearly avoid the conflation between experience and knowledge that Sellars accuses sense-datum theorists of.)
Curiously, Sellars never discusses the possibility that experiences could justify knowledge without entailing knowledge. It seems clear that he would reject such a view, perhaps because he holds that only conceptual states can enter into justification, but this is never made explicit in his article.[*]

[[The one further part of Sellars' article that may be relevant to the view I have put forward is part VI (sections 26-29), where he addresses the traditional empiricist idea that experience involves awareness of determinate repeatables. This is closely related to my claim that experience involves acquaintance with properties. Sellars does not provide any direct argument against this view, however. He simply notes (sections 26-28) that Locke, Berkeley, and Hume take this thesis as a presupposition rather than a conclusion (they use it to give an account of how we can be aware of determinable repeatables). And then he asserts (section 29) that this awareness must either be mediated by concepts (e.g. through the belief that certain experiences resemble each other, or that they are red) or be a purely linguistic matter. He gives no argument for this claim, which I think should be rejected. On my view, our acquaintance with qualities requires neither concepts nor language.]]

Although Sellars does not argue explicitly against this sort of view, such arguments have been given by a number of later philosophers writing in the same tradition. In particular, there is a popular argument against any view on which experiences are nonconceptual states that play a role in justifying beliefs. This argument, which we might call the *justification dilemma*, has been put forward by BonJour (1969), Davidson (19xx), and McDowell (1994), among others. We can represent it as follows:

1. There can be no *inferential* relation between a nonconceptual experience and a belief, as inference requires connections within the conceptual domain.

2. But a mere *causal* relation between experience and belief cannot justify the belief; so

3. Nonconceptual experiences cannot justify beliefs.

The first premise is plausible, as it is plausible that inference is mediated by concepts. The status of the second premise is much less clear. While it is plausible that the mere existence of a causal connection does not suffice to justify a belief, it is far from clear that the right *sort* of causal connection could not serve to justify a belief. McDowell says that a causal connection "offers exculpation where we wanted justification". But clearly causal connections cannot involve mere exculpation simply by virtue of being causal connections, as the case of inference shows: here a causal connection of the right kind between states can be seen to justify. So further argument is required to show that no other sort of causal connection (perhaps with subtle constraints on the content of a belief and on the relationship between belief and experience) can provide justification.

But in any case, even if the two premises are accepted, the conclusion does not follow. An option has been missed: inference and causation do not exhaust the possible justifying relations between nonconceptual experiences and beliefs. On my view, the relation in question is not inference or causation, and neither is it identity or entailment, as on the views that Sellars criticized. Rather, the relation is partial constitution.
I have already given a model of how the justification of a direct phenomenal belief by an experience works, involving three central elements that parallel the three central elements in the case of inference. The analog of the causal element is the constitutive connection between experience and belief; the analog of the content element is the match between epistemic content of belief and quality of experience; and the analog of the epistemic element is the subject's acquaintance with the phenomenal quality. If the model of justification by inference is accepted, there is no clear reason why this model should be rejected.

Some philosophers hold that only a conceptual state can justify another conceptual state. But as with the thesis that only a belief can justify another belief, it is not clear why this thesis should be accepted. It is not supported pretheoretically: pretheoretically, there is every reason to hold that experiences are nonconceptual and can justify beliefs. And there is no clear theoretical support for this claim, either. Proponents sometimes talk of "the space of reasons" in this context, but the slogan alone does not convert easily into an argument. McDowell suggests that justifications for our beliefs should be articulable, which requires concepts; but as Peacocke (2001) points out, we can articulate a justification by referring to a justifying experience under a concept, whether or not the experience itself involves concepts. Perhaps the central motivation for the thesis lies in the fact that we have a clear theoretical model for conceptual justification, but not for other sorts of justification. But again, this is a weak argument, and again, the exhibition of a theoretical model ought to remove this sort of worry.

In any case: the view I have put forward avoids Sellars' central version of the given (an entailment from experience to knowledge), and Bonjour/Davidson/McDowell's central version of the given (a mere causal connection), along with the arguments against those views. It may be that the view I have put forward accepts a "given" in some expanded sense. But the substantive question remains: are there good arguments against the given that are good arguments against this view? I have not been able to find such arguments, but I would welcome hearing candidates.

5 Further questions

I have drawn a number of conclusions about the content and epistemology of phenomenal beliefs. It is natural to ask whether these conclusions apply more generally.

First, regarding content: I have argued that the content of phenomenal concepts and phenomenal beliefs is conceptually irreducible to the physical and functional, because this content itself depends on the constitutive role of experience. Does this sort of irreducibility extend to other concepts or beliefs? Is the content of concepts and beliefs irreducible to the physical and functional quite generally?

There is one class of concepts for which such a conclusion clearly follows. This is the class of concepts that have phenomenal concepts as constituents. Such concepts might include the tallest conscious being in this room, the physical basis of consciousness, and the external cause of R, where R is a pure concept of phenomenal redness. More generally, insofar as a concept has conceptual ties with phenomenal concepts, so that claims involving that concept conceptually and nontrivially entail claims involving pure phenomenal concepts, then the content of such a concept will be irreducible in a similar way.
It is arguable that many or most of our perceptual concepts have this feature. At least some concepts of external colors can be analyzed roughly as the property causally responsible for \( C \) in me, where \( C \) is a pure concept of a phenomenal color. Things are more complex for community-level concepts. Here it is more plausible that an external color concept might be analyzed in terms of community-wide relations to a nonspecific phenomenal concept: perhaps the property causally responsible for the dominant sort of visual experience caused by certain paradigmatic objects in this community, or something like that. But this still has the concept of visual experience as a constituent, and so will still have functionally irreducible content. The alternative is that external color concepts might be analyzed in terms of their relations to certain judgments or other nonexperiential responses, in which case the reducibility or irreducibility will not be so clear. I will not adjudicate this matter here, but my own view is that while there may be some perceptual concepts without an obvious phenomenal component, many or most of the perceptual concepts that we actually possess have such a component.

One might try to extend this further. In the case of theoretical concepts from science, for example, one can argue that these have conceptual ties to various perceptual concepts (as the Ramsey-Lewis analysis of theoretical concepts suggests). If so, and if the perceptual concepts in question have irreducible content, it is arguable that these concepts have irreducible content. And one might argue for conceptual ties between intentional concepts and phenomenal concepts, and between social concepts and intentional concepts, so that a wide range of social concepts will turn out to have irreducible content. If this is right, then a being without consciousness could have at best impoverished versions of these concepts, and perhaps no such concepts at all.

This sort of argument will not work for all concepts. Many mathematical or philosophical concepts have no obvious tie to phenomenal concepts, for example. And in fact there is good reason to think that some concepts do not have an phenomenal component. If all concepts have a phenomenal component, it would be hard to avoid the conclusion that all concepts are entirely constituted by phenomenal concepts, which would lead naturally to phenomenalism or idealism. My own view is that certain central concepts, such as that of causation, have no deep phenomenal component at all. Once this is recognized, it becomes clear that even if a wide range of concepts have a phenomenal component, only a small number of them are entirely phenomenal.

Even if some concepts have no phenomenal component, it is not out of the question that their content might still be irreducible. One intriguing possibility is that something about a subject's phenomenal states could be central to a subject's possessing a concept such as that of causation, or certain mathematical concepts, even though these concepts do not refer to phenomenal states as part of their content. (Compare a reductive view on which neural states might constitute the content of concepts that do not refer to neural states.) There is at least some intuition that a capacity for consciousness may be required to have concepts in the first place; and it is not obviously false that phenomenology plays a role in the possession of even nonphenomenal concepts.

Such a thesis would require much further argument, of course, and I am not certain whether it is true. But even if it is false, the more limited thesis that phenomenology plays a role in constituting the content of...
The Content and Epistemology of Phenomenal Belief

phenomenal concepts, and that phenomenal concepts play a role in determining the content of a wide range of other concepts, has significant consequences. If even the more limited thesis is true, then the project of giving a functional analysis of intentionality cannot succeed across the board, and a central role must be given to phenomenology in the analysis of intentional content.

Second, epistemology: I have in effect argued for a sort of limited foundationalism within the phenomenal domain. Direct phenomenal beliefs are in a certain sense foundational: they receive justification directly from experience, and their prima facie justification does not rely on other beliefs. And I have argued that direct phenomenal beliefs can justify at least some other phenomenal beliefs in turn, when aided by various sorts of a priori reasoning. Does this give any support to foundationalism about a broader class of empirical beliefs, or about empirical knowledge in general?

Nothing I have said implies this. This gap between phenomenal knowledge and knowledge of the external world remains as wide as ever, and I have done nothing to close it. The framework here is compatible with various standard suggestions: that phenomenology might justify external beliefs through inference to the best explanation, or through a principle that gives prima facie justification to a belief that endorses an experience's representational content. But so far, the framework outlined here does nothing special to support these suggestions or to answer skeptical objections. And the framework is equally compatible with many alternative nonfoundationalist accounts of our knowledge of the external world.[*]

[[A particular problem in extending this account to a general foundationalism is that we do not usually form direct phenomenal beliefs associated with a given experience, so such beliefs are not available to help in justifying perceptual beliefs. (Thanks to Alvin Goldman for discussion on this point.) Here there are a few alternatives: (1) deny that perceptual beliefs are usually justified in the strongest sense, but hold that such justification is available; (2) hold that the mere availability of justifying direct phenomenal beliefs confers a sort of justification on perceptual beliefs; or (3) extend the account so that perceptual experiences can justify perceptual beliefs directly, through a constitutive connection to perceptual concepts analogous to the connection to phenomenal concepts. I explore the third possibility in forthcoming work on the content of perceptual experience and perceptual belief.]]

Still, this framework may help to overcome what is sometimes taken to be the largest problem for foundationalism: bridging the gap between experience and belief. I have argued that an independently motivated account of the role of experience in phenomenal belief, and of subject's epistemic relations to them, has the resources to solve this problem, by exploiting the paired notions of constitution and acquaintance.

Any plausible epistemological view must find a central role for experience in the justification of both beliefs about experience and beliefs about the world. If what I have said in this paper is correct, then we can at least see how experience gains a foothold in this epistemic network. Many other problems remain, especially regarding the relationship between experience and beliefs about the external world. But here, as in the case of phenomenal belief, a better understanding of the relationship between experience and belief may take us a long way.

Acknowledgements
I have given versions of this paper (starting in 1997) at Antwerp, ANU, Arizona, Delaware, Fribourg, Miami, Munich, Princeton, Sydney, UC Santa Cruz, the APA (Pacific Division), Metaphysical Mayhem (Syracuse), and the World Congress in Philosophy. Thanks to many people in audiences there, and elsewhere. Special thanks to Mark Johnston, Martine Nida-Rumelin and Daniel Stoljar for lengthy discussions.

Sellars, W. 1956. Empiricism and the philosophy of mind. Minnesota Studies in the Philosophy of
What follows is a brief and simplified introduction to the two-dimensional semantic framework as I understand it. See also Chalmers (2002c; forthcoming).

Let us say that it is epistemically possible in the broad sense that S if the hypothesis that S is not ruled out a priori. Then there will be a wide space of epistemic possible hypotheses (in the broad sense; I omit the qualifier in what follows). Some of these will conflict with each other; some of them will be compatible with each other; and some will subsume each other. We have a systematic way of evaluating and describing epistemic possibilities that differs from our way of evaluating and describing subjunctive counterfactual possibilities. It is this sort of evaluation and description that is captured by the first dimension of the two-dimensional framework.

It is epistemically possible that water is not H2O, in the broad sense that this is not ruled out a priori. And there are many specific versions of this epistemic possibility: intuitively, specific ways our world could turn out such that if they turn out that way, it will turn out that water is not H2O. Take the XYZ-world, one containing superficially identical XYZ in place of H2O. It is epistemically possible that our world is the XYZ-world. When we consider this epistemic possibility - that is, when we consider the hypothesis that our world contains XYZ in the oceans, and so on - then this epistemic possibility can be seen as an instance of the epistemic possibility that water is not H2O. We can rationally say "if our world turns out to have XYZ in the oceans (etc.), it will turn out that water is not H2O". The hypothesis that the XYZ-world is actual rationally entails the belief that water is not H2O, and is rationally inconsistent with the belief that water is H2O.

Here, as with subjunctive counterfactual evaluation, we are considering and describing a world, but we are considering and describing it in a different way. In the epistemic case, we consider a world as actual: that is, we consider the hypothesis that our world is that world. In the subjunctive case, we consider a world as counterfactual: that is, we consider it as a way things might have been, but (probably) are not. These two modes of consideration of a world yield two ways in which a world might be seen to make a sentence or a belief true. When the XYZ-world is considered as actual, it makes true 'water is XYZ'; when it is considered as counterfactual, it does not.

In considering a world as actual, we ask ourselves: what if the actual world is really that way? In the broad sense, it is epistemically possible that Hesperus is not Phosphorus. This is mirrored by the fact that there are specific epistemic possibilities (not ruled out a priori) in which the heavenly bodies visible in
the morning and evening are distinct; and upon consideration, such epistemic possibilities are revealed as
instances of the epistemic possibility that Hesperus is not Phosphorus.

When we consider worlds as counterfactual, we consider and evaluate them in the way that we consider and evaluate subjunctive counterfactual possibilities. That is, we acknowledge that the character of the actual world is fixed, and say to ourselves: what if the world had been such-and-such a way? When we consider the counterfactual hypothesis that the morning star might have been distinct from the evening star, we conclude not that Hesperus would not have been Phosphorus, but rather that at least one of the objects is distinct from both Hesperus and Phosphorus (at least if we take for granted the actual-world knowledge that Hesperus is Phosphorus, and if we accept Kripke's intuitions).

Given a statement $S$ and a world $W$, the *epistemic intension* of $S$ returns the truth-value of $S$ in $W$ considered as actual. (Test: if $W$ actually obtains, is $S$ the case?) The *subjunctive intension* of $S$ returns the truth-value of $S$ in $W$ considered as counterfactual. (Test: if $W$ had obtained, would $S$ have been the case?) We can then say that $S$ is *primarily possible* (or 1-possible) if its epistemic intension is true in some world (i.e. if it is true in some world considered as actual), and that $S$ is *secondarily possible* (or 2-possible) if its subjunctive intension is true in some world (i.e. if it is true in some world considered as counterfactual). Primary and secondary necessity can be defined analogously.

For a world to be considered as actual, it must be a *centered* world -- a world marked with a specified individual and time - as an epistemic possibility is not complete until one's "viewpoint" is specified. So an epistemic intension should be seen as a function from centered world to truth-values. For example, the epistemic intension of 'I' picks out the individual at the center of a centered world; and the epistemic intension of 'water' picks out, very roughly, the clear drinkable (etc.) liquid in the vicinity of the center. No such marking of a center is required for considering a world as counterfactual, or for evaluating subjunctive intensions.

Epistemic and subjunctive intensions can be associated with statements in language, as above, and equally with singular terms and property terms. The intension of a statement will be a function from worlds to truth-values; the intension of a term will be a function from worlds to individuals or properties within those worlds. (In some cases, intensions are best associated with linguistic tokens rather than types.)

Epistemic intensions can also be associated in much the same way with the (token) concepts and thoughts of a thinker, all of which can be used to describe and evaluate epistemic possibilities as well as subjunctive counterfactual possibilities. In "The Components of Content" I argue that the epistemic intension of a concept or a thought can be seen as its "epistemic content" (a sort of internal, cognitive content), and that the subjunctive intension captures much of what is often called "wide content".

A crucial property of epistemic content is that it reflects the rational relations between thoughts. In particular, if a belief $A$ entails a belief $B$ by a priori reasoning, then it will be epistemically impossible (in the broad sense) for $A$ to be true without $B$ being true, so the epistemic intension of $A$ entails the
epistemic intension of $B$. Further, if an identity $a=b$ is a posteriori for a subject, then it is epistemically possible for the subject that the identity is false, and there will be an epistemic possibility in which the referents of the two concepts involved differ, so the subject's concepts $a$ and $b$ will have distinct epistemic intensions. This applies even to beliefs expressed by a posteriori necessities such as 'water is $\text{H}_2\text{O}$' and 'Hesperus is Phosphorus': the epistemic intensions of these beliefs are false at some worlds, so the concepts involved have different epistemic intensions. So epistemic intensions behave something like Fregean senses, individuating concepts according to cognitive significance at least up to the level of a priori equivalence.

(A complication here: on some philosophical views, there may be "strong necessities" whose epistemic intension is false at no world. An example might be 'A god exists', on a theist view on which a god exists necessarily but not a priori. These necessities go well beyond Kripkean a posteriori necessities, and I have argued elsewhere (Chalmers 2002b) that there are no such necessities. If they exist, however, the present framework can accommodate them by moving to a broader class of conceptual or epistemic possibilities, which need not correspond to metaphysical possibilities (see Chalmers (forthcoming) for more details. In the case above, for example, there will be at least a conceptually possible world (or "scenario") in which there is no god; and more generally, any a posteriori belief will have an epistemic intension that is false at some such world.)

Insofar as the two-dimensional framework is used in this paper, it is being applied rather than being discussed or justified in its own right. The discussion here indicates important distinctions among phenomenal concepts whose analysis requires the idea of epistemic content. And importantly, there are epistemological distinctions that turn on these distinctions in content. This reflects a more general phenomenon: the sort of possibility that is most crucial in epistemology is epistemic possibility, and the sort of content that is correspondingly most crucial is epistemic content.
Philosophy 596B: Metaphysics

Mind and Modality

David Chalmers

E-mail: chalmers@arizona.edu
Web: http://www.u.arizona.edu/~chalmers/

Overview

When one thinks about the mind-body problem, or about metaphysics more generally, one is quickly led into thinking about possibility and necessity. Materialism, for example, is naturally understood as making a modal claim -- the physical facts necessitate all the facts -- and questions about the truth of materialism turn on deep questions about the nature of possibility and necessity. How extensive is the space of possible worlds? What is the relationship between conceivability and possibility? How can we have cognitive access to matters of possibility and necessity? In this course, we will use modal considerations in the philosophy of mind as a route into the thickets of modality.

We will start by considering some modal arguments against materialism, and by looking at the varieties of possibility and necessity. Then we will concentrate on the phenomenon of a posteriori necessity, and try to understand its roots (with a detour into two-dimensional semantics, and into the logic of conditionals), and we will try to come to grips with the philosophical concept of a possible world. In the second half of the course, we will concentrate on the relationship between conceivability and possibility, and more generally on the relationship between the epistemology and the metaphysics of modality; and we will look into implications for the philosophy of mind and for metaphysics more generally. We will read recent works by a number of philosophers on these issues, within metaphysics, the philosophy of language, and the philosophy of mind. Along the way, I will present portions of some work in progress on the general theme of "modal rationalism".

Readings

● Saul Kripke, Naming and Necessity.
● David Chalmers, The Conscious Mind. (esp Chap. 1-4)
● David Lewis, On the Plurality of Worlds. (esp Chap. 1-3)
● A reading packet with numerous articles.
● A number of articles on the web.

The Lewis book is out of print, unfortunately, so I will include some of it in the reading packet (which won't be needed for a few weeks; I'll let you know about availability as the time approaches). Where
articles are available on the web, I've indicated this below. All the web articles should be accessible from my page of online papers on consciousness (especially the section on materialism and modality).

You may also want to consult my bibliography of contemporary philosophy of mind (especially section 1.3).

Much of the course will loosely follow the structure of my Princeton lectures on Mind and Modality (especially the first two lectures),

**Mailing list**

I will set up a mailing list, modality@listserv.arizona.edu, for class discussion. This will be the main locus of the course while I am in Australia, and will continue to play a role when I return. Everyone will be expected to make reasonably regular contributions to this list (at least one reasonably substantial posting every week), discussing issues arising from the readings, from class discussion, and from the mailing list itself. Discussion from the mailing list is retrospectively included with the associated weeks below.

**Schedule**

Here is a very approximate week-by-week plan for the course. The correspondence between topics here and weeks will probably be loose. In the first few weeks in particular, things will be done somewhat differently to accommodate the electronic format.

1. **Metaphysics and Modality**

- TCM, Chapter 2.

**Week 1 discussion**

2. **Epistemic Arguments Against Materialism.**

Conceivability arguments: the possibility of disembodiment (Descartes), of zombies, of inverted spectra. Epistemic arguments: Jackson's knowledge argument, etc. Conceptual analysis of phenomenal concepts. Objections. Type-A and type-B materialism.
Week 2 discussion

3. Naming and Necessity

Kripke's *Naming and Necessity*. The modal argument for rigid designation and a posteriori necessities. The epistemic argument against descriptive theories of reference. Names and natural kind terms. Application to metaphysical issues.

- Kripke, *Naming and Necessity*.

Week 3 discussion

4. The 2-D account.

The two-dimensional account of a posteriori necessity. Primary and secondary intensions. Two notions of necessity. Link to apriority. Translation of Kripke's main theses into two-dimensional terms. Related ideas (Kaplan, Stalnaker, etc).

- TCM, Section 2.4
- Chalmers, *The components of content*
- Evans, Reference and Contingency
- Davies and Humberstone, Two Notions of Necessity

Week 4 discussion

5. The Tyranny of the Subjunctive.

The different behavior of subjunctive and indicative conditionals in the analysis of possibilities. Links to two-dimensional semantics. The implicit dominance of the subjunctive in contemporary analyses of necessity. How philosophy would look with indicatives instead. The analysis of subjunctives and indicatives. Epistemic vs. subjunctive possibility.

Week 5 discussion

6. Applying the 2-D account to the anti-materialist argument.

Type-B materialism: relying on a posteriori necessity to save the materialist. Application of the two-

http://www.u.arizona.edu/~chalmers/class/phil596b.html (3 of 6) [4/7/2002 1:44:01 PM]
dimensional analysis of a posteriori necessity to this position. From an epistemic gap to an ontological
gap? Loopholes.

- TCM, Chapter 4.
- Chalmers, Mind and modality, part 1
- Jackson, Finding the Mind in the Natural World.

**Week 6 discussion**

7. Materialism and the Metaphysics of Modality (Strong Necessities).

The type-B materialist's escape route: strong necessities. Are there strong necessities? What do they
involve? Possible examples and explanations.

- Yablo, Textbook Kripkeanism and the open texture of language
- Loar, Phenomenal states
- Hill, Conceivability, Possibility, and the Mind-Body Problem
- Chalmers, Materialism and the metaphysics of modality

**Week 7 discussion**

8. Does Conceivability Entail Possibility?

Varieties of conceivability: prima facie vs. ideal, primary vs. secondary, positive vs. negative, etc.
Possible counterexamples to the conceivability/possibility link.

- Chalmers, Mind and modality, part 2
- Chalmers, Does conceivability entail possibility?
- Yablo, Is conceivability a guide to possibility?
- van Cleve, Conceivability and the Cartesian argument for dualism

**Week 8 discussion**

9. Modal Rationalism and the Scrutability of Truth

Varieties of modal rationalism. Three loopholes: strong necessities, inscrutable truths, open
inconceivabilities. The analysis of inscrutability. Links to inscrutability of reference (Quine, Putnam,
Benacerraf). Possible examples: inscrutable mathematical truths, epistemic theory of vagueness, etc.
Arguments against inscrutability?
Week 9 discussion

10. Cosmic Hermeneutics

Are all truths entailed a priori by the microphysical (plus phenomenal) truths? Link to inscrutability and modal rationalism. Arguments pro and con.

- TCM, Section 2.5
- Horgan, Supervenience and cosmic hermeneutics
- Block and Stalnaker, Conceptual analysis and the explanatory gap
- Byrne, Cosmic hermeneutics

Week 10 discussion

11. Constructing Possible Worlds

What is a possible world? Concrete vs. "ersatz" conceptions of possible worlds. Constructing "ersatz" worlds. Constructing conceivable worlds, handling epistemic vs. subjunctive possibilities and two-dimensional semantics, etc.

- Lewis, On the Plurality of Worlds, Chapters 2 & 3.
- Stalnaker, Possible worlds.
- Adams, Theories of actuality.

Week 11 discussion

12. Modal Monism and Modal Dualism

The argument for modal rationalism. Do strong necessities commit one to modal dualism? Should there be just one modal primitive? Constitutive links between modal and rational notions. Handling tricky cases, e.g. haecceities.

- Chalmers, Mind and modality, part 2
- Chalmers, Materialism and the metaphysics of modality
- Salmon, The logic of what might have been

Week 12 discussion

13. The Components of Content
Wide content and narrow content. Using two-dimensional semantics to give an account of narrow content. Application to the explanation of behavior, to the semantics of belief ascription, and to belief puzzles. Objections and subtleties.

- Chalmers, *The components of content*
- Stalnaker, Narrow Content
- Block, *What Narrow Content is Not.*

**Week 13 discussion**

14. Further Directions

Hyperintensionality and the analysis of epistemic possibility. The theory of concepts, meaning, and understanding. Realism and anti-realism.

15. From Mind to Modality and Back Again

Where are we left in the philosophy of mind? The menu of options re the metaphysics of consciousness. The analysis of mental content. Links between consciousness and content?

**Assessment**

The major item for assessment will be a paper due at the end of term. There may also be some smaller written assignments along the way, and student presentations in class. All students are expected to participate in class discussion (both online and in person).

**Mailing list**

I will set up a mailing list, modality@listserv.arizona.edu, for class discussion. Everyone will be expected to make reasonably regular contributions to this list (at least one reasonably substantial posting every week), discussing issues arising from the readings, from class discussion, and from the mailing list itself.
Responses to articles on my work

This page is mostly for brief responses to published or forthcoming articles that discuss my work. I've starred [*] the more technical entries so nonphilosophers can skip them. (The first entry is probably the best place for nonphilosophers to start.) These responses are "unofficial", but if you'd like to use them in an article, feel free to ask. See also online discussions of my work for some further papers and other discussion (without responses).

Table of contents: what follows includes three collections of articles replied to elsewhere, followed by articles by Katalin Balog, Tim Bayne, Ned Block & Robert Stalnaker, Anthony Brueckner, Alex Byrne, Alex Byrne & Ned Hall, Paul Churchland, William Greenberg, Christopher Hill, Jenann Ismael, Mark Johnston, Robert Kirk, Noa Latham, Joseph Levine, Harry Lewis, Andrew Melnyk, Nigel Thomas, John Perry, Robert Stalnaker, Robert Stalnaker, Bram van Heuveln et al, and Stephen Yablo. (These links are within this page.)

Journal of Consciousness Studies symposium on the "hard problem". (Articles by Baars, Bilodeau, Churchland, Clark, Clarke, Crick & Koch, Dennett, Hameroff & Penrose, Hardcastle, Hodgson, Hut & Shepard, Libet, Lowe, MacLennan, McGinn, Mills, O'Hara & Scutt, Price, Robinson, Rosenberg, Seager, Shear, Stapp, Velmanes, Warner.)

See my Moving Forward on the Problem of Consciousness.

*Philosophy and Phenomenological Research symposium on The Conscious Mind. (Articles by Hill & McLaughlin, Loar, Shoemaker, Yablo.)

See my Materialism and the Metaphysics of Modality.

Reviews of The Conscious Mind.

See my page of reviews of The Conscious Mind. See also response to Papineau (TLS), response to Mulhauser (PSYCHE), response to Searle (NYRB), second response to Searle.

Balog appeals to zombies in order show that Jackson's and my anti-materialist arguments are self-defeating. She argues that a zombie could make the same arguments, with true premises but a
false conclusion (materialism is true in the zombie world), and concludes that the arguments are invalid. She locates the problem in the inference from conceivability to possibility, or in the thesis that materialism requires *a priori* entailment.

This is an intriguing argument, but I think the problem with it is clear. Balog's parallel argument requires that a zombie's claim "I am conscious" is true; otherwise the argument doesn't get off the ground. Balog supports this by suggesting that the zombie's "consciousness" concept will pick out a physical/functional property to which it is causally related. But I think it is much more plausible that the zombie's claim is false. The easiest way to see this is to consider an argument in the zombie world, perhaps between Zombie Chalmers and Zombie Dennett. Zombie Chalmers says "Qualia exist", Zombie Dennett says "Qualia do not exist". Balog's analysis implies that in the zombie world, Zombie Chalmers is right. But this seems wrong. Surely in the zombie world, at least, Zombie Dennett is right.

See "The Content and Epistemology of Phenomenal Belief" for more on this sort of thing.

Bayne focuses on the epistemological discussion in Chapter 5 of my book. There I argue that a reliabilist account of phenomenal knowledge can't work, since a reliabilist account can't deliver certain knowledge. When knowledge is grounded only in a reliable connection, we can't be certain that the reliable connection holds, so we can't rule out alternative skeptical scenarios; but we are certain that we are conscious, and can rule out our alternative skeptical scenarios. Bayne argues that the same applies to my "acquaintance" account. He notes that I accept in the book that acquaintance alone doesn't suffice for full justification (acquaintance alone is compatible with fallibility, e.g. in cases of inattention, etc). So various further "background conditions" (e.g. concerning attention, etc) are required for full justification. But we can't know for certain that those background conditions hold; so we can't know for certain that we are justified. So by parity of reasoning, the acquaintance model can't deliver certain phenomenal knowledge, either.

I think this argument rests on a natural misreading of my discussion of reliabilism. The argument is not: reliabilism can't deliver certainty that we are fully justified, certainty that we are fully justified is required for certainty, so reliabilism can't deliver certainty. That argument would rest on a problematic "CJ" thesis (analogous to the "KJ" thesis that knowledge requires knowledge that one is justified, but with certainty instead of knowledge). Rather, the argument is: when knowledge is grounded only in a reliable connection, we can't be certain that the reliable connection holds, so we can't rule out alternative skeptical scenarios about what's at the other end of the connection, so we can't have certain knowledge.

The first argument (resting on the CJ thesis) just might deliver an analogous argument against the acquaintance model. But I'll respond by denying the CJ thesis (even accepting CJ, one could also
argue that "positive" certainty of justification doesn't require "negative" infallibility). And an argument analogous to the second argument won't work. Even if an acquaintance theorist accepts that we can't be certain that we are justified, that merely shows that one can't rule out skeptical scenarios in which one's belief in the experience is not fully justified; it doesn't show that one can't rule out skeptical scenarios in which the experiences are not present. Presumably an acquaintance theorist can hold that we're certain about qualia but not about such cognitive matters as full justification, so that we can rule out skeptical scenarios without qualia, but not those without full justification. (To resist this would require the dubious CJ claim.) The analogous move is not open to a reliabilist: by its nature, reliabilism can never deliver "knowledge beyond skepticism". Again, see "The Content and Epistemology of Phenomenal Belief" for more.

Frank Jackson and I have written a response to this article, forthcoming in the Philosophical Review: "Conceptual Analysis and Reductive Explanation".

This paper is a bit puzzling. It starts by saying that others have misunderstood my argument, and then gives a reasonably (though not completely) accurate reconstruction of some aspects of my two-dimensional modal argument. Then in the last section Brueckner says that I don't establish that the conceivability of zombies entails the relevant possibility. But this is a straightforward consequence of the independently argued thesis that conceivability in the relevant sense entails possibility of primary intension (which is all I need). Brueckner doesn't even discuss my positive case for this thesis, so something has gone awry -- I'm not sure what. It may be that the argument in the book was insufficiently formal and explicit: people have misunderstood it more often than I expected. There are more formal versions, as well as defenses of the relevant principles, in "Mind and Modality" and especially "Does Conceivability Entail Possibility".

Byrne argues against the a priori entailment of most macro facts by micro facts. Along the way it addresses two of my arguments: the argument from conceivability, in which I argue that a scenario in which the micro facts are the same but the macro facts are different is inconceivable; and one of the arguments from epistemology, in which I argue that a good enough reasoner given only the micro facts would be in a position to ascertain the macro facts. Byrne's main objection to the conceivability argument is that given that we don't yet know just what the micro facts are, we can't know that the scenario in question is inconceivable. His main objection to the epistemological argument is that the strategy I outline relies on the reasoner reaching certain intermediate high-level conclusions, and that the entailment of these conclusions is just as questionable as the entailment of the original macro facts.
I think Byrne misses a key aspect of the arguments in the book (which are admittedly brief). The argument in general is to argue that the micro facts specify micro structure and dynamics, that micro structure and dynamics \textit{a priori} entail macro structure and dynamics, and that macro structure and dynamics entails most macro facts (except those that depend on mentality or indexicals). The middle level of macro structure and dynamics can be thought of as a "geometric" characterization of the structure and evolution of macro objects -- their overall shapes, masses, positions, causal relations, etc. As long as microphysics has information about mass, position, etc, of micro objects, the information about macro objects will be easily derivable from the micro information (e.g. by considerations about macroscopic mass densities in various locations, and so on). So this point is robust over microphysical theories. The second entailment is made plausible not least by the fact that this sort of macro structure and dynamics (plus facts about appearance, which I can also help myself to) is all the information we have to go on in ordinary perception.

Byrne's objection to the conceivability argument can be rebutted by noting that however microphysics turns out, it will be inconceivable that there be the microstructure without the macrostructure, and it will be inconceivable that there be the macrostructure without the macro facts. His objection to the epistemological argument can be rebutted by noting that the reasoner will easily be able to ascertain facts about macrostructure, and from facts about macrostructure (plus facts about appearance) they will be able to ascertain the macro facts in question (just as we can through perceptual information). Byrne does not address my second epistemological argument, which is that the absence of a priori entailment of macro facts will lead to a sort of skeptical problem concerning those macro facts (two epistemic possibilities with the same micro facts and different macro facts would "look" just the same) that we are not in fact faced with in most cases, except in the case of consciousness. All this is now discussed at greater length in \textit{"Conceptual Analysis and Reductive Explanation"}.

This paper addresses the "dessert" in my book, in which I try to use the ideas about consciousness to support a version of the Everett interpretation of quantum mechanics, on which the world is a giant superposition but on which there are minds with discrete experiences like ours. I argue that my principle of organizational invariance predicts that a superposition of a physical state with an orthogonal physical state will give rise to at least the same experiences as the original physical state, since one can show that any computations implemented in the original state will be implemented in the superposed state. Byrne and Hall point out an apparently absurd consequence: that the same organization and experience will be present in any system not orthogonal to the original system.

I have to eat some crow on this one: there is a mistake in the reasoning in the book. The mistake (first pointed out to me by \textit{Jacques Mallah}) is a technical one in the discussion on p. 350 arguing...
that a superposition implements the original computation. I establish a mapping between states of the superposed system and the original implementing states of the original system by projection onto the hyperplane of the original system. I then say that since the Schrodinger equation is linear, the state-transitions among the superposed states as defined will mirror the transitions among the original states. But this last step does not follow. In effect, it presupposes that projection commutes with Schrodinger evolution, which is false in general.

How to fix this up? One needs to find a special class of superpositions, with associated projections (or other relevant operators) onto subspaces, such that within this class, projection commutes (or approximately commutes) with Schrodinger evolution. This is what's needed to capture the Everett-style idea that evolution in distinct "components" of the superposition will sometimes be more or less independent. I think that ideas drawn from decoherence theory may be useful here -- so the result won't hold for superpositions in general, but will hold for "decoherent superpositions". This makes for some interesting links with other ideas, but I haven't yet worked out all the details. If you have any ideas about this, please let me know!

Byrne and Hall have some other objections to my treatment, but I think that this is easily the most serious. I think they mislocate the source of the absurd consequence in a principle about causal relevance (ultimately stemming from preferred bases), rather than in the mistake above, which they don't discuss. If the above problem can be fixed (e.g. via the decoherence idea), I think all the causal relevance one needs will follow, on a natural treatment of causal relevance. And the independence of evolution in the subspaces will deliver all the "preferredness" of bases that one needs.

This parodies various antireductionist arguments, including my "hard problem"/"easy problem" arguments, by giving analogous arguments that someone might have given about "light" a couple of centuries ago. A response is here (contained within my JCS response).

Greenberg makes the same sort of point against my "dancing qualia" argument as that made by van Heuveln et al (below): i.e., because there are two "instantiations" of the system, there is no "inner eye" before which the experiences dance. My response is similar: I think the existence of a single subject is enough to make the argument go through. Greenberg responds to my discussion of this in the book by granting that the systems might have an experienced *sense* of personal identity, and will report continued personal identity, but noting that that's not enough. I agree that's not enough, but this misses the point of making the change small. Presumably the "sense" and the report will also be preserved in a 75% replacement, but actual personal identity won't be; whereas replacing a small subsystem seems enough to preserve not just sense and report but
Greenberg also objects to my talk of "tepid pink" as the consequence of "fading" red qualia, but obviously this is quite inessential to the argument. And he says the argument assumes that functionally equivalent silicon replacement of neurons is possible, but that isn't so; see my JCS response (#3.5), for more on that.

Hill notes that the arguments in my book depend on the claim that we have a priori access to logical possibility of statements according to their primary intensions, and suggests that my arguments for this claim in Chapter 2 beg the question, because they assume a priori access to the space of logically possible worlds (which Hill disputes).

I think Hill misunderstands the passages he discusses. At this point (p. 68) I have argued that the two-dimensional framework handles all the standard Kripkean a posteriori necessities, with just one space of worlds (the conceivable worlds) and two intensions. The standard examples thus give no reason to deny that conceivability of a world (as opposed to conceivable truth of a statement) implies possibility. I then stipulate that a "logically possible" world is an (ideally) conceivable world, noting that any reasons for believing in a narrower class of "metaphysically possible" worlds must be independent of the standard reasons. Given this stipulation, the claim about access to logical possibility that Hill finds question-begging is relatively trivial.

The real locus of disagreement is whether the class of metaphysically possible worlds is narrower than the class of logically possible worlds (so construed). This issue is discussed in the section on "strong metaphysical necessity" in Chapter 4; the passages Hill discusses in Chapter 2 are irrelevant. For more clarification of the structure of my argument here, see "Materialism and the Metaphysics of Modality", section 3.1.

This interesting paper argues that there is a cognitive explanation for our conceivability intuitions about consciousness (in terms of different modes of access to physical and phenomenal states), so that these conceivability intuitions don't imply anything about metaphysical possibility or about ontology. I address this matter in section 3.4 of "Materialism and the Metaphysics of Modality", in which I respond to a related paper by Hill and McLaughlin.

Ismael argues that phenomenal properties are ostensively identified properties of physical space,
Responses to articles on my work

used to "interpret the map" associated with physical theories. The epistemic gap between physical and phenomenal in effect stems from the gap between knowing the objective "co-ordinates" of the property and knowing that the property is the ostended one (analogous to the gap between knowing the co-ordinates of a location and know that that location is here).

The philosophy of science here is very interesting, but all the argumentive work against me is done by the analogy with indexicals such as "I" and "here". I discuss this analogy in the book, but it's a popular strategy (e.g. it plays a role in John Perry's recent work), so it may be useful to say more here. I think the analogy can't work, for a number of reasons. First, indexical information "disappears" from the third-person point of view: an objectively omniscient third party has no significant epistemic ignorance regarding any indexical facts about another. But phenomenal information does not: a physically omniscient third party may be epistemically ignorant of phenomenal facts about another. So phenomenal information is "objective" in a way that indexicals are not. This can also be brought out by the fact that the identity between indexically identified states and phenomenal states is cognitively significant, as discussed in "The Content and Epistemology of Phenomenal Belief".

Indexical ignorance always stems from ignorance of "locating information" concerning the identification of certain objective parts of the map with "I" and "here" and "this". (We can think of this information as coming in the forms of "arrows" pointing to certain qualitative parts of the map, giving information about the "center" of a centered world.) Once an agent has all the qualitative information and all the locating information, they're in a position to know everything. But we can give Mary, or any third party, all the locating information we like about their own location in the world -- even information about the phenomenal states they ostend, if you like (though there are tricky issues here) -- and they'll still be ignorant about phenomenal states of others (what it's like to see red, what it's like to be a bat). So locating information cannot cross the relevant epistemic gap.

Ismael handles the zombie scenario by noting that imagining C-fiber firings (etc) that no-one is conscious of is just like imagining bits of space that are not "here" for anybody. But I think this point backfires: the space scenario (unlike the zombie scenario) involves a change in objective physical matters. Given all the physical information, one will know whether or not the bit of space is "here" for anyone (modulo worries about consciousness); but one will not analogously know whether the physical states are "conscious" for anyone. As before, there's no epistemic gap for facts about the objectified "x is at P" relation, but there is for the objectified "x is conscious of Q" relation.

This article mostly argues that the water-H2O relation (and such) should be seen as constitution rather than identity. An appendix applies the discussion to issues about the explanatory gap raised by Frank Jackson and me. He argues that when things are put in terms of constitution rather than
identity, the problems fall away. For example, the identity of pain with C-fibers doesn't follow *a priori* from a story about C-fibers playing a relevant causal role, but the constitution of pain by C-fibers does.

In response: first, identity plays no special role in my arguments. All that matters is that the macro facts are entailed by the micro facts. In fact I'm happier with talk of constitution than with talk about identity here. Johnston thinks the arguments don't go through when constitution is invoked, as he claims that "if C-fibers explain the causal powers of pain, then C-fibers constitute pain" is *a priori*. Response: whether or not this is *a priori*, it is not the relevant conditional for reductive explanation. What matters is entailment of the pain facts by the physical facts. Johnston's conditional can't ground such an entailment, as it builds claims about "pain" into the antecedent. For it to do the job, we would have to replace "the causal powers of pain" by a list of specific, neutrally characterized causal powers (e.g., being caused by tissue damage, causing avoidance behavior, etc.). But then the modified conditional clearly will not be *a priori*, as it's epistemically possible that any such list be satisfied without pain. In the cases of "water" and such, by contrast, it's much more plausible that there is such a list that makes the analogous conditional *a priori*. Johnston says that derivability may fail even in other cases (slipperiness, redness, wetness), as we can't derive facts about appearance *a priori*. I agree with this, but think that this failure is a consequence of the underderivability of facts about consciousness. As I say in the book, those facts are still derivable "modulo consciousness".

Kirk is a onetime zombiephile turned zombiephobe. He argues that (1) on the zombiephile view, we are compounds of a physical zombie and nonphysical qualia, (2) a zombie can't detect nonphysical qualia, and qualia can't detect nonphysical qualia, (3) their compound (i.e. us) can't detect nonphysical qualia, either, so (4) the zombiephile view has the absurd consequence that we can't detect qualia.

I could take issue with (1), but I think the deepest problems are with the second conjunct of (2) and with (3). I think there's a case to be made that our phenomenology alone implies knowledge of qualia; e.g. a disembodied being with exactly my phenomenology would know it had qualia. If so, the second conjunct of (2) is in effect false. The problem is that Kirk assumes a "thin" notion of the phenomenal on which it implies nothing cognitive; I am increasingly inclined to think this is wrong. Further, the step from (2) to (3) is invalid: it's simply false that if neither A nor B can know that P, then a compound of A and B cannot know that P (e.g., on a physicalist view, split the brain in two jagged halves). So even if a zombiephile accepts (2), they might reject (3), presumably by holding that phenomenal knowledge is supported by some combination of a physical and a phenomenal state (e.g. by a physical judgment in combination with acquaintance with a quale, as I suggest in the book). So the argument can't do the work it needs to do.
Latham gives a number of arguments against my view that consciousness supervenes naturally but not logically on physics. His first main argument is that the view requires an extraordinarily large number of new psychophysical laws, at least one for every basic sensory quality, and possibly more. I think this is thinking about the laws the wrong way. Rather than a swarm of separate laws, one could (for example) imagine a relatively simple transformation operator from physical space to phenomenal space. These spaces may be high-dimensional, and the collection of the projections onto individual dimensions (which seems to be what Latham is looking at) may be quite complex, but this is consistent with the overall mapping being very simple; witness simple mappings between infinite-dimensional spaces in mathematics. It may also be that the dimensionality of phenomenal space can be reduced considerably by constructing it from a few protophenomenal properties. (Here Latham responds that we don't know what these properties are; but of course this is not to say they don't exist.)

Latham also considers cases such as pleasure/pain inversions (keeping physical facts constant), and related cases where experience become "inappropriately" matched with functional role. Latham argues that if these case were logically possible (as they are on my view), then we could not rule out the epistemic possibility that they are actual and that we are ourselves inverted in this way. After all, what could our certainty that we are not so inverted be grounded in? It could not be grounded in our acquaintance with the experiences, as this acquaintance is also present in the inversion cases, and it couldn't be in our beliefs, for the same reason.

In response: it's not obvious to me that the notion of "appropriateness" is entirely clear and absolute (as opposed to a product of familiar association), and it's also not obvious that we are certain we are in an "appropriate matching" state. (I'm certain when I am in pleasure, but I am not certain about functional roles in my brain and behavior.) But even conceding those points, I don't see that the logical possibility of inversion rules out my knowledge that I am not inverted. It is plausible, for example, that the justification of our beliefs about experiences lies not just in the experiences, and not just in the beliefs, but in the relations between the beliefs and the experiences. Those relations are not present in the inversion cases, and so the knowledge may be present in our cases even though it is not present in those. It's an interesting issue to investigate further, though.

Latham also adapts my own "dancing qualia" arguments to suggest that these are not just naturally but logically impossible. He thinks we can be certain our experience hasn't changed radically in the very recent past (whereas we couldn't be certain if dancing qualia were logically possible); I think we can't be certain of this any more than we can be certain that the world wasn't created in the very recent past. Latham suggests that although he can't rule out zombie worlds by this sort of strategy, the strong logical constraints (of functioning on phenomenology) he has established give indirect evidence for logical determination. I think this is a nice strategy, but that all the
arguments for logical constraints go wrong.

Although a review, I mention this here because it is substantial and because it makes a point related to Melnyk's point below. Levine also challenges my arguments on the grounds that primary intensions need not be a priori accessible. He has two arguments for this: (1) infants and animals may have concepts without having any sort of access to their primary intensions; (2) certain contemporary theories of content (e.g. nomic covariation theories) suggest that concept's application-conditions may be not be cognitively accessible in this way, because they have "nonascriptive" modes of presentation.

In response: (1) the infant/animal case isn't a counterexample to the a priori accessibility claim, any more than the fact that animals can't do mathematics shows that mathematics isn't a priori. Cases turning on cognitive limitations are never counterexamples to a claim of a priori knowability. (2) I think this is a better argument against those theories of content than it is against the accessibility claim. Levine suggests that the application-conditions of "water" and "chair" may be inaccessible in this way, but he does not address the obvious point (made in the book) that given qualitative knowledge of the external world, we are in a position to know what "water" and "chair" refer to. I take it that this is a datum that any theory must either take into account or else provide substantial arguments against; I have seen no such arguments in the literature on these theories. So it seems to me that the accessibility claim is not threatened. At best, Levine needs to take the "consciousness" concept as a special case.

I also think that even if Levine is right about inaccessibility, this is not enough to threaten the anti-materialist argument. This sort of inaccessibility would not deliver "strong necessities" (which are what the materialist needs), but at best "inscrutable truths". See Does Conceivability Entail Possibility for the distinction.

Lewis makes a few criticisms of the view set out in my "hard problem" paper, arguing that the problem is still harder than I say, mostly because I don't take adequate account of the ineffability of consciousness. He doesn't like my listing "awareness" and "reportability" among the easy problems, for reasons bound up with this; I clarify my usage here in my JCS response (#3.1). There are a few places where he seems to misplace my view, but I've clarified those things elsewhere. Lewis's central point is that the ineffability of experience precludes a theory bridging processing to experience, but this is far from clear to me, and he gives little explicit argument for this conclusion. It may be that we can develop some sort of phenomenological formalism (geometric, informationa, mathematical, linguistic?) within which experiences can be described and taxonomized. We already know we can do this for some aspects of experience (the more
obvious structural aspects), and I think it is an open question how far we can take it. Certainly this is an area that needs to be investigated carefully in coming years.

*Andrew Melnyk. Chalmers' argument for dualism about phenomenal properties. (APA presentation.)*

Melnyk argues against the move from conceivability to possibility. In particular he argues that the conceivability of P does not entail the existence of a possible world on which P's primary intension is true. He does this by arguing that the primary intension of a concept need not be known a priori by a user of that concept. He points to concepts such as "water" to suggest that I can have these concepts without knowing their (primary) application-conditions.

I agree that one can have a concept without "knowing" its primary intension in the sense of being able to articulate explicit conditions characterizing it. But this is a much stronger claim than I need. All I need is the claim that a primary intension is accessible, i.e. that I have a priori access to the relevant function from worlds to referents, i.e. that given a specification of a world, I am in a position to determine the referent. This is a much weaker claim, both because it doesn't require explicit definition, and more importantly because a priori knowability is much weaker than automatic knowledge (a lot of a priori truths are highly nontrivial). It seems to be a fact about us that given knowledge of the actual world, we're in a position to assess reference and truth-value (see pp. 57-60 of the book); this suggests that the conditional from world to reference/truth-value is knowable, prior to knowledge of how the external world actually turns out. And nothing in Melnyk's discussion suggests otherwise. At least, it is the a priori accessibility claim that Melnyk needs to challenge. (I believe Melnyk is revising the paper to take this sort of point into account.)

Perry discusses my work at a number of places in this book. I have written a response (destined for a symposium in Philosophy and Phenomenological Research): "Insentience, Indexicality, and Intensions".

I reply to the main argument in this paper at the end of "Does Conceivability Entail Possibility?".

This discusses two-dimensional semantics as a way to analyze Kripkean a posteriori necessity. Stalnaker defends his own "metasemantic" account and argues against the sort of "semantic"
account given by me and others. I think the metasemantic account is pretty clearly unsatisfactory, as it can't capture the distinction between a priori and a posteriori necessities. His objections to the semantic account are brief and inconclusive, but he appears to commit his opponent to a version on which primary intensions are evaluated by finding the extension of a token with the same meaning as the original token, placed in the new context. I think that's the wrong way to do things: see the discussion of "epistemic" and "contextual" interpretations of 2-D semantics in "The Foundations of Two-Dimensional Semantics".

Thomas argues that the concept of a zombie is incoherent, by appealing to the fact that zombies will claim to be "conscious". He considers the possibility that we might interpret this claim as true, false, or meaningless, and argues that trouble threatens each way.

I discuss this sort of thing at length in Chapter 5 of my book, where I argue that the zombie's claim is best taken to be false (though I have occasional sympathy with the "meaningless" option), e.g. because the zombie's "consciousness" concept is empty, a bit like "phlogiston". So the zombie is mistaken. In response, Thomas notes that the zombie's claim is formed by the same "cognitive process" as an ordinary conscious being's claim, so if the zombie is mistaken, this cognitive process is unreliable, throwing strong doubt on our own claims that we are conscious. This line of reasoning was anticipated in the book, where I suggest that the justification for my belief that I am conscious lies not just in my cognitive mechanisms but also in my direct evidence; the zombie lacks that evidence, so his mistake does not threaten the grounds for our beliefs. (One can also note that the zombie doesn't have the same beliefs as us, because of the role that experience plays in constituting the contents of those beliefs.) Thomas's discussion, although it raises some intriguing issues, never addresses this natural line of defense.

This paper tries to escape the dancing qualia argument by on the grounds that the argument assumes that one system is present throughout, but it may be the case that on switching subsystems two different systems come into and out of existence. So really two distinct 'phenomenal worlds' are present, and it's not surprising that no change is noticed.

What really matters here is whether two distinct *individuals* (i.e. subjects) are involved. If two distinct individuals are involved, the argument won't go through. I tried to handle this point in the book by making the changed area small enough (less than 10 percent of the brain) that it was plausible that the same individual was present throughout. It seems unlikely to that replacing some small part of the visual cortex (say) will be enough to change my identity. If one thinks 10 percent is too much, we can even make the replacement 5 percent or less, without too much cost.
The authors don't really address this point. I think they hold that the mere presence of two physically distinct subsystems is enough to make their point, but I don't see this. If we grant that all this involves changes in *my* consciousness, as seems plausible, I think the argument goes through.

The purported "equivocation" is one between 'change in experience" and "experience a change". They argue that although the experiences changes, no single individual experiences a change. I do require that a single individual experiences a change, at least in the sense that the experiences that change are those of an individual, although not in the sense that the individual notices the change, which obviously can't happen in this set-up. The point of the small replacement is precisely to make it plausible that this happens.

This paper is a critique of two-dimensional semantics and my use of it in establishing a link between apriority and possibility. It's a rich paper with a number of different arguments. I reply to most of them in "Does Conceivability Entail Possibility?", which is forthcoming in the same volume. Note that my responses are interspersed with the main text, at three different locations in the article: here, here, and here. The second of these also serves as a response to Yablo's "Modal Rationalism and Logical Empiricism: Some Similarities", and the third serves as a response to his "Grokking Pain". See also our earlier exchange in *Philosophy and Phenomenological Research*, referenced above.

THE TYRANNY OF THE SUBJUNCTIVE

David Chalmers
Idaho, March 24, 2000

(1) A CONTRAST BETWEEN INDICATIVE AND SUBJUNCTIVE CONDITIONALS

(1a) If Prince Albert Victor killed those people, he is Jack the Ripper (and Jack the Ripper killed those people).

(1b) If Prince Albert Victor had killed those people, Jack the Ripper wouldn't have (and Prince Albert wouldn't have been Jack the Ripper).

(2a) If XYZ is the liquid in the oceans and lakes, water is XYZ (etc).

(2b) If XYZ were the liquid in the oceans and lakes, water wouldn't be in the oceans and lakes (etc).

The above all seem to be intuitively correct, even though (1a) and (2a) have "metaphysically impossible" consequents.

What's the relevant difference? Indicatives take the antecedent as a hypothesis about the actual world, whereas subjunctives take it as a description of a way the world might have been but actually isn't (Fowler: "it belongs to utopia"). That is, indicatives consider the antecedent as actual; subjunctives consider it as counterfactual.

In terms of the 2-D semantic framework: evaluation of indicatives tracks the primary intensions of the expressions involved, whereas evaluation of subjunctives tracks their secondary intensions. "Metaphysical necessity" reflects secondary intensions, not primary intensions.

(2) THE ANALYSIS OF NECESSITY AND POSSIBILITY

S is necessary <-> S is true in all possible worlds.
S is possible  <-> S is true in some possible world.

QUESTION: How to evaluate "S is true in W"?

SUBJUNCTIVE READING: "S is true in W" iff

If W were the case, S would be the case.

INDICATIVE READING: "S is true in W" iff

If W is the case, S is the case.

The first tracks familiar "subjunctive" (utopian) evaluation of possibilities. The second tracks "indicative" (epistemic) evaluation of possibilities. (Is the epistemic possibility that W is actual an instance of the epistemic possibility that P?)

There are two resulting sorts of "necessity": subjunctive necessity and indicative (epistemic) necessity. And two sorts of "possibility", etc.

Plausibly: S is subjunctively necessary if S's secondary intension is true in all possible worlds. S is indicatively necessary if S's primary intension is true in all (centered) possible worlds.
Primary intension: is S true of W considered as actual?
(evaluated in the way in which we evaluate epistemic possibilities)

Secondary intension: is S true of W considered as counterfactual?
(evaluated as we evaluate explicitly counterfactual possibilities)

e.g. S = "water is H2O". W = the Twin Earth world (with XYZ).

(3a) If W is the case, water is not H2O (it's XYZ).
(3b) If W were the case, water would still be H2O (and XYZ merely watery).

This mirrors the fact that the secondary intension of S is true in W,
but the primary intension of S is false in W. So "water is H2O" is
not indicatively (epistemically) necessary, although it may be
subjunctive necessary.

(3) THE SYMMETRY THESIS

In contemporary philosophy (post-Kripke), "necessity" (simpliciter) is
always read as subjunctive necessity, and "P is true in W" is always
evaluated by the subjunctive reading.

In fact: subjunctive conditionals *ground* the contemporary evaluation
of statements in worlds, and the consequent analysis of necessity.
Kripke's arguments in _Naming and Necessity_ are always ultimately
grounded in intuitions about subjunctives.

QUESTIONS: Why is this? Arbitrary? Argued or stipulated? Is indicative
necessity an equally good candidate for "necessity"?

SYMMETRY THESIS: Indicative necessity is as good a candidate for
"necessity" as subjunctive necessity. And epistemic evaluation is
just as reasonable a reading of "P is true in W" as subjunctive
evaluation.

If the symmetry thesis holds, it should be just as reasonable to say that:

"Hesperus is visible in the evening (if it exists)" is necessary;
"water is H2O" is contingent;
"I am here now (if I exist)" is necessary;
"the meter stick in Paris is one meter long (if it exists)" is necessary;
the necessity of identity doesn't hold;

and

In the XYZ-world, water is XYZ;
It's not necessary that I am David Chalmers;
In some possible worlds, Cicero is not Tully;
etc.

(4) SIX POSSIBLE REASONS FOR FAVORING THE SUBJUNCTIVE

(a) Indicative necessity is "merely epistemic".

[Answer: So? Before 1970, almost everyone thought necessity was tied
to the epistemic (cf. Pap's book). Kripke *argued* that necessity
and epistemic notions came apart, by appeal to the subjunctive, but
one can't simply presuppose it.]

(b) S is necessary <-> S "could not have been otherwise" -- subjunctive!

[Answer: (i) "Could not have been otherwise" is ambiguous between epistemic/subjunctive readings. (ii) This reading doesn't seem to have been in wide currency pre-1970.]

(c) Indicative necessity requires centered worlds.

[Answer: Possible worlds are a technical device, and there doesn't seem to be anything in the notion of necessity itself to bar an indexical element.]

(d) Subjunctive necessity supports quantified modal logic, whereas indicative necessity doesn't.

[Answer: True enough. But whether necessity allows quantifying in was a live issue -- it can't be a prior constraint on necessity that it does! (Though one can see why Kripke would be attracted to a notion of necessity that does.) At best a split verdict: Quine right about indicative necessity, Kripke about subjunctive necessity. cf. Burgess.]

(e) The relevant indicative conditionals aren't true/false, just assertible, due to epistemic relativity. (e.g. Sly Pete)

[Answer: This epistemic relativity doesn't affect epistemic evaluation of statements in worlds. At most it affects the move from incomplete antecedents to relevant worlds.

N.B. Possible-worlds analysis of indicative conditionals:

"If P, then Q" is correct/true/assertible <->

The epistemically closest P-world(s) is a Q-world

(where here a P-world is a world satisfying the primary intension of P).]

(f) Some indicative "necessities" will vary in truth-value between users, as primary intensions of some terms (e.g. names) can vary between users.

[Answer: True, but the same is the case for subjunctive necessities, e.g. "I am DC", as secondary intensions of some terms (e.g. indexicals) vary between users. At worst, bring in a sentence-meaning/utterance-content distinction.]

(5) THE TYRANNY OF THE SUBJUNCTIVE

Necessity plays a central role in almost every area of philosophy. So the analysis of necessity affects almost every area of philosophy. Kripke's analysis has been central in supporting essentialism in metaphysics, direct reference views in the philosophy of language, externalism in the philosophy of mind, and so on. Has led to a lot of interesting remaking of philosophical views, with "marvelous internal coherence". But.

Imagine an alternative universe in which Kripke* used indicative conditionals instead. His book Naming and Contingency_ might have

* defended a strong link between the a priori and the necessary (plausibly S is a priori iff it is indicatively necessary)

* have argued against the necessity of identity and de re necessities (identities aren't indicatively necessary, and indicatives don't allow substitution or quantifying in, so de re necessities don't make sense [except for numbers?]).
* have argued for a Fregean view of meaning and content
  (since primary intensions can plausibly play the role of sense --
  they both determine reference and reflect cognitive significance).

Imagine that the ensuing philosophical analysis of necessity had been as
biased toward indicative necessity as recent philosophy has been toward
subjunctive necessity. The resulting dominant views in various areas of
philosophy might have been very different:

* philosophy of language: Fregean views, not direct reference.
* philosophy of mind: internalism, not externalism
* metaphysics: nominalism, not essentialism; etc.

Neither our world nor W* is the right outcome. The best outcome, given the
symmetry thesis, is one in which the notion of "necessity" is recognized as
ambiguous. Kripke** (importantly) recognizes the modality of subjunctive
necessity and its distinctive properties. This leads the pretheoretical
notion of "necessity" to split into two varieties, along with two

* Metaphysics: A split verdict about essentialism, with Quine right
about indicative necessity but essentialists right about subjunctive
necessity. But "subjunctive essentialism" is a significant sort of
essentialism (it's significant that there are ways an entity could
not have been) -- so the door is reopened to essentialism in philosophy.

* Philosophy of mind, epistemology: Here it's plausible that the central
role of modality by far (at least where belief content is concerned) is
epistemic -- e.g. considerations of rational inference, cognitive
significance, and so on. And that the most relevant application
conditions of concepts to worlds are epistemic, not subjunctive. So
the intensional analysis of mental content ends up internalist. (There
are still issues about externalist belief attribution to handle, but
they can be handled straightforwardly.) As a bonus, we have a notion
of belief content that is much more useful in epistemology.

* Philosophy of language: A split verdict? Expressions have complex
semantic value, with something like a primary intension (more or
less Fregean) and a secondary intension (more or less referential,
for some terms). The latter are needed to analyze subjunctive
conditionals and maybe belief attributions (though: scope analysis?).
The former are needed to analyze indicative conditionals, belief
attributions, etc; and to analyze the rational connections among
statements, and to analyze the connection between language and thought.
The modality inherent in Frege's notion of sense is arguably epistemic
(sense determines the epistemic application-conditions of a concept),
so Fregean sense is vindicated as above (modulo the introduction of an
indexical element and the occasional variation of sense between tokens).
Is there synonymy in Ockham's mental language?

[[Published in The Cambridge Companion to Ockham, edited by Paul Vincent Spade. Cambridge University Press, 1999.]]

1 Introduction

William of Ockham's semantic theory was founded on the idea that thought takes place in a language not unlike the languages in which spoken and written communication occur. This mental language was held to have a number of features in common with everyday languages. For example, mental language has simple terms, not unlike words, out of which complex expressions can be constructed. As with words, each of these terms has some meaning, or signification; in fact Ockham held that the signification of everyday words derives precisely from the signification of mental terms. Furthermore, the meaning of a mental expression depends directly on the meaning of its constituent terms, as is the case with expressions in more familiar languages.

As one might expect, there are important differences between mental language and everyday languages. For example, mental languages signify their objects naturally rather than conventionally. At a more concrete level, Ockham suggested that numerous features of spoken or written language - participles and pronouns, for example - might not exist in mental language.

Two ubiquitous features of everyday languages are the phenomena of equivocation and synonymy. The first of these is exemplified in English words such as `bank', which have two entirely different meanings. The second is exemplified by pairs of terms such as `bachelor' and `unmarried man', which share a common meaning. The question arises: are these features are also found in mental language? It seems to be commonly accepted that they are not. Ockham himself is not entirely clear on the matter, but Trentman and Spade have argued, based on both textual and theoretical considerations, that the most coherent position broadly compatible with Ockham's work is that neither synonymy or equivocation may occur in mental language.[1] I shall not discuss the status of equivocation in this paper, as I find the arguments on that topic persuasive. However, I wish to argue that the case against synonymy is not as strong.

My argument for synonymy is largely theoretical, although it also has a textual element. The theoretical
Is there synonymy in Ockham's mental language?

The case has a positive and a negative part. On the positive side, I will argue that there are a number of reasons why mental synonymy might exist, and that a mental language without synonymy would be relatively clumsy, with a number of ad hoc features. On the negative side, I will address various arguments that have been put forward against the possibility of synonymy, and will try to show that they are not conclusive. Textually, I will argue that although Ockham appears to deny the possibility of synonymy in mental language, he also makes remarks that commit him to that possibility. I do not think that my arguments are entirely conclusive, but I hope to demonstrate that the possibility of mental synonymy is not as implausible as has sometimes been thought.

2 Positive Arguments

2.1 Logical Equivalence

The first argument is based on the observation that once certain logical primitives are admitted into a language, then it seems to follow immediately that certain complex expressions are synonymous. Consider, for example, the English expressions `man and (cat or dog)' and `(man and cat) or (man and dog)'. The parentheses are introduced for clarity, but they are not strictly necessary, being straightforwardly replaceable by longer locutions (for instance, `a man with either a cat or a dog' and `either a man with a cat or a man with a dog'). Call the two expressions E1 and E2. It seems apparent that E1 and E2 are synonymous. It is a straightforward logical inference to go from a sentence involving E1 to the corresponding sentence involving E2, and vice versa. It is plain that the two expressions come to exactly the same thing in the matter of signification.

As it is with written language, so it should be with mental language, at least in this case. Mental language presumably has among its simple terms such logical operators as `and' and `or'; if it does not have these, then it presumably possesses others with equivalent power, on the basis of which a similar case could be made. There is no doubt that simple expressions such as `dog' and `cat' exist in mental language (if not these, then any simple nouns will do). And there seems to be no reason why these expressions and logical operators should not be combined to form complex expressions. So mental language contains the expressions `man and (dog or cat)' and `(man and dog) or (man and cat)', or other expressions that make the same point. These expressions, it seems, must be synonymous, for just the reasons given above. Therefore there is synonymy in mental language.

There are two paths that an opponent of mental synonymy might take in countering this argument. She could argue that the two expressions are not in fact synonymous, or she could argue that the two expressions are in fact identical in mental language, so that no synonymy between different expressions need be introduced. I will consider these objections in turn.

2.1.1 The First Strategy

In the Summa logicae,[2] Ockham says that for two terms to be synonymous, they must signify exactly
the same things, and they must signify these *in the same way*. An opponent of mental synonymy might argue that although the two expressions given above signify the same things, they signify them in different ways, and so are not synonymous.

It is not entirely clear what Ockham meant by `to signify in the same way'. Spade argues that two mental expressions signify in the same way if and only if they are syntactically equivalent - that is, if and only if the consist of exactly the same categorematic expressions in exactly the same syntactic constructions.[3] If this were the case, then our two given expressions would certainly not be synonymous. However, it seems to me that this construal of synonymy buys the conclusion entirely too cheaply, by defining mental synonymy out of existence, and I will argue against it below. For now, let us consider a weaker construal of `in the same way'. This construal captures our intuition that what is required of synonymy is not just that two terms signify the same things, but that they *must* signify the same things. To be more precise, under this construal of synonymy, two terms are synonymous if their equivalence is *a priori* and necessary.

This yields a strong criterion for synonymy. The coextensive pair of terms "renate" and "cordate" fail the test, for example, as they are not necessarily coextensive. The coextensive pair of terms "Hesperus" and "Phosphorus" fail the test, as they are not *a priori* coextensive. It is difficult to know whether this criterion corresponds to Ockham's intentions, but it seems to capture a large part of our intuitions behind what is meant by `synonymy, and in particular to capture the extra strength carried by synonymy compared to mere coextensiveness. And the logically equivalent pair of terms given above clearly satisfy this criterion.

(One might also invoke a criterion according to which synonymous terms are those that are substitutable *salva veritate* even in modal contexts. I do not use this criterion here, as it yields counterintuitive results when combined with the contemporary understanding of necessity: for example, "Hesperus" and "Phosphorus" come out synonymous. But on the medieval understanding of necessity, this criterion may yield the same results as the criterion given above, and less anachronistically.)

An opponent might try to argue that this criterion is not strong enough: although the logically equivalent pair of terms satisfies the criterion, the terms nevertheless signify in subtly different ways. For example, our opponent might argue that the two terms are not intersubstitutable in certain epistemic contexts, and are therefore not synonymous. For example, it might be the case that John believes that to gain admission to the party, one must be accompanied by a man with either a dog or a cat; but John does not believe that to gain admission to the party, one must be accompanied by either a man with a dog or a man with a cat. The reason for this, presumably, would be that John is not very capable at logic, and so has not made the straightforward inference. Now, we might respond to this by arguing that in fact, if John has the first belief, he has the second belief whether he knows it or not. He believes it implicitly, one might say. But for the sake of argument let us accept that John has the first belief but not the second. If this is so, then it is apparent that in this epistemic context, the two terms are not intersubstitutable.

It seems to me, however, that intersubstitutability in such epistemic contexts is too strong a condition to
require for synonymy. If we admit this as a criterion, it would seem to follow that there are no synonyms at all. For given any pair of purported synonyms - e.g., `bachelor' and `unmarried man' - we can construct examples like those given above. For example, John might believe that all bachelors are invited for dinner, but might not believe that all unmarried men are invited for dinner - presumably because he is once again too muddled to make the required inference. (Again one might argue that if John has the first belief, he has the second whether he knows it or not. But as we disallowed this line of reasoning for the sake of argument in the paragraph above, we must equally disallow it here.) This conclusion shows that the suggested criterion is too strong. In fact, it seems that even Ockham himself would reject intersubstitutability in epistemic contexts as a criterion for synonymy, as the following passage demonstrates:

Those synonyms are broadly so called even though not all users believe them to signify the same [thing] but rather, under a deception, they judge something to be signified by the one that is not signified by the other.

It follows that this argument provides no reason to reject the synonymy of E1 and E2, or at least no more reason than there is for rejecting the synonymy of such terms as `bachelor' and `unmarried man'. Logical synonymy seems to be at least as strong as common-or-garden conceptual synonymy, so that if we want to retain the notion of synonymy at all, we had best admit the possibility of logical synonymy, at least in written language.

Once we have accepted the possibility that the two written expressions E1 and E2 are synonymous, then it follows that either (a) they are subordinated to synonymous mental expressions, thus establishing my case, or (b) they are subordinated to identical mental expressions, thus saving the same for the opponent of mental synonymy. I will consider possibility (b) next.

2.1.2 The Second Strategy

An opponent's second strategy is to argue that only one expression in mental language is involved here: the two mental expressions that we are labeling `man and (cat or dog)' and `(man and cat) or (man and dog)' are in fact the same expression. It might be claimed that the fact that they look like different expressions is an artifact of English, not mental language: the different written expressions E1 and E2 are in fact subordinated to the same mental expression. To get an idea of how this argument might run, consider a simpler pair of expressions: `man and dog' and `dog and man'. For reasons similar to those given above, these expressions seem to be synonymous. But an opponent of synonymy could very plausibly argue that these are not different expressions in mental language at all, as the only difference between them is one of word order - a feature that need not be preserved in mental language. For example, it could well be argued that the term `and' in mental language is not interpolated sequentially between two terms in a particular order, but rather is bound to them both in some symmetrical fashion, such as a tree structure, or perhaps as a common ending (something like `man-and dog-and', where we take it that the two words are unordered). On this plausible account, the difference in the two expressions `man and dog' and `dog and man' would not persist into mental language.
Is there synonymy in Ockham's mental language?

It is difficult to see, however, how we could apply an argument like this to more complex cases, such as our `man and (dog or cat)' vs. `(man and dog) or (man and cat)'. These two expressions are not just superficially different; they are structurally different. One of them is a conjunction; the other is a disjunction. However we represent `and' and `or' in mental language, they will need to be put together hierarchically on occasion, and it seems clear that the differences in their hierarchical order must be represented in mental language.

One way out for our opponent might be to argue that logical expressions in mental language must be reduced to some common form such as disjunctive normal form. It would then be the case that any two logically equivalent terms or propositions would be represented identically. The trouble with this is that is an ad hoc restriction that places limits on how mental terms may be combined. On the face of it, would take it that if `man', `dog', `cat', `and' and `or' are admissible mental terms, then `man and (dog or cat)' would be an admissible expression in mental language; but according to the present proposal this expression would somehow be debarred from being formed, for no apparent reason other than to preserve a theoretical claim. Indeed, to place such a restriction on combination of terms would seem to reduce mental language's claim to being a language in the first place, one of the key properties of language being that complex expressions can be generated recursively and compositionally, whereas according to this proposal, while `man' and `dog or cat' would be valid mental expressions, `man and (dog or cat)', their conjunction, would not be. This seems arbitrary and implausible.

It seems much more plausible for mental language to consist of a set of simple terms that can be combined and recombined without any limits other than syntactic requirements. In particular, logical operators ought to be able to combine nominal terms in any combination. But once we admit this, no matter what set of logical operators we choose, logically equivalent but non-identical expressions will be able to be formed. We might be able to get around certain superficial differences in structure, such as that in the `man and dog' case, by proposing certain symmetries in our operators, but there will always be propositions with different structures that turn out to be logically identical. One can see this easily by noting, for example, that while there are only four logically distinct truth-functional combinations of two propositions, any compositional system will yield an infinite number of syntactically distinct complex sentences formed by combining these propositions under truth-functional operators. Logical equivalence is thus endemic in any combinatorial system.

The conclusion is that given that logical equivalence implies synonymy, it follows that synonymy will be ubiquitous in mental language, unless we put ad hoc restrictions on the manner of combination of mental terms.

Before passing to the next topic, I should respond to a natural response, based on textual considerations, that may have occurred to the reader. This response notes that according to Ockham, synonymous written expressions are subordinated to the same mental expression,[8] so that no matter what I say above, the expressions E1 and E2 must be subordinated to a single expression in mental language. My response to this objection is of course to point out that the arguments I am giving for the existence of synonymy in mental language are equally arguments for the rejection of the claim that synonymous written

http://www.u.arizona.edu/~chalmers/papers/ockham.html (5 of 18) [4/7/2002 1:44:12 PM]
Is there synonymy in Ockham's mental language?

expressions are subordinated to the same mental expression. If there is synonymy in mental language, a
more plausible criterion is that synonymous written expressions must be subordinated to synonymous
mental expressions. Of course, this means that I am going against an explicit claim of Ockham's; but I
am giving a theoretical argument, after all. I will address this issue further below.

2.2 Conceptual Change

I now pass to a quite different line of argument in favor of mental synonymy. This argument stems from
the observation that many terms in everyday languages, and presumably in mental language, undergo
gradual changes in meaning. Many current terms do not mean exactly what they meant fifty years ago.
Even within a single individual, the meaning of a term can gradually shift over time. Sometimes it may
even occur that two terms that originally had quite different meanings gradually drift until the mean
the same thing. Perhaps, for instance, when one was a child one used the term `stone' only for small objects,
and used the term `rock' for large ones, but over time one's use of the term has drifted until now they are
used in exactly the same way, so that the terms are synonymous. Nothing in my argument turns on the
specific example - all that is required for the argument is the possibility of this kind of graduate drift into
synonymy taking place, and this seems indisputable.

So let us say that Y and Z are two terms that start out with different meaning, but which through a
continuous process over time come to mean the same thing. This might even occur without the individual
within whom it is happening being conscious of the drift to synonymy. He might realize at some later
point that `stone' and `rock' are synonymous for him, whereas they were not twenty years ago, and the
drift might have occurred without his realizing it at the time. Ockham himself endorses the possibility
that synonymy might go unrecognized, in the passage quoted above.

Now as these terms gradually drift toward synonymy, what is happening in the mental language?
Presumably Y and Z are subordinated to mental terms Y' and Z', and Y' and Z' are also undergoing a
slow drift in meaning. Now what happens on the day when Y and Z finally become synonymous? Do the
terms Y' and Z' suddenly become the same term? Does one of them suddenly disappear, so that for
example Y and Z are now both subordinated to Y', and Z' is gone? Neither of these possibilities are
strikingly plausible. The process of change is sufficiently slow that is hard to imagine that any sudden
change could be taking place in mental language. In practice, it will be very hard to locate a precisely
moment at which Y and Z become synonymous; there may be a long period of approximate synonymy
before we can say with confidence that they are definitely synonymous. Are we to suggest that the
mental language has hair-trigger sensitivity to the process, so that at the exact moment when the
meanings come to coincide, a jump suddenly occurs?

It seems at least as plausible to argue that as the drift takes place, the two mental terms remain distinct,
gradually becoming synonymous but nevertheless oblivious, at least for a while, to each other's presence.
It may well be for a long period that the subject does not make the expected inferences from propositions
involving Y to those involving Z, because the subject does not consciously realize that the two concepts
have become synonymous for him. If the corresponding mental concepts had become identical, this
Is there synonymy in Ockham's mental language?

inferential gap would be harder to explain. After a time, the subject may consciously realize that the concepts are synonymous, and perhaps the mental terms will then be "fused" into one, but until then there seems no reason in principle why the terms should not be distinct.

The other possibility to be considered is that as Y and Z drift in meaning, they are subordinated to a series of different terms in mental language, Y'1, Y'2, ... and Z'1, Z'2, ... Upon every change in the meaning of Y, no matter how small, Y becomes subordinated to a new Y' in the mental language. Over time, the corresponding Y' terms gradually become more like the Z' terms, until finally the become identical. This account has the virtue of avoiding the sudden change required by the previous story, but it still seems problematic. For a start, it seems to be very extravagant with terms in mental language, postulating a large number of different terms where we previously needed only two. Further, it does not solve the problem mentioned above, of the possible inferential gap in the subject's abilities - one would think that if the corresponding concepts have become identical, any inferences from one to the other would be automatic. This seems in turn to imply that two terms cannot become synonymous without a subject recognizing that fact, which appears to contradict Ockham's own claim quoted above.

On the balance of things it seems to me that conceptual change provides a strong argument but not a knockdown argument for mental synonymy. The opposing story just given seems feasible enough that it could be the case, although it does raise a serious question about compatibility with Ockham's own views on the recognition of synonymy, an issue I discuss further below. However, the story that I sketched of gradual drift into synonymy without identity seems equally if not more plausible, giving more reason why mental synonymy is not an altogether unreasonable idea.

2.3 Efficiency

My final argument in favor of mental synonymy is a pragmatic one. Ockham, in his writings, give very little idea about how mental language functions - how it enables one to make inferences from one proposition to another, for instance, or how mental propositions help determine the actions we take toward the world. We can imagine, however, that this functioning does not come for free, but rather takes some work. Evidence for this can be seen in the fact that we find it harder to make inferences from complex propositions than from simple propositions. The more complex a proposition, it seems, the harder it is for our mental system to deal with. Therefore one might draw the conclusion that in order for our mental system to function as well as it can, mental propositions should be as simple as possible (as long as they are complex enough to express the required meaning).

Now in mental language, presumably, there are certain complex expressions that get used repeatedly.[9] In the interests of efficient functioning of the mental system, it might seem to be advantageous for it to introduce interval abbreviations for these complex expressions. Instead of having to deal with expressions like `man who cuts cloth and makes suits', the system would only have to deal with the simple expression `tailor' instead. We certainly find this kind of abbreviation useful in our external practice; I am here suggesting that it might have a role in internal functioning as well. If, as we have supposed, complex expressions are more difficult for the mind to deal with, then the systematic
replacement of these by simple expressions might allow a significant enhancement to our cognitive capacities.

Of course, there would have to be systematic links between a term and its abbreviation, so that thoughts about 'tailor' could easily lead back to conclusions about suits and cloth when necessary. But inferences involving tailors would in general be much easier to make in the above form. The only downside is that we would have introduced synonymy into mental language, but it seems to me that in this context this is only advantageous. A typical argument against mental synonymy has the form "Who needs it?" - in other words, what is the point of mental synonymy if synonyms are truth-conditionally equivalent and so have the same expressive power? Any distinction between synonyms would be a difference that makes no expressive difference, and so would be unnecessary in mental language. Here, we have seen that pragmatic considerations show that there might be relevant differences that are not expressive differences. Rather, they are differences that aid mental function.

This is obviously not a knock-down argument. For a start, it may be anachronistic in focusing on the way that mental propositions are processed, a way of thinking that was not so common in Ockham's time. Nevertheless, all that is required to see the point is that complex mental propositions might be more cumbersome to deal with than simple ones, and this does not seem to be a particularly advanced consideration. Of course, the argument is only a plausibility argument demonstrating why mental synonymy might be a reasonable thing, and as such is a weaker argument than two arguments given above, but nevertheless it helps in breaking down the intuition that mental synonymy would be an entirely useless thing.

3 Textual Considerations

I now consider some textual issues. In particular, I must confront what seems to be the strongest argument against synonymy in Ockham's mental language: the fact that on at least on occasion, Ockham appears to deny that mental synonymy exists. This occurs in his Quodlibet V.812:

To the principal argument, I say that everything that is an accident of a mental term is an accident of a spoken term, but not the other way around. For some [things] are accidents of spoken terms because of the necessity of signification and expression, and they belong to mental names. Others are accidents of spoken terms for the sake of the decoration of speech (like synonyms) and for the sake of well-formedness, and they do not belong to mental terms.

Now, it is not entirely clear that this is a blanket denial of the possibility of mental synonymy. It might alternatively be interpreted as a denial that synonymy in spoken language is reflected in mental synonymy, leaving open the possibility of mental synonymy that arises in other ways. Or it might be interpreted as the denial that certain synonyms in spoken language - those that exist merely for the sake of decoration - are reflected in mental synonyms, leaving open the possibility that other (nondecorative) spoken synonyms correspond to mental synonyms. Furthermore, even if we accept this as a denial of the
possibility of mental synonymy, it seems to be the only occurrence of such a denial in Ockham's writing, so that even Spade (who argues against synonymy in mental language) concedes that the textual support is not as strong as it could be.13

In any case, my central purpose is to make a theoretical argument about what Ockham should have held, rather than about what he in fact did hold. In other words, insofar as Ockham can be seen to have denied the possibility of mental synonymy, this paper should perhaps be taken more as a criticism of Ockham than as an interpretation. Of course this is a somewhat delicate matter, as if one jettisons too much of Ockham's theory one runs the risk of not so much criticizing him as ignoring him. Nevertheless, I believe that the position I am putting forward is compatible with Ockham's overall thrust, and only requires the rejection of one or two specific claims. And I argue below that Ockham's claims on this matter appear to be inconsistent, so that any interpretation must reject some of them. So this interpretation may not be worse off than any other.

The other specific claim of Ockham that causes problems for mental synonymy is his statement on a number of occasions that synonyms in spoken or written language are subordinated to identical terms in mental language. As Spade points out,[14] it does not necessarily follow from this that mental synonyms cannot exist; all that follows is that if they do exist, they do not have associated synonyms in spoken or written language. However, this seems too weak a ground to base a defense of mental synonymy on. For a start, if our mental synonyms had any written or spoken terms subordinated to them, these terms would be synonyms, in violation of Ockham's claim; and on the face of it it seems reasonable that any given mental term should at least possibly have an associated written or spoken term. If we were to retain Ockham's claim and to argue for mental synonymy, we would be committed to the existence of mental terms that could not have associated spoken or written terms, and while this is not impossible it at least seems ad hoc and unmotivated. Furthermore, my best evidence for the existence of mental synonymy[15] came precisely from the consideration of synonymous spoken or written expressions that I argued had to be subordinated to different mental expressions.

For these reasons, it is best for the defender of mental synonymy to argue that Ockham's claim should be jettisoned along with his denial (insofar as it is a denial) of mental synonymy. The correct criterion for synonymy of spoken or written terms is that they should be subordinated to synonymous mental terms, rather than to identical mental terms. This jettisoning of Ockham's claim may reduce this account's chances of being an interpretation of Ockham, but I believe that it does not reduce its overall plausibility.

I now come to the internal tension within Ockham's text. This casts further doubt on the subordination of synonymous terms to identical mental terms, and indeed suggests that Ockham may be committed to the possibility of mental synonymy, despite what appear to be claims to the contrary. In a passage quoted earlier, Ockham says:[16]

Those synonyms are broadly so called ... even though not all users believe them to signify the same [thing] but rather, under a deception, they judge something to be signified by the one that is not signified by the other.
Is there synonymy in Ockham's mental language?

Ockham goes on to point out that this is the sense of synonymy with which he is dealing for most of his text. According to this passage, then, it is possible that a user can judge that `That object is an X' is true, and at the same time judge that `That object is a Y' is false, even thought the terms X and Y are synonymous. But this implies that X and Y cannot be subordinated to the same term of mental language! For if X and Y were subordinated to the same mental term, then all mental judgments about X's and Y's would coincide. The two propositions `That object is an X' and `That object is a Y' would be subordinated to identical propositions in mental language, and it is impossible that one could be judged to be true and the other simultaneously be judged to be false. Therefore this passage seems to contradict his claim that synonymous terms are subordinated to identical mental terms.

In fact, if we accept the above passage at face value, it is hard not to draw the conclusion that the terms X and Y must be subordinated to different but synonymous mental terms (as it is surely impossible that synonymous spoken or written terms are subordinated to nonsynonymous mental terms), which would directly establish that synonymy exists in mental language.

It is difficult to say how we should deal with this contradiction, or how Ockham would have dealt with it, had it been pointed out to him. He might have chosen to retract the claim made in the passage above; the opposing claim that synonymous terms are subordinated to identical mental terms is certainly made more often. On the other hand, he might have seen the possibility of unrecognized synonymy in spoken or written language as providing grounds to reject the claim about subordination of synonymous terms. In any case, the internal tension revealed here further weakens the plausibility of the claim that synonymous terms are subordinated to identical mental expressions, and indicates that the claim might be rejected without doing too much violence to the rest of Ockham's system.

Furthermore, insofar as Ockham's own claims are inconsistent, it follows that any consistent interpretation must reject one or more of these claims. So Ockham's apparent denials of mental synonymy do not provide any overwhelming reason to reject the view I have offered in favor of any other consistent interpretation. This opens the way to accepting the possibility of synonymy in Ockham's mental language.

4 Other Negative Arguments

The central negative argument against the possibility of mental synonymy is the textual argument I have just discussed. Three other negative arguments deserve consideration, however. These are (1) the argument by analogy with Ockham's treatment of grammatical features; (2) Spade's argument that signification "in the same way" requires syntactic identity in mental propositions; and (3) the argument from the fact that concepts bear a "natural likeness" to their objects.

4.1 The Analogy With Grammatical Features

A significant argument against the existence of mental synonymy derives from Ockham's criterion for
determining which grammatical features do and do not persist into mental language. As Spade puts it[17]:

... grammatical features of spoken or written language that do not serve the "needs of signification" by affecting truth conditions are not present in mental grammar. That this rules out all synonymy in mental language seems to be the clear intention of Ockham's whole discussion in Quodlibet 5, q. 8, with its repeated statement that what is in mental language is there only because of the "needs of signification", not for the sake of "decoration" or "well-formedness", and that synonymy does not serve the "needs of signification".

For example, such grammatical features as gender of nouns and the difference conjugations of verbs do not persist into mental language, as they are irrelevant to signification - that is, they have no effect on truth conditions. Such features would be unnecessary in mental language. If they existed there, they would have the status of mere ornaments. It seems plausible that the differences between any synonymous expressions in written language would be equally unnecessary in mental language. Such differences would therefore not persist into mental language, implying that that mental language has no synonymy.

As an initial reply, one might point out that it is not unreasonable to suppose that there could be other relevant needs besides the "needs of signification." For example, I argued above that synonymous mental expressions might sometimes serve the needs if efficiency in mental language, by providing a simpler expression for complex thoughts. This would seem to be a more relevant reason for the presence of synonyms than mere "decoration." Grammatical features such as gender and different conjugations, of course, would not serve even this purpose (in fact they would achieve the opposite, by making mental expressions more complex than necessary), and so would not make it into mental language, but there are conceivably other instances of synonymy that would qualify.

As perhaps a more compelling reply, one might argue that certain instances of synonymy in mental language are not there because they serve any particular needs, but rather because they must exist as a byproduct of other properties of mental language. Logical synonymy would be one example of this. If we assume that mental language has a need for certain primitive logical operators, and for the ability to combine any expressions according to these operators, then as we saw above we are forced to the conclusion that some complex expressions must be synonymous. This fact in itself does not serve any particularly useful purpose for mental language; rather, it is a consequence of other facts about mental language.

This leads us to another line of reply to the argument above. We might argue that Ockham's criterion should apply to the determination of those grammatical features that persist into the *lexicon* - that is, the set of simple terms - of mental language, but that once we have determined the simple terms, then complex expressions should be derived directly from these according to combinatorial principles, just as English sentences are derived from words according to such principles. So although no two lexical items
Is there synonymy in Ockham's mental language?

in mental language might be synonymous, it could nevertheless be the case that certain complex expressions could be synonymous. To stipulate that two apparently quite different but synonymous complex expressions should in fact be identical in mental language would require ad hoc tinkering with the structure of mental language, as we saw above. By contrast, the elimination of irrelevant grammatical features from simple terms in mental language is not ad hoc at all, precisely because it can be achieved by a correct specification of the elements of mental language at the basic level.

Of course, if we accept this argument against lexical synonymy, it would follow that the argument from conceptual change, above, might have to be rejected. Although I am less convinced by the conceptual change argument than by the logical equivalence argument, I should nevertheless point out that a similar defense of it could be mounted. As with logical synonymy, the synonymy of two mental concepts that have drifted together is not in mental language to serve any need. Rather, it is there as a simple byproduct of the process of conceptual change, and of the way that conceptual change works. And the distinction between two synonymous terms might not be immediately eliminated from mental language, as irrelevant grammatical features are, because the synonymy might not be immediately apparent. If two independent concepts have by coincidence drifted together, there might be no obvious marker of their synonymy, so we might expect it to take a while before mental language became sensitive to the fact of their common meaning. The existence of synonymous mental terms would not serve any purpose in mental language, and we could expect that the terms might be merged at some future time, for instance when the subject becomes aware of their synonymy. Until that time, however, the synonymous terms might both exist, with their coexistence being a byproduct of the terms' divergent histories.

4.2 Signification "in the same way"

As we saw earlier, Ockham's criterion for the synonymy of two terms is that they not only signify the same things, but they signify those things in the same way. It is not clear what Ockham meant by signification "in the same way," but Spade has presented a construal of this phrase that, if correct, would immediately destroy any possibility of synonymy in mental language.[18] It is therefore vital that we come to grips with this interpretation of Ockham's criterion.

Spade's suggestion is that a "way" of signifying should be interpreted syntactically[19]:

A mental expression or concept signifies a thing x in a given syntactic mode m if and only if x is signified by some constituent non-complex categorematic term occurring within that mental expression in the grammatical or syntactical construction m.

If this is the case, then any two synonymous expressions must be made up of identical simple categorematic concepts, in identical syntactic constructions. In other words, they must be identical. It follows that there can be no synonymy in mental language.

The ease with which this argument buys its conclusion is suspicious. It seems to define mental synonymy out of existence; but we have already seen plenty of cases where the idea of mental synonymy at least
Is there synonymy in Ockham's mental language? It seems coherent. It may be for a variety of reasons that there turns out to be no synonymy in mental language, but this does not seem on the face of it to be an analytic truth. The case discussed earlier - that of synonymous, logically equivalent but distinct propositions - seems at least to be a possible example, even if certain facts about the way mental language functions might indicate that it is not actual. Therefore on the face of it it would seen unlikely that mental synonymy can be debarred definitionally.

Spade's argument for this definition is not entirely clear to me. He argues that a "way of signifying" should not be construed as one of Ockham's four "modes" of signification in S. log. I.33.20. He then leaps from this claim to the claim that a "way" should be construed purely syntactically, but the grounds for this transition are not obvious. The closest thing I can find to an argument for this conclusion is the following (in the context of a discussion of why 'blind' and 'sight' are not synonymous, despite both signifying sight)[21]:

Now, in the case of a nominal definition, or indeed of complex expressions generally, it is relatively clear what it might mean to signify a thing x "negatively". It could mean that the expression as a whole signifies x in virtue of some constituent non-complex categorematic term which signifies x and which occurs within the scope of a negation- sign in that expression. This is, in part at least, a syntactic criterion.

But it does not seem to me that "negative" signification must be construed purely syntactically. It does not seem unlikely that a semantic characterization could be arrived at. For instance, there might be a characterization that exploited the fact that although 'blind' and 'sight' signify the same things, expressions in which they are embedded have opposite truth-values (for instance, 'James is blind' is true precisely when 'James is sighted' is not true). This might well be more along the lines of what "signifying in the same way" comes to. Indeed, it is interesting to note that on the later "adverbial" theory of signification (used by Peter of Ailly, among others[22]), the same locution - that is, the locution of signify "in a given manner" - is used for that part of signification (of a proposition, in this case) from which truth-values derive. Perhaps this is not entirely coincidental. If we are to speculate, it does not seem unlikely that Ockham might have had a similar semantic criterion in mind, although it is quite possible that he never formalized the criterion, leaving it at the level of intuition.

Furthermore, even if we accept Spade's argument in the quoted passage, it seems to fall short of establishing that signification "in a given way" is a purely syntactic notion. All that is established is that "negative" signification - just a small aspect of what counts in determining a "way" of signifying - might have a criterion that is at least partly syntactic. This seems too weak to establish the broad conclusion suggested by Spade when he states,[23]: "The considerations of section VII, above, suggest that ... the `ways' at stake here are ... syntactic modes of signification."

It seems to me that there is something wrong with the idea that there are syntactic criteria for a notion such as synonymy, which is a deeply semantic notion. It is more plausible that synonymy ought to be characterized purely semantically, in terms of the relationship between elements of language and their actual or possible referents. Looking at Ockham's criterion for synonymy, it seems to me that this is what
Is there synonymy in Ockham's mental language?

he may have been doing, although he left the crucial strengthening clause ("signify in the same way") somewhat vague. Nevertheless it seems intuitively plausible that there is an extra semantic criterion required of synonymous terms, over and mere coincidence of signification. This can be captured by the modern idea that this coextensiveness is necessary and a priori. Ockham may not have thought about the issue in explicitly this way, but the intuitive notion is clear enough. I would therefore suggest that this is what Ockham's strengthening clause in the criterion for synonymy should come to.

It seems to me that if we accept the claim that there is no synonymy in mental language, then Spade's syntactic construal of the strengthening criterion will be correct in practice - but this will be precisely because synonymy does not exist, so that a syntactic check will be sufficient to check for identity of meaning. It seems to me further that there are no compelling grounds, other than the nonexistence of synonymy, for supposing the syntactic construal to be correct. If so, then it follows that the syntactic construal cannot be used to provide support for the nonexistence of synonymy.

A further argument in favor of a semantic construal of the strengthening criterion is that it satisfies our intuition that mental expressions corresponding to `man and (dog or cat)' and `(man and dog) or (man and cat)' are synonymous whether or not they are identical. For all these reasons, I believe that the case for the syntactic construal of "ways" of signification is at best inconclusive, and does not provide compelling evidence against the possibility of synonymy in mental language.

While on this topic, I should note that a semantic criterion for synonymy would answer another argument against mental synonymy, also given by Spade[24]:

What would equivocation or synonymy in mental language amount to? Since there is no supramental language to appeal to in the way one appeals to mental language to account for synonymy and equivocation in spoken and written language, how could it even arise in mental language?

This argument seems to assume that the only real criterion for mental synonymy could be appeal to some higher language25 - that is, the criterion must be a formal criterion. It seems to ignore the possibility of a semantic criterion, in terms for instance of referents and/or truth-values. If we have a semantic criterion for synonymy, the problem posed here by Spade is no problem at all.

4.3 Natural Likenesses

The final argument rests on Ockham's contention that concepts bear natural likenesses to their objects. Spade argues that it is unlikely that two concepts could bear a natural likeness in the relevant sense to their objects, but still be more than numerically distinct.[26] If this is correct, it would follow that mental synonyms could not exist.

The reply to this argument is simply to say that it does not seem too implausible that distinct mental terms could bear natural likenesses to a common object, especially if they are complex expressions rather than simple terms. Going back to our favorite example, it seems plausible that the two concepts `man and
Is there synonymy in Ockham's mental language?

...(dog or cat)' and `(man and dog) or (man and cat)' both bear a natural likeness to their object, despite the apparent difference in the expressions. These two mental expressions seem to differ in form or structure, but they are nevertheless concepts of exactly the same things. It might be difficult to imagine how two distinct simple terms could bear the relevant likenesses simultaneously, but this difficulty vanishes in the case of complex expressions. So this does not seem to be a compelling objection to mental synonymy.

5 Simple Connotative Terms

Before concluding, I should note the possible effect of the discussion above on the question of whether there exist simple connotative terms in mental language. Spade has argued that simple connotative mental terms cannot exist, as if they did, they would be synonymous with their expanded nominal definitions[27]; but of course there is no synonymy in mental language! Panaccio has pointed out another possibility: that simple connotative terms exist, but in fact are not synonymous with their nominal definitions.[28]

The present discussion raises a third possibility: that simple connotative terms exist, and are synonymous with their nominal definitions. Spade and Panaccio reject this possibility because of the supposed impossibility of mental synonymy; but if we accept the above arguments for the possibility of mental synonymy, then this becomes a live option. Indeed, once we have gotten over the hurdle of mental synonymy, it may even fit certain textual evidence better than either of these claims, as Ockham certainly claimed that simple connotative terms exist, and there are strong reasons to believe that connotative terms are synonymous with their definitions (although Panaccio's argument may have weakened this evidence somewhat).

The discussion I have given here even provides a reason why simple connotative terms might exist: namely, to act as abbreviations for their nominal definitions, for the sake of making mental language less cumbersome. This is perhaps the reason why many connotative terms exist in everyday languages. It does not seem wholly unreasonable that they might exist in mental language for the same purpose.

Of course, I do necessarily wish to maintain that Ockham actually held this position, as the existence of mental synonymy seems to contradict textual evidence, at least as the evidence has traditionally been interpreted. Nevertheless I should point out that this instance of mental synonymy is less difficult to reconcile with textual evidence than the other instances we have looked at. This is because we can maintain the synonymy between simple connotative terms and their nominal definitions in mental language without giving up Ockham's claim that spoken or written synonyms are subordinated to identical mental expressions. Instead, we can hold that a spoken or written connotative term and its nominal definition are both subordinated to the corresponding term (the complex expression) in mental language. The simple connotative mental term is introduced entirely within the mental sphere, for the purposes of abbreviation. No spoken or written term is subordinated to it, as it is solely a construct introduced for mental efficiency, just as connotative terms in spoken or written language are frequently introduced for efficiency.
While this position may or may not be independently plausible, we should note that it seems to be at least as compatible with the textual evidence as Spade's and Panaccio's accounts. The only claim of Ockham that it might explicitly contradict is the passage from Quodlibet V.8,[29] and even that passage might be interpreted in a manner compatible with the position maintained here. In any case, whether or not this position was actually held by Ockham, it seems quite attractive as a theoretical possibility.

6 Conclusion

I have done my best to act as an advocate for the possibility that synonymy could exist in mental language. Now is the time to pass considered judgment.

First, the question: did Ockham believe there is synonymy in mental language? To this I believe the answer is probably no. For a start, he seems to deny it on one occasion. Furthermore, as we have seen, two of my arguments for synonymy have required overturning a claim that Ockham made a number of times, that is, the claim that synonyms in spoken or written language are subordinated to identical terms in mental language. On the other hand, the third argument, the argument from efficiency, is independent of this claim, as we can suppose that abbreviation of complex expressions could be entirely internal to the mental system; and this argument also gains some additional textual support from Ockham's otherwise anomalous claim that simple connotative terms exist in mental language. Still, overall, it seems most plausible to me that Ockham was at least implicitly committed to the nonexistence of mental synonyms, although we have seen that internal tensions arise in his theory due to this commitment.

Next, the question: should Ockham have believed that there is synonymy in mental language? To this, my answer is less clear. I believe that there is a very strong argument for the possibility of mental synonymy, in the argument from logical equivalence. As far as I can tell, Ockham never considered this argument. If he had, it is possible that it might have caused him at least to have some doubts about the impossibility of synonymy. Even if he had eventually come down against the possibility, he might have been required to modify his theory in some serious way, or at least to make a number of its features more explicit. As for the second and third argument, those from conceptual change and from efficiency, I believe that neither of these is conclusive, but that both provide some added plausibility for the notion of mental synonymy, by demonstrating how it might come about and even perhaps serve a useful purpose. Finally, Ockham's belief that synonymy in spoken or written language can go unrecognized seems to yield the existence of synonymous mental terms as a natural consequence. This provides further grounds for thinking that whether or not Ockham accepted synonymy, he ought to have.

Of the negative arguments (apart from the textual considerations), I believe that the argument from analogy with grammatical features has been cast into doubt, by showing how certain instances of synonymy might exist without having to serve any need, but rather because they are byproducts of other features of mental language. The argument from signifying "in the same way" seems to me to be quite inconclusive, due to the difficulty in ascertaining just what Ockham meant by his phrase. It does not seem too unlikely that he had a semantic criterion in mind, rather than a syntactic criterion. It is possible that the final argument, from natural likenesses, could be made into a strong argument against mental
Is there synonymy in Ockham's mental language?

I have been concerned to reply to the argument as it is given by Spade, but it is not impossible that stronger versions of the argument exist. Still, such arguments would have to deal with the apparent existence of complex expressions that are distinct but clearly have the same meaning. If some version of natural likeness theory had the consequence that these expressions are not synonymous, then it might not be unreasonable to suggest that that version of the theory should be thrown out, rather than the possibility of synonymy.

Overall, I must adjudicate the case "not proven," but with some strong evidence in favor of mental synonymy that must be dealt with before a retrial. Whichever way the verdict comes down, it seems to me that the possibility of mental synonymy is not as objectionable as has commonly been supposed.

Notes

0 This paper was written when I was a graduate student in Paul Spade's class on Medieval Logic at Indiana University in 1991. I owe an enormous debt to Spade for his insights and encouragement.

Moving Forward on the Problem of Consciousness

David J. Chalmers

Department of Philosophy
University of Arizona
Tucson, AZ 85721

chalmers@arizona.edu

This paper is a response to the commentaries in the Journal of Consciousness Studies on my paper "Facing Up to the Problem of Consciousness." I have written it so that it can be understood independently of the commentaries, however, and so that it provides a detailed elaboration and extension of some of the ideas in the original paper.

The 26 commentaries (with links to online versions when they exist) were by Bernard Baars, Douglas Bilodeau, Patricia Churchland, Tom Clark, C.J.S. Clarke, Francis Crick & Christof Koch, Daniel Dennett, Stuart Hameroff & Roger Penrose, Valerie Hardcastle, David Hodgson, Piet Hut & Roger Shepard, Benjamin Libet, E.J. Lowe, Bruce MacLennan, Colin McGinn, Eugene Mills, Kieron O'Hara & Tom Scutt, Mark Price, William Robinson, Gregg Rosenberg, William Seager, Jonathan Shear, Henry Stapp, Francisco Varela, Max Velmans, and Richard Warner. The complete symposium has been collected into a book, Explaining Consciousness: The Hard Problem, published by MIT Press.

CONTENTS

- Introduction
- Deflationary critiques
  - Deflationary analogies (Dennett, Churchland)
  - Is explaining the functions enough? (Dennett, Churchland)
  - Type-B materialism (Clark, Hardcastle)
  - Other deflationary approaches (McGinn, O'Hara & Scutt, Price)
- Nonreductive analyses
  - Conceptual foundations (Hodgson, Lowe, Velmans)
  - The roots of the hard problem (McGinn, Robinson, Warner)
  - Fundamental laws (Mills, Price)
  - Epiphenomenalism and interactionism (Hodgson, Seager, Stapp, Warner)
  - My psychophysical laws (Hardcastle, Libet, Lowe, Seager, Varela, Velmans)
- Positive proposals
  - Neuroscientific and cognitive approaches (Baars, Crick & Koch, MacLennan)
  - Phenomenological approaches (Shear, Varela)
  - Physics-based approaches (Bilodeau, Clarke, Hameroff & Penrose, McGinn, Stapp)
  - Fundamental psychophysical theories (Hut & Shepard, Rosenberg, Seager)
1 INTRODUCTION

I am very grateful to all the contributors to this symposium for their thoughtful comments. The various papers reflect a wide range of approaches and of views, yielding a rich snapshot of the current state of play on the problem of consciousness. There are some interesting criticisms of my point of view, which I hope to address in this reply in a way that clarifies the central issues at hand, and there are also a number of intriguing positive proposals for confronting the problem. I am honored to have provided an opportunity to bring such a thought-provoking collection of ideas together.

When I wrote my paper, I had no idea that it would be subject to such close analysis. That may be a good thing, as all the hedges, qualifications, and citations I would have added if I had known might have made the paper close to unreadable, or at any rate twice the size. But it also means that the paper - intended as a crisp presentation of some central issues, mostly for non-philosophers - skates quickly over some subtleties and has less flesh on its bones than it might. I will try to flesh out the picture in this piece, while still keeping the discussion at a non-technical level. A more detailed presentation can be found in my book *The Conscious Mind*, to which I will occasionally point in this response.

Because of the unexpected influence of the "hard problem" formulation, I have occasionally received far more credit than I deserve. So let me state the obvious: the reason the formulation has caught on is that everyone knew what the hard problem was all along. The label just makes it a little harder to avoid. Any number of thinkers in the recent and distant past - including a number of contributors to this symposium - have recognized the particular difficulties of explaining consciousness and have tried to face up to them in various ways. All my paper really contributes is a catchy name, a minor reformulation of philosophically familiar points, and a specific approach to dealing with them.

The papers in the symposium are divided fairly evenly into those that take issue with aspects of my analysis, and those that provide positive approaches of their own. I will concentrate mostly on those in the first class, though I will make a few comments on those in the second. A quick glance at the relevant papers may give the appearance of much disagreement and a sprawling landscape of mutually contradictory points of views; but I think a closer look reveals a much more coherent picture. Once a few minor misunderstandings and verbal disagreements are cleared up, and the various contributions are aligned, one is left with a small number of central "choice points" on which the central disagreements turn. I hope that my reply helps to clarify this landscape.

The reply has three main parts. In the first I consider the critiques of a generally reductive or "deflationary" orientation; in the second I consider those of a generally nonreductive orientation; and in the third I make some comments on the various positive proposals.

2 DEFLATIONARY CRITIQUES
Recall the main conceptual distinction between the easy and hard problems. The easy problems - explaining discrimination, integration, accessibility, internal monitoring, reportability, and so on - all concern the performance of various functions. For these phenomena, once we have explained how the relevant functions are performed, we have explained what needs to be explained. The hard problem, by contrast, is not a problem about how functions are performed. For any given function that we explain, it remains a nontrivial further question: why is the performance of this function associated with conscious experience? The sort of functional explanation that is suited to answering the easy problems is therefore not automatically suited to answering the hard problem.

There are two quite different ways in which a materialist might respond to this challenge. The type-A materialist denies that there is a "hard problem" distinct from the "easy" problems; the type-B materialist accepts (explicitly or implicitly) that there is a distinct problem, but argues that it can be accommodated within a materialist framework all the same. Both of these strategies are taken by contributors to this symposium. I will discuss the first strategy in the next two sections, and the second strategy after that.

2.1 Deflationary analogies

The type-A materialist, more precisely, denies that there is any phenomenon that needs explaining, over and above explaining the various functions: once we have explained how the functions are performed, we have thereby explained everything. Sometimes type-A materialism is expressed by denying that consciousness exists; more often, it is expressed by claiming that consciousness may exist, but only if the term "consciousness" is defined as something like "reportability", or some other functional capacity. Either way, it is asserted that there is no interesting fact about the mind, conceptually distinct from the functional facts, that needs to be accommodated in our theories. Once we have explained how the functions are performed, that is that.

Note that type-A materialism is not merely the view that consciousness is identical to some function, or that it plays a functional role, or that explaining the functions will help us explain consciousness. It is the much stronger view that there is not even a distinct question of consciousness: once we know about the functions that a system performs, we thereby know everything interesting there is to know. Type-A materialism subsumes philosophical positions such as eliminativism, behaviorism, analytic functionalism, and others, but it does not include positions (such as those embraced by Clark and Hardcastle) that rely on an a posteriori identity between consciousness and some physical/functional property. Positions of the latter sort accept that there is a real phenomenon to be accounted for, conceptually distinct from the performance of functions (the a posteriori identity ties together a priori distinct concepts), and therefore count as type-B materialism. Type-A materialism, by contrast, denies that there is a conceptually distinct explanatory target at all.

This is an extremely counterintuitive position. At first glance, it seems to simply deny a manifest fact about us. But it deserves to be taken seriously: after all, counterintuitive theories are not unknown in science and philosophy. On the other hand, to establish a counterintuitive position, strong arguments are needed. And to establish this position - that there is really nothing else to explain - one might think that extraordinarily strong arguments are needed. So what arguments do its proponents provide?
Moving Forward on the Problem of Consciousness

Perhaps the most common strategy for a type-A materialist is to deflate the "hard problem" by using analogies to other domains, where talk of such a problem would be misguided. Thus Dennett imagines a vitalist arguing about the hard problem of "life", or a neuroscientist arguing about the hard problem of "perception". Similarly, Paul Churchland (1996) imagines a nineteenth century philosopher worrying about the hard problem of "light", and Patricia Churchland brings up an analogy involving "heat". In all these cases, we are to suppose, someone might once have thought that more needed explaining than structure and function; but in each case, science has proved them wrong. So perhaps the argument about consciousness is no better.

This sort of argument cannot bear much weight, however. Pointing out that analogous arguments do not work in other domains is no news: the whole point of anti-reductionist arguments about consciousness is that there is a disanalogy between the problem of consciousness and problems in other domains. As for the claim that analogous arguments in such domains might once have been plausible, this strikes me as something of a convenient myth: in the other domains, it is more or less obvious that structure and function are what need explaining, at least once any experiential aspects are left aside, and one would be hard pressed to find a substantial body of people who ever argued otherwise.

When it comes to the problem of life, for example, it is just obvious that what needs explaining is structure and function: How does a living system self-organize? How does it adapt to its environment? How does it reproduce? Even the vitalists recognized this central point: their driving question was always "How could a mere physical system perform these complex functions?", not "Why are these functions accompanied by life?" It is no accident that Dennett's version of a vitalist is "imaginary". There is no distinct "hard problem" of life, and there never was one, even for vitalists.

In general, when faced with the challenge "explain X", we need to ask: what are the phenomena in the vicinity of X that need explaining, and how might we explain them? In the case of life, what cries out for explanation are such phenomena as reproduction, adaptation, metabolism, self-sustenance, and so on: all complex functions. There is not even a plausible candidate for a further sort of property of life that needs explaining (leaving aside consciousness itself), and indeed there never was. In the case of consciousness, on the other hand, the manifest phenomena that need explaining are such things as discrimination, reportability, integration (the functions), and experience. So this analogy does not even get off the ground.

Or take Churchland's example of heat. Here, what cries out for explanation are such things as: heat's abilities to expand metals, the causation of fire, heat transmission between substances, the experience of hotness. All but the last of these are clearly functions, and it is these functions that reductive explanations of heat explain. The existence of such functions is entailed by the microphysical story about heat: in any world that is physically identical to ours, such functions will automatically be present.

If someone were to claim that something were "left out" by reductive explanations of heat (as Churchland suggests they might), or of light (as Paul Churchland suggests they might), what something might they be referring to? The only phenomenon for which the suggestion would be even remotely plausible is our
subjective experience of light and of hotness. The molecular theory of heat does not explain the sensation of heat; and the electromagnetic theory of light does not explain what it is like to see. And understandably so: the physicists explaining heat and light have quite reasonably deferred the explanation of their experiential manifestations until the time when we have a reasonable theory of consciousness. One need not explain everything at once. But with consciousness itself, subjective experience is precisely what is at issue, so we cannot defer the question in the same way. Thus once again, the analogy is no help to a reductionist.

In his article "The Rediscovery of Light" (1996), Paul Churchland suggests that parallel antireductionist arguments could have been constructed for the phenomenon of "luminescence", and might have been found plausible at the time. I have my doubts about that plausibility, but in any case it is striking that his arguments about luminescence all depend on intuitions about the conscious experience of light. His hypothetical advocate of a "hard problem" about light appeals to light's "visibility" and the "visual point of view"; his advocate of a "knowledge argument" about light appeals to blind Mary who has never had the experience of seeing; and the advocate of a "zombie" argument appeals to the conceivability of a universe physically just like ours, but in which everything is dark. That the first two arguments trade on intuitions about experience is obvious; and even for the third, it is clear on a moment's reflection that the only way such a universe might make sense is as a universe in which the same electromagnetic transmission goes on, but in which no-one has the experience of seeing.

Churchland might insist that by "luminescence" he means something quite independent of experience, which physical accounts still do not explain: but then the obvious reply is that there is no good reason to believe in luminescence in the first place. Light's structural, functional, and experiential manifestations exhaust the phenomena that cry out for explanation, and the phenomena in which we have any reason to believe. By contrast, conscious experience presents itself as a phenomenon to be explained, and cannot be eliminated in the same way.

A similar critique applies to such examples such as Dennett's "cuteness" (what needs explaining is the structure and functioning of cute people, and our experience and judgment of them as cute), his "perception" (the functioning of perceptual systems plus the experience of perception), and so on. In all such cases, either the analogous arguments are not even prima facie plausible (as in the case of life), or at best, they gain their plausibility through pointing to experiential properties that reductive accounts omit (as in the cases of perception and light). So they can do no work at all in arguing for reductionism about experience.

Indeed, similar remarks can be made about any phenomenon that we observe in the external world. When we observe external objects, we observe their structure and function; that's all. Such observations give no reason to postulate any new class of properties, except insofar as they explain structure and function; so there can be no analog of a "hard problem" here. Even if further properties of these objects existed, we could have no access to them, as our external access is physically mediated: such properties would lie on the other side of an unbridgeable epistemic divide. Consciousness uniquely escapes these arguments by lying at the center of our epistemic universe, rather than at a distance. In this case alone, we can have access to something other than structure and function.
2.2 Is explaining the functions enough?

So, analogies don't help. To have any chance of making the case, a type-A materialist needs to argue that for consciousness, as for life, the functions are all that need explaining. Perhaps some strong, subtle, and substantive argument can be given, establishing that once we have explained the functions, we have automatically explained everything. If a sound argument could be given for this surprising conclusion, it would provide as valid a resolution of the hard problem as any.

Is there any compelling, non-question-begging argument for this conclusion? The key word, of course, is "non-question-begging". Often, a proponent will simply assert that functions are all that need explaining, or will argue in a way that subtly assumes this position at some point. But that is clearly unsatisfactory. Prima facie, there is very good reason to believe that the phenomena a theory of consciousness must account for include not just discrimination, integration, report, and such functions, but also experience, and prima facie, there is good reason to believe that the question of explaining experience is distinct from the questions about explaining the various functions. Such prima facie intuitions can be overturned, but to do so requires very solid and substantial argument. Otherwise, the problem is being "resolved" simply by placing one's head in the sand.

Upon examining the materialist papers in this symposium, such arguments are surprisingly hard to find. Indeed, despite their use of various analogies, very few of the contributors seem willing to come right out and say that in the case of consciousness, the functions are all that need explaining. Only Dennett embraces this position explicitly, and even he does not spend much time arguing for it. But he does spend about a paragraph making the case: presumably this paragraph bears the weight of his piece, once the trimmings are stripped away. So it is this paragraph that we should examine.

Dennett's argument here, interestingly enough, is an appeal to phenomenology. He examines his own phenomenology, and tells us that he finds nothing other than functions that need explaining. The manifest phenomena that need explaining are his reactions and his abilities; nothing else even presents itself as needing to be explained.

This is daringly close to a simple denial - one is tempted to agree that it might be a good account of Dennett's phenomenology - and it raises immediate questions. For a start, it is far from obvious that even all the items on Dennett's list - "feelings of foreboding", "fantasies", "delight and dismay" - are purely functional matters. To assert without argument that all that needs to be explained about such things are the associated functions seems to beg the crucial question at issue. And if we leave these controversial cases aside, Dennett's list seems to be a systematically incomplete list of what needs to be explained in explaining consciousness. One's "ability to be moved to tears" and "blithe disregard of perceptual details" are striking phenomena, but they are far from the most obvious phenomena that I (at least) find when I introspect. Much more obvious are the experience of emotion and the phenomenal visual field themselves; and nothing Dennett says gives us reason to believe that these do not need to be explained, or that explaining the associated functions will explain them.
What might be going on here? Perhaps the key lies in what Dennett has elsewhere described as the foundation of his philosophy: "third-person absolutism". If one takes the third-person perspective on oneself -- viewing oneself from the outside, so to speak - these reactions and abilities are no doubt the main focus of what one sees. But the hard problem is about explaining the view from the first-person perspective. So to shift perspectives like this - even to shift to a third-person perspective on one's first-person perspective, which is one of Dennett's favorite moves - is again to assume that what needs explaining are such functional matters as reactions and reports, and so is again to argue in a circle.

Dennett suggests "subtract the functions and nothing is left". Again, I can see no reason to accept this, but in any case the argument seems to have the wrong form. An analogy suggested by Gregg Rosenberg is useful here. Color has properties of hue, saturation, and brightness. It is plausible that if one "subtracts" hue from a color, nothing phenomenologically significant is left, but this certainly doesn't imply that color is nothing but hue. So even if Dennett could argue that function was somehow required for experience (in the same way that hue is required for color), this would fall a long way short of showing that function is all that has to be explained.

A slight flavor of non-circular argument is hinted at by Dennett's suggestion: "I wouldn't know what I was thinking about if I couldn't identify them by their functional differentia". This tantalizing sentence suggests various reconstructions, but all the reconstructions that I can find fall short of making the case. If the idea is that functional role is essential to the (subpersonal) process of identification, this falls short of establishing that functioning is essential to the experiences themselves, let alone that functioning is all there is to the experiences. If the idea is rather than function is all we have access to at the personal level, this seems false, and seems to beg the question against the intuitive view that we have knowledge of intrinsic features of experience. But if Dennett can elaborate this into a substantial argument, that would be a very useful service.

In his paper, Dennett challenges me to provide "independent" evidence (presumably behavioral or functional evidence) for the "postulation" of experience. But this is to miss the point: conscious experience is not "postulated" to explain other phenomena in turn; rather, it is a phenomenon to be explained in its own right. And if it turns out that it cannot be explained in terms of more basic entities, then it must be taken as irreducible, just as happens with such categories as space and time. Again, Dennett's "challenge" presupposes that the only explananda that count are functions.[*]

[*][Tangentially: I would be interested to see Dennett's version of the "independent" evidence that leads physicists to "introduce" the fundamental categories of space and time. It seems to me that the relevant evidence is spatiotemporal through and through, just as the evidence for experience is experiential through and through.]]

Dennett might respond that I, equally, do not give arguments for the position that something more than functions needs to be explained. And there would be some justice here: while I do argue at length for my conclusions, all these arguments take the existence of consciousness for granted, where the relevant concept of consciousness is explicitly distinguished from functional concepts such as discrimination, integration, reaction, and report. Dennett presumably disputes this starting point: he thinks that the only sense in which people are conscious is a sense in which consciousness is defined as reportability, as a
But let us be clear on the dialectic. It is *prima facie* obvious to most people that there is a further phenomenon here: in informal surveys, the large majority of respondents (even at Tufts!) indicate that they think something more than functions needs explaining. Dennett himself - faced with the results of such a survey, perhaps intending to deflate it - has accepted that there is at least a *prima facie* case that something more than functions need to be explained; and he has often stated how "radical" and "counterintuitive" his position is. So it is clear that the default assumption is that there is a further problem of explanation; to establish otherwise requires significant and substantial argument.

I would welcome such arguments, in the ongoing attempt to clarify the lay of the land. The challenge for those such as Dennett is to make the nature of these arguments truly clear. I do not think it a worthless project - the hard problem is so hard that we should welcome all attempts at a resolution - but it is clear that anyone trying to make such an argument is facing an uphill battle.[*]

[*][[[One might look to Dennett's book *Consciousness Explained* for non-circular arguments, but even here such arguments for the relevant conclusion are hard to find. The plausible attacks on a "place in a brain where it all comes together" do nothing to remove the hard problem. The book's reliance on "heterophenomenology" (verbal reports) as the central source of data occasionally slips into an unargued assumption that such reports are all that need explaining, especially in the discussion of "real seeming", which in effect assumes that the only "seemings" that need explaining are dispositions to react and report. I think there may be a substantial argument implicit in the "Orwell/Stalin" discussion - essentially taking materialism as a premise and arguing that if materialism is true then the functional facts exhaust all the facts - but even this is equivalent to "if something more than functions needs explaining, then materialism cannot explain it", and I would not disagree. At best, Dennett's arguments rule out a middle-ground "Cartesian materialism"; the hard problem remains as hard as ever.]]]

In Churchland's paper, this sort of argument is even harder to find. Indeed, it is not always clear who Churchland is arguing with: she does not address the central arguments in the keynote paper at any point, and she often seems to be arguing with someone with views quite different from mine. Her arguments have premises that are consistently more plausible than Dennett's, but they do not come close to establishing the relevant conclusion. I include Churchland as a type-A materialist as she suggests that there is no principled difference between the "hard" and "easy" problems, but her position is sufficiently inexplicit that it is hard to know for sure.

Churchland asks for a systematic difference between the "easy" and "hard" problems, not mentioning the detailed analysis of this difference in my paper. The difference is, of course, that the easy problems are all clearly problems of explaining how functions are performed, and the hard problem is not. Perhaps Churchland, like Dennett, would deny this; unlike Dennett, however, she never addresses the question directly. If she truly holds that the functions (discrimination, integration, access, control, report, ...) are all that we need to account for, then clearly some explicit argument is required. If she does not, then the relevant distinction is present right there.

Churchland notes correctly that phenomena such as attention have an experiential component. I am not sure how this is meant to deflate the problem of experience. Vision has an experiential component, too;
Moving Forward on the Problem of Consciousness

that's the "hard" part. We can give neural or cognitive accounts of the functions associated with these phenomena, but it remains unclear why the experiential aspect should accompany those functions. This isn't to deny that it does accompany them. There are deep and intimate links between the "hard" and "easy" phenomena, of which I note some in my paper, and more in my book. So when Churchland criticizes somebody's proposal for ruling out such links, it is not my proposal she is addressing.

Perhaps the problem is that Churchland sets up the "easy"/"hard" distinction as the distinction between the problems of (e.g.) attention, learning, and short-term memory on one hand, and the problem of consciousness on the other. This is not quite my way of doing things: I set up the distinction as that between explaining how functions are performed and explaining subjective experience. It is plausible that the notions of "memory", "attention", and perhaps even "consciousness" subsume elements both of functioning and of subjective experience, as Churchland in effect points out - so there are "easy" and "hard" aspects of memory, attention, and consciousness. To keep things clear, it is best to set up the distinction directly.

Churchland is also right to note that it is not always obvious just where experience is present and where it is not, especially in fringe cases. But it is a philosophical truism that we should not let the existence of fringe cases blind us to the facts about clear cases. One goal of a theory of experience will be to clarify the status of those fringe cases; in the meantime, in cases where experience is clearly present, it is as hard to explain as ever.

And Churchland is also quite right that there is much about the "easy" problems that we do not understand. "Easy" is of course a term of art, and nothing substantial in my arguments rests on it. Churchland's point would be a relevant rebuttal to an argument that rested on it, or to an argument from ignorance, but my argument is nothing of the sort. Facts of the form "we don't know" or "I can't imagine" play no explicit or implicit role in my arguments. Rather, the key is the conceptual point: the problem of consciousness is not a problem about how functions are performed. No matter how much we find out about the mechanisms that perform these functions, the basic explanatory point is unaffected.

Contrast Churchland's case of sensorimotor integration. It's true that we do not know much about the mechanisms here. But we do know what we need to do to explain sensorimotor integration: we need to explain how information from different sensory areas is brought together and put to use in the control of action. This is a problem about how functions are performed: it is guaranteed that once we find the mechanism that performs the function and explain how it works, we will have explained sensorimotor integration. But for consciousness, this guarantee fails: it is not just functions that need to be explained. So the research program that promises so much on the easy problems needs to be augmented where the hard problem is concerned.

So Churchland either needs to argue that functions are all that need to be explained, or she needs to face up to the disanalogy and the explanatory problem directly. Homilies about the progress of science do not carry much weight in this context. We have seen that "normal" (function-explaining) science in the neuroscientific mode has limitations that have to be confronted, not ignored; and if one relies instead on a gesture in the direction of a major conceptual revolution sometime in the future, then one is in effect
conceding that the hard problem is very hard indeed.

Proponents of the "no problem" view sometimes like to suggest that their view is supported by the results of modern science, but all the science that I know is quite neutral here: I have never seen any experimental result that implies that functions are all that need to be explained. Rather, this view seems to be rooted in a *philosophical* claim. This claim does not seem to be supported either by empirical evidence or by non-circular argument; at the end of the day, it may be that the position is grounded instead in some sort of unargued axiom, such as Dennett's third-person absolutism. And to anyone who is impressed by the first-person phenomenology of consciousness, such an axiom will always beg the crucial questions. The position reduces to an unargued denial.

This is not to say that type-A materialism cannot be argued for at all. There are a few sophisticated arguments for such a position in the literature (for example, Shoemaker 1975 and White 1986), but even these ultimately come down to "consider the alternatives", isolating the difficulties that one gets into if one accepts that there is a further phenomenon that needs explaining. There is no doubt that these difficulties (both ontological and epistemological) are considerable; life would be a lot easier if the hard problem did not exist. But I think these difficulties are solvable; and in any case, to deny the problem because of the difficulties has the flavor of solution by decree. So while I think such arguments need to be taken very seriously, they do little to actually remove the problem. To truly make the problem go away, one needs *positive* and *non-circular* arguments for the counterintuitive conclusion that the functions are all that need explaining; and such arguments are very hard to find.

Of course, type-A materialism is unlikely to disappear any time soon, and we will probably just have to get used to the fact that there is a basic division in the field: that between those who think the "easy" problems are the only problems, and those who think that subjective experience needs to be explained as well. We can therefore expect two quite distinct sorts of theories of consciousness: those which explain the functions and then say "that's all", and those which take on an extra burden. In the end, the most progress will probably come from internal advances in the respective research programs, rather from the endless battle between the two. So beyond a certain point in the argument, theorists in these camps might just agree to disagree and get on with their respective projects. This way, everyone can move forward.

### 2.3 Type-B materialism

Type-A materialism offers a clean and consistent way to be a materialist, but the cost is that it seems not to take consciousness seriously. Type-B materialism tries to get the best of both worlds. The type-B materialist accepts that there is a phenomenon that needs to be accounted for, conceptually distinct from the performance of functions, but holds that the phenomenon can still be explained within a materialist framework. This is surely the most attractive position at a first glance. It promises to avoid the extremes of both hard-line reductionism and property dualism, which respectively threaten to deny the phenomenon and to radically expand our ontology.

I was attracted to type-B materialism for many years myself, until I came to the conclusion that it simply
cannot work. The basic reason for this is simple. Physical theories are ultimately specified in terms of structure and dynamics: they are cast in terms of basic physical structures, and principles specifying how these structures change over time. Structure and dynamics at a low level can combine in all sort of interesting ways to explain the structure and function of high-level systems; but still, structure and function only ever adds up to more structure and function. In most domains, this is quite enough, as we have seen, as structure and function are all that need to be explained. But when it comes to consciousness, something other than structure and function needs to be accounted for. To get there, an explanation needs a further ingredient.

The type-A materialist gets around this problem by asserting that for consciousness, too, structure and function are all that need to be explained. But this route is not open to the type-B materialist. Given that we have accepted that something more than structure and function needs to be accounted for, we are forced to the conclusion that the "further question" will arise for any account of physical processing: why is this structure and function accompanied by conscious experience? To answer this question, we need to supplement our story about structure and function with something else; and in doing so we move beyond truly reductive explanation.

So while many people think they can reject a Dennett-style "no problem" view and still expect a purely physical explanation of consciousness one day, this view seems untenable for systematic reasons. An account of physical processing may provide the bulk of a theory of human consciousness; but whatever account of processing we give, the vital step - the step where we move from facts about structure and function to facts about experience - will always be an extra step, requiring some substantial principle to bridge the gap. To justify this step, we need a new component in our theories.

There is one route to type-B materialism that one might think remains open; this is the route taken by Clark and Hardcastle. These two are clearly realists about phenomenal consciousness, and they are equally clearly materialists. They reconcile the two by embracing an empirical identity between conscious experiences and physical processes. Although consciousness is not equivalent a priori to a structural or functional property (as type-A materialists might suggest), the two are nevertheless identical a posteriori. We establish this identity through a series of correlations: once we find that consciousness and certain physical processes are correlated, the best hypothesis is that the two are identical. And this postulated identity bridges the explanatory gap.

This is a popular approach, but it has a number of problems. The problems are all rooted in the same place: it makes the identity an explanatorily primitive fact about the world. That is, the fact that certain physical/functional states are conscious states is taken as a brute fact about nature, not itself to be further explained. But the only such explanatorily primitive relationships found elsewhere in nature are fundamental laws; indeed, one might argue that this bruteness is precisely the mark of a fundamental law. In postulating an explanatorily primitive "identity", one is trying to get something for nothing: all of the explanatory work of a fundamental law, at none of the ontological cost. We should be suspicious of such free lunches; and indeed, I think there is something deeply wrong with the idea.

To evaluate the truth of materialism, what matters is whether all facts follow from the physical facts. As I
argue at length in my book, in *most* domains it seems that they certainly do. The low-level facts about physical entities determine the facts about physical structure and function at all levels with conceptual necessity, which is enough to determine the facts about chemistry, about biology, and so on. The facts about genes "fall out" of the facts about the structure and function of DNA, for example. A geneticist does not need a primitive Genetic Identity Hypothesis to cross the divide - "what do you know, whenever there is some unit that encodes and transmits hereditary characteristics, there is a gene!". Rather, to encode and transmit such characteristics is roughly all it *means* to be a gene; so there is an *a priori* implication from the facts about the structure and functioning of DNA in a reproductive context to the facts about genes. Even Mary in her black-and-white room could figure out the facts about genes, in principle, if she was equipped with the facts about DNA and the concepts involved.

But the facts about consciousness do not just fall out of the facts about the structure and functioning of neural processes, at least once type-A materialism is rejected. As usual, there is a further question -- "why are these processes accompanied by consciousness?" - and merely repeating the story about the physical processes does not provide an answer. If we have rejected type-A materialism, there can be no conceptual implication from one to the other.

Clark and Hardcastle's answer is to *augment* one's account of physical processes with an "identity hypothesis" (Clark) or an "identity statement" (Hardcastle), asserting that consciousness is identical to some physical or functional state. Now, it is certainly true that if we augment an account of physical processes with an identity statement of this form, the existence of consciousness can be derived; and with a sufficiently detailed and systematic identity statement, detailed facts about consciousness might be derived. But the question is now: what is the relationship between the physical facts and the identity statement itself?

Neither Clark nor Hardcastle gives us any reason to think that the identity statement *follows* from the physical facts. When answering the question "why does this physical process give rise to consciousness?", their answer is always "because consciousness and the physical process are identical", where the latter statement is something of a primitive. It is inferred to explain the correlation between physical processes and consciousness in the actual world, but no attempt is made to explain or derive it in turn. And without it, one does not come close to explaining the existence of consciousness.

This identity statement therefore has a very strange status indeed. It is a fact about the world that cannot be derived from the physical facts, and therefore has to be taken as axiomatic. No other "identity statement" above the level of fundamental physics have this status. The fact that DNA is a gene can be straightforwardly derived from the physical facts, as can the fact that H2O is water, given only that one has a grasp of the concepts involved. Papineau (1996) argues that identities are not the sort of thing that one explains; I think this is wrong, but in any case they are certainly the kind of thing that one can *derive*. Even the fact that Samuel Clemens is Mark Twain, to use Papineau's example, could be derived in principle from the physical facts by one who possesses the relevant concepts. But even if one possesses the concept of consciousness, the identity involving consciousness is not derivable from the physical facts.
(It might be objected that if one possessed an *a posteriori* concept of consciousness - on which consciousness was identified with some neural process, for example - then the facts about consciousness could be derived straightforwardly. But this would be cheating: one would be building in the identity to derive the identity. In all other cases - genes, water, and so on - one can derive the high-level facts from the low-level facts using the *a priori* concept alone. One does not *need* the identity between genes and DNA to derive the fact that DNA is a gene, for example: all one needs is a grasp of the meaning of "gene". That is, in all the other cases, the implication from micro to macro is *a priori*.)

We might call this the "magic bullet" version of the identity theory: it treats identity as a magic bullet which one can use to kill off all our explanatory problems by drawing disparate phenomena together. But identities do not work like this: elsewhere, they have to be *earned*. That is, an identity requires an actual or possible explanation of how it is that two phenomena are identical. ("No identification without explanation.") One earns the DNA-gene identity, for example, by showing how DNA has all the properties that are required to qualify as a gene. The original identity theorists in the philosophy of mind (Place 1956; Smart 1959) understood this point well. They consequently buttressed their account with a "topic-neutral" analysis of experiential concepts, asserting that all it means to be an orange sensation is to be the sort of state caused by orange things, and so on; this suffers from all the problems of type-A materialism, but at least it recognizes what is required for their thesis to be true. The type-B materialist, by contrast, posits an identification *in place of* an explanation.

Indeed, type-B materialism seems to give up on the reductive *explanation* of consciousness altogether. The very fact that it needs to appeal to an explanatorily primitive axiom to bridge the gap shows that consciousness is not being wholly explained in terms of physical processes: a primitive bridging principle is carrying the central part of the burden, just as it does on the sort of theory I advocate. Calling this principle an "identity" may save the letter of materialism, but it does not save the spirit. When it comes to issues of *explanation*, this position is just as nonreductive as mine.

Elsewhere in science, this sort of explanatorily primitive link is found only in fundamental laws. In fact, this primitiveness is just what makes such laws fundamental. We explain complex data in terms of underlying principles, we explain those principles in terms of simpler principles, and when we can explain no further we declare a principle fundamental. The same should hold here: by positing a fundamental law, we recognize the price of explanatory primitiveness, rather than pretending that everything is business as usual.

One can draw out the problems in other ways. For example, once it is noted that there is no conceptually necessary link from physical facts to phenomenal facts, it is clear that the idea of a physically identical world *without* consciousness is internally consistent. (By comparison, a physically identical world without life, or without genes, or without water is not even remotely conceivable.) So the fact that physical processes go along with consciousness seems to be a *further* fact about our world. To use a common philosophical metaphor: God could have created our world without consciousness, so he had to do extra work to put consciousness in.

Type-B materialists sometimes try to get around this by appealing to Saul Kripke's treatment of *a
posteriori necessity: such a world is said to be conceivable but not "metaphysically possible", precisely because consciousness is identical to a physical process. (Hardcastle embraces this line, and Clark says something similar). But as I argue in my book, this misunderstands the roots of a posteriori necessity: rather than ruling conceivable worlds impossible, a posteriori constraints simply cause worlds to be redescribed, and the problem returns as strongly as ever in a slightly different form. The issues are technical, but I think it is now well-established that Kripkean a posteriori necessity cannot save materialism here. To declare that the relevant worlds are all "metaphysically impossible", one would have to appeal instead to a far stronger notion of necessity which would put inexplicable constraints on the space of possible worlds. This is a notion in which we have no reason to believe.

So the problems of type-B materialism can be expressed both on intuitive and technical grounds. On the most intuitive grounds: it is a solution by stipulation, which "solves" the problem only by asserting that brain states are conscious states, without explaining how this can be. On slightly more technical grounds: it requires an appeal to a primitive axiom identifying consciousness with a physical process, where this identity is not derivable from the physical facts and is thus unlike any identity statement found elsewhere. On the most technical grounds: it either rests on an invalid appeal to Kripke's a posteriori necessity or requires a new and stronger notion of metaphysical necessity in which there is no reason to believe.

On to some specific points. Clark suggests that the explanatory gap arises only from assuming that consciousness and physical processes are distinct in the first place, and he faults my use of phrases such as "arises from" for begging that question. I think this misses the point: one can phrase the question just as well by asking "Why are certain physical systems conscious?", or even "Why is there something it is like to engage in certain processes?". Such questions are just as pressing, and clearly do not beg any questions against identity.

In fact, ontological assumptions are irrelevant to posing the explanatory question. All that matters is the conceptual distinction between structural/functional concepts and consciousness, a distinction that Clark explicitly accepts. (His talk of "correlation" makes even more clear, as does his observation that it could turn out that the functions do not correlate with experience). Given that it is not a priori that the performance of these functions should be conscious, it follows that an explanation of the functions is not ipso facto an explanation of consciousness, and we need to supplement the explanation with some further a posteriori component. Clark's "identity hypothesis" provides this extra component; but its primitive nature makes it clear that a wholly reductive explanation is not on offer. Indeed, Levine (1983), who introduced the term "explanatory gap", embraces an "identity" picture just like this, but he is under no illusion that he is providing a reductive explanation.

Hardcastle offers her own diagnosis of the roots of the debate, painting a picture of "committed materialists" who can't take the issue seriously, and "committed skeptics" who are entirely sure that materialism is false. I think this picture is far too bleak: in my experience the majority of people are more than a little torn over these issues, and there is plenty of common ground. In particular, I think Hardcastle does materialists a disservice: to characterize materialism as a "prior and fundamental commitment" is to make it into a religion. Materialism is an a posteriori doctrine, held by most because it explains so much in so many domains. But precisely because of this a posteriori character, its truth stands or falls with how
Moving Forward on the Problem of Consciousness

well it can explain the phenomena. So materialists cannot just circle the wagons and plead a prior commitment; they have to face up to the problems directly.

In any case, I think the basic intuitive divide in the field is not that between "materialists" and "skeptics", but that between those who think there is a phenomenon that needs explaining and those who think there is not: that is, between type-A materialists and the rest. The issue between Dennett and myself, for example, comes down to some basic intuitions about first-person phenomenology. But once one accepts that there is a phenomenon that needs explaining - as Hardcastle clearly does - the issues are more straightforwardly debatable. In particular, the problems of the type-B position are straightforwardly philosophical, rooted in its need for explanatorily primitive identities and brute metaphysical necessities.

Indeed, I think Hardcastle's defense of her identities makes straightforwardly philosophical missteps. Against someone who raises an explanatory gap question ("why couldn't these physical processes have gone on without consciousness?") she responds with an analogy, pointing to a water-mysterian who asks "why couldn't water have been made of something else?", and a life-mysterian who asks "why couldn't living things be made from something other than DNA?". But such questions are disanalogous and irrelevant, as they get the direction of explanation backward. In reductive explanation, the direction is always from micro to macro, not vice versa. So even if life could have been made of something else, this blocks the DNA-explanation of life not in the slightest. What matters is that in these cases, the low-level facts imply the high-level facts, with no primitive identity statements required. But this is not so in the case of consciousness; so Hardcastle requires a primitive identity of an entirely different kind, for which analogies cannot help.

For a truly consistent type-B materialism, one would have to face up to these problems directly, rather than trying to slide over them. One would have to embrace explanatorily primitive identities that are logically independent of the physical facts and thus quite unlike any identities found elsewhere in science. One would have to embrace inexplicable metaphysical necessities that are far stronger than any a posteriori necessities found elsewhere in philosophy. And one will have to make a case that such postulates are a reasonable thing to believe in. I am skeptical about whether this is possible, but it is at least an interesting challenge.

But even if type-B materialism is accepted, the explanatory picture one ends up with looks far more like my naturalistic dualism than a standard materialism. One will have given up on trying to explain consciousness in terms of physical processes alone, and will instead be relying on primitive bridging principles. One will have to infer these bridging principles from systematic regularities between physical processes and phenomenological data, where the latter play an ineliminable role. One will presumably want to systematize and simplify these bridging principles as much as possible. (If there are to be brute identities in the metaphysics of the world, one hopes they are at least simple!) The only difference will be that these primitive principles will be called "identities" rather than "laws".

I think it makes far more sense to regard such primitive principles as laws, but if someone insists on using the term "identity", after a while I will stop arguing with them. In the search for a theory of consciousness - the truly interesting question - their theories will have the same shape as mine. The epistemology will be
the same, the methodology will be the same, the explanatory relations between principles and data will be the same, and all will be quite unlike those on standard materialist theories in other domains. The names may be different, but for all explanatory purposes, consciousness might as well be irreducible.

2.4 Other deflationary approaches

A different sort of "deflationary" approach is taken by O'Hara and Scutt. Their paper has the juicy title of "There is no hard problem of consciousness", suggesting a Dennett-like reductionism, but the substance of their paper suggests quite the opposite. In fact, they hold that the hard problem is so hard that we should ignore it for now, and work on the easy problems instead. Then perhaps all will become clear, in a decade or a century or two.

Now there is not much doubt that progress on the easy problems is much faster than progress on the hard problem, but O'Hara and Scutt's policy suggestion seems quite redundant. Researchers working on the easy problems already outnumber those working on the hard problem by at least a hundred to one, so there is not much danger of the world suddenly falling into unproductive navel-gazing. But if O'Hara and Scutt are suggesting that no-one should be working on the hard problem, this seems to move beyond pragmatism to defeatism. Granted that the hard problem is hard, it nevertheless seems quite reasonable for a community to invest a fraction of its resources into trying to solve it. After all, we do not know when a solution to the hard problem will come. Even if we do not solve it immediately, it may well be that the partial understanding that comes through searching for a solution will help us in the further search, in our work on the easy problems, and in our understanding of ourselves. It is in the scientific spirit to try.

Sociological issues aside, the substantive issue arising from O'Hara and Scutt's article is that of whether there is any chance of progress on the hard problem any time soon. O'Hara and Scutt do not really provide much argument against this possibility; they simply reiterate that the hard problem is very hard, that we are not assured of a solution, and that scientific progress has often made hard problems seem easier. All this tells us that the prospects for a solution are uncertain, but it does not tell us that they are nonexistent.

In my article I advocated a positive methodology for facing up to the hard problem. Pay careful attention both to physical processing and to phenomenology; find systematic regularities between the two; work down to the simpler principles which explain these regularities in turn; and ultimately explain the connection in terms of a simple set of fundamental laws. O'Hara and Scutt offer no reason to believe that this must fail. They reserve most of their criticism for reductive methods such as those of Crick and Edelman, but that criticism does not apply here. They very briefly criticize a specific suggestion of mine, saying "it is impossible to understand how information can have a phenomenal aspect". They do not substantiate this remark (for my part, I do not find it impossible to understand at all, as long as we realize that a fundamental law rather than a reduction is being invoked) but in any case the criticism seems quite specific to my theory. O'Hara and Scutt give us no reason to believe that a fundamental theory could not be formulated and understood.

I should also clarify a common misunderstanding. O'Hara and Scutt attribute to me the view that
understanding the easy problems does not help at all in understanding the hard problem, and others have attributed to me the view that neurobiology has nothing to contribute in addressing the hard problem. I did not make these claims, and do not agree with them. What I do say is that any account of the easy problems, and indeed any neurobiological or cognitive account, will be incomplete, so something more is needed for a solution to the hard problem. But this is not to say that they will play no role in a solution at all. I think it is obvious that empirical work has enriched our understanding of conscious experience a great deal, and I expect that it will continue to do so. A final theory of human consciousness will almost certainly lie in a combination of processing details and psychophysical principles: only using both together will the facts about experience be explained.

So I agree with O'Hara and Scutt that research on the easy problems is of the utmost importance: it is here that the meat and potatoes of consciousness research resides, and attention to this sort of work can help even a philosopher in staying grounded. But to ignore the hard problem entirely would be futile, as understanding conscious experience per se is the raison d'être of the field. Some of us will continue to focus on it directly, and even those working on the easy problems will do well to keep the hard problem in sight out of the corner of their eyes. To paraphrase Kant and stretch things a bit, we might say: hard without easy is empty; easy without hard is blind.

Another proposal that could be construed as "deflationary" comes from Price, who suggests that much of the problem lies in our heads. We should not expect to feel as if we understand consciousness, but this may be no big deal. There are similar explanatory gaps accompanying every causal nexus ("why does event A cause event B?"); it's just that in most cases we have gotten used to them. The explanatory gap in the case of consciousness is analogous, but we are not yet as used to it.

I agree with Price's analogy, but I think it ultimately supports my view of the problem. Why are causal nexi accompanied by explanatory gaps? Precisely because of their contingency (as Price says, there is no "a priori necessity" to them), which is in turn due to the brute contingency of fundamental laws. If we ask "why did pressing the remote control cause the TV set to turn on?", we might get a partial answer by appealing to principles of electromagnetic transmission, along with the circuitry of the two objects, ultimately seeing how this causal chain is the natural product of the underlying dynamics of electromagnetism (for example) as it applies to the material in the vicinity. But this answer is only partial, as we have no answer to the question of "why do those fundamental principles hold?". Those principles are apparently just a brutally contingent fact about the world, and this contingency is inherited by the causal chain at the macroscopic level.

If Price is right that the explanatory gap between brain and consciousness is analogous, then this suggests that the gap is due to some contingency in the connecting principles, because of underlying brutally contingent fundamental laws. Which of course is just what I suggest. We have here an inter-level relationship that could have been otherwise, just as Price points to intra-level relationships in physics that could have been otherwise. Either way, this arbitrariness is ultimately grounded at the point where explanation stops: the invocation of fundamental laws.

It is worth noting that for other inter-level relationships - that between biochemistry and life, for example,
or between statistical mechanics and thermodynamics - there is no explanatory gap analogous to the brain-consciousness gap. The reason is precisely that the high-level facts in these cases are *necessitated* by the low-level facts. The low-level facts themselves may be contingent, but there is no further contingency in the inter-level bridge. (Indeed, the inter-level relationship in these cases is not really causation but *constitution*.) Because there is no contingency here, the relationship between the levels is transparent to our understanding. Contrapositively, the lack of transparency in the brain-consciousness case is precisely due to the contingency of the psychophysical bridge.

In any case, Price's analogy between the brain-consciousness relation and ordinary causal relations is helpful in seeing why belief in an explanatory gap need not lead one to mysterianism. Rather than elevating the explanatory gap to a sui generis mystery, we recognize that it is of the sort that is ubiquitous elsewhere in science, and especially in fundamental physics. This case is unusual only in that here, the gap is found in an inter-level rather than an intra-level relationship; but the same strategy that works for intra-level relationships works here. Once we introduce fundamental psychophysical laws into our picture of nature, the explanatory gap has itself been explained: it is only to be expected, given that nature is the way it is.

A final view that might be considered "deflationary" has been discussed by McGinn, not so much in his contribution to this symposium as in an earlier paper (McGinn 1989) and most explicitly in his review of my book (McGinn 1996). On McGinn's view, the explanatory gap also arises for psychological reasons, but his reasons differ from Price's. He suggests that there may be a conceptual implication from physical facts to facts about consciousness, which would be *a priori* for a being that possessed the relevant concepts; but we do not and cannot possess the concepts, due to our cognitive limitations, so we can never grasp such an implication. On this view, materialism turns out to be true, but we can never grasp the theory that reveals its truth.

This intriguing view seems at first glance to offer an attractive alternative to both dualism and hard-line reductionism, but in the end, I am not sure how much of an alternative is. The problem lies in the concept (or concepts) which support the implication from physical to phenomenal facts. What sort of concept could this be? If it is a structural/functional concept, then it will suffer from the same conceptual gap with experiential concepts as any other structural/functional concept (the existence of a gap here is independent of *specific* details about structure and function, after all). If it is not a structural/functional concept, then there appear to be principled reasons why it cannot be entailed by the physical story about the world, as physics deals only in structure and function.

So we are still faced with the problem that structure and function adds up only to more structure and function. This claim holds true for systematic reasons quite independent of considerations about cognitive limitations, and I doubt that McGinn would deny it. So it seems that McGinn need to assert either that (1) explaining experience *is* just a problem of explaining structure and function, if only we could grasp this fact, or (2) that something more than structure and function is present in fundamental physics. The first option would make McGinn's position remarkably like Dennett's (the only difference being that Dennett holds that only *some* of us are limited in this way!), and the second position would fall into the category of expanding fundamental physics, which I will consider below. Either way, once made specific, this view
is subject to the pros and cons of the specific position to which it is assimilated. So in the end, it may not open up a distinct metaphysical option.

### 3 NONREDUCTIVE ANALYSES

#### 3.1 Conceptual foundations

I will now address some critiques from those who take nonreductive positions. It appears that I staked out some middle ground; having discussed objections from my right, it is now time for objections from the left. The intermediate nature of my position may stem from an inclination toward simplicity and toward science. Reductive materialism yields a compellingly simple view of the world in many ways, and even if it does not work in the case of consciousness, I have at least tried to preserve as many of its benefits as possible. So where reductionists think that I have overestimated the difficulty of the hard problem, some nonreductionists think that I may have underestimated it, or alternatively that I have underestimated the difficulty of the "easy" problems.

The latter position - that the hard problem is hard, but that explaining discrimination, reportability, and so on is just as hard - is taken by Lowe and Hodgson, for two apparently different reasons. Hodgson thinks these problems are hard because a physical account cannot even explain how the functions are performed; Lowe thinks they are hard because they require explaining more than the performance of functions. (It is possible that Lowe intends to make both points.) I will address Lowe's position first, and save Hodgson's for my discussion of interactionism and epiphenomenalism.

Why say that explaining reportability, discrimination, and so on requires explaining more than the performance of functions? Lowe says this because he holds that true "reports" and "discriminations" can be made only in systems which have the capacity for thought, which in turn requires consciousness. If externally indistinguishable functions were performed in a system without consciousness, they would qualify as "reports" (and so on) only in a "jejune" sense. So an account of non-jejune reportability requires explaining more than functions.

I have some sympathy with Lowe's position here; in particular, I find it plausible that there is an intimate relationship between consciousness and thought (Lowe suggests that I think otherwise, but I don't think that suggestion can be found in my article). But it seems to me that the issue about "reportability" and so on is largely verbal. Does a sound uttered by a functionally identical zombie really qualify as a "report"? The answer is surely: yes in one sense of "report", and no in another. If Lowe objects to calling it a "report" in any sense at all, one can simply call it a "pseudo-report". Then the easy problems are those of explaining pseudo-reportability, pseudo-discrimination, and the like. Nothing important to my article changes; the distinction between the easy problems (explaining functions) and the hard problem (explaining conscious mentality) is as strong as ever.

Lowe might reply that reportability, so construed, is not a problem of consciousness at all. Again I am sympathetic, but again I think that this is a verbal issue. Plenty of people who take functional approaches...
to these problems take themselves to be explaining aspects of consciousness in some sense; and there is little point getting into territorial arguments about a word. It’s more productive to accept the characterization - if someone holds that "consciousness" has some functionally definable senses, I will not argue with them - but to point out the key problems of consciousness that are being skipped over all the same.

The same goes for Lowe's concerns, shared by Velmans and Libet, about my use of the term "awareness" for a functionally defined concept distinct from that of full-blown consciousness. Again, a word is just a word. As long as we are clear that "awareness" is being used in a stipulative sense, the substantive issues should be clear. In particular, there is certainly no implication that humans are "aware" only in this attenuated sense, as Lowe somehow infers; and it is hard to see how this terminological choice helps blur the "function/sentence" distinction, as Velmans suggests. If anything, explicitly separating consciousness and awareness makes the distinction harder to avoid. Nevertheless, it is clear that enough people are uneasy about the terminology that it it is unlikely to catch on universally. Perhaps another term can play the role, although I suspect that any word choice that dimly suggests mentality would meet similar opposition from some. It's a pity that there is no universal term for this central functional concept; in the meantime I will go on using the term "awareness", with the stipulative nature of the usage always made clear.

The exact relationship between consciousness and "intentional" (or semantic) mental states such as belief, thought, and understanding raises deep and subtle questions that I did not intend to address in my article. Lowe seems to have gotten the impression of a straightforward functionalism about these aspects of mentality, but such an impression was not intended. I am torn on the question of intentionality, being impressed on one hand by its phenomenological aspects, and on the other hand being struck by the potential for functional analyses of specific intentional contents. In my book, I try to hew a neutral line on these deep questions, noting that there is a "deflationary" construal of concepts such as "belief" so that even a zombie might be said to have beliefs (pseudo-beliefs, if you prefer), and an inflationary construal such that true belief requires consciousness. Over time I am becoming more sympathetic with the second version: I think there may be something in the intuition that consciousness is the primary source of meaning, so that intentional content may be grounded in phenomenal content, as Lowe puts it. But I think the matter is far from cut and dried, and deserves a lengthy treatment in its own right. For now, phenomenal content is my primary concern.

### 3.2 The roots of the hard problem

Robinson, McGinn, and Warner offer proposals about why the hard problem is hard. These are not direct critiques of my view, for the most part, but they fall into the general category of nonreductive analyses, so I will address them briefly here.

Robinson suggests that the hardness lies in the fact that some phenomenal properties - hue properties, for example - have no structural expression. I think there is a considerable insight here. Elsewhere in science, instantiations of structural properties are generally explicable in terms of basic components and their relations, and it seems to be precisely their structure that makes them explicable in this way. The
Moving Forward on the Problem of Consciousness

structural properties of experience itself (the geometry of a visual field, for example) form an interesting intermediate case: while they are more amenable to physical explanation than other phenomenal properties, this explanation still requires a nonreductive principle to cross the gap. But these properties may be reducible to structureless phenomenal properties and their relations. If so Robinson may be correct that the core of phenomenal irreducibility lies at the more basic level.

A few questions remain: for example, if it turned out that phenomenal properties had structure "all the way down", might they not be irreducible to physical properties all the same? For reasons like this, I sometimes lean toward an alternative view which locates the irreducibility in an independence of the kind of structure found in the physical domain, and ultimately in the intrinsicness of phenomenal properties, which contrasts with the relational nature of all our physical concepts. But clearly these views are not far apart.

McGinn offers a closely related analysis. He locates the problem in the non-spatial character of consciousness: that is, in the fact that it lacks spatial extension and structure, and therefore does not fit easily into physical space. I think the overall intuition is very powerful. The detailed claim needs to be carefully unpacked, to avoid lumping in consciousness with less problematic non-spatial states and properties (e.g. the legality of an action, which is a complex dispositional property but not a spatial property; and possibly even the charge of a particle), while simultaneously avoiding the need to appeal more controversially to a non-spatial entity bearing the state or property (McGinn seems not to want to rest his case on this appeal; see e.g. his footnote 3). I suspect that once this work is done - adding appropriate restrictions on the class of properties, perhaps - McGinn's analysis will be even closer to those above.

Warner locates the source of the problem in a different place: the incorrigibility of our knowledge of consciousness. I agree with Warner that there is some sense in which some knowledge of consciousness is incorrigible - I know with certainty that I am conscious right now, for example - but it is remarkably tricky to isolate the relevant sense and the relevant items of knowledge. Warner himself notes that plenty of our beliefs about our experiences are mistaken. He gets around this problem by limiting this to cases where our ability to recognize experiences is "unimpaired", but this seems to come dangerously close to trivializing the incorrigibility claim. After all, it is arguably a tautology that an "unimpaired" belief about an experience will be correct. Warner may have a way to unpack the definition of "impairment" so that the claim is non-circular, but this is clearly a non-trivial project.

In Chapter 5 of my book (pp. 207-8), I make some brief suggestions about how to make sense of an incorrigibility claim. In essence, I think that experiences play a role in constituting some of our concepts of experience; and when a belief directs such a concept at the experience which constitutes it, there is no way that the belief can be wrong (in essence, because one's current experience has got "inside" the content of one's belief). Many or most beliefs about experience do not have this specific form, and are therefore corrigible; nevertheless, this may isolate a certain limited class of beliefs about experience that cannot be wrong. (This limited class of beliefs can arguably ground the first-person epistemology of conscious experience, but this is a further complex issue.)
In any case, Warner and I are agreed that there are some beliefs about conscious experience that cannot be wrong. What follows? Warner holds that it follows from this alone that experience cannot be physically explained, as physical science cannot countenance the necessary connections that incorrigibility requires. I am not sure about this. On my account, for example, the necessary connection between belief and experience is an automatic product of the role that the experience plays in constituting the content of the belief; and it is not obvious to me that materialists could not avail themselves of a similar account. Shoemaker (1990) gives an alternative account of incorrigibility from a functionalist perspective, relying on the interdefinition of pains and pain-beliefs. Perhaps Warner would object that neither of these accounts captures the kind of incorrigibility that he is after; but perhaps they capture the kind of incorrigibility in which there is reason to believe. So I am not yet convinced that incorrigibility is truly the source of the mind-body problem, but it is clear that there is much more to be said.

Warner uses these considerations about incorrigibility to suggest, like Lowe, that even reportability - one of my "easy" problems - cannot be physically explained. My reply here is as before. I did not intend reportability to be read in a strong sense that requires the presence of experience. Rather, I intended it to require merely the presence of the reports, functionally construed, so in particular I did not intend it to encompass the incorrigibility of beliefs about experience. (If I were writing the article now, I would modify the wording in the list of "easy" problems to make it absolutely clear that functioning is all that matters.) Certainly, if "reportability" is read in a sense that requires conscious experience, then it cannot be reductively explained.

### 3.3 Fundamental laws

A further set of issues is raised by my appeal to fundamental laws in a theory of consciousness. Mills thinks that because I invoke such laws to bridge physics and consciousness, I am not really solving the hard problem at all (Price suggests something similar). At best I am providing a sophisticated set of correlations, and finding such correlations was an easy problem all along.

Mills reaches this conclusion because he construes the hard problem as the problem of giving a constitutive (or "non- causal") explanation of consciousness in physical terms. If the problem is construed that way, Mills is quite right that it is not being solved at all. But to define the problem of consciousness this way would be to define it so that it becomes unsolvable: one might call that problem the "impossible problem".

I prefer to set up the hard problem in such a way that a solution is not defined out of existence. The hard problem, as I understand it, is that of explaining how and why consciousness arises from physical processes in the brain. And I would argue the sort of theory I advocate can in principle offer a good solution to this problem. It will not solve the impossible problem of providing a reductive explanation of consciousness, but it will nevertheless provide a theory of consciousness that goes beyond correlation to explanation.

A good analogy is Newton's theory of gravitation. The Newton of legend wanted to explain why an apple
Moving Forward on the Problem of Consciousness

fell to the ground. If he had aimed only at correlation, he would have produced a taxonomic theory that noted that when apples were dropped from such-and-such heights, they fell to the ground taking such-and-such time, and so on. But instead he aimed for explanation, ultimately explaining the macroscopic regularities in terms of a simple and fundamental gravitational force. In Newton's time, some objected that he had not explained why the gravitational force should exist; and indeed he had not. But we take Newton's account to be a good explanation of the apple's falling all the same. We have grown used to taking some things as fundamental.

Something similar holds for a theory of consciousness. It would be deeply unsatisfying for a theory of consciousness to stop at "complex brain state B is associated with complex experience C", and so on for a huge array of data points. As in Newton's case, we want to know how and why these correlations hold; and we answer this question by pointing to simple and fundamental underlying laws. Just as one can say "the apple fell because of the law of gravity", we will eventually be able to say "brain state B produced conscious state C because of fundamental law X".

Because something is being taken as primitive, this does not yield as strong an explanatory connection as one finds in cases of reductive explanation, such as the explanation of genes in terms of DNA. But it is an explanation all the same. The case of gravity suggests that what counts in an explanation is that one reduces the primitive component to something as simple as possible, not that one reduces it to zero.

Mills suggests that this is no better than explaining why a sheep is black in terms of the fact that it is a member of the class of black things. But here the explanatory posit is just as complex as what needs to be explained; whereas in our case, the fundamental laws are far simpler than the data. If our "explanation" was "brain B yields experience E" or even "certain oscillations yield consciousness", we would have a problem like Mills': these posits would be so complex and macroscopic that they stand in need of further explanation themselves. For a comprehensive explanation, our basic principles need to be so simple and universal that they are plausibly part of the basic furniture of the world.

Of course one can always ask "why does the fundamental law hold", as Mills and also Robinson suggest. But we should not expect any answer to that question. In physics, we have grown used to the idea that explanation stops somewhere, and that the fundamental laws of nature are not further explained. That is what makes them fundamental. If my negative arguments about consciousness are correct, then we will have to do the same here. We will explain and explain and explain, and eventually our psychophysical explanations will be reduced to a simple core which we will take as primitive. So we do not get something for nothing, but we get a perfectly adequate theory all the same.

Mills is right that once we view things this way, there is a sense in which the hard problem becomes an easy problem (although not an Easy problem), in that there is a clear research program for its solution and there is no reason why it should be intractable in principle. This I take to be precisely the liberating force of taking consciousness as fundamental. We no longer need to bash our head against the wall trying to reduce consciousness to something it is not; instead we can engage in the search for a constructive explanatory theory.
In any case, it seems that Mills does not disagree with me on the issues of substance. Whichever problems one takes to be "hard" or "easy", the deepest problem of consciousness is that of how we can construct an explanatory theory of consciousness which accommodates consciousness in the natural world. And a fundamental theory of consciousness, we agree, is the best way to do just that. I will be happy if we can come up with a theory of consciousness that is only as good as Newton's theory of gravitation!

3.4 Epiphenomenalism and interactionism

A number of contributors worry that my position may lead to epiphenomenalism, the view that consciousness has no effect on the physical world. If the physical domain is causally closed, so that there is a physical explanation for every physical event, and if consciousness is non-physical, then it can seem that there is no room for consciousness to play any causal role. Conversely, it can seem that if consciousness is non-physical and plays a causal role, then there will not be a physical solution even to the "easy" problems. Hodgson and Warner spend some time discussing this issue, and Seager and Stapp allude to it. I discuss this issue at considerable length in my book, but will summarize the state of play as I see it below.

In essence, I think that (1) while epiphenomenalism has no clear fatal flaws, it is to be avoided if possible; that (2) the causal closure of the physical domain is not to be denied lightly; and that (3) denying causal closure does not really help solve the problems of epiphenomenalism, which run deeper than this. Most importantly, I think that (4) it may be possible to avoid epiphenomenalism even while embracing the causal closure of the physical domain, by taking the right view of the place of consciousness in the natural order. I will consider these issues in order.

First, is epiphenomenalism an acceptable view, or should it be rejected out of hand? There is no doubt that the view is counterintuitive to many, but it is also hard to find fatal flaws in it. While we certainly have strong intuitions that consciousness plays a causal role, our evidence for these intuitions lies largely in the fact that certain conscious events tend to be systematically followed by certain physical events. As always, when faced with such a constant conjunction, we infer a causal connection. But the epiphenomenalist can account for this evidence in a different way, by pointing to psychophysical laws, so our intuitions may not carry too much weight here.

Hodgson argues vigorously against epiphenomenalism, largely by appealing to "common sense". I think common sense should not be undervalued here, but it is also inconclusive. At best, it establishes a presumption against epiphenomenalism if other things are equal, not a solid argument against it if other things are not. Hodgson also points to various functions that he thinks could not be performed as well without consciousness; but his arguments all depend once again on the intuition that consciousness is playing a causal role, rather than on an objective analysis of the functions themselves. He also makes an appeal to evolution, but an epiphenomenalist can account for the evolution of consciousness without too many problems: evolution selects for certain physical processes directly, and psychophysical laws do the rest, ensuring that consciousness will evolve alongside those processes. Like all fundamental laws, these psychophysical laws are universal, so we do not need an evolutionary explanation of why these laws hold
in the first place.

Other anti-epiphenomenalist arguments can be made by appealing to the relationship between consciousness and the things we say and judge about consciousness. It seems that the epiphenomenalist must hold that consciousness is causally irrelevant to our utterances about consciousness, which is at least very odd. Some argue that it is more than odd, suggesting that if consciousness were epiphenomenal we could not refer to consciousness, or that we could not know about consciousness; but I think that a close analysis, as I give in my book, suggests that these arguments do not go through, as our knowledge of and reference to consciousness depends on a relationship to consciousness that is much tighter than mere causation.

Warner gives a novel argument against epiphenomenalism, and against any other view that has a causally closed physical domain plus psychophysical laws. He suggests that psychophysical laws must interfere with physical laws, as they automatically entail violations of physical conservation laws. I do not see why this is the case: surely it is at least coherent to suppose that the physical picture of the universe might be supplemented by some psychophysical laws that introduce consciousness but leave the physical domain untouched, Warner's argument relies on the claim that the "production" of experience by a physical process must involve a corresponding decrease in some physical quantity, but I see no reason why this must be so: there will be some physical criterion for the existence of an experience, to be sure, but this criterion may be one that can be satisfied perfectly well in a causally closed physical world. So the conceptual coherence of epiphenomenalism, and that of other views with causal closure plus psychophysical laws, is unthreatened.

Still, all this establishes at best that epiphenomenalism has no fatal flaws. It does not establish that epiphenomenalism is plausible. Not only does epiphenomenalism violate certain aspects of common sense; it also leads to an inelegant picture of nature, with consciousness "dangling" on top of physical processes as a kind of add-on extra. If it turns out that every other position has fatal flaws, then we may have reason to embrace epiphenomenalism; but in the meantime, we have good reason to investigate alternatives.

There are two sorts of alternatives that one might consider. First, we might see if it is plausible to deny the causal closure of the physical domain, thus leaving room for a causal role for experience in an interactionist dualism. Second, we might see if a causal role for experience might be reconciled with the causal closure of the physical domain. The second alternative may sound paradoxical at first, but I think there is a very natural way to make sense of it, which may ultimately provide the deepest resolution of this issue.

But first: is the physical world causally closed? In the paper I accepted that it was, not because I think things have to be that way, but because to deny this is to go a long way out on a limb. One does not have to go out on that limb to embrace the irreducibility of consciousness, so I prefer to stay neutral, lest the baby of consciousness once more be thrown out with the bathwater of Cartesian dualism. Still, are there any good reasons to deny causal closure, and to assert that physical explanations of the various functions are incomplete?
Perhaps the most common such reason is an indirect one: "it must be the case that physical explanations of the functions are incomplete, if consciousness is to play a causal role." This reason has some force, although I think both of its premises can be questioned: we have seen above that it is not obvious that consciousness must have a causal role, and we will see below that consciousness might have a causal role even if the physical domain is causally closed. But in any case, I set this indirect reason aside: the question for now is whether there are any direct reasons. That is, if we set consciousness aside and take a third-person view of the world, is there any reason to believe that physical explanations of these functions are impossible?

Hodgson offers an array of reasons to deny causal closure, but they are mostly grounded in the indirect reason above. Hodgson does not deny that some physical system might perform the functions with which the "easy" problems are concerned; he simply thinks that that is not the way that we do it, as consciousness plays a role in our own case. So his case that the "easy" problems are hard depends largely on the existence of the hard problem, and not on considerations intrinsic to the easy problems themselves. Indeed, I think that "objective" reasons suggesting that no physical systems could perform these functions are very thin on the ground.

The main place where third-person considerations may give reason to deny causal closure is in the intriguing case of quantum mechanics, which both Hodgson and Stapp appeal to. While there are interpretations of quantum mechanics on which the physical domain is causally closed - the interpretations of Bohm and Everett, for example - there are also interpretations on which it is not, and which leave a potential causal role for consciousness wide open. Stapp, for example, favors an interpretation on which consciousness is responsible for "collapsing" the wave function, and Hodgson favors an interpretation on which consciousness determines certain apparent quantum indeterminacies.

Indeed, it can seem that quantum mechanics provides about as perfect a causal role for consciousness as one could imagine in a physical theory. Any indeterminism in quantum mechanics comes in at the point of "collapse", which on the most common interpretations is triggered by "measurement", and it can seem that consciousness is the only non-arbitrary way to distinguish a measurement from other physical events. If so, then consciousness may be present in quantum mechanics' very foundations. Such interpretations are controversial among physicists, but mainly because they presuppose that consciousness is non-physical; if we have already accepted this for independent reasons, this concern loses its bite. (It is interesting that philosophers reject interactionist dualism because they think it is incompatible with physics, whereas physicists reject the relevant interpretations of quantum mechanics because they are dualistic!)

On most days of the week, I lean toward a different interpretation of quantum mechanics (Everett's), but interactionist collapse interpretations have obvious attractions and are not to be dismissed lightly. (I lean toward them about two days a week, and toward Bohm's interpretation on Sundays.) At least it seems clear that interactionist dualism is not incompatible with physical theory, as we understand it today. But I think there is a deeper reason why an appeal to interactionist dualism does not really solve the problems of epiphenomenalism. This is because even interactionism is subject to an epiphenomenalist worry of its
The worry is as follows: for any given interactionist theory, it seems that we can remove the facts about experience, and still be left with a coherent causal story. Take Eccles' theory on which "psychons" in the mind affect physical processes in the brain. Here one can tell a perfectly coherent causal story about psychons and their effect on the brain without ever mentioning the fact that psychons are experiential. On this story, psychons will be viewed as causal entities analogous to electrons and protons in physical theories, affected by certain physical entities and affecting them in turn; and just as with protons and electrons, the fact that psychons have any experiential qualities will be quite inessential to the dynamic story. So one can still give a causal explanation of behavior that does not involve or imply experience. The same would go for a Cartesian theory involving ectoplasm, for Libet's proposal involving a "conscious mental field", and even for the theories that Stapp and Hodgson advocate.

Consider Stapp's view, for example. Presumably when this view is filled out, it will say that certain physical states P give rise to certain experiential states E, and that these states E bring about physical collapses in turn. But however this story works, the fact that the states E are experiential will be quite inessential to the story. One can imagine that a formally identical theory might be formulated from a "God's-eye" point of view, invoking such states E in causing collapses, but never mentioning experience at all. So it is not easy to see how Stapp is giving experience an essential role.

Stapp has sometimes advocated his view by pointing to the "zombie" possibility for classical physics: if physics is causally closed, there is a logical possibility of physically identical zombies with the same behavior, suggesting that experience plays no essential role in our behavior. But interestingly, a similar objection can be made to Stapp's own view. Given that physics works as Stapp suggests, there is a logically possible world with a "quantum zombie". In this world, instead of P causing experience E which causes collapse, P causes collapse directly. There is no consciousness in this world, but all the functions are performed just the same. So there is a sense in which the fact that experience is associated with collapses in our world is superfluous. One can tell a similar conceptually coherent "zombie" story for any interactionist picture, whether Hodgson's or Eccles - just move to a possible world in which any intermediate causal roles are played without any associated experience -- thus suggesting that these problems are not unique to the picture on which the physical world is causally closed.

The real "epiphenomenalism" problem, I think, does not arise from the causal closure of the physical world. Rather, it arises from the causal closure of the world! Even on an interactionist picture, there will be some broader causally closed story that explains behavior, and such a story can always be told in a way that neither includes nor implies experience. Even on the interactionist picture, we can view minds as just further nodes in the causal network, like the physical nodes, and the fact that these nodes are experiential is inessential to the causal dynamics. The basic worry arises not because experience is logically independent of physics, but because it is logically independent of causal dynamics more generally.

The interactionist has a reasonable solution to this problem, I think. Presumably, the interactionist will respond that some nodes in the causal network are experiential through and through. Even though one can
Moving Forward on the Problem of Consciousness

tell the causal story about psychons without mentioning experience, for example, psychons are intrinsically experiential all the same. Subtract experience, and there is nothing left of the psychon but an empty place-marker in a causal network, which is arguably to say there is nothing left at all. To have real causation, one needs something to do the causing; and here, what is doing the causing is experience.

I think this solution is perfectly reasonable; but once the problem is pointed out this way, it becomes clear that the same solution will work in a causally closed physical world. Just as the interactionist postulates that some nodes in the causal network are intrinsically experiential, the "epiphenomenalist" can do the same.

Here we can exploit an idea that was set out by Bertrand Russell (1926), and which has been developed in recent years by Grover Maxwell (1978) and Michael Lockwood (1989). This is the idea that physics characterizes its basic entities only extrinsically, in terms of their causes and effects, and leaves their intrinsic nature unspecified. For everything that physics tells us about a particle, for example, it might as well just be a bundle of causal dispositions; we know nothing of the entity that carries those dispositions. The same goes for fundamental properties, such as mass and charge: ultimately, these are complex dispositional properties (to have mass is to resist acceleration in a certain way, and so on). But whenever one has a causal disposition, one can ask about the categorical basis of that disposition: that is, what is the entity that is doing the causing?

One might try to resist this question by saying that the world contains only dispositions. But this leads to a very odd view of the world indeed, with a vast amount of causation and no entities for all this causation to relate! It seems to make the fundamental properties and particles into empty placeholders, in the same way as the psychon above, and thus seems to free the world of any substance at all. It is easy to overlook this problem in the way we think about physics from day to day, given all the rich details of the mathematical structure that physical theory provides; but as Stephen Hawking (1988) has noted, physical theory says nothing about what puts the "fire" into the equations and grounds the reality that these structures describe. The idea of a world of "pure structure" or of "pure causation" has a certain attraction, but it is not at all clear that it is coherent.

So we have two questions: (1) what are the intrinsic properties underlying physical reality?; and (2) where do the intrinsic properties of experience fit into the natural order? Russell's insight, developed by Maxwell and Lockwood, is that these two questions fit with each other remarkably well. Perhaps the intrinsic properties underlying physical dispositions are themselves experiential properties, or perhaps they are some sort of proto-experiential properties that together constitute conscious experience. This way, we locate experience inside the causal network that physics describes, rather than outside it as a dangler; and we locate it in a role that one might argue urgently needed to be filled. And importantly, we do this without violating the causal closure of the physical. The causal network itself has the same shape as ever; we have just colored in its nodes.

This ideas smacks of the grandest metaphysics, of course, and I do not know that it has to be true. But if the idea is true, it lets us hold on to irreducibility and causal closure and nevertheless deny epiphenomenalism. By placing experience inside the causal network, it now carries a causal role. Indeed,
fundamental experiences or proto-experiences will be the basis of causation at the lowest levels, and high-level experiences such as ours will presumably inherit causal relevance from the (proto)-experiences from which they are constituted. So we will have a much more integrated picture of the place of consciousness in the natural order. [*]

*[[There may be other ways to reconcile a causal role for experience with the causal closure of the physical. See Mills (1995) for a different strategy that relies on causal overdetermination. But even if this view avoids epiphenomenalism, it retains a fragmented, inelegant picture of nature.]]

The Russellian view still qualifies as a sort of "naturalistic dualism", as it requires us to introduce experience or proto-experience as fundamental, and it requires a deep duality between the intrinsic and extrinsic features of physical reality. But underlying this dualism, there is a deeper monism: we have an integrated world of intrinsic properties connected by causal relations. The view can even be seen as an odd sort of "materialism", as it says that physical reality is all there is - but it says that there is much more in physical reality than physical theory tells us about! In the end the name does not matter too much, as long as the picture is clear. (I would be tempted by "fundamentalism" as the most accurate coverall for the sorts of view I embrace, were it not for the associations!)

There are obvious concerns about this view. The first is the threat of panpsychism, on which more later. The second is the problem of how fundamental experiential or proto-experiential properties at the microscopic level somehow together constitute the sort of complex, unified experience that we possess. (This is a version of what Seager calls the "combination problem".) Such constitution is almost certainly required if our own experiences are not to be epiphenomenal, but it is not at all obvious how it should work: would not these tiny experiences instead add up to a jagged mess? I discuss some approaches to this problem later. If it can be avoided, then I think the Russellian view (which turns out to be particularly compatible with an informational "it from bit" view) is clearly the single most attractive way to make sense of the place of experience in the natural order.

It is notable that even an interactionist dualism can be seen as a sort of Russellian view. It draws a slightly different picture of the causal network, and takes certain nodes in this network - the "psychon" or "collapse" nodes, for example - and colors them in. The differences are that not all nodes in the network are colored in in this way (presumably there are some different, unknown intrinsic properties in fundamental matter), and that the experiential nodes in this picture are at a fairly high level. This may actually help avoid the problem above: instead of trying to constitute our consciousness out of innumerable different fundamental nodes, there might turn out to be a single node in each case (or just a few?) which carries the burden. (Though one may well wonder why this single node should have such a complex of intrinsic properties, in the way that our consciousness does!) This avoidance of the constitution problem may in the end turn out to be the greatest virtue of a quantum interactionism.

In the meantime, I think this question is wide open. There are at least three potential ways of seeing the metaphysics here: the epiphenomenalist version, the interactionist version, and the Russellian version. All have pros and cons, and I think the question of their mutual merits is one that deserves much further investigation.
3.5 My psychophysical laws

A few contributors made comments on the three specific proposals I made about psychophysical laws: the principle of structural coherence, the principle of organizational invariance, and the double-aspect view of information. Taking these in turn:

(1) The principle of structural coherence. This is the least controversial of the three proposals, and unsurprisingly there was not much argument with it. It has long been recognized that there is a detailed correspondence between structural properties of the information processed in the brain and structural properties of conscious experience (see the "psychophysical axioms" of Muller 1896 and the "structural isomorphism" of Kohler 1947, for example). My slightly more specific proposal, specifying that the relevant information is that made available for global control, is also implicitly or explicitly present in much current research.

The only criticism is by Libet, who thinks that my equation of the structure of consciousness with the structure of awareness is either trivial or false. I think he is placing too much weight on the use of the word "awareness" here, however; I use the term stipulatively to refer to global availability of information (availability for such processes as verbal report, among other things), and might easily have used another term instead. I suspect that when this verbal issue is set aside, Libet will not find much to disagree with.

(2) The somewhat functionalist principle of organizational invariance, and my arguments for it, met with a bit more disagreement. Velmans objects to it on the grounds that a cortical implant might produce a refined version of blindsight, with excellent performance but no verbal reports of consciousness and hence no experience. But this is no counterexample to the principle: the very absence of verbal reports in these subjects show that they are functionally inequivalent to normal subjects. Perhaps they are "functionally equivalent" in some very loose sense, but the invariance principle requires a much stricter isomorphism than this. The moral is that the processes involved in the production of verbal reports are just as much part of a subject's functional organization as the processes responsible for discrimination and motor action. Indeed, these aspects of organization may be among the prime determinants of conscious experience.

Similarly, Libet says that I rely on a "behavioral" criterion for conscious experience, instead of more convincing criteria such as a subject's verbal report. But a verbal report is a sort of behavioral criterion in its own right; and in any case, it is clear that any subject who is functionally isomorphic to me in the strict sense that the principle requires will produce exactly the same verbal reports, and so will satisfy Libet's criterion. Libet is quite right that there are cases where performance on many tasks is dissociated from verbal report, but such cases are irrelevant to assessing the principle.
A fairly common reaction to these thought-experiments is to suggest that no silicon chip could in fact duplicate the function of a neuron, or at least that one should not beg that question. I agree that this is clearly an open empirical question. The principle says only that if a system is a functional isomorph of a conscious system, it will have the same sort of experiences; it makes no claims about just how such isomorphs might be realized. Silicon chips are just an example. If silicon isomorphs turn out to be possible, then the principle applies to them; if they do not, the scope of the principle will be more limited. Either way, the idea that functional organization fully determines conscious experience is unthreatened by this line of questioning.[*]

[*][[That being said: if the laws of physics are computable, a neuron's behavior is in principle computable too, and it is not implausible that the relevant computations could be hooked up to electrical and chemical mediators with other neurons, at least in principle if not easily in practice. We already have seen artificial hearts, and people are working on artificial retinas; my own money is on the eventual possibility of artificial neurons.]]

Hardcastle wonders if we can really know what will happen upon duplicating neural function in silicon. Here the answer is no and yes. No, we can't know for sure that neural function can be duplicated perfectly in silicon - that's the same open question as above. But we do know that if function-preserving substitution is possible, the resulting system will make just the same claims, the same behavior, and so on, as the original system. In fact we can know, in advance, precisely how the system will look from the third-person point of view. And even from the first-person point of view, I know that if some of my neurons are switched with identically-functioning silicon chips, I will come out swearing up and down that my qualia never changed. So in the relevant sense, I think we already know as much as we will ever know about how such a system will be.

Indeed, I think that if such substitution is ever possible, nobody will doubt the invariance principle for long. All it will take is a couple of substitutions, with subjects asserting that nothing has changed, and we will hear that there is "empirical evidence" that function-preserving substitution preserves conscious experience. The conclusion may be disputed by a handful of skeptical philosophers, but the subject's own word will be hard to resist. So I think that even now, the conditional assertion - if a functional isomorph is possible, then it will have the same sort of conscious experience - is at least as safe a bet.

Lowe thinks that the invariance principle "sells out completely" to functionalism, but this is a misunderstanding. Even many dualists hold that two subjects with the same brain state will have the same conscious state; presumably they are not thereby "selling out to physicalism", except in a highly attenuated sense of the latter. Consciousness is not reduced to a physical state; it is merely associated with one. By the same measure, to hold that two subjects in the same functional state have the same conscious state is not to sell out to functionalism, except in an attenuated sense. Consciousness is not reduced to a functional state; it is merely associated with one. Functional states, like physical states, turn out to determine conscious states with natural but not logical necessity. The resulting position, nonreductive functionalism, is compatible with the rich construal of mentality that reductive functionalism tacitly denies, precisely because a logical connection between function and experience is avoided.
Lowe may think that even a nonreductive functionalism is a bad thing, but to make that case, further reasons are required. For my part, I think that nonreductive functionalism stands a chance of capturing the most plausible and attractive elements of functionalist doctrines, while ignoring their reductive excesses.

Seager finds it odd that there should be laws connecting complex functional organizations to experience. I think that he is right and wrong to be worried about this. It would indeed be very odd if there were \textit{fundamental} laws connecting complex organizations to experience (just as it would be odd if there were fundamental laws about telephones), but I do not claim that such laws exist. The invariance principle is intended as a non-fundamental law: eventually it should be the consequence of more fundamental laws that underlie it. Such laws need not invoke complex functional organization directly; they might instead invoke some simple underlying feature, such as information. As long as this feature is itself an organizational invariant (as information plausibly is), the invariance principle may be a consequence.

Seager also worries about the fineness of organizational grain required to duplicate experience. I discuss this in my book: the grain needed for the fading and dancing qualia argument to go through is one that is sufficiently fine to capture the mechanisms that support our behavioral dispositions, such as our dispositions to make certain claims, and also sufficiently fine to allow either (a) that any two realizations be connected by a near-continuous spectrum of realizations (for the fading qualia argument), or (b) that any two realizations be connected by a chain of realizations such that neighboring links in the chain differ only over a small region (for the dancing qualia argument). It is not impossible that a less fine grain will also suffice to duplicate experience, but the arguments will give no purchase on these cases. Seager worries that nature does not know about levels of organization, but again this would be a worry only if the invariance principle were held to be a fundamental law.

Finally, Seager thinks that the association of experience with functional organization leads to a particularly worrisome form of epiphenomenalism. I think it is clear, however, that the arguments he invokes apply to any association of experience with physical properties. There is indeed an interesting problem of "explanatory exclusion" to worry about, as I discussed above, but nothing about this problem is specific to the invariance principle or to any of the psychophysical laws I propose.

(3) The double-aspect analysis of information is by far the most speculative and tentative part of my article, and it is surely the most likely to be wrong. Indeed, as I say in my book, I think it is more likely than not to be wrong, but I put it forward in the hope that it might help progress toward a more satisfactory theory. So I am far from sure that I can defend it against every possible criticism. That being said, I think that a couple of the criticisms of the information-based approach may rest on misinterpretations.

Lowe resists my invocation of Shannonian information as "inappropriate for characterizing the cognitive states of human beings." But as before, I am not trying to \textit{reduce} mental states to information processing. Such processing is instead invoked as a potential key to the physical \textit{basis} of consciousness. True, the double-aspect view implies that consciousness has formal properties that mirror the formal properties of
the underlying information; I think this claim is clearly plausible from phenomenological investigation, but it is nowhere claimed that these formal properties exhaust the properties of consciousness. Just because the skeletal framework is syntactic, for example, there is nothing to prevent irreducible non-syntactic properties from being present as well. In fact, it is obvious that there are phenomenal properties over and above these formal properties: such properties are precisely what make the phenomenal realization of the information so different from the physical realization. Shannonian information at best provides a framework around which a theory of these intrinsic properties can be hung.

Varela is similarly "dumbfounded" by my appeal to this sort of information, because of the "outmoded cybernetic tradition" it invokes. I am not nearly as certain as Varela that Shannonian information (as opposed to the cyberneticist use of it) is outmoded; indeed, I think one can argue that information states of the kind I describe in my book play a central role even in the computationalist, connectionist, and "embodied" frameworks that Varela endorses. These frameworks may add something to information states - such as a semantic content, or a context within the world - but all these frameworks invoke certain "difference structures" and their causal roles in a cognitive system. And precisely because this difference structure captures an important formal isomorphism between aspects of conscious states and the underlying physical states, the concept of information may provide a framework within which we can make progress. Once it is clear that experience is not being reduced to information, I think the way is cleared for information to play a useful formal role, and perhaps even to play a role in the underlying metaphysics.

Libet, Hardcastle, and Velmans note that some information is nonconscious. As I discuss in my book, there are two ways to deal with this. The first is to find further constraints on the sort of information that is associated with experience; it is entirely possible that some such constraint may play a role in the psychophysical laws. (Velmans offers some interesting suggestions about such constraints, although none of them seem likely candidates to be truly fundamental.) The other possibility is to accept that all information has an experiential aspect: while not all information is realized in my consciousness, all information is realized in some consciousness. This is counterintuitive to many, but I do not think the possibility can be immediately dismissed. I will discuss it when I discuss panpsychism below.

The ontology underlying the informational picture (which Velmans worries about) remains open. I discuss a number of possible interpretations of it in my book. I am most attracted to a Russellian interpretation on which experience forms the "intrinsic" (or realizing) aspect of informational states which are fundamental to physics but characterized by physics only extrinsically. There is at least a kinship between the informational model and the Russellian metaphysics here, and exploiting it would lead to definite double-aspect ontology. ("Physics is information from the outside; experience is information from the inside.") But I am not certain that this can be made to work, and more straightforwardly dualistic interpretations are also available.

I favor the informational view largely because when I look for regularities between experience and the physical processes that underlie it, the most striking correspondences all lie at the level of information structures. We have to find something in underlying physical processes to link experience to, and information seems a plausible and universal candidate. Perhaps the biggest concern about this view is that
these informational structures do not lie at a fundamental level in physical processes; as Bilodeau notes, they are curiously abstract to play a role in a fundamental theory. On the other hand, there are ways of seeing information as fundamental to physics itself, so there may be ways in which a connection at a fundamental level can be leveraged to support this striking connection at the macroscopic level. But all that is very much in the realm of open questions.

4 POSITIVE PROPOSALS

A number of contributors made positive proposals about how the hard problem might be approached. These divide into (1) neuroscientific and cognitive approaches; (2) phenomenological approaches; (3) physics-based approaches, and (4) fundamental psychophysical theories. I will not try to assess each proposal at great length, but I will say a few words about the approaches and their relationship to my framework.

4.1 Neuroscientific and cognitive approaches

Proposals with a neurobiological and cognitive flavor were made by Crick and Koch, Baars, and MacLennan. The philosophical orientations of these range from reductionism to property dualism; this alone illustrates that a neurobiological approach to consciousness is compatible with many different philosophical views. Even if neurobiology and cognitive science alone cannot solve the hard problem, they may still play a central role in developing a theory.

Crick and Koch come closest to a reductionist view, although they are appropriately tentative about it. They first divide up the hard problem into three parts and offer an interesting solution to the third, concerning the incommunicability of experience. I think their idea here - that only relations are communicable because only relations are preserved throughout processing - is largely correct. That is, all that is communicable are differences that make a difference, or information states. Of course this is strictly speaking one of the "easy" problems, but it clearly has a close connection to the hard problem; I expect that a good cognitive account of what we can and cannot communicate about consciousness will lead to some very useful insights about the hard problem itself. I develop this point and tie it to an informational view of consciousness in Chapter 8 of my book.

On the hard problem, Crick and Koch suggest that it may be promising to focus first on "meaning". I am less sure about this: meaning seems to be almost as difficult a concept as consciousness, and perhaps even more ambiguous. If one invokes a purely functional construal of meaning - so that meaning comes down to certain correlations with the environment and certain effects on later processing - then a neurobiological account of meaning may be forthcoming, but such a functional account will not tell us why the meaning should be consciously experienced. And if one invokes a richer construal of meaning - one on which meaning is more closely tied to consciousness, for example - then there is more chance that an account of meaning may yield an account of consciousness, but a functional explanation of meaning becomes much less likely. Nevertheless I imagine there are useful insights to be had by treading this path, whether or not it leads to a solution to the hard problem.
An intermediate line is taken by **Baars**, who argues that a functional theory can at least shed considerable light on subjective experience, but who does not claim that it solves the hard problem. Indeed, he thinks the hard problem is too hard to be solved for now, because it involves an implausible criterion. I think that Baars misinterprets the hard problem slightly, however. To solve the hard problem we need not actually evoke all relevant experiences in ourselves (his "empathy criterion"). The point is not to *experience* what it is like to be a bat (although that would be nice!), but rather to explain why there is anything it is like to be a bat or a human at all. And this seems like a perfectly reasonable scientific question.

Baars also notes that there are deep causal connections between "easy" and "hard" aspects of our mental lives. This is certainly correct; indeed, I pointed out some such connections in my article. There seems to be a tight connection between global availability and consciousness, for example, as Baars suggests. So this sort of connection is quite compatible with my framework: the distinction between the easy and hard problems is a *conceptual* distinction, not a claim that the two have nothing to do with each other.

In particular, even once these causal interconnections are granted, one can still ask how and why the "easy" aspects are tied to the "hard". In conversation, Baars has suggested that one should just regard this as a brute fact, noting that psychologists are used to dealing in brute facts! So one might just take it as a brute fact that the contents of a global workspace are consciously experienced, for example. I think there is something to this, but one has to note that this brute fact has some strong consequences. For a start, it implies that a theory of consciousness requires explanatorily primitive principles over and above the facts about processing. Even if "easy" and "hard" phenomena are two different aspects of the same thing, as Baars suggests, this still requires some further principle to tie the two aspects together, and indeed to explain why there are two aspects in the first place.

Of course it is most unlikely that the whole problem will be solved in one bite, so it is entirely reasonable for Baars to leave things at the level of a connection between the global workspace and consciousness. This reflects a common strategy for dealing with consciousness in those areas of psychology that take it seriously: take the existence of consciousness for granted, and investigate just how and where it maps onto cognitive processing. (The literature on the properties of conscious vs. unconscious processes can be read this way, for example.) This way the roots of consciousness may be located, and the path may be cleared for a theory of the underlying connection.

**MacLennan** aims to take the next step, searching for a simple theory that explains the connection. He accepts that there is an irreducible phenomenal aspect that is systematically associated with neural processes, yielding a property dualism similar to mine but with a neurodynamical flavor; and he develops some ideas about the "deep structure" of the link between neural processes and experience.

I think MacLennan's idea of "protophenomena" (or "phenomenisca") as basic elements of consciousness is particularly interesting, and promises considerable rewards if it can be further developed. For a precise theory, I think we will need an account of (a) precisely when a protophenomenon is associated with a physical process, (b) what sort of protophenomena will be associated, depending on the characteristics of the physical process, and (c) the principles by which protophenomena combine into a unified conscious
None of these questions are trivial, although MacLennan makes a start on all of them. His answer to (a) relies on a one-activity-site-one-protophenomenon principle; for my part I would be surprised if things were so straightforward. It might be that protophenomena are determined by informational states of the system that are not straightforwardly localized, for example. He does not have too much to say about (b) - precisely what makes for the difference between visual and auditory protophenomena, for example? - but he has a preliminary analysis of (c). I suspect that (c) (an analog of the problems faced by the Russellian metaphysics described earlier) may turn out to be the hardest question of all.

In any case, I see the central parts of the projects of Crick and Koch, Baars, and MacLennan as all being compatible with the research program I envisage on the hard problem. At the nuts-and-bolts level, we must try to isolate the neural processes associated with consciousness, and to find detailed and systematic associations between these processes and characteristics of conscious experience. We should do the same at a cognitive level, where it may be that we will find "cleaner" associations if less detail, along with a way of integrating key elements of the neural story into a big picture. A clean association between global availability and consciousness, for example, promises to help make sense of messier associations involving various specific neural processes. Finally, we should search for the fundamental principles that underlie and explain these associations, boiling things down to as simple a system as possible.

All this is compatible both with the scientific worldview and with the irreducibility of consciousness. Once released from the insistent tug of the reductive dream, we are free to engage in the project of relating consciousness to physical processes on its own terms. The resulting science may be all the richer for it.

### 4.2 Phenomenological approaches

Shear and Varela concentrate on phenomenological approaches to the hard problem. I think that such an approach must be absolutely central to an adequate science of consciousness: after all, it is our own phenomenology that provides the data that need to be explained! If we are to have a detailed psychophysical theory, as opposed to a mere ontology, then we will have to catalog and systematize these data much as happens elsewhere in science; and to do this, patient attention to one's own experience is required.

Of course there are deep methodological problems here. The first is the old problem that the mere act of attention to one's experience transforms that experience. As we become more patient and careful, we may find that we are studying data that are transformed in subtle ways. This is not too much of a problem at the start of investigation -- we have a long way to go until this degree of subtlety even comes into play - but it may eventually lead to deep paradoxes of observership. Phenomenologists from both East and West have proposed ways to deal with this problem, but I think it has a certain resilience. Even if there do turn out to be limits on the fineness of this method's grain, however, I have no doubt that coarse-grained methods can take us a long way.
The second problem is that of developing a language - or better, a formalism - in which phenomenological data can be expressed. In other areas, the advent of such formalisms has led to rapid progress. We still seem to be far from such a formalism here, however. The notorious "ineffability" of conscious experience plays a role here: the language we have for describing experiences is largely derivative on the language we have for describing the external world. Perhaps, as Thomas Nagel has suggested, the structural properties of experience (e.g., the geometric structure of a visual field) will be most amenable to the possibility of formal expression, whether in informational, geometric, or topological terms, or in other terms entirely. I suspect that the residual non-structural properties will pose special problems.

The third difficulty lies in the failure, or at least the limitations, of incorrigibility: our judgments about experience can be wrong. I don't think this difficulty is as damning for phenomenology as it is sometimes made out to be; after all, our judgments about external data can be wrong, too, but science manages just fine. What is important is that our judgments about experience are accurate by and large, particularly when we are paying careful and patient attention. Our introspection must also be critical: we must take care to consider any ways in which it might be going wrong. But if our phenomenological judgments pass these tests, I think one is justified in taking them to be reliable.

Shear's and Varela's papers together make a strong case that a sophisticated phenomenological study is possible. In Shear's wide-ranging paper, the remarks about "pure consciousness" are particularly intriguing. I confess that I find myself among the skeptics where this notion is concerned. I am not sure that I can imagine a consciousness without quality: would not even a "void" experience have a certain voidish quality? (Shear's own position is appropriately cautious here.) But perhaps this is only because I have never experienced such a thing myself. The idea is appealing, at any rate, in the same sort of way that the Russellian idea of a physical world without intrinsic qualities is appealing: the appeal manifests itself both in spite of and because of its flirtation with incoherence. And the potential link that Shear suggests between this idea and a fundamental theory is certainly suggestive.

I am also sympathetic with much of Varela's discussion, in its shape if not in every detail. Varela takes himself to differ with me on some central points, but I am not sure why. The main difference between us seems to be one of emphasis: he emphasizes the phenomenological data, whereas I emphasize the systematicity in the relationship between these data and underlying processes. Perhaps he takes my "extra ingredient" or "theoretical fix" to be something more reductive than I intended. Varela himself seems to endorse the need for an extra ingredient in our theories - namely experience itself - which fits my program well. He may differ by doubting the likelihood of simple underlying laws connecting the physical and phenomenal domains; but if so, he does not give his reasons in this article. In any case, the idea of "neurophenomenology" sounds eminently sensible to me. The test will be whether it can be cashed out in the form of detailed results.

It would be overambitious to suppose that phenomenology by itself offers a solution to the hard problem. The ontological debates are as hard as ever, and phenomenology is largely neutral on them (except, perhaps, in rejecting type-A materialism). But it is absolutely central to the epistemology of the hard
problem: without it, we would not even know what needs explaining. In most areas of science, we need an adequate epistemology to get a detailed theory off the ground, and there is no reason to suspect that the case of consciousness will be any different. If so, the sort of careful study advocated by Shear and Varela will be a central component in the path to a solution.

4.3 Physics-based approaches

In getting an empirical theory of consciousness off the ground, the two areas just discussed will play the central roles. Neuro/cognitive science will provide the third-person data and phenomenology will provide the first-person data. As all this goes on, theorists of all stripes will seek to systematize the connection between the two. In the early stages, this connection will be strongest at the "surface" level: researchers will isolate correlations between fairly complex neuro/cognitive processes and relatively familiar characteristics of conscious experience. This high-level project may well be the solid core of consciousness research for many years to come. As the project develops, though, there will be an increasing drive to find the deep structure that underlies and explains these high-level connections, with the ultimate goal being a fundamental psychophysical theory.

We are not close to having such a fundamental theory yet, but this need not stop us from speculating about its form. Many contributors to this symposium do just that, offering proposals about links between consciousness and physical processes at the most fundamental level. In this section and the next, I will discuss these proposals. Those with conservative tastes might stop here: what follows is largely untrammeled speculation in physics and metaphysics about what may be required to bring consciousness within the natural order. I do not know whether any of this is on the right track, but there are plenty of interesting ideas with which I am more than happy to play along.

A number of contributors suggest approaches in which physics plays a central role. I expressed some criticism of physics-based proposals in the keynote paper, but mostly insofar as these were offered as reductive explanations of consciousness. ("Neurons can't do the job, but quantum mechanics can."). None of the current contributors offer that sort of account. Most of them instead offer proposals on which consciousness is taken as fundamental, and is related nonreductively to the entities in physical theories, perhaps in the hopes of finding a natural place for consciousness in the natural order. Such suggestions are not subject to the same sort of criticism, and they certainly cannot be ruled out a priori.

The difference between the two sorts of physics-based proposals is most apparent in the article by Hameroff and Penrose. Previous work had given me the impression that their aim was to explain consciousness wholly in terms of quantum action in microtubules; but this paper makes it explicit that consciousness is instead to be taken as fundamental. In essence, Hameroff and Penrose offer a psychophysical theory, postulating that certain quantum-mechanical reductions of the wave function, brought on when a certain gravitational threshold is attained, are each associated with a simple event of experience. They suggest a kinship with Whitehead's metaphysics; the view might also fit comfortably into the Russellian framework outlined earlier.
This is an intriguing and ambitious suggestion. Of course the details are a little sketchy: after their initial postulate, Hameroff and Penrose concentrate mostly on the physics of reduction and its functioning in microtubules, and leave questions about the explanation of experience to one side. Eventually it would be nice to see a proposal about the precise form of the psychophysical laws in this framework, and also to see how these billions of microscopic events of experience might somehow yield the remarkable structural properties of the single complex consciousness that we all possess. I am cautious about this sort of quantum-mechanical account myself, partly because it is not yet clear to me that quantum mechanics is essential to neural information-processing, and partly because it is not easy to see how quantum-level structure corresponds to the structure one finds in consciousness. But it is not impossible that a theory might address these problems. To know for sure, we will need a detailed explanatory bridge.

Stapp offers a very different sort of quantum-mechanical proposal. Instead of trying to constitute experience out of many low-level quantum-mechanical events, he takes consciousness as a given, and offers a theory of the role it plays in collapsing physical wave functions, thus showing how it might have an impact on the physical world. As I said earlier, this sort of "collapse" interpretation of quantum mechanics needs to be taken very seriously - in the interests both of giving a good account of quantum mechanics and of giving a good account of consciousness - and Stapp's, as developed in a number of papers, is perhaps the most sophisticated version of such an interpretation to date. It certainly offers the most natural picture in which consciousness plays a role in influencing a non-causally-closed physical world.

Stapp's paper is neutral on some central questions that a theory of consciousness needs to answer. He says quite a lot about his mental-to-physical laws, characterizing the role of consciousness in wave-function collapse, but he does not say much about the physical-to-mental laws which will presumably be at the heart of a theory. Such laws will tell us just which physical processes are associated with consciousness, and what sort of conscious experience will be associated with a given physical process. (Of course, we know that experiences have "actualizations" as a physical correlate; but given that Stapp wants pre-existing experiences to cause the actualizations, we need some independent physical criterion for experience. This would then yield a physical criterion for actualization in turn.) As it stands, Stapp's picture seems compatible with almost any physical-to-mental laws. Stapp offers some suggestions about such laws in his book (Stapp 1993), where he proposes that experience goes along with "top-level processes" in the brain; but perhaps it is a virtue of Stapp's broader proposal about the causal role of consciousness that many different psychophysical theories can benefit by invoking it.[*]

[*][[One intriguing if far-out possibility: if Stapp's proposal were granted, it might even be that experimental physics could help determine the psychophysical laws, and determine which systems are conscious, at least in principle. It turns out that different proposals about the physical criteria for collapse have subtly different empirical consequences, although they are consequences that are practically impossible to test in general (see Albert 1992 for discussion). So at least in principle, if not in practice, one could test for the presence or absence of collapse in a given system, and thus for the presence or absence of experience!!]]

Clarke suggests a different connection between physics and consciousness, rooted in the nonlocality of both. The nonlocality of the former is less controversial, in a way: nonlocal causal influences are present in most interpretations of quantum mechanics, with the exception of those by Everett (1973) and Cramer
Moving Forward on the Problem of Consciousness

(1986), and nonlocal constitution of physical states is present on most of these in turn. The sense in which mind is nonlocal is less clear to me. I am sympathetic with Clarke's point that mind is not located in physical space, but I am not sure of the link between these two sorts of nonlocality. Clarke argues that the physical structure that supports mind has to be nonlocal; but all that is clear to me is that it has to be nonlocalized, or distributed across space, which is equally possible on a classical theory. But perhaps nonlocal constitution of a physical state could be linked to the unity of consciousness, especially on a view which identifies consciousness with a physical state in such a way that unified consciousness requires a unified substrate: nonlocal physical constitution might unify the basis? The idea might also help in a Russellian metaphysics, though I am not sure that it is required.

Another appeal to physics is made by McGinn, who suggests that accommodating consciousness within the natural order will require a radically revised theory of space. A question immediately suggests itself: will this theory be forced on us to explain (third-person) empirical evidence, or just to accommodate consciousness? I suspect that it must be the latter. All sorts of revisions in our physical theories are made to explain the external world, but they always leave theories cast in terms of some basic mathematical structures and dynamics (whether Euclidean space, four-dimensional space-time, or infinite-dimensional Hilbert space). There are principled reasons why structure and dynamics is all we could possibly need to explain external evidence; and given any theory cast solely in terms of structure and dynamics, the further question of consciousness will arise.

So it seems to me that McGinn needs an empirically adequate theory of space to be revised or supplemented in some fundamental way to accommodate consciousness, while leaving its external predictions intact. But McGinn also strongly wants to avoid epiphenomenalism (see McGinn 1996). I think that the natural way (perhaps the only way) to satisfy these requirements is along the Russellian lines suggested above: there is a pervasive intrinsic property of physical reality, a property which carries the structure and dynamics specified in physical theory but is nevertheless not revealed directly by empirical investigation, and which enables the existence of consciousness. This picture seems to square well with McGinn's remarks about a "hidden dimension" of physical reality. Concentrating on space in particular, we might perhaps think of this property as the "medium" in which the mathematical structures of space are embedded.

It seems clear, at any rate, that McGinn's "hidden dimension" requires us to postulate something new and fundamental over and above what is empirically adequate. As such it seems that he is embracing option (2) of the dilemma I posed him earlier in this paper. And this new fundamental property is a sort of "proto-experience", at least in the sense that it enables the existence of experience. If so then McGinn's view, when unpacked, is in the same sort of ballpark as the views I am advocating. Of course McGinn could be right that we will never be able to form such a theory, for example because of our inability to grasp the relevant proto-experiential concept. On the other hand, he could be wrong; so I for one will keep trying.

Bilodeau takes the most radical physics-based approach, holding (I think) that we have to abandon the idea that there are objectively existing states in fundamental physics. Instead, physical reality crystallizes in some way as a product of experience and the process of inquiry. Once we see that experience is fundamental to the very nature of physical reality in this way, the hard problem may go way.
Bilodeau suggests that this picture is the most natural upshot of quantum mechanics, appealing especially to the writings of Bohr. Now I think this picture is certainly not forced on us by quantum mechanics - there are plenty of ways of making sense of quantum mechanics while maintaining the idea that fundamental physical reality has an objective existence, if only in the form of a superposed wave function. Bilodeau clearly finds these interpretations unappealing, but I (like many others) find them much more comprehensible. Given that macroscopic physical reality has an objective existence, it seems that its causal antecedents must have objective existence (otherwise why would it come into existence?), and in the process of explanation we are relentlessly driven to causal antecedents at more and more fundamental levels. So the only way I can make sense of the idea that fundamental physical reality does not have objective existence is as a form of idealism, on which all physical reality is present only within experience. Bilodeau disclaims this interpretation, however, so this may be a cognitive limitation on my part.

In any case it seems that even under Bilodeau's reasoning, there still needs to be an explanatory theory connecting experiences and brain processes. I am not quite sure what the shape of such a theory will be, but perhaps his version of the metaphysics will be able to give a natural version of it. It would be very interesting to see some of the details.

4.4 Fundamental psychophysical theories

Some of the most intriguing pieces, to me, are those that speculate about the shape of a fundamental theory of consciousness. Many of these proposals invoke some form of panpsychism. Panpsychism is not required for a fundamental theory; it is not written in stone that fundamental properties have to be ubiquitous. Libet and Stapp, for example, both invoke fundamental theories without invoking panpsychism. But the idea of a fundamental theory certainly fits well with panpsychism, and the proposals by Hut and Shepard, Rosenberg, and Seager are all explicitly panpsychist.

Some contributors (e.g. Mills and Hardcastle) roll their eyes at the idea of panpsychism, but explicit arguments against it are surprisingly hard to find. Rosenberg and Seager give nice defenses of panpsychism against various objections. Indeed, both upbraid me for not being panpsychist enough. I do not know whether panpsychism is true, but I find it an intriguing view, and in my book I argue that it deserves attention. If a simple and powerful predictive theory of consciousness ends up endorsing panpsychism, then I do not see why we should not accept it.

Panpsychist views need not ascribe much of a mind to simple entities. Sometimes the term "panexperientialism" is used instead, to suggest that all that is being ascribed is some sort of experience (not thought, not intelligence, not self-awareness), and a particularly simple form of experience at that. And some versions do not even go this far. Instead of suggesting that experience is ubiquitous, such views suggest that some other property is ubiquitous, where instantiations of this property somehow jointly constitute experience in more complex systems. Such a property might be thought of as a proto-experiential property, and the associated view might more accurately be thought of as panprotopsychism.
Of course it is very hard to form a conception of protoexperiential properties. We know no set of physical properties can constitute experience, for familiar reasons. But perhaps some quite alien property might do the job. I was particularly intrigued by Hut and Shepard's postulation of a property `X', where X stands to consciousness as time stands to motion. That is, just as time enables the existence of motion, in combination with space, X enables the existence of consciousness, in combination with the basic dimensions of space-time. This offers an elegant picture of proto-experience quite different from the tempting picture on which proto-experience is "just like experience but less so".

In a way, Hut and Shepard's proposal has a lot in common with McGinn's suggestion of a "hidden dimension" of space which enables the existence of consciousness. As with McGinn, once can ask whether the dimension is truly "hidden", or whether it will manifest itself in our external observations (the physics we have now does a pretty good job, after all). As before, I suspect that such a property has to be hidden, as an empirically adequate theory can always be cast in terms of structure and dynamics that are compatible with the absence of experience. Thus, as before it seems that the new dimension will either (a) be epiphenomenal to the other dimensions (or at least to the projections of those dimensions that we have access to), or (b) related to them as a sort of Russellian "realizing" property, carrying the structure in one of these dimensions and making it real. The latter would be particularly compatible with the idea of turning the hard problem "upside down", on which physical reality is itself somehow derivative on underlying (proto)experiences.

Rosenberg offers a detailed defense of panpsychism, and makes a number of points with which I am particularly sympathetic. He makes a strong case against the existence of fundamental laws that connect consciousness to mere complexity, to aspects of functioning, or to biological properties. While I think there is nothing wrong with the idea of a nonpanpsychist fundamental theory, Rosenberg's discussion eliminates some of the most obvious candidates. (Another possibility worth considering, though: several simple laws might combine to imply that experience only comes into existence in certain complex cases.) And he begins to unpack what panpsychism might involve in a way that makes it clear that the idea is at least coherent.

Rosenberg also makes a strong case for an integrated view of nature, on which consciousness is not a mere tacked-on extra. My keynote paper may carry a flavor of the latter (except for the final paragraph of section VII), but I think the former is the ultimate goal. Perhaps the best path to such an integrated view is offered by the Russellian picture on which (proto)experiential properties constitute the intrinsic nature of physical reality. Such a picture is most naturally associated with some form of panpsychism. The resulting integration may be panpsychism's greatest theoretical benefit.

Seager also provides some motivation for panpsychism, and gives a particularly interesting accounting of its problems. I think his "completeness problem" (a version of the epiphenomenalism problem) is mitigated by embracing the Russelian interpretation, on which the fundamental (proto)experiences are part of the causal order, although there will always be residual worries about explanatory superfluity. (Giving experiences certain anomalous effects doesn't help here; experience-free structural explanations are just as possible either way.) This view would also solve his "no-sign" problem: we cannot expect to have external access to the intrinsic properties that underlie physical dispositions. A solution to the "not-
mental" problem must likely wait until we have a theory; presumably we will then be justified in attributing (proto-) mentality in certain cases precisely because of the theory's indirect explanatory benefits in explaining our own experiences. A version of the "unconscious mentality" problem will apply to any view that postulates proto-experiential rather than experiential properties at the fundamental level (how does experience emerge from non-experience?), but this need not be quite as hard as the original hard problem. We know that physical properties cannot imply experience, because of the character of physics, but novel intrinsic proto-experiential properties cannot be ruled out in the same way.

This leaves the "combination problem", which is surely the hardest. This is the problem of how low-level proto-experiential and other properties somehow together constitute our complex unified conscious experiences. (One might also think of it as the "constitution problem", to avoid the implication that constitution must work by simple combination; consider Hut and Shepard's non-combinatorial proposal, for example.) The problem could be bypassed altogether by suggesting that complex experiences are not constituted by the micro-experiences, but rather arise autonomously. This would hold true under many psychophysical theories, including some versions of an informational theory; its main disadvantage is that it once again threatens epiphenomenalism. To make experience causally relevant in the Russelian way, it seems that it has to be constituted out of the intrinsic natures of the fundamental causally relevant entities in physical theory. Unless we embrace an interactionist picture like Stapp's where there is fundamental causation at a high level, it seems that integrating experience into the causal order leads inevitably to the combination problem.

To solve the problem, we have to investigate the principles of composition to which experience is subject. The "problem" may well arise from thinking of experiential composition along the lines of physical composition, when it might well work quite differently. I suggest in my book, for example, that something more like informational composition might be more appropriate. Alternatively, we may try to keep a closer isomorphism between experiential composition and physical composition, but investigate nonstandard manners of physical composition. Seager's invocation of quantum coherence is an intriguing example of such a strategy: in this case physical composition yields a unity that might mirror the unity of experience. To the best of my knowledge, the evidence for widespread stable quantum coherent states at a macroscopic level in the brain is not strong, but this is nevertheless a strategy to keep in mind. A related quantum-mechanical strategy is discussed by Lockwood (1992), who also provides an illuminating discussion of the problem in general. There may well be other interesting ideas waiting to be explored in addressing the problem; it is likely to be a fruitful area for further inquiry.

Of course everything in these last two sections has the air of something put together in the metaphysical laboratory, to use Seager's phrase. It is all extraordinarily speculative, and has to be taken with a very large grain of salt. Like my own speculations about information, these suggestions have not yet been remotely developed to the point where they can be given a proper assessment - indeed, their largely undefined nature may be the reason that I am able to speak reasonably warmly of all of them! And most of them have not yet begun to provide a detailed explanatory bridge from the fundamental level to the complex experiences we know and love. I favor the informational view partly because it seems closer to providing such a bridge than proposals based directly in physics or elsewhere, but even this view is very sketchy in crucial places.
To have a fundamental theory that we can truly assess, we will need a fundamental theory with details. That is, we will need specific proposals about psychophysical laws, and specific proposals about how these laws combine, if necessary, so that ultimately we will be able to (1) take the physical facts about a given system, (2) apply the psychophysical theory to these facts, and thus (3) derive a precise characterization of the associated experiences that the theory predicts. As yet, we do not have a single theory that allows this sort of derivation. Indeed, as I noted above, we may first need to develop a proper formalism (informational, geometrical, topological?) for characterizing experiences before this project can get off the ground. And once we have such a formalism, it may well be extremely hard to devise a theory that even gives the right results in the simplest familiar cases. Once we do have a detailed theory that gives approximately correct results in familiar cases, however, we will know we are on the right track. The ultimate goal is a simple theory that gets things exactly right.

I imagine that it may well be many years until we have a good detailed theory. We will probably first have to concentrate on understanding the "macroscopic" regularities between processing and experience, and gradually work our way down to the fundamental principles that underlie and explain these regularities. Most researchers are now working at the macroscopic level, insofar as they are working on experience at all, and this is as it should be. But we can at least speculate about the form of a fundamental theory, in our more philosophical moments, and there is no reason why we should not try to come up with some details. Perhaps we will prove to have been terribly premature, but we will not know until we try. And in the meantime, I am sure that the attempt will be enlightening.

5 CONCLUSION

Taking a broad view of the metaphysics of the hard problem, here is the lay of the land as I see it.

(1) The first "choice point" is the question of whether there is a problem of consciousness at all, distinct from the problem of explaining functions. Some, the type-A materialists, deny this, though we have seen that there seem to be few good arguments for such a counterintuitive conclusion. Given that there is a further phenomenon that needs explaining, we have seen that one is forced to the conclusion that no reductive explanation of consciousness can be given, and that explanatorily primitive bridging principles are required.

(2) In a second choice point, some (the type-B materialists) try to preserve materialism by arguing that these principles are "identities". But we have seen that these explanatorily primitive identities are unparalleled elsewhere in science, are philosophically problematic, and require the invocation of a new and ungrounded form of necessity. In any case, the form of a theory of this sort will be just like the form of a theory that takes consciousness as fundamental, and these "identities" will function in our explanations just like fundamental laws.

(3) All other theories take experience (or proto-experience) as irreducible, along with irreducible principles relating it to the physical domain. The next choice point is whether to hold onto the causal closure of the physical. Denying this, perhaps through an invocation of wavefunction collapse in quantum
mechanics, leads to an interactionist dualism. But the advantages of this denial can be questioned.

(4) Given that the physical domain is a closed causal network, the next choice is that between views which put experience outside this network, with psychophysical laws that make experience epiphenomenal, or which put experience inside this network, by virtue of a Russellian monism on which the intrinsic properties of matter are proto-experiential. The latter offers the most attractive and integrated view, if the "combination problem" can be solved.

(5) The final choice point turns on the form of the psychophysical laws in our theory. This is the meatiest question of all, and can be engaged by researchers in all fields: the earlier questions require some tolerance for metaphysics, but this question is more straightforwardly "scientific". Much work on this question will be independent of specific choices on questions (2)-(4), though some aspects of these choices may inform one's approach to this question at some point.

Progress on the hard problem will likely take place at two levels. On the philosophical level, there will be an ongoing clarification of the issues surrounding (1)-(4), and the arguments for and against the various options at the various choice points. For my part I think the case for introducing new irreducible properties is hard to resist, but the choice points at (3) and especially (4) are still open. On a more concrete level, there will be progress toward specific laws as in (5). A combination of experimental study, phenomenological investigation, and philosophical analysis will lead us to systematic principles bridging the domains, and eventually we hope to be led to the underlying fundamental laws. In this way we may eventually arrive at a truly satisfactory theory of conscious experience.

Bibliography

Response to Papineau

This is a letter I sent to the *Times Literary Supplement* in response to David Papineau's review of my book *The Conscious Mind: In Search of a Fundamental Theory*. The letter was published in their issue of August 2, 1996, in a somewhat mangled form that made a few points hard to follow.

How do we explain the existence of consciousness in a physical world? In his review of my book *The Conscious Mind*, David Papineau defends an odd form of materialism, holding that brain states are conscious states, and that is that. To one who asks for an explanation of this fact - why does being in a brain state feel any way at all? - Papineau insists that we unask the question. The identity between brain states and conscious states is not something to be further explained, but rather is a sort of explanatory primitive.

This seems to make consciousness more mysterious than ever, except that Papineau puts a positive spin on his views by holding that identities are not the sort of thing one explains. But this is false, or at least misleading. The only explanatorily primitive principles elsewhere in science are the fundamental laws of physics: from these (plus boundary conditions), all else follows. Someone possessing the concepts of "Samuel Clemens" and "Mark Twain" (to use Papineau's example) but ignorant of their identity could deduce that identity from a specification of the microphysical facts, for example. But Papineau concedes that the brain-mind link cannot be deduced from microphysics; so this link is explanatorily primitive in a much stronger sense.

I think that such explanatory primitiveness is the mark of a fundamental law of nature, and so (in my book) go on to investigate a "fundamental theory" of the mind-brain link, analogous to fundamental theories in physics. Papineau chooses to call the primitive relation an "identity" rather than a law, thus saving materialism in letter if not in spirit. I suspect that many will find that the most important point has already been conceded; but in any case there are further technical reasons, discussed in the book, why this maneuver does not make sound philosophical sense.

In brief: Papineau's position commits him to a notion that I call "strong metaphysical necessity", in which there is little reason to believe (it is unlike any necessity found elsewhere in philosophy), and which suffers from all sorts of problems. He avoids this issue by misrepresentation and elision: he wrongly implies that my analysis assumes a "descriptive" view of reference, and he unaccountably ignores the treatment of strong metaphysical necessity, which is there to handle precisely his sort of "escape route". His further talk of "reference by simulation" and an "antipathetic fallacy" merely reiterates, rather than justifies, his commitment to explanatorily primitive identities and strong metaphysical necessities.

Technicalities aside, it is hard to see how Papineau's declaring the mind-brain relationship an "identity" gets him off the hook in providing a detailed theory of consciousness. We would still like a theory to predict just how various brain states will feel, whether it feels like anything to be a different system such
as a computer, and so on (unless Papineau implausibly denies that there is a fact of the matter here). And
as elsewhere in science, one would like to systematize and simplify the relevant principles as far as
possible. The result might well look like the fundamental theories I recommend, whether one talks of
identities or laws.

Papineau's critique of my positive views consists in the observation that I am committed to
epiphenomenalism - another misrepresentation. Although I don't share Papineau's phobia toward this
view, I discuss at length an interpretation that avoids both epiphenomenalism and Cartesian dualism.
This is an adaptation of the Russellan idea, recently advocated by Michael Lockwood, that the intrinsic
qualities of experience can play the role of the intrinsic qualities of matter, on which physics is silent.
This idea turns out to fit nicely with the information-based theories sketched in the constructive half of
the book (which Papineau skips entirely). I think the choice between ontologies here is still open, but
there are plenty of interesting options.

It would be terrific if the problem of consciousness could be removed by a magic bullet as simple as
Papineau's, and life would be a lot easier if every opponent's argument could be shoehorned into a
familiar stereotype. But deep problems and real arguments have a habit of popping straight back up
again.

[This appeared in the Journal of Consciousness Studies in 1995. Also online is my response, "Moving Forward on the Problem of Consciousness", to 26 articles commenting on this paper. That paper elaborates and extends many of the ideas in this one.]

1 Introduction

Consciousness poses the most baffling problems in the science of the mind. There is nothing that we know more intimately than conscious experience, but there is nothing that is harder to explain. All sorts of mental phenomena have yielded to scientific investigation in recent years, but consciousness has stubbornly resisted. Many have tried to explain it, but the explanations always seem to fall short of the target. Some have been led to suppose that the problem is intractable, and that no good explanation can be given.

To make progress on the problem of consciousness, we have to confront it directly. In this paper, I first isolate the truly hard part of the problem, separating it from more tractable parts and giving an account of why it is so difficult to explain. I critique some recent work that uses reductive methods to address consciousness, and argue that such methods inevitably fail to come to grips with the hardest part of the problem. Once this failure is recognized, the door to further progress is opened. In the second half of the paper, I argue that if we move to a new kind of nonreductive explanation, a naturalistic account of consciousness can be given. I put forward my own candidate for such an account: a nonreductive theory based on principles of structural coherence and organizational invariance and a double-aspect view of information.

2 The easy problems and the hard problem

There is not just one problem of consciousness. "Consciousness" is an ambiguous term, referring to many different phenomena. Each of these phenomena needs to be explained, but some are easier to explain than others. At the start, it is useful to divide the associated problems of consciousness into "hard" and "easy" problems. The easy problems of consciousness are those that seem directly susceptible to the standard methods of cognitive science, whereby a phenomenon is explained in terms of computational or neural...
Facing Up to the Problem of Consciousness

mechanisms. The hard problems are those that seem to resist those methods.

The easy problems of consciousness include those of explaining the following phenomena:

- the ability to discriminate, categorize, and react to environmental stimuli;
- the integration of information by a cognitive system;
- the reportability of mental states;
- the ability of a system to access its own internal states;
- the focus of attention;
- the deliberate control of behavior;
- the difference between wakefulness and sleep.

All of these phenomena are associated with the notion of consciousness. For example, one sometimes says that a mental state is conscious when it is verbally reportable, or when it is internally accessible. Sometimes a system is said to be conscious of some information when it has the ability to react on the basis of that information, or, more strongly, when it attends to that information, or when it can integrate that information and exploit it in the sophisticated control of behavior. We sometimes say that an action is conscious precisely when it is deliberate. Often, we say that an organism is conscious as another way of saying that it is awake.

There is no real issue about whether these phenomena can be explained scientifically. All of them are straightforwardly vulnerable to explanation in terms of computational or neural mechanisms. To explain access and reportability, for example, we need only specify the mechanism by which information about internal states is retrieved and made available for verbal report. To explain the integration of information, we need only exhibit mechanisms by which information is brought together and exploited by later processes. For an account of sleep and wakefulness, an appropriate neurophysiological account of the processes responsible for organisms' contrasting behavior in those states will suffice. In each case, an appropriate cognitive or neurophysiological model can clearly do the explanatory work.

If these phenomena were all there was to consciousness, then consciousness would not be much of a problem. Although we do not yet have anything close to a complete explanation of these phenomena, we have a clear idea of how we might go about explaining them. This is why I call these problems the easy problems. Of course, "easy" is a relative term. Getting the details right will probably take a century or two of difficult empirical work. Still, there is every reason to believe that the methods of cognitive science and neuroscience will succeed.

The really hard problem of consciousness is the problem of experience. When we think and perceive, there is a whirl of information-processing, but there is also a subjective aspect. As Nagel (1974) has put it, there is something it is like to be a conscious organism. This subjective aspect is experience. When we see, for example, we experience visual sensations: the felt quality of redness, the experience of dark and light, the quality of depth in a visual field. Other experiences go along with perception in different modalities: the sound of a clarinet, the smell of mothballs. Then there are bodily sensations, from pains to
Facing Up to the Problem of Consciousness

orgasms; mental images that are conjured up internally; the felt quality of emotion, and the experience of a stream of conscious thought. What unites all of these states is that there is something it is like to be in them. All of them are states of experience.

It is undeniable that some organisms are subjects of experience. But the question of how it is that these systems are subjects of experience is perplexing. Why is it that when our cognitive systems engage in visual and auditory information-processing, we have visual or auditory experience: the quality of deep blue, the sensation of middle C? How can we explain why there is something it is like to entertain a mental image, or to experience an emotion? It is widely agreed that experience arises from a physical basis, but we have no good explanation of why and how it so arises. Why should physical processing give rise to a rich inner life at all? It seems objectively unreasonable that it should, and yet it does.

If any problem qualifies as the problem of consciousness, it is this one. In this central sense of "consciousness", an organism is conscious if there is something it is like to be that organism, and a mental state is conscious if there is something it is like to be in that state. Sometimes terms such as "phenomenal consciousness" and "qualia" are also used here, but I find it more natural to speak of "conscious experience" or simply "experience". Another useful way to avoid confusion (used by e.g. Newell 1990, Chalmers 1996) is to reserve the term "consciousness" for the phenomena of experience, using the less loaded term "awareness" for the more straightforward phenomena described earlier. If such a convention were widely adopted, communication would be much easier; as things stand, those who talk about "consciousness" are frequently talking past each other.

The ambiguity of the term "consciousness" is often exploited by both philosophers and scientists writing on the subject. It is common to see a paper on consciousness begin with an invocation of the mystery of consciousness, noting the strange intangibility and ineffability of subjectivity, and worrying that so far we have no theory of the phenomenon. Here, the topic is clearly the hard problem - the problem of experience. In the second half of the paper, the tone becomes more optimistic, and the author's own theory of consciousness is outlined. Upon examination, this theory turns out to be a theory of one of the more straightforward phenomena - of reportability, of introspective access, or whatever. At the close, the author declares that consciousness has turned out to be tractable after all, but the reader is left feeling like the victim of a bait-and-switch. The hard problem remains untouched.

3 Functional explanation

Why are the easy problems easy, and why is the hard problem hard? The easy problems are easy precisely because they concern the explanation of cognitive abilities and functions. To explain a cognitive function, we need only specify a mechanism that can perform the function. The methods of cognitive science are well-suited for this sort of explanation, and so are well-suited to the easy problems of consciousness. By contrast, the hard problem is hard precisely because it is not a problem about the performance of functions. The problem persists even when the performance of all the relevant functions is explained. (Here "function" is not used in the narrow teleological sense of something that a system is designed to do, but in the broader sense of any causal role in the production of behavior that a system
To explain reportability, for instance, is just to explain how a system could perform the function of producing reports on internal states. To explain internal access, we need to explain how a system could be appropriately affected by its internal states and use information about those states in directing later processes. To explain integration and control, we need to explain how a system's central processes can bring information contents together and use them in the facilitation of various behaviors. These are all problems about the explanation of functions.

How do we explain the performance of a function? By specifying a mechanism that performs the function. Here, neurophysiological and cognitive modeling are perfect for the task. If we want a detailed low-level explanation, we can specify the neural mechanism that is responsible for the function. If we want a more abstract explanation, we can specify a mechanism in computational terms. Either way, a full and satisfying explanation will result. Once we have specified the neural or computational mechanism that performs the function of verbal report, for example, the bulk of our work in explaining reportability is over.

In a way, the point is trivial. It is a conceptual fact about these phenomena that their explanation only involves the explanation of various functions, as the phenomena are functionally definable. All it means for reportability to be instantiated in a system is that the system has the capacity for verbal reports of internal information. All it means for a system to be awake is for it to be appropriately receptive to information from the environment and for it to be able to use this information in directing behavior in an appropriate way. To see that this sort of thing is a conceptual fact, note that someone who says "you have explained the performance of the verbal report function, but you have not explained reportability" is making a trivial conceptual mistake about reportability. All it could possibly take to explain reportability is an explanation of how the relevant function is performed; the same goes for the other phenomena in question.

Throughout the higher-level sciences, reductive explanation works in just this way. To explain the gene, for instance, we needed to specify the mechanism that stores and transmits hereditary information from one generation to the next. It turns out that DNA performs this function; once we explain how the function is performed, we have explained the gene. To explain life, we ultimately need to explain how a system can reproduce, adapt to its environment, metabolize, and so on. All of these are questions about the performance of functions, and so are well-suited to reductive explanation. The same holds for most problems in cognitive science. To explain learning, we need to explain the way in which a system's behavioral capacities are modified in light of environmental information, and the way in which new information can be brought to bear in adapting a system's actions to its environment. If we show how a neural or computational mechanism does the job, we have explained learning. We can say the same for other cognitive phenomena, such as perception, memory, and language. Sometimes the relevant functions need to be characterized quite subtly, but it is clear that insofar as cognitive science explains these phenomena at all, it does so by explaining the performance of functions.

When it comes to conscious experience, this sort of explanation fails. What makes the hard problem hard...
Facing Up to the Problem of Consciousness

and almost unique is that it goes beyond problems about the performance of functions. To see this, note that even when we have explained the performance of all the cognitive and behavioral functions in the vicinity of experience - perceptual discrimination, categorization, internal access, verbal report - there may still remain a further unanswered question: Why is the performance of these functions accompanied by experience? A simple explanation of the functions leaves this question open.

There is no analogous further question in the explanation of genes, or of life, or of learning. If someone says "I can see that you have explained how DNA stores and transmits hereditary information from one generation to the next, but you have not explained how it is a gene", then they are making a conceptual mistake. All it means to be a gene is to be an entity that performs the relevant storage and transmission function. But if someone says "I can see that you have explained how information is discriminated, integrated, and reported, but you have not explained how it is experienced", they are not making a conceptual mistake. This is a nontrivial further question.

This further question is the key question in the problem of consciousness. Why doesn't all this information-processing go on "in the dark", free of any inner feel? Why is it that when electromagnetic waveforms impinge on a retina and are discriminated and categorized by a visual system, this discrimination and categorization is experienced as a sensation of vivid red? We know that conscious experience does arise when these functions are performed, but the very fact that it arises is the central mystery. There is an explanatory gap (a term due to Levine 1983) between the functions and experience, and we need an explanatory bridge to cross it. A mere account of the functions stays on one side of the gap, so the materials for the bridge must be found elsewhere.

This is not to say that experience has no function. Perhaps it will turn out to play an important cognitive role. But for any role it might play, there will be more to the explanation of experience than a simple explanation of the function. Perhaps it will even turn out that in the course of explaining a function, we will be led to the key insight that allows an explanation of experience. If this happens, though, the discovery will be an extra explanatory reward. There is no cognitive function such that we can say in advance that explanation of that function will automatically explain experience.

To explain experience, we need a new approach. The usual explanatory methods of cognitive science and neuroscience do not suffice. These methods have been developed precisely to explain the performance of cognitive functions, and they do a good job of it. But as these methods stand, they are only equipped to explain the performance of functions. When it comes to the hard problem, the standard approach has nothing to say.

4 Some case-studies

In the last few years, a number of works have addressed the problems of consciousness within the framework of cognitive science and neuroscience. This might suggest that the analysis above is faulty, but in fact a close examination of the relevant work only lends the analysis further support. When we investigate just which aspects of consciousness these studies are aimed at, and which aspects they end up

http://www.u.arizona.edu/~chalmers/papers/facing.html (5 of 24) [4/7/2002 1:44:37 PM]
explaining, we find that the ultimate target of explanation is always one of the easy problems. I will illustrate this with two representative examples.

The first is the "neurobiological theory of consciousness" outlined by Crick and Koch (1990; see also Crick 1994). This theory centers on certain 35-75 hertz neural oscillations in the cerebral cortex; Crick and Koch hypothesize that these oscillations are the basis of consciousness. This is partly because the oscillations seem to be correlated with awareness in a number of different modalities - within the visual and olfactory systems, for example - and also because they suggest a mechanism by which the binding of information contents might be achieved. Binding is the process whereby separately represented pieces of information about a single entity are brought together to be used by later processing, as when information about the color and shape of a perceived object is integrated from separate visual pathways. Following others (e.g., Eckhorn et al 1988), Crick and Koch hypothesize that binding may be achieved by the synchronized oscillations of neuronal groups representing the relevant contents. When two pieces of information are to be bound together, the relevant neural groups will oscillate with the same frequency and phase.

The details of how this binding might be achieved are still poorly understood, but suppose that they can be worked out. What might the resulting theory explain? Clearly it might explain the binding of information contents, and perhaps it might yield a more general account of the integration of information in the brain. Crick and Koch also suggest that these oscillations activate the mechanisms of working memory, so that there may be an account of this and perhaps other forms of memory in the distance. The theory might eventually lead to a general account of how perceived information is bound and stored in memory, for use by later processing.

Such a theory would be valuable, but it would tell us nothing about why the relevant contents are experienced. Crick and Koch suggest that these oscillations are the neural correlates of experience. This claim is arguable - does not binding also take place in the processing of unconscious information? - but even if it is accepted, the explanatory question remains: Why do the oscillations give rise to experience? The only basis for an explanatory connection is the role they play in binding and storage, but the question of why binding and storage should themselves be accompanied by experience is never addressed. If we do not know why binding and storage should give rise to experience, telling a story about the oscillations cannot help us. Conversely, if we knew why binding and storage gave rise to experience, the neurophysiological details would be just the icing on the cake. Crick and Koch's theory gains its purchase by assuming a connection between binding and experience, and so can do nothing to explain that link.

I do not think that Crick and Koch are ultimately claiming to address the hard problem, although some have interpreted them otherwise. A published interview with Koch gives a clear statement of the limitations on the theory's ambitions.

Well, let's first forget about the really difficult aspects, like subjective feelings, for they may not have a scientific solution. The subjective state of play, of pain, of pleasure, of seeing blue, of smelling a rose - there seems to be a huge jump between the materialistic level, of explaining molecules and neurons, and the subjective level. Let's focus on things
Facing Up to the Problem of Consciousness

that are easier to study - like visual awareness. You're now talking to me, but you're not looking at me, you're looking at the cappuccino, and so you are aware of it. You can say, 'It's a cup and there's some liquid in it.' If I give it to you, you'll move your arm and you'll take it - you'll respond in a meaningful manner. That's what I call awareness." ("What is Consciousness", Discover, November 1992, p. 96.)

The second example is an approach at the level of cognitive psychology. This is Baars' global workspace theory of consciousness, presented in his book A Cognitive Theory of Consciousness. According to this theory, the contents of consciousness are contained in a global workspace, a central processor used to mediate communication between a host of specialized nonconscious processors. When these specialized processors need to broadcast information to the rest of the system, they do so by sending this information to the workspace, which acts as a kind of communal blackboard for the rest of the system, accessible to all the other processors.

Baars uses this model to address many aspects of human cognition, and to explain a number of contrasts between conscious and unconscious cognitive functioning. Ultimately, however, it is a theory of cognitive accessibility, explaining how it is that certain information contents are widely accessible within a system, as well as a theory of informational integration and reportability. The theory shows promise as a theory of awareness, the functional correlate of conscious experience, but an explanation of experience itself is not on offer.

One might suppose that according to this theory, the contents of experience are precisely the contents of the workspace. But even if this is so, nothing internal to the theory explains why the information within the global workspace is experienced. The best the theory can do is to say that the information is experienced because it is globally accessible. But now the question arises in a different form: why should global accessibility give rise to conscious experience? As always, this bridging question is unanswered.

Almost all work taking a cognitive or neuroscientific approach to consciousness in recent years could be subjected to a similar critique. The "Neural Darwinism" model of Edelman (1989), for instance, addresses questions about perceptual awareness and the self-concept, but says nothing about why there should also be experience. The "multiple drafts" model of Dennett (1991) is largely directed at explaining the reportability of certain mental contents. The "intermediate level" theory of Jackendoff (1988) provides an account of some computational processes that underlie consciousness, but Jackendoff stresses that the question of how these "project" into conscious experience remains mysterious.

Researchers using these methods are often inexplicit about their attitudes to the problem of conscious experience, although sometimes they take a clear stand. Even among those who are clear about it, attitudes differ widely. In placing this sort of work with respect to the problem of experience, a number of different strategies are available. It would be useful if these strategic choices were more often made explicit.

The first strategy is simply to explain something else. Some researchers are explicit that the problem of
experience is too difficult for now, and perhaps even outside the domain of science altogether. These researchers instead choose to address one of the more tractable problems such as reportability or the self-concept. Although I have called these problems the "easy" problems, they are among the most interesting unsolved problems in cognitive science, so this work is certainly worthwhile. The worst that can be said of this choice is that in the context of research on consciousness it is relatively unambitious, and the work can sometimes be misinterpreted.

The second choice is to take a harder line and deny the phenomenon. (Variations on this approach are taken by Allport 1988, Dennett 1991, and Wilkes 1988.) According to this line, once we have explained the functions such as accessibility, reportability, and the like, there is no further phenomenon called "experience" to explain. Some explicitly deny the phenomenon, holding for example that what is not externally verifiable cannot be real. Others achieve the same effect by allowing that experience exists, but only if we equate "experience" with something like the capacity to discriminate and report. These approaches lead to a simpler theory, but are ultimately unsatisfactory. Experience is the most central and manifest aspect of our mental lives, and indeed is perhaps the key explanandum in the science of the mind. Because of this status as an explanandum, experience cannot be discarded like the vital spirit when a new theory comes along. Rather, it is the central fact that any theory of consciousness must explain. A theory that denies the phenomenon "solves" the problem by ducking the question.

In a third option, some researchers claim to be explaining experience in the full sense. These researchers (unlike those above) wish to take experience very seriously; they lay out their functional model or theory, and claim that it explains the full subjective quality of experience (e.g. Flohr 1992, Humphrey 1992). The relevant step in the explanation is usually passed over quickly, however, and usually ends up looking something like magic. After some details about information processing are given, experience suddenly enters the picture, but it is left obscure how these processes should suddenly give rise to experience. Perhaps it is simply taken for granted that it does, but then we have an incomplete explanation and a version of the fifth strategy below.

A fourth, more promising approach appeals to these methods to explain the structure of experience. For example, it is arguable that an account of the discriminations made by the visual system can account for the structural relations between different color experiences, as well as for the geometric structure of the visual field (see e.g., Clark 1992 and Hardin 1992). In general, certain facts about structures found in processing will correspond to and arguably explain facts about the structure of experience. This strategy is plausible but limited. At best, it takes the existence of experience for granted and accounts for some facts about its structure, providing a sort of nonreductive explanation of the structural aspects of experience (I will say more on this later). This is useful for many purposes, but it tells us nothing about why there should be experience in the first place.

A fifth and reasonable strategy is to isolate the substrate of experience. After all, almost everyone allows that experience arises one way or another from brain processes, and it makes sense to identify the sort of process from which it arises. Crick and Koch put their work forward as isolating the neural correlate of consciousness, for example, and Edelman (1989) and Jackendoff (1988) make related claims. Justification of these claims requires a careful theoretical analysis, especially as experience is not directly
Facing Up to the Problem of Consciousness

observable in experimental contexts, but when applied judiciously this strategy can shed indirect light on the problem of experience. Nevertheless, the strategy is clearly incomplete. For a satisfactory theory, we need to know more than which processes give rise to experience; we need an account of why and how. A full theory of consciousness must build an explanatory bridge.

5 The extra ingredient

We have seen that there are systematic reasons why the usual methods of cognitive science and neuroscience fail to account for conscious experience. These are simply the wrong sort of methods: nothing that they give to us can yield an explanation. To account for conscious experience, we need an extra ingredient in the explanation. This makes for a challenge to those who are serious about the hard problem of consciousness: What is your extra ingredient, and why should that account for conscious experience?

There is no shortage of extra ingredients to be had. Some propose an injection of chaos and nonlinear dynamics. Some think that the key lies in nonalgorithmic processing. Some appeal to future discoveries in neurophysiology. Some suppose that the key to the mystery will lie at the level of quantum mechanics. It is easy to see why all these suggestions are put forward. None of the old methods work, so the solution must lie with something new. Unfortunately, these suggestions all suffer from the same old problems.

Nonalgorithmic processing, for example, is put forward by Penrose (1989; 1994) because of the role it might play in the process of conscious mathematical insight. The arguments about mathematics are controversial, but even if they succeed and an account of nonalgorithmic processing in the human brain is given, it will still only be an account of the functions involved in mathematical reasoning and the like. For a nonalgorithmic process as much as an algorithmic process, the question is left unanswered: why should this process give rise to experience? In answering this question, there is no special role for nonalgorithmic processing.

The same goes for nonlinear and chaotic dynamics. These might provide a novel account of the dynamics of cognitive functioning, quite different from that given by standard methods in cognitive science. But from dynamics, one only gets more dynamics. The question about experience here is as mysterious as ever. The point is even clearer for new discoveries in neurophysiology. These new discoveries may help us make significant progress in understanding brain function, but for any neural process we isolate, the same question will always arise. It is difficult to imagine what a proponent of new neurophysiology expects to happen, over and above the explanation of further cognitive functions. It is not as if we will suddenly discover a phenomenal glow inside a neuron!

Perhaps the most popular "extra ingredient" of all is quantum mechanics (e.g. Hameroff 1994). The attractiveness of quantum theories of consciousness may stem from a Law of Minimization of Mystery: consciousness is mysterious and quantum mechanics is mysterious, so maybe the two mysteries have a common source. Nevertheless, quantum theories of consciousness suffer from the same difficulties as neural or computational theories. Quantum phenomena have some remarkable functional properties, such
Facing Up to the Problem of Consciousness

as nondeterminism and nonlocality. It is natural to speculate that these properties may play some role in the explanation of cognitive functions, such as random choice and the integration of information, and this hypothesis cannot be ruled out a priori. But when it comes to the explanation of experience, quantum processes are in the same boat as any other. The question of why these processes should give rise to experience is entirely unanswered.

(One special attraction of quantum theories is the fact that on some interpretations of quantum mechanics, consciousness plays an active role in "collapsing" the quantum wave function. Such interpretations are controversial, but in any case they offer no hope of explaining consciousness in terms of quantum processes. Rather, these theories assume the existence of consciousness, and use it in the explanation of quantum processes. At best, these theories tell us something about a physical role that consciousness may play. They tell us nothing about how it arises.)

At the end of the day, the same criticism applies to any purely physical account of consciousness. For any physical process we specify there will be an unanswered question: Why should this process give rise to experience? Given any such process, it is conceptually coherent that it could be instantiated in the absence of experience. It follows that no mere account of the physical process will tell us why experience arises. The emergence of experience goes beyond what can be derived from physical theory.

Purely physical explanation is well-suited to the explanation of physical structures, explaining macroscopic structures in terms of detailed microstructural constituents; and it provides a satisfying explanation of the performance of functions, accounting for these functions in terms of the physical mechanisms that perform them. This is because a physical account can entail the facts about structures and functions: once the internal details of the physical account are given, the structural and functional properties fall out as an automatic consequence. But the structure and dynamics of physical processes yield only more structure and dynamics, so structures and functions are all we can expect these processes to explain. The facts about experience cannot be an automatic consequence of any physical account, as it is conceptually coherent that any given process could exist without experience. Experience may arise from the physical, but it is not entailed by the physical.

The moral of all this is that you can't explain conscious experience on the cheap. It is a remarkable fact that reductive methods - methods that explain a high-level phenomenon wholly in terms of more basic physical processes - work well in so many domains. In a sense, one can explain most biological and cognitive phenomena on the cheap, in that these phenomena are seen as automatic consequences of more fundamental processes. It would be wonderful if reductive methods could explain experience, too; I hoped for a long time that they might. Unfortunately, there are systematic reasons why these methods must fail. Reductive methods are successful in most domains because what needs explaining in those domains are structures and functions, and these are the kind of thing that a physical account can entail. When it comes to a problem over and above the explanation of structures and functions, these methods are impotent.

This might seem reminiscent of the vitalist claim that no physical account could explain life, but the cases are disanalogous. What drove vitalist skepticism was doubt about whether physical mechanisms
Facing Up to the Problem of Consciousness

could perform the many remarkable functions associated with life, such as complex adaptive behavior and reproduction. The conceptual claim that explanation of functions is what is needed was implicitly accepted, but lacking detailed knowledge of biochemical mechanisms, vitalists doubted whether any physical process could do the job and put forward the hypothesis of the vital spirit as an alternative explanation. Once it turned out that physical processes could perform the relevant functions, vitalist doubts melted away.

With experience, on the other hand, physical explanation of the functions is not in question. The key is instead the conceptual point that the explanation of functions does not suffice for the explanation of experience. This basic conceptual point is not something that further neuroscientific investigation will affect. In a similar way, experience is disanalogous to the *élan vital*. The vital spirit was put forward as an explanatory posit, in order to explain the relevant functions, and could therefore be discarded when those functions were explained without it. Experience is not an explanatory posit but an explanandum in its own right, and so is not a candidate for this sort of elimination.

It is tempting to note that all sorts of puzzling phenomena have eventually turned out to be explainable in physical terms. But each of these were problems about the observable behavior of physical objects, coming down to problems in the explanation of structures and functions. Because of this, these phenomena have always been the kind of thing that a physical account might explain, even if at some points there have been good reasons to suspect that no such explanation would be forthcoming. The tempting induction from these cases fails in the case of consciousness, which is not a problem about physical structures and functions. The problem of consciousness is puzzling in an entirely different way. An analysis of the problem shows us that conscious experience is just not the kind of thing that a wholly reductive account could succeed in explaining.

6 Nonreductive explanation

At this point some are tempted to give up, holding that we will never have a theory of conscious experience. McGinn (1989), for example, argues that the problem is too hard for our limited minds; we are "cognitively closed" with respect to the phenomenon. Others have argued that conscious experience lies outside the domain of scientific theory altogether.

I think this pessimism is premature. This is not the place to give up; it is the place where things get interesting. When simple methods of explanation are ruled out, we need to investigate the alternatives. Given that reductive explanation fails, nonreductive explanation is the natural choice.

Although a remarkable number of phenomena have turned out to be explicable wholly in terms of entities simpler than themselves, this is not universal. In physics, it occasionally happens that an entity has to be taken as fundamental. Fundamental entities are not explained in terms of anything simpler. Instead, one takes them as basic, and gives a theory of how they relate to everything else in the world. For example, in the nineteenth century it turned out that electromagnetic processes could not be explained in terms of the wholly mechanical processes that previous physical theories appealed to, so Maxwell and others
introduced electromagnetic charge and electromagnetic forces as new fundamental components of a physical theory. To explain electromagnetism, the ontology of physics had to be expanded. New basic properties and basic laws were needed to give a satisfactory account of the phenomena.

Other features that physical theory takes as fundamental include mass and space-time. No attempt is made to explain these features in terms of anything simpler. But this does not rule out the possibility of a theory of mass or of space-time. There is an intricate theory of how these features interrelate, and of the basic laws they enter into. These basic principles are used to explain many familiar phenomena concerning mass, space, and time at a higher level.

I suggest that a theory of consciousness should take experience as fundamental. We know that a theory of consciousness requires the addition of something fundamental to our ontology, as everything in physical theory is compatible with the absence of consciousness. We might add some entirely new nonphysical feature, from which experience can be derived, but it is hard to see what such a feature would be like. More likely, we will take experience itself as a fundamental feature of the world, alongside mass, charge, and space-time. If we take experience as fundamental, then we can go about the business of constructing a theory of experience.

Where there is a fundamental property, there are fundamental laws. A nonreductive theory of experience will add new principles to the furniture of the basic laws of nature. These basic principles will ultimately carry the explanatory burden in a theory of consciousness. Just as we explain familiar high-level phenomena involving mass in terms of more basic principles involving mass and other entities, we might explain familiar phenomena involving experience in terms of more basic principles involving experience and other entities.

In particular, a nonreductive theory of experience will specify basic principles telling us how experience depends on physical features of the world. These psychophysical principles will not interfere with physical laws, as it seems that physical laws already form a closed system. Rather, they will be a supplement to a physical theory. A physical theory gives a theory of physical processes, and a psychophysical theory tells us how those processes give rise to experience. We know that experience depends on physical processes, but we also know that this dependence cannot be derived from physical laws alone. The new basic principles postulated by a nonreductive theory give us the extra ingredient that we need to build an explanatory bridge.

Of course, by taking experience as fundamental, there is a sense in which this approach does not tell us why there is experience in the first place. But this is the same for any fundamental theory. Nothing in physics tells us why there is matter in the first place, but we do not count this against theories of matter. Certain features of the world need to be taken as fundamental by any scientific theory. A theory of matter can still explain all sorts of facts about matter, by showing how they are consequences of the basic laws. The same goes for a theory of experience.

This position qualifies as a variety of dualism, as it postulates basic properties over and above the
properties invoked by physics. But it is an innocent version of dualism, entirely compatible with the scientific view of the world. Nothing in this approach contradicts anything in physical theory; we simply need to add further bridging principles to explain how experience arises from physical processes. There is nothing particularly spiritual or mystical about this theory - its overall shape is like that of a physical theory, with a few fundamental entities connected by fundamental laws. It expands the ontology slightly, to be sure, but Maxwell did the same thing. Indeed, the overall structure of this position is entirely naturalistic, allowing that ultimately the universe comes down to a network of basic entities obeying simple laws, and allowing that there may ultimately be a theory of consciousness cast in terms of such laws. If the position is to have a name, a good choice might be naturalistic dualism.

If this view is right, then in some ways a theory of consciousness will have more in common with a theory in physics than a theory in biology. Biological theories involve no principles that are fundamental in this way, so biological theory has a certain complexity and messiness to it; but theories in physics, insofar as they deal with fundamental principles, aspire to simplicity and elegance. The fundamental laws of nature are part of the basic furniture of the world, and physical theories are telling us that this basic furniture is remarkably simple. If a theory of consciousness also involves fundamental principles, then we should expect the same. The principles of simplicity, elegance, and even beauty that drive physicists' search for a fundamental theory will also apply to a theory of consciousness.

(A technical note: Some philosophers argue that even though there is a conceptual gap between physical processes and experience, there need be no metaphysical gap, so that experience might in a certain sense still be physical (e.g. Hill 1991; Levine 1983; Loar 1990). Usually this line of argument is supported by an appeal to the notion of a posteriori necessity (Kripke 1980). I think that this position rests on a misunderstanding of a posteriori necessity, however, or else requires an entirely new sort of necessity that we have no reason to believe in; see Chalmers 1996 (also Jackson 1994 and Lewis 1994) for details. In any case, this position still concedes an explanatory gap between physical processes and experience. For example, the principles connecting the physical and the experiential will not be derivable from the laws of physics, so such principles must be taken as explanatoryy fundamental. So even on this sort of view, the explanatory structure of a theory of consciousness will be much as I have described.)

7 Outline of a theory of consciousness

It is not too soon to begin work on a theory. We are already in a position to understand certain key facts about the relationship between physical processes and experience, and about the regularities that connect them. Once reductive explanation is set aside, we can lay those facts on the table so that they can play their proper role as the initial pieces in a nonreductive theory of consciousness, and as constraints on the basic laws that constitute an ultimate theory.

There is an obvious problem that plagues the development of a theory of consciousness, and that is the paucity of objective data. Conscious experience is not directly observable in an experimental context, so we cannot generate data about the relationship between physical processes and experience at will. Nevertheless, we all have access to a rich source of data in our own case. Many important regularities
between experience and processing can be inferred from considerations about one's own experience. There are also good indirect sources of data from observable cases, as when one relies on the verbal report of a subject as an indication of experience. These methods have their limitations, but we have more than enough data to get a theory off the ground.

Philosophical analysis is also useful in getting value for money out of the data we have. This sort of analysis can yield a number of principles relating consciousness and cognition, thereby strongly constraining the shape of an ultimate theory. The method of thought-experimentation can also yield significant rewards, as we will see. Finally, the fact that we are searching for a fundamental theory means that we can appeal to such nonempirical constraints as simplicity, homogeneity, and the like in developing a theory. We must seek to systematize the information we have, to extend it as far as possible by careful analysis, and then make the inference to the simplest possible theory that explains the data while remaining a plausible candidate to be part of the fundamental furniture of the world.

Such theories will always retain an element of speculation that is not present in other scientific theories, because of the impossibility of conclusive intersubjective experimental tests. Still, we can certainly construct theories that are compatible with the data that we have, and evaluate them in comparison to each other. Even in the absence of intersubjective observation, there are numerous criteria available for the evaluation of such theories: simplicity, internal coherence, coherence with theories in other domains, the ability to reproduce the properties of experience that are familiar from our own case, and even an overall fit with the dictates of common sense. Perhaps there will be significant indeterminacies remaining even when all these constraints are applied, but we can at least develop plausible candidates. Only when candidate theories have been developed will we be able to evaluate them.

A nonreductive theory of consciousness will consist in a number of psychophysical principles, principles connecting the properties of physical processes to the properties of experience. We can think of these principles as encapsulating the way in which experience arises from the physical. Ultimately, these principles should tell us what sort of physical systems will have associated experiences, and for the systems that do, they should tell us what sort of physical properties are relevant to the emergence of experience, and just what sort of experience we should expect any given physical system to yield. This is a tall order, but there is no reason why we should not get started.

In what follows, I present my own candidates for the psychophysical principles that might go into a theory of consciousness. The first two of these are nonbasic principles - systematic connections between processing and experience at a relatively high level. These principles can play a significant role in developing and constraining a theory of consciousness, but they are not cast at a sufficiently fundamental level to qualify as truly basic laws. The final principle is my candidate for a basic principle that might form the cornerstone of a fundamental theory of consciousness. This final principle is particularly speculative, but it is the kind of speculation that is required if we are ever to have a satisfying theory of consciousness. I can present these principles only briefly here; I argue for them at much greater length in Chalmers (1996).
1. The principle of structural coherence. This is a principle of coherence between the structure of consciousness and the structure of awareness. Recall that "awareness" was used earlier to refer to the various functional phenomena that are associated with consciousness. I am now using it to refer to a somewhat more specific process in the cognitive underpinnings of experience. In particular, the contents of awareness are to be understood as those information contents that are accessible to central systems, and brought to bear in a widespread way in the control of behavior. Briefly put, we can think of awareness as direct availability for global control. To a first approximation, the contents of awareness are the contents that are directly accessible and potentially reportable, at least in a language-using system.

Awareness is a purely functional notion, but it is nevertheless intimately linked to conscious experience. In familiar cases, wherever we find consciousness, we find awareness. Wherever there is conscious experience, there is some corresponding information in the cognitive system that is available in the control of behavior, and available for verbal report. Conversely, it seems that whenever information is available for report and for global control, there is a corresponding conscious experience. Thus, there is a direct correspondence between consciousness and awareness.

The correspondence can be taken further. It is a central fact about experience that it has a complex structure. The visual field has a complex geometry, for instance. There are also relations of similarity and difference between experiences, and relations in such things as relative intensity. Every subject's experience can be at least partly characterized and decomposed in terms of these structural properties: similarity and difference relations, perceived location, relative intensity, geometric structure, and so on. It is also a central fact that to each of these structural features, there is a corresponding feature in the information-processing structure of awareness.

Take color sensations as an example. For every distinction between color experiences, there is a corresponding distinction in processing. The different phenomenal colors that we experience form a complex three-dimensional space, varying in hue, saturation, and intensity. The properties of this space can be recovered from information-processing considerations: examination of the visual systems shows that waveforms of light are discriminated and analyzed along three different axes, and it is this three-dimensional information that is relevant to later processing. The three-dimensional structure of phenomenal color space therefore corresponds directly to the three dimensional structure of visual awareness. This is precisely what we would expect. After all, every color distinction corresponds to some reportable information, and therefore to a distinction that is represented in the structure of processing.

In a more straightforward way, the geometric structure of the visual field is directly reflected in a structure that can be recovered from visual processing. Every geometric relation corresponds to something that can be reported and is therefore cognitively represented. If we were given only the story about information-processing in an agent's visual and cognitive system, we could not directly observe that agent's visual experiences, but we could nevertheless infer those experiences' structural properties.

In general, any information that is consciously experienced will also be cognitively represented. The fine-
grained structure of the visual field will correspond to some fine-grained structure in visual processing. The same goes for experiences in other modalities, and even for nonsensory experiences. Internal mental images have geometric properties that are represented in processing. Even emotions have structural properties, such as relative intensity, that correspond directly to a structural property of processing; where there is greater intensity, we find a greater effect on later processes. In general, precisely because the structural properties of experience are accessible and reportable, those properties will be directly represented in the structure of awareness.

It is this isomorphism between the structures of consciousness and awareness that constitutes the principle of structural coherence. This principle reflects the central fact that even though cognitive processes do not conceptually entail facts about conscious experience, consciousness and cognition do not float free of one another but cohere in an intimate way.

This principle has its limits. It allows us to recover structural properties of experience from information-processing properties, but not all properties of experience are structural properties. There are properties of experience, such as the intrinsic nature of a sensation of red, that cannot be fully captured in a structural description. The very intelligibility of inverted spectrum scenarios, where experiences of red and green are inverted but all structural properties remain the same, show that structural properties constrain experience without exhausting it. Nevertheless, the very fact that we feel compelled to leave structural properties unaltered when we imagine experiences inverted between functionally identical systems shows how central the principle of structural coherence is to our conception of our mental lives. It is not a logically necessary principle, as after all we can imagine all the information processing occurring without any experience at all, but it is nevertheless a strong and familiar constraint on the psychophysical connection.

The principle of structural coherence allows for a very useful kind of indirect explanation of experience in terms of physical processes. For example, we can use facts about neural processing of visual information to indirectly explain the structure of color space. The facts about neural processing can entail and explain the structure of awareness; if we take the coherence principle for granted, the structure of experience will also be explained. Empirical investigation might even lead us to better understand the structure of awareness within a bat, shedding indirect light on Nagel's vexing question of what it is like to be a bat. This principle provides a natural interpretation of much existing work on the explanation of consciousness (e.g. Clark 1992 and Hardin 1992 on colors, and Akins 1993 on bats), although it is often appealed to inexplicitly. It is so familiar that it is taken for granted by almost everybody, and is a central plank in the cognitive explanation of consciousness.

The coherence between consciousness and awareness also allows a natural interpretation of work in neuroscience directed at isolating the substrate (or the neural correlate) of consciousness. Various specific hypotheses have been put forward. For example, Crick and Koch (1990) suggest that 40-Hz oscillations may be the neural correlate of consciousness, whereas Libet (1993) suggests that temporally-extended neural activity is central. If we accept the principle of coherence, the most direct physical correlate of consciousness is awareness: the process whereby information is made directly available for global control. The different specific hypotheses can be interpreted as empirical suggestions about how
awareness might be achieved. For example, Crick and Koch suggest that 40-Hz oscillations are the gateway by which information is integrated into working memory and thereby made available to later processes. Similarly, it is natural to suppose that Libet's temporally extended activity is relevant precisely because only that sort of activity achieves global availability. The same applies to other suggested correlates such as the "global workspace" of Baars (1988), the "high-quality representations" of Farah (1994), and the "selector inputs to action systems" of Shallice (1972). All these can be seen as hypotheses about the mechanisms of awareness: the mechanisms that perform the function of making information directly available for global control.

Given the coherence between consciousness and awareness, it follows that a mechanism of awareness will itself be a correlate of conscious experience. The question of just which mechanisms in the brain govern global availability is an empirical one; perhaps there are many such mechanisms. But if we accept the coherence principle, we have reason to believe that the processes that explain awareness will at the same time be part of the basis of consciousness.

2. The principle of organizational invariance. This principle states that any two systems with the same fine-grained functional organization will have qualitatively identical experiences. If the causal patterns of neural organization were duplicated in silicon, for example, with a silicon chip for every neuron and the same patterns of interaction, then the same experiences would arise. According to this principle, what matters for the emergence of experience is not the specific physical makeup of a system, but the abstract pattern of causal interaction between its components. This principle is controversial, of course. Some (e.g. Searle 1980) have thought that consciousness is tied to a specific biology, so that a silicon isomorph of a human need not be conscious. I believe that the principle can be given significant support by the analysis of thought-experiments, however.

Very briefly: suppose (for the purposes of a reductio ad absurdum) that the principle is false, and that there could be two functionally isomorphic systems with different experiences. Perhaps only one of the systems is conscious, or perhaps both are conscious but they have different experiences. For the purposes of illustration, let us say that one system is made of neurons and the other of silicon, and that one experiences red where the other experiences blue. The two systems have the same organization, so we can imagine gradually transforming one into the other, perhaps replacing neurons one at a time by silicon chips with the same local function. We thus gain a spectrum of intermediate cases, each with the same organization, but with slightly different physical makeup and slightly different experiences. Along this spectrum, there must be two systems \(A\) and \(B\) between which we replace less than one tenth of the system, but whose experiences differ. These two systems are physically identical, except that a small neural circuit in \(A\) has been replaced by a silicon circuit in \(B\).

The key step in the thought-experiment is to take the relevant neural circuit in \(A\), and install alongside it a causally isomorphic silicon circuit, with a switch between the two. What happens when we flip the switch? By hypothesis, the system's conscious experiences will change; from red to blue, say, for the purposes of illustration. This follows from the fact that the system after the change is essentially a
version of B, whereas before the change it is just A.

But given the assumptions, there is no way for the system to notice the changes! Its causal organization stays constant, so that all of its functional states and behavioral dispositions stay fixed. As far as the system is concerned, nothing unusual has happened. There is no room for the thought, "Hmm! Something strange just happened!". In general, the structure of any such thought must be reflected in processing, but the structure of processing remains constant here. If there were to be such a thought it must float entirely free of the system and would be utterly impotent to affect later processing. (If it affected later processing, the systems would be functionally distinct, contrary to hypothesis). We might even flip the switch a number of times, so that experiences of red and blue dance back and forth before the system's "inner eye". According to hypothesis, the system can never notice these "dancing qualia".

This I take to be a reductio of the original assumption. It is a central fact about experience, very familiar from our own case, that whenever experiences change significantly and we are paying attention, we can notice the change; if this were not to be the case, we would be led to the skeptical possibility that our experiences are dancing before our eyes all the time. This hypothesis has the same status as the possibility that the world was created five minutes ago: perhaps it is logically coherent, but it is not plausible. Given the extremely plausible assumption that changes in experience correspond to changes in processing, we are led to the conclusion that the original hypothesis is impossible, and that any two functionally isomorphic systems must have the same sort of experiences. To put it in technical terms, the philosophical hypotheses of "absent qualia" and "inverted qualia", while logically possible, are empirically and nomologically impossible.

(Some may worry that a silicon isomorph of a neural system might be impossible for technical reasons. That question is open. The invariance principle says only that if an isomorph is possible, then it will have the same sort of conscious experience.)

There is more to be said here, but this gives the basic flavor. Once again, this thought experiment draws on familiar facts about the coherence between consciousness and cognitive processing to yield a strong conclusion about the relation between physical structure and experience. If the argument goes through, we know that the only physical properties directly relevant to the emergence of experience are organizational properties. This acts as a further strong constraint on a theory of consciousness.

3. The double-aspect theory of information. The two preceding principles have been nonbasic principles. They involve high-level notions such as "awareness" and "organization", and therefore lie at the wrong level to constitute the fundamental laws in a theory of consciousness. Nevertheless, they act as strong constraints. What is further needed are basic principles that fit these constraints and that might ultimately explain them.

The basic principle that I suggest centrally involves the notion of information. I understand information
in more or less the sense of Shannon (1948). Where there is information, there are *information states* embedded in an *information space*. An information space has a basic structure of *difference* relations between its elements, characterizing the ways in which different elements in a space are similar or different, possibly in complex ways. An information space is an abstract object, but following Shannon we can see information as *physically embodied* when there is a space of distinct physical states, the differences between which can be transmitted down some causal pathway. The states that are transmitted can be seen as themselves constituting an information space. To borrow a phrase from Bateson (1972), physical information is a *difference that makes a difference*.

The double-aspect principle stems from the observation that there is a direct isomorphism between certain physically embodied information spaces and certain *phenomenal* (or experiential) information spaces. From the same sort of observations that went into the principle of structural coherence, we can note that the differences between phenomenal states have a structure that corresponds directly to the differences embedded in physical processes; in particular, to those differences that make a difference down certain causal pathways implicated in global availability and control. That is, we can find the *same* abstract information space embedded in physical processing and in conscious experience.

This leads to a natural hypothesis: that information (or at least some information) has two basic aspects, a physical aspect and a phenomenal aspect. This has the status of a basic principle that might underlie and explain the emergence of experience from the physical. Experience arises by virtue of its status as one aspect of information, when the other aspect is found embodied in physical processing.

This principle is lent support by a number of considerations, which I can only outline briefly here. First, consideration of the sort of physical changes that correspond to changes in conscious experience suggests that such changes are always relevant by virtue of their role in constituting *informational changes* - differences within an abstract space of states that are divided up precisely according to their causal differences along certain causal pathways. Second, if the principle of organizational invariance is to hold, then we need to find some fundamental *organizational* property for experience to be linked to, and information is an organizational property *par excellence*. Third, this principle offers some hope of explaining the principle of structural coherence in terms of the structure present within information spaces. Fourth, analysis of the cognitive explanation of our *judgments* and *claims* about conscious experience - judgments that are functionally explainable but nevertheless deeply tied to experience itself - suggests that explanation centrally involves the information states embedded in cognitive processing. It follows that a theory based on information allows a deep coherence between the explanation of experience and the explanation of our judgments and claims about it.

Wheeler (1990) has suggested that information is fundamental to the physics of the universe. According to this "it from bit" doctrine, the laws of physics can be cast in terms of information, postulating different states that give rise to different effects without actually saying what those states *are*. It is only their position in an information space that counts. If so, then information is a natural candidate to also play a role in a fundamental theory of consciousness. We are led to a conception of the world on which information is truly fundamental, and on which it has two basic aspects, corresponding to the physical and the phenomenal features of the world.
Facing Up to the Problem of Consciousness

Of course, the double-aspect principle is extremely speculative and is also underdetermined, leaving a number of key questions unanswered. An obvious question is whether all information has a phenomenal aspect. One possibility is that we need a further constraint on the fundamental theory, indicating just what sort of information has a phenomenal aspect. The other possibility is that there is no such constraint. If not, then experience is much more widespread than we might have believed, as information is everywhere. This is counterintuitive at first, but on reflection I think the position gains a certain plausibility and elegance. Where there is simple information processing, there is simple experience, and where there is complex information processing, there is complex experience. A mouse has a simpler information-processing structure than a human, and has correspondingly simpler experience; perhaps a thermostat, a maximally simple information processing structure, might have maximally simple experience? Indeed, if experience is truly a fundamental property, it would be surprising for it to arise only every now and then; most fundamental properties are more evenly spread. In any case, this is very much an open question, but I believe that the position is not as implausible as it is often thought to be.

Once a fundamental link between information and experience is on the table, the door is opened to some grander metaphysical speculation concerning the nature of the world. For example, it is often noted that physics characterizes its basic entities only extrinsically, in terms of their relations to other entities, which are themselves characterized extrinsically, and so on. The intrinsic nature of physical entities is left aside. Some argue that no such intrinsic properties exist, but then one is left with a world that is pure causal flux (a pure flow of information) with no properties for the causation to relate. If one allows that intrinsic properties exist, a natural speculation given the above is that the intrinsic properties of the physical - the properties that causation ultimately relates - are themselves phenomenal properties. We might say that phenomenal properties are the internal aspect of information. This could answer a concern about the causal relevance of experience - a natural worry, given a picture on which the physical domain is causally closed, and on which experience is supplementary to the physical. The informational view allows us to understand how experience might have a subtle kind of causal relevance in virtue of its status as the intrinsic nature of the physical. This metaphysical speculation is probably best ignored for the purposes of developing a scientific theory, but in addressing some philosophical issues it is quite suggestive.

8 Conclusion

The theory I have presented is speculative, but it is a candidate theory. I suspect that the principles of structural coherence and organizational invariance will be planks in any satisfactory theory of consciousness; the status of the double-aspect theory of information is less certain. Indeed, right now it is more of an idea than a theory. To have any hope of eventual explanatory success, it will have to be specified more fully and fleshed out into a more powerful form. Still, reflection on just what is plausible and implausible about it, on where it works and where it fails, can only lead to a better theory.

Most existing theories of consciousness either deny the phenomenon, explain something else, or elevate the problem to an eternal mystery. I hope to have shown that it is possible to make progress on the
Facing Up to the Problem of Consciousness

problem even while taking it seriously. To make further progress, we will need further investigation, more refined theories, and more careful analysis. The hard problem is a hard problem, but there is no reason to believe that it will remain permanently unsolved.[*]

*[[The arguments in this paper are presented in greater depth in my book The Conscious Mind (Oxford University Press, 1996). Thanks to Francis Crick, Peggy DesAutels, Matthew Elton, Liane Gabora, Christof Koch, Paul Rhodes, Gregg Rosenberg, and Sharon Wahl for their comments.]]

Gregory Mulhauser's vigorous review of my book *The Conscious Mind* includes a number of misrepresentations and philosophical misunderstandings. I would not like these to be perpetuated, so I will make a few comments in reply. I will go through the review, attempting to find objections of substance and to answer them where they are found. Amidst the rhetoric and the impressive repertoire of adjectives, I think a couple of interesting points on minor issues can be discerned.

First, I should clarify the notion of "taking consciousness seriously", which serves as a premise in my work. Mulhauser characterizes this as the assumption that no cognitive theory of consciousness will suffice. The latter assumption would indeed beg some crucial questions, but it is not the assumption that I make. I make an assumption about the problem of consciousness, not about any solution. To quote (p. xii):

> Throughout the book, I have assumed that consciousness exists, and that to redefine the problem as that of explaining how certain cognitive and behavioral functions are performed is unacceptable. This is what I mean by taking consciousness seriously.

That is, the premise is simply that there is a phenomenon to be explained, and that the problems of explaining such functions as discrimination, integration, self-monitoring, reportability, and so on do not exhaust all the problems in the vicinity. The deepest problem of consciousness, as I understand it, is not the problem of how all these functions are performed, but rather the problem of explaining how and why all this activity supports states of subjective experience.

This isn't to make any assumptions about the nature of the solution: plenty of people agree with the premise but still think that one way or another they can get a cognitive or materialist theory of consciousness to work. Of course, I do go on to argue that if the premise is granted, it turns out that such theories will always be incomplete.

Like many people (materialists and dualists alike), I find this premise obvious, although I can no more "prove" it than I can prove that I am conscious. At the very least, to deny this premise would require extraordinarily strong arguments, of a type that I have never seen. In my experience the large majority of people find it obvious; but certainly there are some that deny it, and arguments over whether the premise
is true or false rapidly descend into table-pounding. Wishing to avoid that dead end, I prefer to simply state the assumption up front. Mulhauser complains that the assumption is not "discharged", but of course that is the whole point of making it a premise. I do argue for it where I can, but there is no denying that such arguments - on either side - ultimately come down to a bedrock of intuition at some point. The result, as I also say up front, is that the minority of people who don't see a "hard problem" aren't going to find the book of more than intellectual interest.

The first point that looks like a substantial objection to my analysis is in Mulhauser's discussion of Chapter 2, where he appears to object to my notion of logical necessity and its relation to formal systems. As elsewhere, he does not say what his objection is, but simply says that he objects. Objections of this sort are difficult to answer.

His discussion of the central Chapter 3 mostly centers around the conceivability of zombies. I say explicitly in the text that this conceivability argument is more inconclusive than some of the others (due to the difficulty of assessing claims about conceivability), and that it does not bear the central burden of the argument, but commentators have often focused on it nevertheless. Mulhauser's description of my zombies as "a particularly strong variety: a physical, functional, and psychological duplicate", with its emphasis, makes the claim seem stronger than it is: "psychological" is being used here in a stipulative sense that adds nothing over and above "functional". What is relevant to the arguments is that a zombie be a physical and functional duplicate; that's all.

Mulhauser's objection to the argument is the standard "how do we know we can really conceive this". He doesn't address the real point, which is the challenge to isolate an inconsistency in the notion, and in particular to demonstrate the aspect of the concept of consciousness which could ground an conceptual entailment from the physical facts to the facts about consciousness. He neither comes out and embraces a functional definition of consciousness (equating what needs to be explained with reportability, integration, or some such complex function), which would require facing up to all the problems with such a definition, nor does he even hint at another way that such an entailment might go through, which would require facing up to the fact (stressed in the book) that structure and function only ever adds up to more structure and function. So we are left in a position of assertion without enlightenment.

Mulhauser's discussion of epistemic asymmetry makes an interesting point: a logical entailment from physical facts to facts about consciousness requires a grasp of the concept of consciousness, so the mere fact that someone without consciousness wouldn't derive facts about consciousness from the physical facts can be explained away by the observation that they lack the concept. This is a minor point - there is still a striking disanalogy here between our epistemic access to consciousness and other phenomena - but nevertheless I should have rephrased things in a way that brings that disanalogy out more directly. In any case, I also point out the epistemic asymmetry of consciousness in ways that aren't vulnerable to this objection, e.g. by giving the observer the concept of consciousness and noting that the facts about consciousness in others remain underdetermined.

His second interesting point is the idea that the explanatory gap may arise for reasons of formal
undecidability or computational intractability. There are obvious problems to be addressed: either consciousness is a structural/functional concept, in which case (a) it is most unclear why the facts about it should be any more undecidable or intractable than the facts about any other such concept (learning, reportability, or whatever), and (b) the view will presumably be vulnerable to arguments just like mine, establishing a gap between the structural/functional concept and consciousness while leaving the "intractable" physical details to one side; or it is not a structural/functional concept, in which case there are systematic reasons why it cannot be logically necessitated by the physical facts, intractability/undecidability or no. So I think even this sort of position is vulnerable to the sort of critique I provide. But in any case it would be very interesting to see such a view worked out in detail, and the project of doing so would be sure to be enlightening. I do address this view briefly on my pp. 138-40 - not in much depth, as the view had not been explicitly set out in the literature as far as I know - but there is no doubt that there is more to say about it, and it would be a very useful service to see the view worked out systematically.

Mulhauser’s discussion of "explanatory exclusion" is off the point. His claim that my intuitions about consciousness are based in "explanatory exclusion" intuitions that apply equally to planets, dolphins, and so on ignores the many pages of argument earlier in the book analyzing the disanalogy in depth. Indeed, none of the arguments I give about consciousness would have a hope of getting off the ground when applied to planets, dolphins, and the like.

His discussion of the epistemological problems of consciousness adds nothing of substance. There are, of course, serious problems here - the first-person epistemology of consciousness poses some of the deepest questions in the field, and questions to which I have at best tentative and incomplete answers. But Mulhauser gives no reason to believe that these answers must be bad ones; he simply reiterates the problems, as I have laid them out. He is of course absolutely right that many of these problems can be avoided if we embrace a reductive functionalist view of consciousness (where all that needs to be explained is discrimination, integration, reportability, and other complex functions). In fact, if we embrace such a view, almost all the problems of consciousness are removed! Those who think this sort of "solution" provides any enlightenment are welcome to it.

The entire second half of Mulhauser's review is thrown deeply astray by his "discovery" of my "little secret" that I think functional awareness is logically necessary for consciousness: a "discovery" based solely on my statement "awareness is necessary for consciousness". But in context it is obvious that natural necessity is at issue - what is under discussion are the bridging laws connecting processing and consciousness - and the sentence at the end of the paragraph makes it clear that logical necessity couldn't possibly be what is meant. Indeed, this "discovery" is so much at odds with everything else in the book that its invocation suggests that the reviewer is holding a principle of charity far in abeyance.

Mulhauser also seems to think that my suggestions for psychophysical bridging principles are a priori deductions from the single fact that consciousness exists. This is false: they are inferences drawn from apparent regularities between facts about functioning and facts about experience, especially in the first-person case. I start by drawing connections between (1) functional facts about reportability, behavioral control, and the like, and (2) phenomenological observations about the structure and properties of
experience in the first-person case. These connections are certainly quite coarse (I make no claim to be a sophisticated phenomenologist) and I would be all for a project of refining them. But in all of them phenomenological data - observations about the structure of experience, for example, or its presence or absence in different sorts of cases - play a significant role. In every case the relevant data go well beyond "consciousness exists"; Mulhauser is quite right that no substantial inferences about the nature of psychophysical laws could be drawn from that datum alone.

(Some may object to using phenomenological data, but I would argue that without an appeal to such data, a theory of conscious experience as such cannot even get off the ground - it will be a third-person theory that never connects to the first-person. And indeed I would argue that everyone who draws conclusions about experience from processing data is implicitly relying on bridging principles that are partly based on first-person knowledge of phenomenology; I am just trying to bring them into the open.)

Mulhauser's discussion of the fading and dancing qualia arguments makes a number of mistakes. The arguments cannot come close to establishing that absent or inverted qualia are logically impossible, for reasons I address directly: first, nothing in the arguments suggests that fading and dancing qualia scenarios are incoherent, and second, they all take the empirical fact of the existence of consciousness as a premise. Mulhauser somehow slides from this second observation of mine to the reiterated "conclusion" that my psychophysical principles are all deduced a priori from this observation, but this is an elementary mistake - to say that an argument takes something as a premise is not to say that it takes it as its only premise! Mulhauser also makes a lot of play out of a tension between my arguments here and my supposed view that awareness is logically necessary for consciousness; but as noted above, this view is a product of his imagination.

For what it's worth, Mulhauser's suggestion that this supposed view implies that dancing qualia are logically impossible commits another philosophical mistake: someone could believe that awareness is logically necessary for consciousness but not logically sufficient, and in particular could believe that facts about awareness do not logically entail facts about the intrinsic character of specific qualia.

Mulhauser's vigorous discussion of the last three chapters of the book contains few criticisms of substance, on examination. He complains that I don't appeal to his favorite sort of information theory, namely Chaitin's. I think Chaitin's work is fascinating (certainly it is intrinsically much more interesting than Shannon's), but it is an entirely different creature and I didn't see its application here. If Mulhauser can find a way to exploit it in a theory of consciousness, more power to him. His further observations (e.g., that some sorts of information processing seem to happen without consciousness) simply go over ground already covered in the book, without addressing my discussion.

His complaints about my chapter on strong AI rest on my "failure to grasp the vacuity of naive functional theorizing", and on his appeal to philosophers such as Putnam who have pointed out this "vacuity". Like many, I am not deeply impressed by these arguments, although they have some interest. I have a lengthy analysis of the Putnam considerations in my "Does a Rock Implement Every Finite State Automaton?" (Synthese 108:309-33, 1996), and the general issues are discussed in "A Computational Foundation for
the Study of Cognition (of which a shorter version appeared in Minds and Machines, 1994). Mulhauser provides nothing more than an appeal to authority here, though, so there is little I can say in reply. And although Mulhauser suggests that a giant look-up table might be constructed to satisfy my CSA definition, I would be very interested to see such a CSA that is naturally possible (remember, it is natural possibility that is relevant here). As I discuss in my paper on Putnam's argument, the only such "false implementations" are probably beyond the bounds of natural possibility.

Mulhauser says nothing of substance in objecting to my discussion of incompleteness - once again, he simply spends a long paragraph asserting vigorously that he has objections. The same goes for his discussion of discreteness vs. continuity, in the next paragraph. Those who understand the issues will know that the Siegelmann/Sontag machine he refers to does not threaten anything I say: like every other "super-Turing" machine that has been proposed, it requires an infinite resource or infinitely precise initial conditions in order to compute a super-Turing number-theoretic function. With bounded precision, or even with unbounded precision but a fixed finite initial state, it does no better than a Turing machine. As with many other places in the review, the argument strategy seems to be "unargued appeal to irrelevant authority".

In his discussion of my analysis of the Everett interpretation of quantum mechanics, Mulhauser asserts quite correctly that (1) a similar analysis might be available to a materialist (assuming a materialist theory of consciousness could work at all), and (2) that these considerations do not provide knockdown support for the interpretation (as I say in the book, they simply remove one sort of objection, and thus give it indirect support; the interpretation still has serious problems, and indeed I am not sure whether I believe it). He apparently intends these remarks as criticisms, but it is hard to see why. The chapter is not intended as religious warfare either for this interpretation or for dualism; it is simply an exploration of the issues.

I will end with a few comments on the more unusual aspects of Mulhauser's review. Mulhauser is concerned to point out everywhere that an argument I use has appeared in the literature before. This seems redundant, as I acknowledge my multiple debts right up front, and I cite every debt as the book goes along (it's not for nothing that the book has a 400-entry bibliography). Apparently he is spurred on by "the widespread publicity...suggesting it would contain startling new arguments and thought experiments". He would not be the first person to review the media rather than the book, but it would be nice to have the book reviewed for what it is.

In reality, it's a book written by a mortal, and a book which tries to present the arguments - some old, some new - as carefully and as completely as possible. There's no question that anti-reductionist arguments have been around a long time, and negative arguments with the same general thrust as mine have been seen before, though they have usually been presented in a very piecemeal way. In the book, I try to really make the case properly: maybe I succeed and maybe I fail, but I make no apologies for retreading old ground at those points where I think it is the best way to do things.

I must respond to one particularly odd remark of Mulhauser's in this context. A characterization of my
fading and dancing qualia arguments - "both of which, contrary to popular tale, have appeared in one form or another elsewhere in the literature" - seems to suggest that I have borrowed someone else's arguments unacknowledged. In fact both arguments are accompanied by citations to every item I know in the literature to which they bear even a remote similarity. The fading qualia gradual-replacement scenario is of course an old folk tale in the literature, and in the paragraph where it is introduced I cite a number of papers that use it (although they use it in somewhat different ways), and I footnote some more. The dancing qualia argument, as far as I know, was original with me in my 1993 Ph.D. dissertation, although there do exist a couple of distantly related scenarios used to argue for quite different conclusions, and a more closely related version was formulated independently by Arnold Zuboff in a 1994 article. So as with much of the rest of the book, there are a number of elements which are familiar, and a number which are new. That's the way it usually is in philosophy.

Finally, let me express my bemusement at the religious tone that is so common in this sort of discussion. I don't know why discussions of consciousness provoke this tone, which is not nearly so pronounced in other areas of science and philosophy. I don't feel any particular emotional commitment to my conclusions myself (I may be a materialist in my heart, if not in my mind); I have come to the conclusion that they more or less have to be true, for systematic reasons, but if someone thinks they have a better option, that's fine. I tried to write a book setting out the lay of the land as I see it, laying out what seemed to me to be a promising approach, and openly acknowledging the various problems my approach faces along the way. If someone disagrees, then I'm interested to hear about it. It's a fascinating area of intellectual inquiry. But point-scoring and unargued rhetoric are uninteresting. Mulhauser makes a couple of points of substance along the way. I suggest that we are all best served if substance is what we stick to.

Response to Searle

In my book *The Conscious Mind*, I deny a number of claims that John Searle finds "obvious", and I make some claims that he finds "absurd". But if the mind/body problem has taught us anything, it is that nothing about consciousness is obvious, and that one person's obvious truth is another person's absurdity. So instead of throwing around this sort of language, it is best to examine the claims themselves and the arguments that I give for them, to see whether Searle says anything of substance that touches them.

The first is my claim that consciousness is a nonphysical feature of the world. I resisted this claim for a long time, before concluding that it is forced on one by a sound argument. The argument is complex, but the basic idea is simple: the physical structure of the world - the exact distribution of particles, fields, and forces in spacetime - is logically consistent with the absence of consciousness, so the presence of consciousness is a further fact about our world. Searle says this argument is "invalid": he suggests that the physical structure of the world is equally consistent with the addition of flying pigs, but that it does not follow that flying is nonphysical.

Here Searle makes two elementary mistakes. First, he gets the form of the argument wrong. To show that flying is nonphysical, we would need to show that the world's physical structure is consistent with the *absence* of flying. From the fact that one can *add* flying pigs to the world, nothing follows. Second, the scenario he describes is not consistent. A world with flying pigs would have a lot of extra matter hovering meters above the earth, for example, so it could not possibly have the same physical structure as ours. Putting these points together: the idea of a world physically identical to ours but without flying, or without pigs, or without rocks, is self-contradictory. But there is no contradiction in the idea of a world physically identical to ours without consciousness, as Searle himself admits.

The underlying point is that the position of pigs - and almost everything else about the world - is logically derivable from the world's physical structure, but the presence of consciousness is not. So to explain why and how brains support consciousness, an account of the brain alone is not enough; to bridge the gap, one needs to add independent "bridging" laws. One can resist this conclusion only by adopting a hard-line deflationism about consciousness. That path has its own problems, but in any case it is not open to Searle, who holds that consciousness is irreducible. Irreducibility has its consequences. Consistency requires that one face them directly.

The next issue is my nonreductive functionalism. This bridging law claims that systems with the same functional organization have the same sort of conscious experiences. My detailed argument for this claim...
is not recognizable in the trivial argument that Searle presents as mine and rebuts. The basic idea, presented in Chapter 7 of the book but ignored by Searle, is that if the claim is false, then there can be massive changes in conscious experience which a subject can never notice. (Searle's own position is rebutted on p. 258.) He also points to patients with Guillain-Barre syndrome as a counterexample to my claim, but this once again gets the logic wrong. My claim concerns functionally identical beings, so it is irrelevant to point to people who function differently. I certainly do not claim that beings whose functioning differs from ours are unconscious.

The final issue is panpsychism: the claim that some degree of consciousness is associated with every system in the natural world. Here Searle misstates my view: he says that I am "explicitly committed" to this position, when I merely explore it and remain agnostic; and he says incorrectly that it is an implication of property dualism and nonreductive functionalism. One can quite consistently embrace those views and reject panpsychism, so the latter could not possibly function as a "reductio ad absurdum" of the former. I note also that the view which I describe as "strangely beautiful", and which Searle describes as "strangely self-indulgent", is a view I reject.

I do argue that panpsychism is not as unreasonable as is often supposed, and that there is no knockdown argument against it. Searle helps confirm the latter claim: while protesting "absurdity", his arguments against panpsychism have no substance. He declares that to be conscious, a system must have the right "causal powers", which turn out to be the powers to produce consciousness: true, but trivial and entirely unhelpful. And he says that simple systems (such as thermostats) do not have the "structure" required for consciousness; but this is precisely the claim at issue, and he provides no argument to support it (if we knew what sort of structure were required for consciousness, the mind-body problem would be half-solved). So we are left where we started. Panpsychism remains counterintuitive, but it cannot be ruled out at the start of inquiry.

In place of substantive arguments, Searle provides gut reactions: every time he disagrees with a view I discuss, he calls it "absurd". In the case of panpsychism (a view not endorsed by me), many might agree. In other cases, the word is devalued: it is not even surprising, for example, that mental terms such as "perception" are ambiguous between a process and a subjective experience; and given that a trillion interacting neurons can result in consciousness, there is no special absurdity in the idea that a trillion interacting silicon chips or humans might do the same. I do bite one bullet, in accepting that brain-based explanations of behavior can be given that do not invoke or imply consciousness (although this is not to say that consciousness is causally irrelevant). But Searle's own view on irreducibility would commit him to this view too, if he could only draw the implication.

Once we factor out mistakes, misrepresentations, and gut feelings, we are left with not much more than Searle's all-purpose critique: "the brain causes consciousness". Although this mantra (repeated at least ten times) is apparently intended as a source of great wisdom, it settles almost nothing that is at issue. It is entirely compatible with all of my views: we just need to distinguish cause from effect, and to note that it does not imply that only the brain causes consciousness. Indeed, Searle's claim is simply a statement of the problem, not a solution. If one accepts it, the real questions are: Why does the brain cause consciousness? In virtue of which of its properties? What are the relevant causal laws? Searle has nothing
to say about these questions. A real answer requires a theory: not just a theory of the brain, but also a
detailed theory of the laws that bridge brain and consciousness. Without fulfilling this project, on which I
make a start in my book, our understanding of consciousness will always remain at a primitive level.

- On "Consciousness and the Philosophers" (second response to Searle)

John Searle's reply to my letter continues the odd combination of mistakes, misrepresentations, and unargued gut reactions found in his original review. I will go through his response and address all his points, major and minor. I will also include a few comments on the original review which could not be included in the letter for reasons of space.

(1) Searle says

Chalmers thinks each of the psychological words "pain", "belief", etc., has two completely independent meanings, one where it refers to nonconscious functional processes and one where it refers to states of consciousness.

To clarify: I don't say that mental terms are ambiguous between consciousness and "nonconscious functional processes". I say that many such terms have two interpretations (not "completely independent" interpretations), one of which requires consciousness and one of which doesn't. For example, in the strong sense, "perception" has to be conscious; in the weak sense, it does not. So "subliminal perception" will count as "perception" in the weak but not the strong sense. I think this is just common sense. Note that the weak sense doesn't require that a process be "nonconscious"; rather, it is neutral on the question of consciousness. Subliminal perception and conscious perception count equally as perception in the weak sense; what matters isn't consciousness or its absence, but the way a state functions. So Searle is wrong to suggest that this distinction implies that there is a nonconscious "pain" correlated with every conscious "pain".

(2) On the question of explanatory irrelevance of consciousness to physical actions. It is true that I bite this bullet, in a certain sense. But the view can be made to seem stranger than it is. So I should make some clarifications.

First, I do not say that consciousness is *causally* irrelevant to action. That is a question I am neutral on, and I think there are interesting views that give consciousness causal relevance without doing any damage to the scientific world view. (For example, by making consciousness correspond to the intrinsic aspect of physical states which physics characterizes only extrinsically.)
Second, I do not say that consciousness can never be used to explain action, so that explanations that involve consciousness are invalid. I simply say that invoking consciousness is not necessary to explain actions; there will always be a physical explanation that does not invoke or imply consciousness. A better phrase would have been "explanatorily superfluous", rather than "explanatorily irrelevant". Something can be superfluous and still be relevant.

Third, it isn't true that my view implies that "if you think you are reading because you consciously want to read, you are mistaken". On my view, it is very likely that you are reading because you want to read. It is just that fact that the wanting is consciously experienced is not required for the explanation to go through. Conscious wants can explain actions, and nonconscious wants can explain actions too. Similarly, you drink because you are thirsty, but the consciously experienced aspect of that thirst needn't be appealed to to explain your action.

Of course there remains something counterintuitive about the explanatory superfluity of consciousness. But I think one is forced to it by sound arguments. And in the book I defend it at length, arguing that it is merely counterintuitive and has no fatal flaws. Searle does not address this discussion.

(3) On panpsychism (the view that consciousness is everywhere): In Searle's review he said I was "explicitly committed" to this view. I corrected this and said I was agnostic about the view, although I do explore it at length. Searle apparently thinks I am lying about this:

The most astonishing thing in Chalmers's letter is the claim that he did not "endorse" panpsychism, that he is "agnostic" about it. Well, in his book he presents extensive arguments for it and defenses of it. Here is what he actually says. First, he tells us that "consciousness arises from functional organization" (p. 249). And what is it about functional organization that does the job? It is, he tells us, "information", in the special sense of that word according to which everything in the world has information in it. "We might put this by suggesting as a basic principle that information (in the actual world) has two aspects, a physical and a phenomenal aspect" (p. 286). The closest he gets to agnosticism is this: "I do not have any knockdown arguments to prove that information is the key to the link between physical processes and conscious experience," but he immediately adds, "but there are some indirect ways of giving support to the idea." Whereupon he gives us several arguments for the double-aspect principle (p. 287). He hasn't proven panpsychism, but it is a hypothesis he thinks is well-supported. Since information in his sense is everywhere then consciousness is everywhere. If he argues that functional organization gives rise to consciousness, that it does so in virtue of information, that anything that has information would be conscious and that everything has information, then he is arguing that everything is conscious, by any logic that I am aware of.

Searle clearly does not grasp what is going on in this chapter of the book. First, with regard to the double-aspect theory of information: I am not committed even to this view, and indeed I say in the chapter (p. 310) that it is more likely wrong than right. But further, it simply isn't the case that the double-aspect view implies panpsychism. In the passage setting out the double-aspect view on p. 286, Searle has
apparently missed the sentence two sentences after the one he quotes:

Conversely, for at least some physically realized information spaces, whenever an information state in that space is realized physically, it is also realized phenomenally. [TCM, p. 286; italics added.]

And a couple of sentences later:

In fleshing the principle out into a theory, all sorts of questions need to be answered. For example, to just which physically realized information spaces does the basic principle apply? I will discuss this question further in section 4, but in the meantime I leave it open. [TCM, p. 286]

In section 4, I go on to say that there are two quite different ways in which the view can be developed. One can go for a constrained version of the view, putting constraints on the kind of information which has a conscious aspect; or one can go for an unconstrained version, on which all information has a conscious aspect. Only the latter implies panpsychism. In the book I explore both these options and remain neutral between them.

Searle asks

If he is not supporting panpsychism, why does he devote an entire section of a chapter to "What is it like to be a thermostat?", in which he describes the conscious life of thermostats?

Here he has simply lost the context. I spend some time exploring both the unconstrained and constrained views, considering how they might be developed and drawing out their implications. In the pages exploring the unconstrained view, I argue that panpsychism is not an unreasonable view, I defend it against various criticisms that might be raised, and I try to elaborate on consequences such as how we might conceive of the conscious experience of a thermostat, just as I elaborate on the constrained view after that. Apparently he mistakes this exploration of the consequences of one possible view for a statement of what I explicitly endorse. A quick glance at the context should rule out this interpretation: e.g., I say explicitly that I am considering both versions (p. 293), and I say explicitly that I consider the question of panpsychism open (p. 299).

I do say that I think there aren't any compelling arguments against panpsychism, and once again Searle helps to confirm this view. He tells us the only systems that we "know for a fact" are conscious are living systems with a certain sort of nervous systems. This is quite true, but it does not imply that simple systems are not conscious; it simply implies that we do not know for a fact that they are. So this might be grounds for agnosticism about panpsychism, but it is not grounds for rejection. He repeats his remarks about thermostats and such "not being remote candidates for consciousness", but this is again just assertion without argument. And he says that what goes on in a thermostat is quite different from the "specific features" in a brain: true, but to assume that these specific features are required for consciousness is again to beg the question.
On "Consciousness and the Philosophers"

(4) Searle apparently does not believe me when I say that the view that I characterize as "strangely beautiful" in the book is a view I rejected. He appears not to have read the relevant passages closely enough. The view so characterized is not, as Searle suggests, the view that "the universe consists of little bits of consciousness"; that is indeed a view I am agnostic about. Rather, it is the view on which the universe consists of "pure information" without any intrinsic nature (p. 303). This is a very different view, entirely incompatible with the other view, and I reject it on the grounds that some intrinsic nature is needed for the universe to be a universe at all.

(5) Searle's discussion of the argument for property dualism once again makes elementary mistakes. I argue that there is a logically possible world that is physically identical to ours without consciousness, and draw the conclusion that consciousness is a nonphysical feature of the world. Searle objects because this world would have different laws from ours.

Quite so, but in order to imagine such a world, you have to imagine a change in the laws of nature, a change in the laws by which physics and biology cause and realize consciousness. [...] From the facts of nature, including the laws, you can derive logically that this brain must be conscious.

Of course this is true, but it is also irrelevant. The point is that to derive the facts about consciousness, the physical facts and laws are not enough. You need to add in the bridging laws relating physical process and consciousness. Whereas in almost any other domains, you don't need any bridging laws: the physical facts and laws alone are enough to derive the position of pigs, the facts about digestion, the shape of rocks, the functioning of living processes, and so on. This is witnessed by the logical impossibility of a world physically identical to ours but in which rocks have different shape or in which pigs fly, and similarly for all the others. So Searle has simply evaded the point. Indeed, he has in effect conceded the point, by agreeing that a world physically identical to ours but without consciousness is logically possible. To be consistent, he too ought to be a property dualist.

Searle also suggests that I beg the question:

If consciousness is a physical feature of brains, then the absence of consciousness is also a change in the physical features of the world. That is, his argument works to establish property dualism only if it assumes that consciousness is not a physical feature, but that is what the argument was supposed to prove.

But nothing in the argument requires any such assumption. We need only stipulate that the world we are considering is a world identical in the facts and laws of microphysics, characterizing the exact distribution of particles, fields, forces, and so on, in space and time. We stipulate nothing one way or the other about consciousness, rocks, pigs, and the like. The point is that from these facts one can derive the facts about rocks, pigs, and the like but one can't derive the facts about consciousness, which is the relevant disanalogy. This argument implies that consciousness is not a physical feature of the world, but it does not assume it. (Except in the very weak sense in which the premises of any argument assume the conclusion: if the conclusion were false, one of the premises would have to be false!)
Of course I agree with Searle that if one builds in facts and laws about consciousness to the basic package of facts and laws from which one can derive everything else (facts about fields, particles, forces, etc), then one can derive the facts about consciousness. But that conclusion is trivial. Indeed, to include consciousness in this basic package is precisely to endorse the view that I hold. To avoid this conclusion, Searle has to derive the facts about consciousness from the set of physical facts and laws alone, and that is what he can't do.

(6) In discussing my arguments for nonreductive functionalism, Searle once again ignores the actual argumentation in the book. To recap: I argue that if consciousness could vary independently of functional organization, then there could be changes in consciousness (e.g. by replacing neurons by silicon) that a subject could never notice. The subject would certainly insist that "Nothing has changed", for example; this is a trivial consequence of the assumption that functional organization is preserved. Searle's position is that although the subject would not produce any "noticing behavior", they might nevertheless notice the change but be unable to express it in behavior. They might feel that they are paralyzed inside a body out of their control, for example.

Searle says that I merely "assume" this option is untenable, by assuming that there must be a match between conscious noticing and noticing behavior. But in fact I argue against this position at some length, around p. 258-59 of the book (as I noted in my letter). In particular, I argue that the view Searle wants to maintain requires a particularly bizarre and arbitrary law connecting physical states and belief contents. Searle does not address these arguments anywhere. Interested readers can find a version of my arguments for nonreductive functionalism in my online paper "Absent Qualia, Fading Qualia, Dancing Qualia".

(7) In Searle's original review, he uses patients with Guillain-Barre syndrome to argue against my nonreductive functionalism, by noting that their functional organization is "inappropriate" but that they are conscious anyway. I responded that this gets the logic wrong:

He also points to patients with Guillain-Barre syndrome as a counterexample to my claim, but this once again gets the logic wrong. My claim concerns functionally identical beings, so it is irrelevant to point to people who function differently. I certainly do not claim that beings whose functioning differs from ours are unconscious.

Searle replies:

He says incorrectly that patients with Guillain-Barre syndrome who have consciousness but the wrong functional organization are irrelevant, because they "function differently". But differently from what? As far as their physical behavior is concerned they function exactly like people who are totally unconscious, and thus on his definition they have exactly the same "functional organization" as unconscious people, even though they are perfectly conscious. Remember "functional organization" for him is always nonconscious. The Guillain-Barre patients have the
same functional organization, but different consciousness. Therefore there is no perfect match
between functional organization and consciousness. Q.E.D.

Searle's point here is subtly different from his original version, but it is equally fallacious. Patients with
Guillain-Barre syndrome certainly do not have the same functional organization as unconscious people.
There is all sorts of complex functioning going on inside their heads that is not present in unconscious
people. They have the same behavior, but that is all. Searle knows well that functional organization and
behavior are quite different things. Indeed, the definition of functional organization that I give (p. 247)
involves much more than mere behavior. And indeed the move from behaviorism to functionalism in the
philosophy of mind was made in part for this reason: to allow more fine-grained distinctions than mere
behavior could capture, and thus to handle cases such as those of perfect actors and paralytics. If Searle
knows any elementary philosophy of mind, he knows this. But it renders his point entirely invalid.

(8) Searle finishes by saying that as candidates for explaining consciousness,

"functional organization" and "information" are nonstarters, because as he uses them, they have no
causal explanatory power. To the extent you make the function and the information specific, they
exist only relative to observers and interpreters.

But this claim is quite false. Searle has made it a number of times, generally without any substantive
supporting argument. I argue in Chapter 9 of the book, and in more detail in my papers "A Computational
Foundation for the Study of Cognition" and "Does a Rock Implement Every Finite-State Automaton?"
that the relevant notions can be made perfectly precise with objective criteria, and are therefore not at all
observer-relative. If a given system has a given functional organization, implements a given computation,
and therefore realizes certain information, it does so as a matter of objective fact. Searle does not address
these arguments at all.

Searle does make one point that might look like supporting argument:

If you strip away the observers and interpreters then the notions become empty, because now
everything has information in it and has some sort of "functional organization" or other.

The latter part of this claim is true, but it no more implies that the notions are empty than the claim that
everything has mass would imply that the notion of mass is empty. Everything has some organization,
and carries some information, but the particular organizations and information realized by a given system
will vary from system to system. A theory of the consciousness associated with a given system will
appeal not just to the fact that some organization or information is present - that would be empty - but to
the specific organizational and informational properties in a given case. (By analogy, an account of the
sun's powerful gravitational force appeals not just to the fact that the sun has mass - that would be empty -
but to the specific large mass that the sun has.) These specific properties will only be present in a small
number of cases, so there is no danger of vacuity. This issue is discussed further in the computation paper
mentioned above.
Finally, are my property dualism and my functionalism compatible? As Searle defines the positions in the first paragraph, they are obviously inconsistent. He defines functionalism as the view that mental states consist in physical functional states, which obviously contradicts the view that mental states are not physical states. My own variety of "functionalism" is very different from this. I don't say that mental states are functional states, merely that they are supported by functional states in the sense that any two functionally identical beings (in the actual world) will have the same conscious states. To make an analogy: almost any property dualist will hold that consciousness is somehow supported by brain states, in the sense that two creatures with identical brains will have identical experiences, but this is not to say that consciousness is the brain state. Likewise, my own view is not that consciousness is the functional state. I argue against that view at length, e.g. on the grounds that it remains logically possible that a being could have the functional state without consciousness. But it is nevertheless empirically impossible to have the physical/functional state without consciousness, on my view; there is a psychophysical law connecting the two.

In his review, Searle suggested that there is a deep tension between my property dualism and my functionalism. Once the nonreductive nature of my functionalism is noted, this claim can be seen to be misguided. Property dualism is entirely neutral on the question of what sort of physical system supports consciousness, and on the precise nature of the laws that connect the two. Presumably the laws will say that consciousness arises from physical systems in virtue of certain of their properties. I simply argue that these properties are organizational properties, so that consciousness might arise equally from neurons and from silicon, for example. There is no tension here. (One might find more tension in a property dualist who held that consciousness is specifically biological!) If one takes the trouble to distinguish the separate issues at play here, it becomes clear that the two views are complementary, not contradictory.

Consciousness and its Place in Nature

David J. Chalmers

Department of Philosophy
University of Arizona
Tucson, AZ 85721.

chalmers@arizona.edu

1 Introduction[*]

[[This paper is an overview of issues concerning the metaphysics of consciousness. Much of the discussion in this paper (especially the first part) recapitulates discussion in Chalmers (1995; 1996; 1997), although it often takes a different form, and sometimes goes beyond the discussion there. I give a more detailed treatment of many of the issues discussed here in the works cited in the bibliography.]]

Consciousness fits uneasily into our conception of the natural world. On the most common conception of nature, the natural world is the physical world. But on the most common conception of consciousness, it is not easy to see how it could be part of the physical world. So it seems that to find a place for consciousness within the natural order, we must either revise our conception of consciousness, or revise our conception of nature.

In twentieth-century philosophy, this dilemma is posed most acutely in C. D. Broad's The Mind and its Place in Nature (Broad 1925). The phenomena of mind, for Broad, are the phenomena of consciousness. The central problem is that of locating mind with respect to the physical world. Broad's exhaustive discussion of the problem culminates in a taxonomy of seventeen different views of the mental-physical relation.[*] On Broad's taxonomy, a view might see the mental as nonexistent ("delusive"), as reducible, as emergent, or as a basic property of a substance (a "differentiating" attribute). The physical might be seen in one of the same four ways. So a four-by-four matrix of views results. (The seventeenth entry arises from Broad's division of the substance/substance view according to whether one substance or two is involved.) At the end, three views are left standing: those on which mentality is an emergent characteristic of either a physical substance or a neutral substance, where in the latter case, the physical might be either emergent or delusive.

[[The taxonomy is in the final chapter, Chapter 14, of Broad's book (set out on pp. 607-11, and discussed until p. 650). The dramatization of Broad's taxonomy as a 4x4 matrix is illustrated on Andrew Chrucky's website devoted to Broad, at http://www.ditext.com/broad/mpn14.html#t.]]

In this paper I take my cue from Broad, approaching the problem of consciousness by a strategy of divide-and-conquer. I will not adopt Broad's categories: our understanding of the mind-body problem has
advanced in the last 75 years, and it would be nice to think that we have a better understanding of the
crucial issues. On my view, the most important views on the metaphysics of consciousness can be divided
almost exhaustively into six classes, which I will label "type A" through "type F." Three of these (A
through C) involve broadly reductive views, seeing consciousness as a physical process that involves no
expansion of a physical ontology. The other three (D through F) involve broadly nonreductive views, on
which consciousness involves something irreducible in nature, and requires expansion or reconception of
a physical ontology.

The discussion will be cast at an abstract level, giving an overview of the metaphysical landscape. Rather
than engaging the empirical science of consciousness, or detailed philosophical theories of consciousness,
I will be examining some general classes into which theories of consciousness might fall. I will not
pretend to be neutral in this discussion. I think that each of the reductive views is incorrect, while each of
the nonreductive views holds some promise. So the first part of this paper can be seen as an extended
argument against reductive views of consciousness, while the second part can be seen as an investigation
of where we go from there.

2 The Problem

The word 'consciousness' is used in many different ways. It is sometimes used for the ability to
discriminate stimuli, or to report information, or to monitor internal states, or to control behavior. We can
think of these phenomena as posing the "easy problems" of consciousness. These are important
phenomena, and there is much that is not understood about them, but the problems of explaining them
have the character of puzzles rather than mysteries. There seems to be no deep problem in principle with
the idea that a physical system could be "conscious" in these senses, and there is no obvious obstacle to an
eventual explanation of these phenomena in neurobiological or computational terms.

The hard problem of consciousness is the problem of experience. Humans beings have subjective
experience: there is something it is like to be them. We can say that a being is conscious in this sense —
or is phenomenally conscious, as it is sometimes put — when there is something it is like to be that being.
A mental state is conscious when there is something it is like to be in that state. Conscious states include
states of perceptual experience, bodily sensation, mental imagery, emotional experience, occurrent
thought, and more. There is something it is like to see a vivid green, to feel a sharp pain, to visualize the
Eiffel tower, to feel a deep regret, and to think that one is late. Each of these states has a phenomonal
character, with phenomenal properties (or qualia) characterizing what it is like to be in the state.[*]

[*][On my usage, qualia are simply those properties that characterize conscious states according to what it is like to have
them. The definition does not build in any further substantive requirements, such as the requirement that qualia are intrinsic
or nonintentional. If qualia are intrinsic or nonintentional, this will be a substantive rather than a definitional point (so the
claim that the properties of consciousness are non-intrinsic or that they are wholly intentional should not be taken to entail
that there are no qualia). Phenomenal properties can also be taken to be properties of individuals (e.g., people) rather than
of mental states, characterizing aspects of what it is like to be them at a given time; the difference will not matter much for
present purposes.][*]
There is no question that experience is closely associated with physical processes in systems such as brains. It seems that physical processes give rise to experience, at least in the sense that producing a physical system (such as a brain) with the right physical properties inevitably yields corresponding states of experience. But how and why do physical processes give rise to experience? Why do not these processes take place "in the dark," without any accompanying states of experience? This is the central mystery of consciousness.

What makes the easy problems easy? For these problems, the task is to explain certain behavioral or cognitive functions: that is, to explain how some causal role is played in the cognitive system, ultimately in the production of behavior. To explain the performance of such a function, one need only specify a mechanism that plays the relevant role. And there is good reason to believe that neural or computational mechanisms can play those roles.

What makes the hard problem hard? Here, the task is not to explain behavioral and cognitive functions: even once one has an explanation of all the relevant functions in the vicinity of consciousness — discrimination, integration, access, report, control — there may still remain a further question: why is the performance of these functions accompanied by experience? Because of this, the hard problem seems to be a different sort of problem, requiring a different sort of solution.

A solution to the hard problem would involve an account of the relation between physical processes and consciousness, explaining on the basis of natural principles how and why it is that physical processes are associated with states of experience. A reductive explanation of consciousness will explain this wholly on the basis of physical principles that do not themselves make any appeal to consciousness. A materialist (or physicalist) solution will be a solution on which consciousness is itself seen as a physical process. A nonmaterialist (or nonphysicalist) solution will be a solution on which consciousness is seen as nonphysical (even if closely associated with physical processes). A nonreductive solution will be one on which consciousness (or principles involving consciousness) is admitted as a basic part of the explanation.

[[Note that I use 'reductive' in a broader sense than it is sometimes used. Reductive explanation requires only that a high-level phenomena can be explained wholly in terms of low-level phenomena. This is compatible with the "multiple realizability" of high-level phenomena in low-level phenomena. For example, there may be many different ways in which digestion could be realized in a physiological system, but one can nevertheless reductively explain a system's digestion in terms of underlying physiology. Another subtlety concerns the possibility of a view on which consciousness can be explained in terms of principles which do not make appeal to consciousness but cannot themselves be physically explained. The definitions above count such a view as neither reductive nor nonreductive. It could reasonably be classified either way, but I will generally assimilate it with the nonreductive class.]]

It is natural to hope that there will be a materialist solution to the hard problem and a reductive explanation of consciousness, just as there have been reductive explanations of many other phenomena in many other domains. But consciousness seems to resist materialist explanation in a way that other phenomena do not. This resistance can be encapsulated in three related arguments against materialism, summarized in what follows.
3 Arguments against Materialism

3.1 The Explanatory Argument[*]

[[A version of the explanatory argument as formulated here is given in Chalmers 1995. For related considerations about explanation, see Levine 1983 on the "explanatory gap" and Nagel 1974. See also the papers in Shear 1997.]]

The first argument is grounded in the difference between the easy problems and the hard problem, as characterized above: the easy problems concern the explanation of behavioral and cognitive functions, but the hard problem does not. One can argue that by the character of physical explanation, physical accounts explain only structure and function, where the relevant structures are spatiotemporal structures, and the relevant functions are causal roles in the production of a system's behavior. And one can argue as above that explaining structures and functions does not suffice to explain consciousness. If so, no physical account can explain consciousness.

We can call this the explanatory argument:

(1) Physical accounts explain at most structure and function.

(2) Explaining structure and function does not suffice to explain consciousness; so

(3) No physical account can explain consciousness.

If this is right, then while physical accounts can solve the easy problems (which involve only explaining functions), something more is needed to solve the hard problem. It would seem that no reductive explanation of consciousness could succeed. And if we add the premise that what cannot be physically explained is not itself physical (this can be considered an additional final step of the explanatory argument), then materialism about consciousness is false, and the natural world contains more than the physical world.

Of course this sort of argument is controversial. But before examining various ways of responding, it is useful to examine two closely related arguments that also aim to establish that materialism about consciousness is false.

3.2 The Conceivability Argument.[*]

According to this argument, it is conceivable that there be a system that is physically identical to a conscious being, but that lacks at least some of that being's conscious states. Such a system might be a zombie: a system that is physically identical to a conscious being but that lacks consciousness entirely. It might also be an invert, with some of the original being's experiences replaced by different experiences, or a partial zombie, with some experiences absent, or a combination thereof. These systems will look identical to a normal conscious being from the third-person perspective: in particular, their brain processes will be molecule-for-molecule identical with the original, and their behavior will be indistinguishable. But things will be different from the first-person point of view. What it is like to be an invert or a partial zombie will differ from what it is like to be the original being. And there is nothing it is like to be a zombie.

There is little reason to believe that zombies exist in the actual world. But many hold that they are at least conceivable: we can coherently imagine zombies, and there is no contradiction in the idea that reveals itself even on reflection. As an extension of the idea, many hold that the same goes for a zombie world: a universe physically identical to ours, but in which there is no consciousness. Something similar applies to inverts and other duplicates.

From the conceivability of zombies, proponents of the argument infer their metaphysical possibility. Zombies are probably not naturally possible: they probably cannot exist in our world, with its laws of nature. But the argument holds that zombies could have existed, perhaps in a very different sort of universe. For example, it is sometimes suggested that God could have created a zombie world, if he had so chosen. From here, it is inferred that consciousness must be nonphysical. If there is a metaphysically possible universe that is physically identical to ours but that lacks consciousness, then consciousness must be a further, nonphysical component of our universe. If God could have created a zombie world, then (as Kripke puts it) after creating the physical processes in our world, he had to do more work to ensure that it contained consciousness.

We can put the argument, in its simplest form, as follows:

(1) It is conceivable that there be zombies

(2) If it is conceivable that there be zombies, it is metaphysically possible that there be zombies.

(3) If it is metaphysically possible that there be zombies, then consciousness is nonphysical.

(4) Consciousness is nonphysical.

A somewhat more general and precise version of the argument appeals to P, the conjunction of all microphysical truths about the universe, and Q, an arbitrary phenomenal truth about the universe. (Here '∧' represents 'and' and '¬' represents 'not').
(1) It is conceivable that P∧¬Q.

(2) If it is conceivable that P∧¬Q, it is metaphysically possible that P∧¬Q.

(3) If it is metaphysically possible that P∧¬Q, then materialism is false.

—

(4) Materialism is false.

3.3 The Knowledge Argument[*]

*[Sources for the knowledge argument include Jackson 1982, Maxwell 1968, Nagel 1974, and others. Predecessors of the argument are present in Broad's discussion of a "mathematical archangel" who cannot deduce the smell of ammonia from physical facts (Broad 1925, pp. 70-71), and Feigl's discussion of a "Martian superscientist" who cannot know what colors look like and what musical tones sound like (Feigl 1958/1967, pp. 64, 68, 140).]

According to the knowledge argument, there are facts about consciousness that are not deducible from physical facts. Someone could know all the physical facts, be a perfect reasoner, and still be unable to know all the facts about consciousness on that basis.

Frank Jackson's canonical version of the argument provides a vivid illustration. On this version, Mary is a neuroscientist who knows everything there is to know about the physical processes relevant to color vision. But Mary has been brought up in a a black-and-white room (on an alternative version, she is colorblind[*]) and has never experienced red. Despite all her knowledge, it seems that there is something very important about color vision that Mary does not know: she does not know what it is like to see red. Even complete physical knowledge and unrestricted powers of deduction do not enable her to know this. Later, if she comes to experience red for the first time, she will learn a new fact of which she was previously ignorant: she will learn what it is like to see red.

*[This version of the thought-experiment has a real life exemplar in Knut Nordby, a Norwegian sensory biologist who is a rod monochromat (lacking cones in his retina for color vision), and who works on the physiology of color vision. See Nordby 1990.]

Jackson's version of the argument can be put as follows (here the premises concern Mary's knowledge when she has not yet experienced red):

(1) Mary knows all the physical facts.

(2) Mary does not know all the facts
(3) The physical facts do not exhaust all the facts.

One can put the knowledge argument more generally:

(1) There are truths about consciousness that are not deducible from physical truths.

(2) If there are truths about consciousness that are not deducible from physical truths, then materialism is false.

(3) Materialism is false.

### 3.4 The Shape of the Arguments

These three sorts of argument are closely related. They all start by establishing an *epistemic gap* between the physical and phenomenal domains. Each denies a certain sort of close epistemic relation between the domains: a relation involving what we can know, or conceive, or explain. In particular, each of them denies a certain sort of *epistemic entailment* from physical truths P to the phenomenal truths Q: deducibility of Q from P, or explainability of Q in terms of P, or conceiving of Q upon reflective conceiving of P.

Perhaps the most basic sort of epistemic entailment is a priori entailment, or *implication*. On this notion, P implies Q when the material conditional 'P ⊃ Q' is a priori; that is, when a subject can know that if P is the case then Q is the case, with justification independent of experience. All of the three arguments above can be seen as making a case against an a priori entailment of Q by P. If a subject who knows only P cannot deduce that Q (as the knowledge argument suggests), or if one can rationally conceive of P without Q (as the conceivability argument suggests), then it seems that P does not imply Q. The explanatory argument can be seen as turning on the claim that an implication from P to Q would require a functional analysis of consciousness, and that the concept of consciousness is not a functional concept.

After establishing an epistemic gap, these arguments proceed by inferring an ontological gap, where ontology concerns the nature of things in the world. The conceivability argument infers from conceivability to metaphysical possibility; the knowledge argument infers from failure of deducibility to difference in facts; and the explanatory argument infers from failure of physical explanation to nonphysicality. One might say that these arguments infer from a failure of epistemic entailment to a failure of ontological entailment. The paradigmatic sort of ontological entailment is *necessitation*: P necessitates Q when the material conditional 'P ⊃ Q' is metaphysically necessary, or when it is metaphysically impossible for P to hold without Q holding. It is widely agreed that materialism requires
that P necessitates all truths (perhaps with minor qualifications). So if there are phenomenal truths Q that P does not necessitate, then materialism is false.

We might call of these arguments *epistemic arguments* against materialism. Epistemic arguments arguably descend from Descartes' arguments against materialism (although these have a slightly different form), and are given their first thorough airing in Broad's book, which contains elements of all three arguments above.[*] The general form of an epistemic argument against materialism is as follows:

(1) There is an epistemic gap between physical and phenomenal truths.

(2) If there is an epistemic gap between physical and phenomenal truths, then there is an ontological gap, and materialism is false.

(3) Materialism is false.

Of course this way of looking at things oversimplifies matters, and abstracts away from the differences between the arguments.[*] The same goes for the precise analysis in terms of implication and necessitation. Nevertheless, this analysis provides a useful lens through which to see what the arguments in common, and through which to analyze various responses to the arguments.

[*][[For a discussion of the relationship between the conceivability argument and the knowledge argument, see Chalmers 1996 and Chalmers 2002b.]]

There are roughly three ways that a materialist might resist the epistemic arguments. A type-A materialist denies that there is the relevant sort of epistemic gap. A type-B materialist accepts that there is an unclosable epistemic gap, but denies that there is an ontological gap. And a type-C materialist accepts that there is a deep epistemic gap, but holds that it will eventually be closed. In what follows, I discuss all three of these strategies.

### 4 Type-A Materialism

According to type-A materialism, there is no epistemic gap between physical and phenomenal truths; or at least, any apparent epistemic gap is easily closed. According to this view, it is not conceivable (at least on reflection) that there be duplicates of conscious beings that have absent or inverted conscious states. On
this view, there are no phenomenal truths of which Mary is ignorant in principle from inside her black-and-white room (when she leaves the room, she gains at most an ability). And on this view, on reflection there is no "hard problem" of explaining consciousness that remains once one has solved the easy problems of explaining the various cognitive, behavioral, and environmental functions.[*]

Type-A materialism sometimes takes the form of eliminativism, holding that consciousness does not exist, and that there are no phenomenal truths. It sometimes takes the form of analytic functionalism or logical behaviorism, holding that consciousness exists, where the concept of "consciousness" is defined in wholly functional or behavioral terms (e.g., where to be conscious might be to have certain sorts of access to information, and/or certain sorts of dispositions to make verbal reports). For our purposes, the difference between these two views can be seen as terminological. Both agree that we are conscious in the sense of having the functional capacities of access, report, control, and the like; and they agree that we are not conscious in any further (nonfunctionally defined) sense. The analytic functionalist thinks that ordinary terms such as 'conscious' should be used in the first sort of sense (expressing a functional concept), while the eliminativist thinks that it should be used in the second. Beyond this terminological disagreement about the use of existing terms and concepts, the substance of the views is the same.

Some philosophers and scientists who do not explicitly embrace eliminativism, analytic functionalism, and the like are nevertheless recognizably type-A materialists. The characteristic feature of the type-A materialist is the view that on reflection there is nothing in the vicinity of consciousness that needs explaining over and above explaining the various functions: to explain these things is to explain everything in the vicinity that needs to be explained. The relevant functions may be quite subtle and complex, involving fine-grained capacities for access, self-monitoring, report, control, and their interaction, for example. They may also be taken to include all sorts of environmental relations. And the explanation of these functions will probably involve much neurobiological detail. So views that are put forward as rejecting functionalism on the grounds that it neglects biology or neglects the role of the environment may still be type-A views.

One might think that there is room in logical space for a view that denies even this sort of broadly functionalist view of consciousness, but still holds that there is no epistemic gap between physical and phenomenal truths. In practice, there appears to be little room for such a view, for reasons that I will discuss under type C, and there are few examples of such views in practice.[*] So I will take it for granted that a type-A view is one that holds that explaining the functions explains everything, and will class other views that hold that there is no unclosable epistemic gap under type C.

[[Two specific views may be worth mentioning. (i) Some views (e.g., Dretske 1995) deny an epistemic gap while at the same time denying functionalism, by holding that consciousness involves not just functional role but also causal and historical relations to objects in the environment. I count these as type-A views: we can view the relevant relations as part of functional role, broadly construed, and exactly the same considerations arise. (ii) Some views (e.g., Stoljar 2001 and Strawson 2000) deny an epistemic gap not by functionally analyzing consciousness but by expanding our view of the physical base to include underlying intrinsic properties. These views are discussed under type F.]]
Consciousness and its Place in Nature

The obvious problem with type-A materialism is that it appears to deny the manifest. It is an uncontested truth that we have the various functional capacities of access, control, report, and the like, and these phenomena pose uncontested explananda (phenomena in need of explanation) for a science of consciousness. But in addition, it seems to be a further truth that we are conscious, and this phenomenon seems to pose a further explanandum. It is this explanandum that raises the interesting problems of consciousness. To flatly deny the further truth, or to deny without argument that there is a hard problem of consciousness over and above the easy problems, would be to make a highly counterintuitive claim that begs the important questions. This is not to say that highly counterintuitive claims are always false, but they need to be supported by extremely strong arguments. So the crucial question is: are there any compelling arguments for the claim that on reflection, explaining the functions explains everything?

Type-A materialists often argue by analogy. They point out that in other areas of science, we accept that explaining the various functions explains the phenomena, so we should accept the same here. In response, an opponent may well accept that in other domains, the functions are all we need to explain. In explaining life, for example, the only phenomena that present themselves as needing explanation are phenomena of adaptation, growth, metabolism, reproduction, and so on, and there is nothing else that even calls out for explanation. But the opponent holds that the case of consciousness is different and possibly unique, precisely because there is something else, phenomenal experience, that calls out for explanation. The type-A materialist must either deny even the appearance of a further explanandum, which seems to deny the obvious, or accept the apparent disanalogy and give further substantial arguments for why, contrary to appearances, only the functions need to be explained.

At this point, type-A materialists often press a different sort of analogy, holding that at various points in the past, thinkers held that there was an analogous epistemic gap for other phenomena, but that these turned out to be physically explained. For example, Dennett (1996) suggests that a vitalist might have held that there was a further "hard problem" of life over and above explaining the biological function, but this would have been misguided.

On examining the cases, however, the analogies do not support the type-A materialist. Vitalists typically accepted, implicitly or explicitly, that the biological functions in question were what needed explaining. Their vitalism arose because they thought that the functions (adaptation, growth, reproduction, and so on) would not be physically explained. So this is quite different from the case of consciousness. The disanalogy is very clear in the case of Broad. Broad was a vitalist about life, holding that the functions would require a non-mechanical explanation. But at the same time, he held that in the case of life, unlike the case of consciousness, the only evidence we have for the phenomenon is behavioral, and that "being alive" means exhibiting certain sorts of behavior. Other vitalists were less explicit, but very few of them held that something more than the functions needed explaining (except consciousness itself, in some cases). If a vitalist had held this, the obvious reply would have been that there is no reason to believe in such an explanandum. So there is no analogy here.[*]

[[In another analogy, Churchland (1996) suggests that someone in Goethe's time might have mounted analogous epistemic arguments against the reductive explanation of "luminescence." But on a close look, it is not hard to see that the only further explanandum that could have caused doubts here is the experience of seeing light (see Chalmers 1997). This

http://www.u.arizona.edu/~chalmers/papers/nature.html (10 of 40) [4/7/2002 1:44:53 PM]
point is no help to the type-A materialist, since this explanandum remains unexplained.]

So these arguments by analogy have no force for the type-A materialist. In other cases, it was always clear that structure and function exhausted the apparent explananda, apart from those tied directly to consciousness itself. So the type-A materialist needs to address the apparent further explanandum in the case of consciousness head on: either flatly denying it, or giving substantial arguments to dissolve it.

Some arguments for type-A materialists proceed indirectly, by pointing out the unsavory metaphysical or epistemological consequences of rejecting the view: e.g., that the rejection leads to dualism, or to problems involving knowledge of consciousness.[*] An opponent will either embrace the consequences or deny that they are consequences. As long as the consequences are not completely untenable, then for the type-A materialist to make progress, this sort of argument needs to be supplemented by a substantial direct argument against the further explanandum.

[*[For an argument from unsavory metaphysical consequences, see White 1986. For an argument from unsavory epistemological consequences, see Shoemaker 1975. The metaphysical consequences are addressed in the second half of this paper. The epistemological consequences are addressed in Chalmers 2002a.]]

Such direct arguments are surprisingly hard to find. Many arguments for type-A materialism end up presupposing the conclusion at crucial points. For example, it is sometimes argued (e.g., Rey 1995) that there is no reason to postulate qualia, since they are not needed to explain behavior; but this argument presupposes that only behavior needs explaining. The opponent will hold that qualia are an explanandum in their own right. Similarly, Dennett's use of "heterophenomenology" (verbal reports) as the primary data to ground his theory of consciousness (Dennett 1991) appears to rest on the assumption that these reports are what need explaining, or that the only "seemings" that need explaining are dispositions to react and report.

One way to argue for type-A materialism is to argue that there is some intermediate X such that (i) explaining functions suffices to explain X, and (ii) explaining X suffices to explain consciousness. One possible X here is representation: it is often held both that conscious states are representational states, representing things in the world, and that we can explain representation in functional terms. If so, it may seem to follow that we can explain consciousness in functional terms. On examination, though, this argument appeals to an ambiguity in the notion of representation. There is a notion of functional representation, on which P is represented roughly when a system responds to P and/or produces behavior appropriate for P. In this sense, explaining functioning may explain representation, but explaining representation does not explain consciousness. There is also a notion of phenomenal representation, on which P is represented roughly when a system has a conscious experience as if P. In this sense, explaining representation may explain consciousness, but explaining functioning does not explain representation. Either way, the epistemic gap between the functional and the phenomenal remains as wide as ever. Similar sorts of equivocation can be found with other X's that might be appealed to here, such as "perception" or "information."

Perhaps the most interesting arguments for type-A materialism are those that argue that we can give a
Consciousness and its Place in Nature

physical explanation of our beliefs about consciousness, such as the belief that we are conscious, the belief that consciousness is a further explanandum, and the belief that consciousness is nonphysical. From here it is argued that once we have explained the belief, we have done enough to explain, or to explain away, the phenomenon (e.g., Clark 2000, Dennett forthcoming). Here it is worth noting that this only works if the beliefs themselves are functionally analyzable; Chalmers (2002a) gives reason to deny this. But even if one accepts that beliefs are ultimately functional, this claim then reduces to the claim that explaining our dispositions to talk about consciousness (and the like) explains everything. An opponent will deny this claim: explaining the dispositions to report may remove the third-person warrant (based on observation of others) for accepting a further explanandum, but it does not remove the crucial first-person warrant (from one's own case). Still, this is a strategy that deserves extended discussion.

At a certain point, the debate between type-A materialists and their opponents usually comes down to intuition: most centrally, the intuition that consciousness (in a nonfunctionally defined sense) exists, or that there is something that needs to be explained (over and above explaining the functions). This claim does not gain its support from argument, but from a sort of observation, along with rebuttal of counterarguments. The intuition appears to be shared by the large majority of philosophers, scientists, and others; and it is so strong that to deny it, a type-A materialist needs exceptionally powerful arguments. The result is that even among materialists, type-A materialists are a distinct minority.

5 Type-B Materialism[*]

According to type-B materialism, there is an epistemic gap between the physical and phenomenal domains, but there is no ontological gap. According to this view, zombies and the like are conceivable, but they are not metaphysically possible. On this view, Mary is ignorant of some phenomenal truths from inside her room, but nevertheless these truths concern an underlying physical reality (when she leaves the room, she learns old facts in a new way). And on this view, while there is a hard problem distinct from the easy problems, it does not correspond to a distinct ontological domain.

The most common form of type-B materialism holds that phenomenal states can be identified with certain physical or functional states. This identity is held to be analogous in certain respects (although perhaps not in all respects) with the identity between water and H₂O, or between genes and DNA.[*] These identities are not derived through conceptual analysis, but are discovered empirically: the concept water is different from the concept H₂O, but they are found to refer to the same thing in nature. On the type-B view, something similar applies to consciousness: the concept of consciousness is distinct from any physical or functional concepts, but we may discover empirically that these refer to the same thing in nature. In this way, we can explain why there is an epistemic gap between the physical and phenomenal domains, while denying any ontological gap. This yields the attractive possibility that we can acknowledge the deep epistemic problems of consciousness while retaining a materialist worldview.
*[[In certain respects, where type-A materialism can be seen as deriving from the logical behaviorism of Ryle and Carnap, type-B materialism can be seen as deriving from the identity theory of Place and Smart. The matter is complicated, however, by the fact that the early identity-theorists advocated "topic-neutral" (functional) analyses of phenomenal properties, suggesting an underlying type-A materialism.]]*

Although such a view is attractive, it faces immediate difficulties. These difficulties stem from the fact that the character of the epistemic gap with consciousness seems to differ from that of epistemic gaps in other domains. For a start, there do not seem to be analogs of the epistemic arguments above in the cases of water, genes, and so on. To explain genes, we merely have to explain why systems function a certain way in transmitting hereditary characteristics; to explain water, we have to explain why a substance has a certain objective structure and behavior. Given a complete physical description of the world, Mary would be able to deduce all the relevant truths about water and about genes, by deducing which systems have the appropriate structure and function. Finally, it seems that we cannot coherently conceive of a world physically identical to our own, in which there is no water, or in which there are no genes. So there is no epistemic gap between the complete physical truth about the world and the truth about water and genes that is analogous to the epistemic gap with consciousness.

(Except, perhaps, for epistemic gaps that derive from the epistemic gap for consciousness. For example, perhaps Mary could not deduce or explain the perceptual appearance of water from the physical truth about the world. But this would just be another instance of the problem we are concerned with, and so cannot help the type-B materialist.)

So it seems that there is something unique about the case of consciousness. We can put this by saying that while the identity between genes and DNA is empirical, it is not epistemically primitive: the identity is itself deducible from the complete physical truth about the world. By contrast, the type-B materialist must hold that the identification between consciousness and physical or functional states is epistemically primitive: the identity is not deducible from the complete physical truth. (If it were deducible, type-A materialism would be true instead.) So the identity between consciousness and a physical state will be a sort of primitive principle in one's theory of the world.

Here, one might suggest that something has gone wrong. Elsewhere, the only sort of place that one finds this sort of primitive principle is in the fundamental laws of physics. Indeed, it is often held that this sort of primitiveness — the inability to be deduced from more basic principles — is the mark of a fundamental law of nature. In effect, the type-B materialist recognizes a principle that has the epistemic status of a fundamental law, but gives it the ontological status of an identity. An opponent will hold that this move is more akin to theft than to honest toil: elsewhere, identifications are grounded in explanations, and primitive principles are acknowledged as fundamental laws.

It is natural to suggest that the same should apply here. If one acknowledges the epistemically primitive connection between physical states and consciousness as a fundamental law, it will follow that consciousness is distinct from any physical property, since fundamental laws always connect distinct properties. So the usual standard will lead to one of the nonreductive views discussed in the second half of this paper. By contrast, the type-B materialist takes an observed connection between physical and
phenomenal states, unexplainable in more basic terms, and suggests that it is an identity. This suggestion is made largely in order to preserve a prior commitment to materialism. Unless there is an independent case for primitive identities, the suggestion will seem at best ad hoc and mysterious, and at worst incoherent.

A type-B materialist might respond in various ways. First, some (e.g., Papineau 1993) suggest that identities do not need to be explained, so are always primitive. But we have seen that identities in other domains can at least be deduced from more basic truths, and so are not primitive in the relevant sense. Second, some (e.g., Block and Stalnaker 1999) suggest that even truths involving water and genes cannot be deduced from underlying physical truths. This matter is too complex to go into here (see Chalmers and Jackson 2001 for a response[*]), but one can note that the epistemic arguments outlined at the beginning suggest a very strong disanalogy between consciousness and other cases. Third, some (e.g., Loar 1990/1997) acknowledge that identities involving consciousness are unlike other identities by being epistemically primitive, but seek to explain this uniqueness by appealing to unique features of the concept of consciousness. This response is perhaps the most interesting, and I will return to it.

[*][Block and Stalnaker (1999) argue against deducibility in part by arguing that there is usually no explicit conceptual analysis of high-level terms such as 'water' in microphysical terms, or in any other terms that could ground an a priori entailment from microphysical truths to truths about water. In response, Chalmers and Jackson (2001) argue that explicit conceptual analyses are not required for a priori entailments, and that there is good reason to believe that such entailments exist in these cases.]

There is another line that a type-B materialist can take. One can first note that an identity between consciousness and physical states is not strictly required for a materialist position. Rather, one can plausibly hold that materialism about consciousness simply requires that physical states necessitate phenomenal states, in that it is metaphysically impossible for the physical states to be present while the phenomenal states are absent or different. That is, materialism requires that entailments $P \supset Q$ be necessary, where $P$ is the complete physical truth about the world and $Q$ is an arbitrary phenomenal truth.

At this point, a type-B materialist can naturally appeal to the work of Kripke (1980), which suggests that some truths are necessarily true without being a priori. For example, Kripke suggests that 'water is H2O' is necessary — true in all possible worlds — but not knowable a priori. Here, a type-B materialist can suggest that $P \supset Q$ may be a Kripkean a posteriori necessity, like 'water is H2O' (though it should be noted that Kripke himself denies this claim). If so, then we would expect there to be an epistemic gap, since there is no a priori entailment from P to Q, but at the same time there will be no ontological gap. In this way, Kripke's work can seem to be just what the type-B materialist needs.

Here, some of the issues that arose previously arise again. One can argue that in other domains, necessities are not epistemically primitive. The necessary connection between water and H2O may be a posteriori, but it can itself be deduced from a complete physical description of the world (one can deduce that water is identical to H2O, from which it follows that water is necessarily H2O). The same applies to the other necessities that Kripke discusses. By contrast, the type-B materialist must hold that the
connection between physical states and consciousness is epistemically primitive, in that it cannot be deduced from the complete physical truth about the world. Again, one can suggest that this sort of primitive necessary connection is mysterious and ad hoc, and that the connection should instead be viewed as a fundamental law of nature.

I will discuss further problems with these necessities in the next section. But here, it is worth noting that there is a sense in which any type-B materialist position gives up on reductive explanation. Even if type-B materialism is true, we cannot give consciousness the same sort of explanation that we give genes and like, in purely physical terms. Rather, our explanation will always require explanatorily primitive principles to bridge the gap from the physical to the phenomenal. The explanatory structure of a theory of consciousness, on such a view, will be very much unlike that of a materialist theory in other domains, and very much like the explanatory structure of the nonreductive theories described below. By labeling these principles identities or necessities rather than laws, the view may preserve the letter of materialism; but by requiring primitive bridging principles, it sacrifices much of materialism's spirit.

6 The Two-Dimensional Argument against Type-B Materialism

As discussed above, the type-B materialist holds that zombie worlds and the like are conceivable (there is no contradiction in \( P \land \neg Q \)) but are not metaphysically possible. That is, \( P \supset Q \) is held to be an a posteriori necessity, akin to such a posteriori necessities as 'water is \( H_2O \)'. We can analyze this position in more depth by taking a closer look at the Kripkean cases of a posteriori necessity. This material is somewhat technical (hence the separate section) and can be skipped if necessary on a first reading.

It is often said that in Kripkean cases, conceivability does not entail possibility: it is conceivable that water is not \( H_2O \) (in that it is coherent to suppose that water is not \( H_2O \)), but it is not possible that water is not \( H_2O \). But at the same time, it seems that there is some possibility in the vicinity of what one conceives. When one conceives that water is not \( H_2O \), one conceives of a world \( W \) (the XYZ-world) in which the watery liquid in the oceans is not \( H_2O \), but XYZ, say. There is no reason to doubt that the XYZ-world is metaphysically possible. If Kripke is correct, the XYZ-world is not correctly described as one in which water is \( H_2O \). Nevertheless, this world is relevant to the truth of 'water is \( H_2O \)' in a slightly different way, which can be brought out as follows.

One can say that the XYZ-world could turn out to be actual, in that for all we know a priori, the actual world is just like the XYZ-world. And one can say that if the XYZ-world turns out to be actual, it will turn out that water is XYZ. Similarly: if we hypothesize that the XYZ-world is actual, we should rationally conclude on that basis that water is not \( H_2O \). That is, there is a deep epistemic connection between the XYZ-world and 'water is not \( H_2O \)'. Even Kripke allows that it is epistemically possible that water is not \( H_2O \) (in the broad sense that this is not ruled out a priori). It seems that the epistemic possibility that the XYZ-world is actual is a specific instance of the epistemic possibility that water is not \( H_2O \).

http://www.u.arizona.edu/~chalmers/papers/nature.html (15 of 40) [4/7/2002 1:44:53 PM]
Here, we adopt a special attitude to a world W. We think of W as an epistemic possibility: as a way the world might actually be. When we do this, we consider W as actual. When we think of W as actual, it may make a given sentence S true or false. For example, when thinking of the XYZ-world as actual, it makes 'water is not H₂O' true. This is brought out in the intuitive judgment that if W turns out to be actual, it will turn out that water is not H₂O, and that the epistemic possibility that W is actual is an instance of the epistemic possibility that water is H₂O.

By contrast, one can also consider a world W as counterfactual. When we do this, we acknowledge that the character of the actual world is already fixed, and we think of W as a counterfactual way things might have been but are not. If Kripke is right, then if the watery stuff had been XYZ, XYZ would nevertheless not have been water. So when we consider the XYZ-world as counterfactual, it does not make 'water is not H₂O' true. Considered as counterfactual, we describe the XYZ-world in light of the actual-world fact that water is H₂O, and we conclude that XYZ is not water but merely watery stuff. These results do not conflict: they simply involve two different ways of considering and describing possible worlds. Kripke's claims consider counterfactual evaluation of worlds, whereas the claims in the previous paragraph concern the epistemic evaluation of worlds.

One can formalize this using two-dimensional semantics (see Chalmers (this volume, chapter 56).[⋆] We can say that if W considered as actual makes S true, then W verifies S, and that if W considered as counterfactual makes S true, then W satisfies S. Verification involves the epistemic evaluation of worlds, whereas satisfaction involves the counterfactual evaluation of worlds. Correspondingly, we can associate S with different intensions, or functions from worlds to truth values. The primary (or epistemic) intension of S is a function that is true at a world W iff W verifies S, and the secondary (or subjunctive) intension is a function that is true at a world W if W satisfies S. For example, where S is 'water is not H₂O', and W is the XYZ-world, we can say that W verifies S but W does not satisfy S; and we can say that the primary intension of S is true at W, but the secondary intension of S is false at W.

[⋆][Two-dimensional semantic frameworks originate in work of Kaplan (1989), Stalnaker (1978), and Evans (1979). The version used in these arguments is somewhat different: for discussion of the differences, see Chalmers (forthcoming).]

With this in mind, one can suggest that when a statement S is conceivable — that is, when its truth cannot be ruled out a priori — then there is some world that verifies S, or equivalently, there is some world at which S's primary intension is true. This makes intuitive sense: when S is conceivable, S represents an epistemic possibility. It is natural to suggest that corresponding to these epistemic possibilities are specific worlds W, such that when these are considered as epistemic possibilities, they verify S. That is, W is such that intuitively, if W turns out to be actual, it would turn out that S.

This model seems to fit all of Kripke's cases. For example, Kripke holds that it is an a posteriori necessity that heat is the motion of molecules. So it is conceivable in the relevant sense that heat is not the motion of molecules. Corresponding to this conceivable scenario is a world W in which heat sensations are caused by something other than the motion of molecules. W represents an epistemic possibility: and we can say that if W turns out to be actual, it will turn out that heat is not the motion of molecules. The same
Consciousness and its Place in Nature

goes in many other cases. The moral is that these Kripkean phenomena involve two different ways of thinking of possible worlds, with just one underlying space of worlds.

If this principle is applied to the case of type-B materialism, trouble immediately arises. As before, let P be the complete physical truth about the world, and let Q be a phenomenal truth. Let us say that S is conceivable when the truth of S is not ruled out a priori. Then one can mount an argument as follows:[*]

*[[This is a slightly more formal version of an argument in Chalmers 1996 (pp. 131-36). It is quite closely related to Kripke's modal argument against the identity theory, though different in some important respects. The central premise 2 can be seen as a way of formalizing Kripke's claim that where there is "apparent contingency", there is some misdescribed possibility in the background. The argument can also be seen as a way of formalizing a version of the "dual property" objection attributed to Max Black by Smart 1959, and developed by Jackson 1979 and White 1986. Related applications of the two-dimensional framework to questions about materialism are given by Jackson 1994 and Lewis 1994.]]

(1) \( P \land \neg Q \) is conceivable

(2) If \( P \land \neg Q \) is conceivable, a world verifies \( P \land \neg Q \).

(3) If a world verifies \( P \land \neg Q \), then a world satisfies \( P \land \neg Q \) or type-F monism is true.

(4) If a world satisfies \( P \land \neg Q \), materialism is false.

—

(5) Materialism is false or type-F monism is true.

The type-B materialist grants premise (1): to deny this would be to accept type-A materialism. Premise (2) is an instance of the general principle discussed above. Premise (4) can be taken as definitive of materialism. As for premise (3): in general one cannot immediately move from a world verifying S to a world satisfying S, as the case of 'water is H₂O' (and the XYZ-world) suggests. But in the case of \( P \land \neg Q \), a little reflection on the nature of P and Q takes us in that direction, as follows.

First, Q. Here, it is plausible that if W verifies 'there is consciousness', then W satisfies 'there is consciousness', and vice versa. This corresponds to the Kripkean point that in the case of consciousness, there is no distinction analogous to that between water itself and mere watery stuff. To put it intuitively, if W verifies 'there is consciousness', it contains something that at least feels conscious, and if something feels conscious, it is conscious. One can hold more generally that the primary and secondary intensions of our core phenomenal concepts are the same (see Chalmers 2002a). It follows that if world W verifies \( \neg Q \), W satisfies \( \neg Q \). (This claim is not required for the argument to go through, but it is plausible and makes things more straightforward.)

Second, P. A type-B materialist might seek to evade the argument by arguing that while W verifies P, it
Consciousness and its Place in Nature

does not satisfy P. On reflection, the only way this might work is as follows. If a world verifies P, it must have at least the structure of the actual physical world. The only reason why W might not satisfy P is that it lacks the intrinsic properties underlying this structure in the actual world. (On this view, the primary intension of a physical concept picks out whatever property plays a certain role in a given world, and the secondary intension picks out the actual intrinsic property across all worlds.) If this difference in W is responsible for the absence of consciousness in W, it follows that consciousness in the actual world is not necessitated by the structural aspects of physics, but by its underlying intrinsic nature. This is precisely the position I call type-F monism, or "panprotopsychism." Type-F monism is an interesting and important position, but it is much more radical than type-B materialism as usually conceived, and I count it as a different position. I will defer discussion of the reasoning and of the resulting position until then.

It follows that premise (4) is correct. If a world verifies P∧¬Q, then either a world satisfies P∧¬Q, or type-F monism is true. Setting aside type-F monism for now, it follows that the physical truth about our world does not necessitate the phenomenal truth, and materialism is false.

This conclusion is in effect a consequence of (i) the claim that P∧¬Q is conceivable (in the relevant sense), (ii) the claim that when S is conceivable, there is a world that verifies S, and (iii) some straightforward reasoning. A materialist might respond by denying (i), but that is simply to deny the relevant epistemic gap between the physical and the phenomenal, and so to deny type-B materialism. I think there is little promise for the type-B materialist in denying the reasoning involved in (iii). So the only hope for the type-B materialist is to deny the central thesis (ii).[*]

[*][I have passed over a few subtleties here. One concerns the role of indexicals: to handle claims such as 'I am here', primary intensions are defined over centered worlds: worlds with a marked individual and time, corresponding to indexical "locating information" about one's position in the world. This change does not help the type-B materialist, however. Even if we supplement P with indexical locating information I (e.g., telling Mary about her location in the world), there is as much of an epistemic gap with Q as ever; so P∧I∧¬Q is conceivable. And given that there is a centered world that verifies P∧I∧¬Q, one can see as above that either there is a world satisfying P∧¬Q, or type-F monism is true.]

To do this, a type-B materialist could deny the coherence of the distinction between verification and satisfaction, or accept that the distinction is coherent but deny that thesis (ii) holds even in the standard Kripkean cases, or accept that thesis (ii) holds in the standard Kripkean cases but deny that it holds in the special case of consciousness. The first two options deserve exploration, but I think they are ultimately unpromising, as the distinction and the thesis appear to fit the Kripkean phenomena very well. Ultimately, I think a type-B materialist must hold that the case of consciousness is special, and that the thesis that holds elsewhere fails here.

On this view, the a posteriori necessities connecting the physical and phenomenal domains are much stronger than those in other domains, in that they are verified by all worlds. Elsewhere, I have called these unusual a posteriori necessities strong necessities, and have argued that there is no good reason to believe they exist. As with explanatorily primitive identities, they appear to be primitive facts postulated in an ad hoc way, largely in order to save a theory, with no support from cases elsewhere. Further, one can argue that this view leads to an underlying modal dualism, with independent primitive domains of logical and
metaphysical possibility; and one can argue that this is unacceptable.

Perhaps the most interesting response from a type-B materialist is to acknowledge that strong necessities are unique to the case of consciousness, and to try to explain this uniqueness in terms of special features of our conceptual system. For example, Christopher Hill (1997) has argued that one can predict the epistemic gap in the case of consciousness from the fact that physical concepts and phenomenal concepts have different conceptual roles. Brian Loar (1990/1997) has appealed to the claim that phenomenal concepts are recognitional concepts that lack contingent modes of presentation. Joseph Levine (1998) has argued that phenomenal concepts have nonascriptive modes of presentation. In response, I have argued (Chalmers 1999) that these responses do not work, and that there are systematic reasons why they cannot work.[*] But it is likely that further attempts in this direction will be forthcoming. This remains one of the key areas of debate on the metaphysics of consciousness.

*[Hill (1997) tries to explain away our modal intuitions about consciousness in cognitive terms. Chalmers (1999) responds that any modal intuition might be explained in cognitive terms (a similar argument could "explain away" our intuition that there might be red squares), but that this has no tendency to suggest that the intuition is incorrect. If such an account tells us that modal intuitions about consciousness are unreliable, the same goes for all modal intuitions. What is really needed is not an explanation of our modal intuitions about consciousness, but an explanation of why these intuitions in particular should be unreliable.

Loar (1990/1997) attempts to provide such an explanation in terms of the unique features of phenomenal concepts. He suggests that (1) phenomenal concepts are recognitional concepts ("that sort of thing"); that (2) like other recognitional concepts, they can corefer with physical concepts that are cognitively distinct; and that (3) unlike other recognitional concepts, they lack contingent modes of presentation (i.e., their primary and secondary intensions coincide). If (2) and (3) both hold (and if we assume that physical concepts also lack contingent modes of presentation), then a phenomenal-physical identity will be a strong necessity in the sense above. In response, Chalmers (1999) argues that (2) and (3) cannot both hold. The coreference of other recognitional concepts with theoretical concepts is grounded in their contingent modes of presentation; in the absence of such modes of presentation, there is no reason to think that these concepts can corefer. So accepting (3) undercuts any support for (2). Chalmers (1999) also argues that by assuming that physical properties can have phenomenal modes of presentation noncontingently, Loar's account is in effect presupposing rather than explaining the relevant strong necessities.]]

Overall, my own view is that there is little reason to think that explanatorily primitive identities or strong necessities exist. There is no good independent reason to believe in them: the best reason to postulate them is to save materialism, but in the context of a debate over whether materialism is true this reasoning is uncompelling, especially if there are viable alternatives. Nevertheless, further investigation into the key issues underlying this debate is likely to be philosophically fruitful.

7 Type-C Materialism

According to type-C materialism, there is a deep epistemic gap between the physical and phenomenal domains, but it is closable in principle. On this view, zombies and the like are conceivable for us now, but they will not be conceivable in the limit. On this view, it currently seems that Mary lacks information about the phenomenal, but in the limit there would be no information that she lacks. And on this view, while we cannot see now how to solve the hard problem in physical terms, the problem is solvable in
This view is initially very attractive. It seems to acknowledge the deep explanatory gap with which we seem to be faced, while at the same time allowing that the apparent gap may be due to our own limitations. There are different versions of the view. Nagel (1974) has suggested that just as the pre-Socratics could not have understood how matter could be energy, we cannot understand how consciousness could be physical, but a conceptual revolution might allow the relevant understanding. Churchland (1997) suggests that even if we cannot now imagine how consciousness could be a physical process, that is simply a psychological limitation on our part that further progress in science will overcome. Van Gulick (1993) suggests that conceivability arguments are question-begging, since once we have a good explanation of consciousness, zombies and the like will no longer be conceivable. McGinn (1989) has suggested that the problem may be unsolvable by humans due to deep limitations in our cognitive abilities, but that it nevertheless has a solution in principle.

One way to put the view is as follows. Zombies and the like are *prima facie* conceivable (for us now, with our current cognitive processes), but they are not *ideally* conceivable (under idealized rational reflection). Or we could say: phenomenal truths are deducible in principle from physical truths, but the deducibility is akin to that of a complex truth of mathematics: it is accessible in principle (perhaps accessible a priori), but is not accessible to us now, perhaps because the reasoning required is currently beyond us, or perhaps because we do not currently grasp all the required physical truths. If this is so, then there will appear to us that there is a gap between physical processes and consciousness, but there will be no gap in nature.

Despite its appeal, I think that the type-C view is inherently unstable. Upon examination, it turns out either to be untenable, or to collapse into one of the other views on the table. In particular, it seems that the view must collapse into a version of type-A materialism, type-B materialism, type-D dualism, or type-F monism, and so is not ultimately a distinct option.

One way to hold that the epistemic gap might be closed in the limit is to hold that in the limit, we will see that explaining the functions explains everything, and that there is no further explanandum. It is at least coherent to hold that we currently suffer from some sort of conceptual confusion or unclarity that leads us to believe that there is a further explanandum, and that this situation could be cleared up by better reasoning. I will count this position as a version of type-A materialism, not type-C materialism: it is obviously closely related to standard type-A materialism (the main difference is whether we have yet had the relevant insight), and the same issues arise. Like standard type-A materialism, this view ultimately stands or fall with the strength of (actual and potential) first-order arguments that dissolve any apparent further explanandum.

Once type-A materialism is set aside, the potential options for closing the epistemic gap are highly constrained. These constraints are grounded in the nature of physical concepts, and in the nature of the concept of consciousness. The basic problem has already been mentioned. First: Physical descriptions of the world characterize the world in terms of structure and dynamics. Second: From truths about structure and dynamics, one can deduce only further truths about structure and dynamics. And third: truths about consciousness are not truths about structure and dynamics. But we can take these steps one at a time.
First: A microphysical description of the world specifies a distribution of particles, fields, and waves in space and time. These basic systems are characterized by their spatiotemporal properties, and properties such as mass, charge, and quantum wavefunction state. These latter properties are ultimately defined in terms of spaces of states that have a certain abstract structure (e.g., the space of continuously varying real quantities, or of Hilbert space states), such that the states play a certain causal role with respect to other states. We can subsume spatiotemporal descriptions and descriptions in terms of properties in these formal spaces under the rubric of *structural* descriptions. The state of these systems can change over time in accord with dynamic principles defined over the relevant properties. The result is a description of the world in terms of its underlying spatiotemporal and formal structure, and dynamic evolution over this structure.

Some type-C materialists hold we do not yet have a complete physics, so we cannot know what such a physics might explain. But here we do not need to have a complete physics: we simply need the claim that physical descriptions are in terms of structure and dynamics. This point is general across physical theories. Such novel theories as relativity, quantum mechanics, and the like may introduce new structures, and new dynamics over those structures, but the general point (and the gap with consciousness) remains.

A type-C materialist might hold that there could be new physical theories that go beyond structure and dynamics. But given the character of physical explanation, it is unclear what sort of theory this could be. Novel physical properties are postulated for their potential in explaining existing physical phenomena, themselves characterized in terms of structure and dynamics, and it seems that structure and dynamics always suffices here. One possibility is that instead of postulating novel properties, physics might end up appealing to consciousness itself, in the way that some theorists hold that quantum mechanics does. This possibility cannot be excluded, but it leads to a view on which consciousness is itself irreducible, and is therefore to be classed in a nonreductive category (type D or type F).

There is one appeal to a "complete physics" that should be taken seriously. This is the idea that current physics characterizes its underlying properties (such as mass and charge) in terms of abstract structures and relations, but it leaves open their intrinsic natures. On this view, a complete physical description of the world must also characterize the intrinsic properties that ground these structures and relations; and once such intrinsic properties are invoked, physics will go beyond structure and dynamics, in such a way that truths about consciousness may be entailed. The relevant intrinsic properties are unknown to us, but they are knowable in principle. This is an important position, but it is precisely the position discussed under type F, so I defer discussion of it until then.

Second: What can be inferred from this sort of description in terms of structure and dynamics? A low-level microphysical description can entail all sorts of surprising and interesting macroscopic properties, as with the emergence of chemistry from physics, of biology from chemistry, or more generally of complex emergent behaviors in complex systems theory. But in all these cases, the complex properties that are entailed are nevertheless structural and dynamic: they describe complex spatiotemporal structures and complex dynamic patterns of behavior over those structures. So these cases support the general principle that from structure and dynamics, one can infer only structure and dynamics.
A type-C materialist might suggest there are some truths that are not themselves structural-dynamical that are nevertheless implied by a structural-dynamical description. It might be argued, perhaps, that truths about *representation* or *belief* have this character. But as we saw earlier, it seems clear that any sense in which these truths are implied by a structural-dynamical description involves a tacitly functional sense of representation or of belief. This is what we would expect: if claims involving these can be seen (on conceptual grounds) to be true *in virtue* of a structural-dynamic descriptions holding, the notions involved must themselves be structural-dynamic, at some level.

One might hold that there is some intermediate notion X, such that truths about X hold in virtue of structural-dynamic descriptions, and truths about consciousness hold in virtue of X. But as in the case of type-A materialism, either X is functionally analyzable (in the broad sense), in which case the second step fails, or X is not functionally analyzable, in which case the first step fails. This is brought out clearly in the case of representation: for the notion of functional representation, the first step fails, and for the notion of phenomenal representation, the second step fails. So this sort of strategy can only work by equivocation.

Third: does explaining or deducing complex structure and dynamics suffice to explain or deduce consciousness? It seems clearly not, for the usual reasons. Mary could know from her black-and-white room all about the spatiotemporal structure and dynamics of the world at all levels, but this will not tell her what it is like to see red. For any complex macroscopic structural or dynamic description of a system, one can conceive of that description being instantiated without consciousness. And explaining structure and dynamics of a human system is only to solve the easy problems, while leaving the hard problems untouched. To resist this last step, an opponent would have to hold that explaining structure and dynamics *thereby* suffices to explain consciousness. The only remotely tenable way to do this would be to embrace type-A materialism, which we have set aside.

A type-C materialist might suggest that instead of leaning on dynamics (as a type-A materialist does), one could lean on structure. Here, spatiotemporal structure seems very unpromising: to explain a system's size, shape, position, motion, and so on is clearly not to explain consciousness. A final possibility is leaning on the structure present in conscious states themselves. Conscious states have structure: there is both internal structure within a single complex conscious state, and there are patterns of similarities and differences between conscious states. But this structure is a distinctively *phenomenal* structure, quite different in kind from the spatiotemporal and formal structure present in physics. The structure of a complex phenomenal state is not spatiotemporal structure (although it may involve the representation of spatiotemporal structure), and the similarities and differences between phenomenal states are not formal similarities and differences, but differences between specific phenomenal characters. This is reflected in the fact that one can conceive of any spatiotemporal structure and formal structure without any associated phenomenal structure; one can know about the first without knowing about the second; and so on. So the epistemic gap is as wide as ever.

The basic problem with any type-C materialist strategy is that epistemic implication from A to B requires some sort of *conceptual hook* by virtue of which the condition described in A can satisfy the conceptual
Consciousness and its Place in Nature

Requirements for the truth of B. When a physical account implies truths about life, for example, it does so in virtue of implying information about the macroscopic functioning of physical systems, of the sort required for life: here, broadly functional notions provide the conceptual hook. But in the case of consciousness, no such conceptual hook is available, given the structural-dynamic character of physical concepts, and the quite different character of the concept of consciousness.

Ultimately, it seems that any type-C strategy is doomed for familiar reasons. Once we accept that the concept of consciousness is not itself a functional concept, and that physical descriptions of the world are structural-dynamic descriptions, there is simply no conceptual room for it to be implied by a physical description. So the only room left is to hold that consciousness is a broadly functional concept after all (accepting type-A materialism), hold that there is more in physics than structure and dynamics (accepting type-D dualism or type-F monism), or holding that the truth of materialism does not require an implication from physics to consciousness (accepting type-B materialism).[*] So in the end, there is no separate space for the type-C materialist.

*[[Of those mentioned above as apparently sympathetic with type-C materialism, I think McGinn is ultimately a type-F monist, Nagel is either a type-B materialist or a type-F monist, and Churchland is either a type-B materialist or a type-Q materialist (below).]]

8 Interlude

Are there any other options for the materialist? One further option is to reject the distinctions on which this taxonomy rests. For example, some philosophers, especially followers of Quine (1951), reject any distinction between conceptual truth and empirical truth, or between the a priori and the a posteriori, or between the contingent and the necessary. One who is sufficiently Quinean might therefore reject the distinction between type-A and type-B materialism, holding that talk of epistemic implication and/or modal entailment is ungrounded, but that materialism is true nevertheless. We might call such a view type-Q materialism. Still, even on this view, similar issues arise. Some Quineans hold that explaining the functions explain everything (Dennett may be an example); if so, all the problems of type-A materialism arise. Others hold that we can postulate identities between physical states and conscious states in virtue of the strong isomorphic connections between them in nature (Paul Churchland may be an example); if so, the problems of type-B materialism arise. Others may appeal to novel future sorts of explanation; if so, the problems of type-C materialism arise. So the Quinean approach cannot avoid the relevant problems.

Leaving this sort of view aside, it looks like the only remotely viable options for the materialist are type-A materialism and type-B materialism. I think that other views are either ultimately unstable, or collapse into one of these (or the three remaining options).[*] It seems to me that the costs of these views — denying the manifest explanandum in the first case, and embracing primitive identities or strong necessities in the second case — suggest very strongly that they are to be avoided unless there are no viable alternatives.

*[[One might ask about specific reductive views, such as representationalism (which identifies consciousness with certain representational states), and higher-order thought theory (which identifies consciousness with the objects of higher-order

http://www.u.arizona.edu/~chalmers/papers/nature.html (23 of 40) [4/7/2002 1:44:53 PM]
thoughts). How these views are classified depends on how a given theorist regards the representational or higher-order states (e.g., functionally definable or not) and their connection to consciousness (e.g., conceptual or empirical). Among representationalists, I think that Dretske 1995 and Harman 1990 are type-A materialists, while Lycan 1996 and Tye 1995 are type-B materialists. Among higher-order thought theorists, Carruthers 2000 is clearly a type-B materialist, while Rosenthal 1997 is either type-A or type-B. One could also in principle hold nonmaterialist versions of each of these views.]

So the residual question is whether there are viable alternatives. If consciousness is not necessitated by physical truths, then it must involve something ontologically novel in the world: to use Kripke's metaphor, after fixing all the physical truths, God had to do more work to fix all the truths about consciousness. That is, there must be ontologically fundamental features of the world over and above the features characterized by physical theory. We are used to the idea that some features of the world are fundamental: in physics, features such as spacetime, mass, and charge, are taken as fundamental and not further explained. If the arguments against materialism are correct, these features from physics do not exhaust the fundamental features of the world: we need to expand our catalog of the world's basic features.

There are two possibilities here. First, it could be that consciousness is itself a fundamental feature of the world, like spacetime and mass. In this case, we can say that phenomenal properties are fundamental. Second, it could be that consciousness is not itself fundamental, but is necessitated by some more primitive fundamental feature X that is not itself necessitated by physics. In this case, we might call X a protophenomenal property, and we can say that protophenomenal properties are fundamental. I will typically put things in terms of the first possibility for ease of discussion, but the discussion that follows applies equally to the second. Either way, consciousness involves something novel and fundamental in the world.

The question then arises: how do these novel fundamental properties relate to the already acknowledged fundamental properties of the world, namely those invoked in microphysics? In general, where there are fundamental properties, there are fundamental laws. So we can expect that there will be some sort of fundamental principles — psychophysical laws — connecting physical and phenomenal properties. Like the fundamental laws of relativity or quantum mechanics, these psychophysical laws will not be deducible from more basic principles, but instead will be taken as primitive.

But what is the character of these laws? An immediate worry is that the microphysical aspects of the world is often held to be causally closed, in that every microphysical state has a microphysical sufficient cause. How are fundamental phenomenal properties to be integrated with this causally closed network?

There seem to be three main options for the nonreductionist here. First, one could deny the causal closure of the microphysical, holding that there are causal gaps in microphysical dynamics that are filled by a causal role for distinct phenomenal properties: this is type-D dualism. Second, one could accept the causal closure of the microphysical and hold that phenomenal properties play no causal role with respect to the physical network: this is type-E dualism. Third, one could accept that the microphysical network is causally closed, but hold that phenomenal properties are nevertheless integrated with it and play a causal role, by virtue of constituting the intrinsic nature of the physical: this is type-F monism.
In what follows, I will discuss each of these views. The discussion is necessarily speculative in certain respects, and I do not claim to establish that any one of the views is true or completely unproblematic. But I do aim to suggest that none of them has obvious fatal flaws, and that each deserves further investigation.

9 Type-D Dualism

Type-D dualism holds that microphysics is not causally closed, and that phenomenal properties play a causal role in affecting the physical world.[*] On this view, usually known as interactionism, physical states will cause phenomenal states, and phenomenal states cause physical states. The corresponding psychophysical laws will run in both directions. On this view, the evolution of microphysical states will not be determined by physical principles alone. Psychophysical principles specifying the effect of phenomenal states on physical states will also play an irreducible role.

The most familiar version of this sort of view is Descartes' substance dualism (hence D for Descartes), on which there are separate interacting mental and physical substances or entities. But this sort of view is also compatible with a property dualism, on which there is just one sort of substance or entity with both physical and phenomenal fundamental properties, such that the phenomenal properties play an irreducible role in affecting the physical properties. In particular, the view is compatible with an "emergentist" view such as Broad's, on which phenomenal properties are ontologically novel properties of physical systems (not deducible from microphysical properties alone), and have novel effects on microphysical properties (not deducible from microphysical principles alone). Such a view would involve basic principles of "downward" causation of the mental on the microphysical (hence also D for downward causation).

It is sometimes objected that distinct physical and mental states could not interact, since there is no causal nexus between them. But one lesson from Hume and from modern science is that the same goes for any fundamental causal interactions, including those found in physics. Newtonian science reveals no causal nexus by which gravitation works, for example; rather, the relevant laws are simply fundamental. The same goes for basic laws in other physical theories. And the same, presumably, applies to fundamental psychophysical laws: there is no need for a causal nexus distinct from the physical and mental properties themselves.

By far the most influential objection to interactionism is that it is incompatible with physics. It is widely held that science tells us that the microphysical realm is causally closed, so that there is no room for mental states to have any effects. An interactionist might respond in various ways. For example, it could be suggested that although no experimental studies have revealed these effects, none have ruled them out. It might further be suggested that physical theory allows any number of basic forces (four as things stand, but there is always room for more), and that an extra force associated with a mental field would be a reasonable extension of existing physical theory. These suggestions would invoke significant revisions to physical theory, so are not to be made lightly; but one could argue that nothing rules them out.
By far the strongest response to this objection, however, is to suggest that far from ruling out interactionism, contemporary physics is positively encouraging to the possibility. On the standard formulation of quantum mechanics, the state of the world is described by a wave function, according to which physical entities are often in a superposed state (e.g., in a superposition of two different positions), even though superpositions are never directly observed. On the standard dynamics, the wave function can evolve in two ways: linear evolution by the Schrödinger equation (which tends to produce superposed states), and nonlinear \textit{collapses} from superposed states into nonsuperposed states. Schrödinger evolution is deterministic, but collapse is nondeterministic. Schrödinger evolution is constantly ongoing, but on the standard formulation, collapses occur only occasionally, on measurement.

The collapse dynamics leaves a door wide open for an interactionist interpretation. Any physical nondeterminism might be held to leave room for nonphysical effects, but the principles of collapse do much more than that. Collapse is supposed to occur on measurement. There is no widely agreed definition of what a measurement is, but there is one sort of event that everyone agrees is a measurement: observation by a conscious observer. Further, it seems that no purely physical criterion for a measurement can work, since purely physical systems are governed by the linear Schrödinger dynamics. As such, it is natural to suggest that a measurement is precisely a conscious observation, and that this conscious observation causes a collapse.

The claim should not be too strong: quantum mechanics does not force this interpretation of the situation onto us, and there are alternative interpretations of quantum mechanics on which there are no collapses, or on which measurement has no special role in collapse.[*] Nevertheless, quantum mechanics appears to be perfectly \textit{compatible} with such an interpretation. In fact, one might argue that if one was to design elegant laws of physics that allow a role for the conscious mind, one could not do much better than the bipartite dynamics of standard quantum mechanics: one principle governing deterministic evolution in normal cases, and one principle governing nondeterministic evolution in special situations that have a prima facie link to the mental.

*[[No-collapse interpretations include Bohm’s "hidden-variable" interpretations, and Everett’s "many-worlds" (or "many-minds") interpretation. A collapse interpretation that does not invoke measurement is the Ghirardi-Rimini-Weber interpretation (with random occasional collapses). Each of these interpretations requires a significant revision to the standard dynamics of quantum mechanics, and each is controversial, although each has its benefits. (See Albert 1993 for discussion of these and other interpretations.) It is notable that there seems to be no remotely tenable interpretation that preserves the standard claim that collapses occur upon measurement, except for the interpretation involving consciousness.]]

Of course such an interpretation of quantum mechanics is controversial. Many physicists reject it precisely because it is dualistic, giving a fundamental role to consciousness. This rejection is not surprising, but it carries no force when we have independent reason to hold that consciousness may be fundamental. There is some irony in the fact that philosophers reject interactionism on largely physical grounds[*] (it is incompatible with physical theory), while physicists reject an interactionist interpretation of quantum mechanics on largely philosophical grounds (it is dualistic). Taken conjointly, these reasons carry little force, especially in light of the arguments against materialism elsewhere in this paper.
I have been as guilty of this as anyone, setting aside interactionism in Chalmers 1996 partly for reasons of compatibility with physics. I am still not especially inclined to endorse interactionism, but I now think that the argument from physics is much too glib. Three further reasons for rejecting the view are mentioned in Chalmers 1996. First, if consciousness is to make an interesting qualitative difference to behavior, this requires that it act nonrandomly, in violation of the probabilistic requirements of quantum mechanics. I think there is something to this, but one could bite the bullet on nonrandomness in response, or one could hold that even a random causal role for consciousness is good enough. Second, I argued that denying causal closure yields no special advantage, as a view with causal closure can achieve much the same effect via type-F monism. Again there is something to this, but the type-D view does have the significant advantage of avoiding the type-F view's "combination problem." Third, it is not clear that the collapse interpretation yields the sort of causal role for consciousness that we expect it to have. I think that this is an important open question that requires detailed investigation.

This sort of interpretation needs to be formulated in detail to be assessed. I think the most promising version of such an interpretation allows conscious states to be correlated with the total quantum state of a system, with the extra constraint that conscious states (unlike physical states) can never be superposed. In a conscious physical system such as a brain, the physical and phenomenal states of the system will be correlated in a (nonsuperposed) quantum state. Upon observation of a superposed system, then Schrödinger evolution at the moment of observation would cause the observed system to become correlated with the brain, yielding a resulting superposition of brain states and so (by psychophysical correlation) a superposition of conscious states. But such a superposition cannot occur, so one of the potential resulting conscious states is somehow selected (presumably by a nondeterministic dynamic principle at the phenomenal level). The result is that (by psychophysical correlation) a definite brain state and state of the observed object are also selected. The same might apply to the connection between consciousness and non-conscious processes in the brain: when superposed non-conscious processes threaten to affect consciousness, there will be some sort of selection. In this way, there is a causal role for consciousness in the physical world.

Consciousness-collapse interpretations of quantum mechanics have been put forward by Wigner (1961), Hodgson (1991), and Stapp (1993). Only Stapp goes into much detail, with an interesting but somewhat idiosyncratic account that goes in a direction different from that suggested above.

Interestingly, such a theory may be empirically testable. In quantum mechanics, collapse theories yield predictions slightly different from no-collapse theories, and different hypotheses about the location of collapse yield predictions that differ from each other, although the differences are extremely subtle and are currently impossible to measure. If the relevant experiments can one day be performed, some outcomes would give us strong reason to accept a collapse theory, and might in turn give us grounds to accept a role for consciousness. As a bonus, this could even yield an empirical criterion for the presence of consciousness.

There are any number of further questions concerning the precise formulation of such a view, its compatibility with physical theory more generally (e.g., relativity and quantum field theory), and its philosophical tenability (e.g., does this view yield the sort of causal role that we are inclined to think consciousness must have). But at the very least, it cannot be said that physical theory immediately rules out the possibility of an interactionist theory. Those who make this claim often raise their eyebrows when
Consciousness and its Place in Nature

a specific theory such as quantum mechanics is mentioned; but this is quite clearly an inconsistent set of attitudes. If physics is supposed to rule out interactionism, then careful attention to the detail of physical theory is required.

All this suggests that there is at least room for a viable interactionism to be explored, and that the most common objection to interactionism has little force. Of course it does not entail that interactionism is true. There is much that is attractive about the view of the physical world as causally closed, and there is little direct evidence from cognitive science of the hypothesis that behavior cannot be wholly explained in terms of physical causes. Still, if we have independent reason to think that consciousness is irreducible, and if we wish to retain the intuitive view that consciousness plays a causal role, then this is a view to be taken very seriously.

10 Type-E Dualism

Type-E dualism holds that phenomenal properties are ontologically distinct from physical properties, and that the phenomenal has no effect on the physical.

This is the view usually known as *epiphenomenalism* (hence type-E): physical states cause phenomenal states, but not vice versa. On this view, psychophysical laws run in one direction only, from physical to phenomenal. The view is naturally combined with the view that the physical realm is causally closed: this further claim is not essential to type-E dualism, but it provides much of the motivation for the view.

As with type-D dualism, type-E dualism is compatible with a substance dualism with distinct physical and mental substances or entities, and is also compatible with a property dualism with one sort of substance or entity and two sorts of properties. Again, it is compatible with an emergentism such as Broad's, on which mental properties are ontologically novel emergent properties of an underlying entity, but in this case although there are emergent qualities, there is no emergent downward causation.

Type-E dualism is usually put forward as respecting both consciousness and science: it simultaneously accommodates the anti-materialist arguments about consciousness and the causal closure of the physical. At the same time, type-E dualism is frequently rejected as deeply counterintuitive. If type-E dualism is correct, then phenomenal states have no effect on our actions, physically construed. For example, a sensation of pain will play no causal role in my hand's moving away from a flame; my experience of decision will play no causal role in my moving to a new country; and a sensation of red will play no causal role in my producing the utterance 'I am experiencing red now.' These consequences are often held to be obviously false, or at least unacceptable.

Still, the type-E dualist can reply that there is no direct *evidence* that contradicts their view. Our evidence reveals only regular connections between phenomenal states and actions, so that certain sorts of experiences are typically followed by certain sorts of actions. Being exposed to this sort of constant conjunction produces a strong *belief* in a causal connection (as Hume pointed out in another context); but
it is nevertheless compatible with the absence of a causal connection. Indeed, it seems that if epiphenomenalism were true, we would have exactly the same evidence, and be led to believe that consciousness has a causal role for much the same reasons. So if epiphenomenalism is otherwise coherent and acceptable, it seems that these considerations do not provide strong reasons to reject it.[*]

*[[Some accuse the epiphenomenalist of a double standard: relying on intuition in making the case against materialism, but going counter to intuition in denying a causal role for consciousness. But intuitions must be assessed against the background of reasons and evidence. To deny the relevant intuitions in the anti-materialist argument (in particular, the intuition of a further explanandum) appears to contradict the available first-person evidence; but denying a causal role for consciousness appears to be compatible on reflection with all our evidence, including first-person evidence.]]

Another objection holds that if consciousness is epiphenomenal, it could not have evolved by natural selection. The type-E dualist has a straightforward reply, however. On the type-E view, there are fundamental psychophysical laws associating physical and phenomenal properties. If evolution selects appropriate physical properties (perhaps involving physical or informational configurations in the brain), then the psychophysical laws will ensure that phenomenal properties are instantiated, too. If the laws have the right form, one can even expect that as more complex physical systems are selected, more complex states of consciousness will evolve. In this way, physical evolution will carry the evolution of consciousness along with it as a sort of byproduct.

Perhaps the most interesting objections to epiphenomenalism focus on the relation between consciousness and representations of consciousness. It is certainly at least strange to suggest that consciousness plays no causal role in my utterances of 'I am conscious'. Some have suggested more strongly that this rules out any knowledge of consciousness. It is often held that if a belief about X is to qualify as knowledge, the belief must be caused in some fashion by X. But if consciousness does not effect physical states, and if beliefs are physically constituted, then consciousness cannot cause beliefs. And even if beliefs are not physically constituted, it is not clear how epiphenomenalism can accommodate a causal connection between consciousness and belief.

In response, an epiphenomenalist can deny that knowledge always requires a causal connection. One can argue on independent grounds that there is a stronger connection between consciousness and beliefs about consciousness: consciousness plays a role in constituting phenomenal concepts and phenomenal beliefs. A red experience plays a role in constituting a belief that one is having a red experience, for example. If so, there is no causal distance between the experience and the belief. And one can argue that this immediate connection to experience and belief allows for the belief to be justified. If there is right, then epiphenomenalism poses no obstacle to knowledge of consciousness.

A related objection holds that my zombie twin would produce the same reports (e.g., 'I am conscious'), caused by the same mechanisms, and that his reports are unjustified; if so, my own reports are unjustified. In response, one can hold that the true bearers of justification are beliefs, and that my zombie twin and I have different beliefs, involving different concepts, because of the role that consciousness plays in constituting my concepts but not the zombie's. Further, the fact that we produce isomorphic reports implies that a third-person observer might not be any more justified in believing that I am conscious than...
that the zombie is conscious, but it does not imply a difference in first-person justification. The first-person justification for my belief that I am conscious is not grounded in any way in my reports but rather in my experiences themselves, experiences that the zombie lacks.

I think that there is no knockdown objection to epiphenomenalism here. Still, it must be acknowledged that the situation is at least odd and counterintuitive. The oddness of epiphenomenalism is exacerbated by the fact that the relationship between consciousness and reports about consciousness seems to be something of a lucky coincidence, on the epiphenomenalist view. After all, if psychophysical laws are independent of physical evolution, then there will be possible worlds where physical evolution is the same as ours but the psychophysical laws are very different, so that there is a radical mismatch between reports and experiences. It seems lucky that we are in a world whose psychophysical laws match them up so well. In response, an epiphenomenalist might try to make the case that these laws are somehow the most "natural" and are to be expected; but there is at least a significant burden of proof here.

Overall, I think that epiphenomenalism is a coherent view without fatal problems. At the same time, it is an inelegant view, producing a fragmented picture of nature, on which physical and phenomenal properties are only very weakly integrated in the natural world. And of course it is a counterintuitive view that many people find difficult to accept. Inelegance and counterintuitiveness are better than incoherence; so if good arguments force us to epiphenomenalism as the most coherent view, then we should take it seriously. But at the same time, we have good reason to examine other views very carefully.

### 11 Type-F Monism

Type-F monism is the view that consciousness is constituted by the intrinsic properties of fundamental physical entities: that is, by the categorical bases of fundamental physical dispositions.[*] On this view, phenomenal or protophenomenal properties are located at the fundamental level of physical reality, and in a certain sense, underlie physical reality itself.

This view takes its cue from Bertrand Russell's discussion of physics in *The Analysis of Matter*. Russell pointed out that physics characterizes physical entities and properties by their relations to one another and to us. For example, a quark is characterized by its relations to other physical entities, and a property such as mass is characterized by an associated dispositional role, such as the tendency to resist acceleration. At the same time, physics says nothing about the intrinsic nature of these entities and properties. Where we have relations and dispositions, we expect some underlying intrinsic properties that ground the dispositions, characterizing the entities that stand in these relations.[*] But physics is silent about the intrinsic nature of a quark, or about the intrinsic properties that play the role associated with mass. So this is one metaphysical problem: what are the intrinsic properties of fundamental physical systems?

*[[There is philosophical debate over the thesis that all dispositions have a categorical basis. If the thesis is accepted, the...]]
Consciousness and its Place in Nature

case for type-F monism is particularly strong, since microphysical dispositional must have a categorical basis, and we have no independent characterization of that basis. But even if the thesis is rejected, type-F monism is still viable. We need only the thesis that microphysical dispositions may have a categorical basis to open room for intrinsic properties here.]

At the same time, there is another metaphysical problem: how can phenomenal properties be integrated with the physical world? Phenomenal properties seem to be intrinsic properties that are hard to fit in with the structural/dynamic character of physical theory; and arguably, they are the only intrinsic properties that we have direct knowledge of. Russell's insight was that we might solve both these problems at once. Perhaps the intrinsic properties of the physical world are themselves phenomenal properties. Or perhaps the intrinsic properties of the physical world are not phenomenal properties, but nevertheless constitute phenomenal properties: that is, perhaps they are protophenomenal properties. If so, then consciousness and physical reality are deeply intertwined.

This view holds the promise of integrating phenomenal and physical properties very tightly in the natural world. Here, nature consists of entities with intrinsic (proto)phenomenal qualities standing in causal relations within a spacetime manifold. Physics as we know it emerges from the relations between these entities, whereas consciousness as we know it emerges from their intrinsic nature. As a bonus, this view is perfectly compatible with the causal closure of the microphysical, and indeed with existing physical laws. The view can retain the structure of physical theory as it already exists; it simply supplements this structure with an intrinsic nature. And the view acknowledges a clear causal role for consciousness in the physical world: (proto)phenomenal properties serve as the ultimate categorical basis of all physical causation.

This view has elements in common with both materialism and dualism. From one perspective, it can be seen as a sort of materialism. If one holds that physical terms refer not to dispositional properties but the underlying intrinsic properties, then the protophenomenal properties can be seen as physical properties, thus preserving a sort of materialism. From another perspective, it can be seen as a sort of dualism. The view acknowledges phenomenal or protophenomenal properties as ontologically fundamental, and it retains an underlying duality between structural-dispositional properties (those directly characterized in physical theory) and intrinsic protophenomenal properties (those responsible for consciousness). One might suggest that while the view arguably fits the letter of materialism, it shares the spirit of antimaterialism.

In its protophenomenal form, the view can be seen as a sort of neutral monism: there are underlying neutral properties X (the protophenomenal properties), such that the X properties are simultaneously responsible for constituting the physical domain (by their relations) and the phenomenal domain (by their collective intrinsic nature). In its phenomenal form, can be seen as a sort of idealism, such that mental properties constitute physical properties, although these need not be mental properties in the mind of an observer, and they may need to be supplemented by causal and spatiotemporal properties in addition. One could also characterize this form of the view as a sort of panpsychism, with phenomenal properties ubiquitous at the fundamental level. One could give the view in its most general form the name panprotopsychism, with either protophenomenal or phenomenal properties underlying all of physical reality.
A type-F monist may have one of a number of attitudes to the zombie argument against materialism. Some type-F monists may hold that a complete physical description must be expanded to include an intrinsic description, and may consequently deny that zombies are conceivable. (We only think we are conceiving of a physically identical system because we overlook intrinsic properties.) Others could maintain that existing physical concepts refer via dispositions to those intrinsic properties that ground the dispositions. If so, these concepts have different primary and secondary intensions, and a type-F monist could correspondingly accept conceivability but deny possibility: we misdescribe the conceived world as physically identical to ours, when in fact it is just structurally identical.[*] Finally, a type-F monist might hold that physical concepts refer to dispositional properties, so that zombies are both conceivable and possible, and the intrinsic properties are not physical properties. The differences between these three attitudes seem to be ultimately terminological rather than substantive.

[*][Hence type-F monism is the sort of "physicalism" that emerges from the loophole mentioned in the two-dimensional argument against type-B materialism. The only way a "zombie world" W could satisfy the primary intension but not the secondary intension of P is for it to share the dispositional structure of our world but not the underlying intrinsic microphysical properties. If this difference is responsible for the lack of consciousness in W, then the intrinsic microphysical properties in our world are responsible for constituting consciousness. Maxwell (1979) exploits this sort of loophole in replying to Kripke's argument.

Note that such a W must involve either a different corpus of intrinsic properties from those in our world, or no intrinsic properties at all. A type-F monist who holds that the only coherent intrinsic properties are protophenomenal properties might end up denying the conceivability of zombies, even under a structural-functional description of their physical state — for reasons very different from those of the type-A materialist.]]

As for the knowledge argument, a type-F monist might insist that for Mary to have complete physical knowledge, she would have to have a description of the world involving concepts that directly characterize the intrinsic properties; if she had this (as opposed to her impoverished description involving dispositional concepts), she might thereby be in a position to know what it is like to see red. Regarding the explanatory argument, a type-F monist might hold that physical accounts involving intrinsic properties can explain more than structure and function. Alternatively, a type-F monist who sticks to dispositional physical concepts will make responses analogous to one of the other two responses above.

The type-F view is admittedly speculative, and it can sound strange at first hearing. Many find it extremely counterintuitive to suppose that fundamental physical systems have phenomenal properties: e.g., that there is something it is like to be an electron. The protophenomenal version of the view rejects this claim, but retains something of its strangeness: it seems that any properties responsible for constituting consciousness must be strange and unusual properties, of a sort that we might not expect to find in microphysical reality. Still, it is not clear that this strangeness yields any strong objections. Like epiphenomenalism, the view appears to be compatible with all our evidence, and there is no direct evidence against it. One can argue that if the view were true, things would appear to us just as they in fact appear. And we have learned from modern physics that the world is a strange place: we cannot expect it to obey all the dictates of common sense.
One might also object that we do not have any conception of what protophenomenal properties might be like, or of how they could constitute phenomenal properties. This is true, but one could suggest that this merely a product of our ignorance. In the case of familiar physical properties, there were principled reasons (based on the character of physical concepts) for denying a constitutive connection to phenomenal properties. Here, there are no such principled reasons. At most, there is ignorance and absence of constitution. Of course it would be very desirable to form a positive conception of protophenomenal properties. Perhaps we can do this indirectly, by some sort of theoretical inference from the character of phenomenal properties to their underlying constituents; or perhaps knowledge of the nature of protophenomenal properties will remain beyond us. Either way, this is no reason to reject the truth of the view.[*]

*[[McGinn (1991) can be read as advocating a type-F view, while denying that we can know the nature of the protophenomenal properties. His arguments rests on the claim that these properties cannot be known either through perception of through introspection. But this does not rule out the possibility that they might be known through some sort of inference to the best explanation of (introspected) phenomenology, subject to the additional constraints of (perceived) physical structure.]]

There is one sort of principled problem in the vicinity. Our phenomenology has a rich and specific structure: it is unified, bounded, differentiated into many different aspects, but with an underlying homogeneity to many of the aspects, and appears to have a single subject of experience. It is not easy to see how a distribution of a large number of individual microphysical systems, each with their own protophenomenal properties, could somehow add up to this rich and specific structure. Should one not expect something more like a disunified, jagged collection of phenomenal spikes?

This is a version of what James called the combination problem for panpsychism, or what Stoljar (2001) calls the structural mismatch problem for the Russellian view (see also Foster 1991, pp. 119-30). To answer it, it seems that we need a much better understanding of the compositional principles of phenomenology: that is, the principles by which phenomenal properties can be composed or constituted from underlying phenomenal properties, or protophenomenal properties. We have a good understanding of the principles of physical composition, but no real understanding of the principles of phenomenal composition. This is an area that deserves much close attention: I think it is easily the most serious problem for the type-F monist view. At this point, it is an open question whether or not the problem can be solved.

Some type-F monists appear to hold that they can avoid the combination problem by holding that phenomenal properties are the intrinsic properties of high-level physical dispositions (e.g., those involved in neural states), and need not be constituted by the intrinsic properties of microphysical states (hence they may also deny panprotopsychism). But this seems to be untenable: if the low-level network is causally closed and the high-level intrinsic properties are not constituted by low-level intrinsic properties, the high-level intrinsic properties will be epiphenomenal all over again, for familiar reasons. The only way to embrace this position would seem to be in combination with a denial of microphysical causal closure, holding that there are fundamental dispositions above the microphysical level, which have phenomenal properties as their grounds. But such a view would be indistinguishable from type-D
Consciousness and its Place in Nature

dualism. So a distinctive type-F monism will have to face the combination problem directly.

In this way, we can see that type-D views and type-F views are quite closely related. We can imagine that if a type-D view is true and there are microphysical causal gaps, we could be led through physical observation alone to postulate higher-level entities to fill these gaps — "psychons", say — where these are characterized in wholly structural/dispositional terms. The type-D view adds to this the suggestion that psychons have an intrinsic phenomenal nature. The main difference between the type-D view and the type-F view is that the type-D view involves fundamental causation above the microphysical level. This will involve a more radical view of physics, but it might have the advantage of avoiding the combination problem.

Overall, type-F monism promises a deeply integrated and elegant view of nature. No-one has yet developed any sort of detailed theory in this class, and it is not yet clear whether such a theory can be developed. But at the same time, there appear to be no strong reasons to reject the view. As such, type-F monism is likely to provide fertile grounds for further investigation, and it may ultimately provide the best integration of the physical and the phenomenal within the natural world.

12 Conclusions

Are there any other options for the nonreductionist? There are two views that may not fit straightforwardly into the categories above.

First, some nonmaterialists hold that phenomenal properties are ontologically wholly distinct from physical properties, that microphysics is causally closed, but that phenomenal properties play a causal role with respect to the physical nevertheless. One way this might happen is by a sort of causal overdetermination: physical states causally determine behavior, but phenomenal states cause behavior at the same time. Another is by causal mediation: it might be that in at least some instances of microphysical causation from A to B, there is actually a causal connection from A to the mind to B, so that the mind enters the causal nexus without altering the structure of the network. And there may be further strategies here. We might call this class type-O dualism (taking overdetermination as a paradigm case). These views share much of the structure of the type-E view (causally closed physical world, distinct phenomenal properties), but escapes the charge of epiphenomenalism. The special causal setups of these views may be hard to swallow, and they share some of the same problems as the type-E view (e.g., the fragmented view of nature, and the "lucky" psychophysical laws), but this class should nevertheless be put on the table as an option.

Second, some nonmaterialists are idealists (in a Berkeleyan sense), holding that the physical world is itself constituted by the conscious states of an observing agent. We might call this view type-I monism. It shares with type-F monism the property that phenomenal states play a role in constituting physical reality, but on the type-I view this happens in a very different way: not by having separate "microscopic" phenomenal states underlying each physical state, but rather by having physical states constituted holistically by a "macroscopic" phenomenal mind. This view seems to be non-naturalistic in a much
deeper sense than any of the views above, and in particular seems to suffer from an absence of causal or explanatory closure in nature: once the natural explanation in terms of the external world is removed, highly complex regularities among phenomenal states have to be taken as unexplained in terms of simpler principles. But again, this sort of view should at least be acknowledged.

As I see things, the best options for a nonreductionist are type-D dualism, type-E dualism, or type-F monism: that is, interactionism, epiphenomenalism, or panprotopsychism. If we acknowledge the epistemic gap between the physical and the phenomenal, and we rule out primitive identities and strong necessities, then we are led to a disjunction of these three views. Each of the views has at least some promise, and none have clear fatal flaws. For my part, I give some credence to each of them. I think that in some ways the type-F view is the most appealing, but this sense is largely grounded in aesthetic considerations whose force is unclear.

The choice between these three views may depend in large part on the development of specific theories within these frameworks. Especially for the type-D view and type-F view, further theoretical work is crucial in assessing the theories (e.g., in explicating quantum interactionism, or in understanding phenomenal composition). It may also be that the empirical science of consciousness will give some guidance. As the science progress, we will be led to infer simple principles that underlie correlations between physical and phenomenal states. It may be that these principles turn out to point strongly toward one or the other of these views: e.g., if simple principles connecting microphysical states to phenomenal or protophenomenal states can do the explanatory work, then we may have reason to favor a type-F view, while if the principles latch onto the physical world at a higher level, then we may have reason to favor a type-D or type-E view. And if consciousness has a specific pattern of effects on the physical world, as the type-D view suggests, then empirical studies ought in principle to be able to find these effects, although perhaps only with great difficulty.

Not everyone will agree that each of these views is viable. It may be that further examination will reveal deep problems with some of these views. But this further examination needs to be performed. There has been little critical examination of type-F views to date, for example; we have seen that the standard arguments against type-D views carry very little weight; and while arguments against type-E views carry some intuitive force, they are far from making a knockdown case against the views. I suspect that even if further examination reveals deep problems for some views in this vicinity, it is very unlikely that all such views will be eliminated.

In any case, this gives us some perspective on the mind-body problem. It is often held that even though it is hard to see how materialism could be true, materialism must be true, since the alternatives are unacceptable. As I see it, there are at least three prima facie acceptable alternatives to materialism on the table, each of which is compatible with a broadly naturalistic (even if not materialistic) worldview, and none of which has fatal problems. So given the clear arguments against materialism, it seems to me that we should at least tentatively embrace the conclusion that one of these views is correct. Of course all of the views discussed in this paper need to be developed in much more detail, and examined in light of all relevant scientific and philosophical developments, in order to be comprehensively assessed. But as things stand, I think that we have good reason to suppose that consciousness has a fundamental place in nature.

chalmers@arizona.edu

[ Scientific American, December 1995 pp. 62-68. N.B. As always at Scientific American, this isn't just me talking. For a more careful treatment of this material, see my "Facing Up to the Problem of Consciousness".]

Conscious experience is at once the most familiar thing in the world and the most mysterious. There is nothing we know about more directly than consciousness, but it is extraordinarily hard to reconcile it with everything else we know. Why does it exist? What does it do? How could it possibly arise from neural processes in the brain? These questions are among the most intriguing in all of science.

From an objective viewpoint, the brain is relatively comprehensible. When you look at this page, there is a whir of processing: photons strike your retina, electrical signals are passed up your optic nerve and between different areas of your brain, and eventually you might respond with a smile, a perplexed frown or a remark. But there is also a subjective aspect. When you look at the page, you are conscious of it, directly experiencing the images and words as part of your private, mental life. You have vivid impressions of colored flowers and vibrant sky. At the same time, you may be feeling some emotions and forming some thoughts. Together such experiences make up consciousness: the subjective, inner life of the mind.

For many years, consciousness was shunned by researchers studying the brain and the mind. The prevailing view was that science, which depends on objectivity, could not accommodate something as subjective as consciousness. The behaviorist movement in psychology, dominant earlier in this century concentrated on external behavior and disallowed any talk of internal mental processes. Later, the rise of cognitive science focused attention on processes inside the head. Still, consciousness remained off-limits, fit only for late-night discussion over drinks.

Over the past several years, however, an increasing number of neuroscientists, psychologists and philosophers have been rejecting the idea that consciousness cannot be studied and are attempting to delve into its secrets. As might be expected of a field so new, there is a tangle of diverse and conflicting theories, often using basic concepts in incompatible ways. To help unsnarl the tangle, philosophical reasoning is vital.

The myriad views within the field range from reductionist theories, according to which consciousness
can be explained by the standard methods of neuroscience and psychology, to the position of the so-called mysterians, who say we will never understand consciousness at all. I believe that on close analysis both of these views can be seen to be mistaken and that the truth lies somewhere in the middle. Against reductionism I will argue that the tools of neuroscience cannot provide a full account of conscious experience, although they have much to offer. Against mysterianism I will hold that consciousness might be explained by a new kind of theory. The full details of such a theory are still out of reach, but careful reasoning and some educated inferences can reveal something of its general nature. For example, it will probably involve new fundamental laws, and the concept of information may play a central role. These faint glimmerings suggest that a theory of consciousness may have startling consequences for our view of the universe and of ourselves.

The Hard Problem

Researchers use the word "consciousness" in many different ways. To clarify the issues, we first have to separate the problems that are often clustered together under the name. For this purpose, I find it useful to distinguish between the "easy problems" and the "hard problem" of consciousness. The easy problems are by no means trivial - they are actually as challenging as most in psychology and biology - but it is with the hard problem that the central mystery lies.

The easy problems of consciousness include the following: How can a human subject discriminate sensory stimuli and react to them appropriately? How does the brain integrate information from many different sources and use this information to control behavior? How is it that subjects can verbalize their internal states? Although all these questions are associated with consciousness, they all concern the objective mechanisms of the cognitive system. Consequently, we have every reason to expect that continued work in cognitive psychology and neuroscience will answer them.

The hard problem, in contrast, is the question of how physical processes in the brain give rise to subjective experience. This puzzle involves the inner aspect of thought and perception: the way things feel for the subject. When we see, for example, we experience visual sensations, such as that of vivid blue. Or think of the ineffable sound of a distant oboe, the agony of an intense pain, the sparkle of happiness or the meditative quality of a moment lost in thought. All are part of what I am calling consciousness. It is these phenomena that pose the real mystery of the mind.
The Puzzle of Conscious Experience

does not yield complete knowledge of conscious experience.

To illustrate the distinction, consider a thought experiment devised by the Australian philosopher Frank Jackson. Suppose that Mary, a neuroscientist in the 23rd century, is the world's leading expert on the brain processes responsible for color vision. But Mary has lived her whole life in a black-and-white room and has never seen any other colors. She knows everything there is to know about physical processes in the brain - its biology, structure and function. This understanding enables her to grasp everything there is to know about the easy problems: how the brain discriminates stimuli, integrates information and produces verbal reports. From her knowledge of color vision, she knows the way color names correspond with wavelengths on the light spectrum. But there is still something crucial about color vision that Man does not know: what it is like to experience a color such as red. It follows that there are facts about conscious experience that cannot be deduced from physical facts about the functioning of the brain.

Indeed, nobody knows why these physical processes are accompanied by conscious experience at all. Why is it that when our brains process light of a certain wavelength, we have an experience of deep purple? Why do we have any experience at all? Could not an unconscious automaton have performed the same tasks just as well? These are questions that we would like a theory of consciousness to answer.

I am not denying that consciousness arises from the brain. We know, for example, that the subjective experience of vision is closely linked to processes in the visual cortex. It is the link itself that perplexes, however. Remarkably, subjective experience seems to emerge from a physical process. But we have no idea how or why this is.

Is Neuroscience Enough?

Given the flurry of recent work on Consciousness in neuroscience and psychology, one might think this mystery is starting to be cleared up. On closer examination, however, it turns out that almost all the current work addresses only the easy problems of consciousness. The confidence of the reductionist view comes from the progress on the easy problems, but none of this makes any difference where the hard problem is concerned.

Consider the hypothesis put forward by neurobiologists Francis Crick of the Salk Institute for Biological Studies in San Diego and Christof Koch of the California Institute of Technology. They suggest that consciousness may arise from certain oscillations in the cerebral cortex, which become synchronized as neurons fire 40 times per second. Crick and Koch believe the phenomenon might explain how different attributes of a single perceived object (its color and shape, for example), which are processed in different parts of the brain, are merged into a coherent whole. In this theory, two pieces of information become bound together precisely when they are represented by synchronized neural firings.

The hypothesis could conceivably elucidate one of the easy problems about how information is integrated in the brain. But why should synchronized oscillations give rise to a visual experience, no matter how much integration is taking place? This question involves the hard problem, about which the
theory has nothing to offer. Indeed, Crick and Koch are agnostic about whether the hard problem can be solved by science at all.

The same kind of critique could be applied to almost all the recent work on consciousness. In his 1991 book *Consciousness Explained*, philosopher Daniel C. Dennett laid out a sophisticated theory of how numerous independent processes in the brain combine to produce a coherent response to a perceived event. The theory might do much to explain how we produce verbal reports on our internal states, but it tells us very little about why there should be a subjective experience behind these reports. Like other reductionist theories, Dennett's is a theory of the easy problems.

The critical common trait among these easy problems is that they all concern how a cognitive or behavioral function is performed. All are ultimately questions about how the brain carries out some task—how it discriminates stimuli, integrates information, produces reports and so on. Once neurobiology specifies appropriate neural mechanisms, showing how the functions are performed, the easy problems are solved. The hard problem of consciousness, in contrast, goes beyond problems about how functions are performed. Even if every behavioral and cognitive function related to consciousness were explained, there would still remain a further mystery: Why is the performance of these functions accompanied by conscious experience? It is this additional conundrum that makes the hard problem hard.

**The Explanatory Gap**

Some have suggested that to solve the hard problem, we need to bring in new tools of physical explanation: nonlinear dynamics, say, or new discoveries in neuroscience, or quantum mechanics. But these ideas suffer from exactly the same difficulty. Consider a proposal from Stuart R. Hameroff of the University of Arizona and Roger Penrose of the University of Oxford. They hold that consciousness arises from quantum-physical processes taking place in microtubules, which are protein structures inside neurons. It is possible (if not likely) that such a hypothesis will lead to an explanation of how the brain makes decisions or even how it proves mathematical theorems, as Hameroff and Penrose suggest. But even if it does, the theory is silent about how these processes might give rise to conscious experience. Indeed, the same problem arises with any theory of consciousness based only on physical processing.

The trouble is that physical theories are best suited to explaining why systems have a certain physical structure and how they perform various functions. Most problems in science have this form; to explain life, for example, we need to describe how a physical system can reproduce, adapt and metabolize. But consciousness is a different sort of problem entirely, as it goes beyond the explanation of structure and function.

Of course, neuroscience is not irrelevant to the study of consciousness. For one, it may be able to reveal the nature of the neural correlate of consciousness - the brain processes most directly associated with conscious experience. It may even give a detailed correspondence between specific processes in the brain and related components of experience. But until we know why these processes give rise to conscious experience at all, we will not have crossed what philosopher Joseph Levine has called the explanatory gap.
gap between physical processes and consciousness. Making that leap will demand a new kind of theory.

BLOOD FLOW variations in the visual cortex demonstrate how a subject's brain responds to a pattern being viewed. The colors in this image show the cortical activity corresponding to the subject's view of either half of the pattern. This activity is a neural correlate of visual experience, but the relationship between the two remains mysterious.

A True Theory of Everything

In searching for an alternative, a key observation is that not all entities in science are explained in terms of more basic entities. In physics, for example, space-time, mass and charge (among other things) are regarded as fundamental features of the world, as they are not reducible to anything simpler. Despite this irreducibility, detailed and useful theories relate these entities to one another in terms of fundamental laws. Together these features and laws explain a great variety of complex and subtle phenomena.

It is widely believed that physics provides a complete catalogue of the universe's fundamental features and laws. As physicist Steven Weinberg puts it in his 1992 book *Dreams of a Final Theory*, the goal of physics is a "theory of everything" from which all there is to know about the universe can be derived. But Weinberg concedes that there is a problem with consciousness. Despite the power of physical theory, the existence of consciousness does not seem to be derivable from physical laws. He defends physics by arguing that it might eventually explain what he calls the objective correlates of consciousness (that is, the neural correlates), but of course to do this is not to explain consciousness itself. If the existence of consciousness cannot be derived from physical laws, a theory of physics is not a true theory of everything. So a final theory must contain an additional fundamental component.

Toward this end, I propose that conscious experience be considered a fundamental feature, irreducible to anything more basic. The idea may seem strange at first, but consistency seems to demand it. In the 19th century it turned out that electromagnetic phenomena could not be explained in terms of previously known principles. As a consequence, scientists introduced electromagnetic charge as a new fundamental entity and studied the associated fundamental laws. Similar reasoning should apply to consciousness. If existing fundamental theories cannot encompass it, then something new is required.
Where there is a fundamental property, there are fundamental laws. In this case, the laws must relate experience to elements of physical theory. These laws will almost certainly not interfere with those of the physical world; it seems that the latter form a closed system in their own right. Rather the laws will serve as a bridge, specifying how experience depends on underlying physical processes. It is this bridge that will cross the explanatory gap.

Thus, a complete theory will have two components: physical laws, telling us about the behavior of physical systems from the infinitesimal to the cosmological, and what we might call psychophysical laws, telling us how some of those systems are associated with conscious experience. These two components will constitute a true theory of everything.

**Searching for a Theory**

Supposing for the moment that they exist, how might we uncover such psychophysical laws? The greatest hindrance in this pursuit will be a lack of data. As I have described it, consciousness is subjective, so there is no direct way to monitor it in others. But this difficulty is an obstacle, not a dead end. For a start, each one of us has access to our own experiences, a rich trove that can be used to formulate theories. We can also plausibly rely on indirect information, such as subjects' descriptions of their experiences. Philosophical arguments and thought experiments also have a role to play. Such methods have limitations, but they give us more than enough to get started.

These theories will not be conclusively testable, so they will inevitably be more speculative than those of more conventional scientific disciplines. Nevertheless, there is no reason they should not be strongly constrained to account accurately for our own first-person experiences, as well as the evidence from subjects' reports. If we find a theory that fits the data better than any other theory of equal simplicity, we will have good reason to accept it. Right now we do not have even a single theory that fits the data, so worries about testability are premature.

We might start by looking for high-level bridging laws, connecting physical processes to experience at an everyday level. The basic contour of such a law might be gleaned from the observation that when we are conscious of something, we are generally able to act on it and speak about it - which are objective, physical functions. Conversely, when some information is directly available for action and speech, it is generally conscious. Thus, consciousness correlates well with what we might call "awareness": the process by which information in the brain is made globally available to motor processes such as speech and bodily action.

The notion may seem trivial. But as defined here, awareness is objective and physical, whereas consciousness is not. Some refinements to the definition of awareness are needed, in order to extend the concept to animals and infants, which cannot speak. But at least in familiar cases, it is possible to see the rough outlines of a psychophysical law: where there is awareness, there is consciousness, and vice versa.
To take this line of reasoning a step further, consider the structure present in the conscious experience. The experience of a field of vision, for example, is a constantly changing mosaic of colors, shapes and patterns and as such has a detailed geometric structure. The fact that we can describe this structure, reach out in the direction of many of its components and perform other actions that depend on it suggests that the structure corresponds directly to that of the information made available in the brain through the neural processes of awareness.

Similarly, our experiences of color have an intrinsic three-dimensional structure that is mirrored in the structure of information processes in the brain's visual cortex. This structure is illustrated in the color wheels and charts used by artists. Colors are arranged in a systematic pattern - red to green on one axis, blue to yellow on another, and black to white on a third. Colors that are close to one another on a color wheel are experienced as similar. It is extremely likely that they also correspond to similar perceptual representations in the brain, as part of a system of complex three-dimensional coding among neurons that is not yet fully understood. We can recast the underlying concept as a principle of structural coherence: the structure of conscious experience is mirrored by the structure of information in awareness, and vice versa.

Another candidate for a psychophysical law is a principle of organizational invariance. It holds that physical systems with the same abstract organization will give rise to the same kind of conscious experience, no matter what they are made of. For example, if the precise interactions between our neurons could be duplicated with silicon chips, the same conscious experience would arise. The idea is somewhat controversial, but I believe it is strongly supported by thought experiments describing the gradual replacement of neurons by silicon chips. The remarkable implication is that consciousness might someday be achieved in machines.

**Information: Physical and Experiential**

The ultimate goal of a theory of consciousness is a simple and elegant set of fundamental laws, analogous to the fundamental laws of physics. The principles described above are unlikely to be fundamental, however. Rather they seem to be high-level psychophysical laws, analogous to macroscopic principles in physics such as those of thermodynamics or kinematics. What might the
underlying fundamental laws be? No one knows, but I don't mind speculating.

I suggest that the primary psychophysical laws may centrally involve the concept of information. The abstract notion of information, as put forward in the 1940s by Claude E. Shannon of the Massachusetts Institute of Technology, is that of a set of separate states with a basic structure of similarities and differences between them. We can think of a 10-bit binary code as an information state, for example. Such information states can be embodied in the physical world. This happens whenever they correspond to physical states (voltages, say), the differences between which can be transmitted along some pathway, such as a telephone line.

We can also find information embodied in conscious experience. The pattern of color patches in a visual field, for example, can be seen as analogous to that of the pixels covering a display screen. Intriguingly, it turns out that we find the same information states embedded in conscious experience and in underlying physical processes in the brain. The three-dimensional encoding of color spaces, for example, suggests that the information state in a color experience corresponds directly to an information state in the brain. We might even regard the two states as distinct aspects of a single information state, which is simultaneously embodied in both physical processing and conscious experience.

A natural hypothesis ensues. Perhaps information, or at least some information, has two basic aspects: a physical one and an experiential one. This hypothesis has the status of a fundamental principle that might underlie the relation between physical processes and experience. Wherever we find conscious experience, it exists as one aspect of an information state, the other aspect of which is embedded in a physical process in the brain. This proposal needs to be fleshed out to make a satisfying theory. But it fits nicely with the principles mentioned earlier - systems with the same organization will embody the same information, for example - and it could explain numerous features of our conscious experience.

The idea is at least compatible with several others, such as physicist John A. Wheeler's suggestion that information is fundamental to the physics of the universe. The laws of physics might ultimately be cast in informational terms, in which case we would have a satisfying congruence between the constructs in both physical and psychophysical laws. It may even be that a theory of physics and a theory of consciousness could eventually be consolidated into a single grander theory of information.

A potential problem is posed by the ubiquity of information. Even a thermostat embodies some information, for example, but is it conscious? There are at least two possible responses. First, we could constrain the fundamental laws so that only some information has an experiential aspect, perhaps depending on how it is physically processed. Second, we might bite the bullet and allow that all information has an experiential aspect - where there is complex information processing, there is complex experience, and where there is simple information processing, there is simple experience. If this is so, then even a thermostat might have experiences, although they would be much simpler than even a basic color experience, and there would certainly be no accompanying emotions or thoughts. This seems odd at first, but if experience is truly fundamental, we might expect it to be widespread. In any case, the choice between these alternatives should depend on which can be integrated into the most powerful theory.
Of course, such ideas may be all wrong. On the other hand, they might evolve into a more powerful proposal that predicts the precise structure of our conscious experience from physical processes in our brains. If this project succeeds, we will have good reason to accept the theory. If it fails, other avenues will be pursued, and alternative fundamental theories may be developed. In this way, we may one day resolve the greatest mystery of the mind.

Dancing Qualia in a Synthetic Brain [Box]

Whether consciousness could arise in a complex, synthetic system is a question many people find intrinsically fascinating. Although it may be decades or even centuries before such a system is built, a simple thought experiment offers strong evidence that an artificial brain, if organized appropriately, would indeed have precisely the same kind of conscious experiences as a human being.

Consider a silicon-based system in which the chips are organized and function in the same way as the neurons in your brain. That is, each chip in the silicon system does exactly what its natural analogue does and is interconnected to surrounding elements in precisely the same way. Thus, the behavior exhibited by the artificial system will be exactly the same as yours. The crucial question is: Will it be conscious in the same way that you are?

Let us assume, for the purpose of argument, that it would not be. (Here we use a reasoning technique known as reductio ad absurdum, in which the opposite hypothesis is assumed and then shown to lead to an untenable conclusion.) That is, it either has different experiences - an experience of blue, say, when you are seeing red - or no experience at all. We will consider the first case; the reasoning proceeds similarly in both cases.

Because chips and neurons have the same function, they are interchangeable, with the proper interfacing. Chips therefore can replace neurons, producing a continuum of cases in which a successively larger proportion of neurons are replaced by chips. Along this continuum, the conscious experience of the system will also change. For example, we might replace all the neurons in your visual cortex with an identically organized version made of silicon. The resulting brain, with an artificial visual cortex, will have a different conscious experience from the original: where you had previously seen red, you may now experience purple (or perhaps a faded pink, in the case where the wholly silicon system has no experience at all).

Both visual cortices are then attached to your brain, through a two-position switch. With the switch in one mode, you use the natural visual cortex; in the other, the artificial cortex is activated. When the switch is flipped, your experience changes from red to purple, or vice versa. When the switch is flipped repeatedly, your experiences 'dance' between the two different conscious states (red and purple), known as qualia.
Because your brain's organization has not changed, however, there can be no behavioral change when the switch is thrown. Therefore, when asked about what you are seeing, you will say that nothing has changed. You will hold that you are seeing red and have seen nothing but red, even though the two colors are dancing before your eyes. This conclusion is so unreasonable that it is best taken as a reductio ad absurdum of the original assumption—that an artificial system with identical organization and functioning has a different conscious experience from that of a neural brain. Retraction of the assumption establishes the opposite: that systems with the same organization have the same conscious experience. -D.J.C.

Why Neuroscience May Be Able to Explain Consciousness [Box]

by Francis Crick and Christof Koch

We believe that at the moment the best approach to the problem of explaining consciousness is to concentrate on finding what is known as the neural correlates of consciousness—the processes in the brain that are most directly responsible for consciousness. By locating the neurons in the cerebral cortex that correlate best with consciousness, and figuring out how they link to neurons elsewhere in the brain, we may come across key insights into what David J. Chalmers calls the hard problem: a full accounting of the manner in which subjective experience arises from these cerebral processes.

We commend Chalmers for boldly recognizing and focusing on the hard problem at this early stage, although we are not as enthusiastic about some of his thought experiments. As we see it, the hard problem can be broken down into several questions: Why do we experience anything at all? What leads to a particular conscious experience (such as the blueness of blue)? Why are some aspects of subjective experience impossible to convey to other people (in other words, why are they private)? We believe we have an answer to the last problem and a suggestion about the first two, revolving around a phenomenon known as explicit neuronal representation.

What does 'explicit' mean in this context? Perhaps the best way to define it is with an example. In response to the image of a face, say, ganglion cells fire all over the retina, much like the pixels on a television screen, to generate an implicit representation of the face. At the same time, they can also respond to a great many other features in the image, such as shadows, lines, uneven lighting and so on. In contrast, some neurons high in the hierarchy of the visual cortex respond mainly to the face or even to the face viewed at a particular angle. Such neurons help the brain represent the face in an explicit manner. Their loss resulting from a stroke or some other injury, leads to prosopagnosia, an individual's inability to recognize familiar faces, consciously—even his or her own, although the person can still identify a face as a face. Similarly, damage to other parts of the visual cortex can cause someone to lose the ability experience color, while still seeing in shades of black and white, even though there is no defect in the color receptors in the eye.
The Puzzle of Conscious Experience

KANIZSA TRIANGLE stimulates neurons that code explicitly for such illusory contours.

At each stage, visual information is re-encoded, typically in a semi-hierarchical manner. Retinal ganglion cells respond to areas of light. Neurons in the primary visual cortex are most adept at responding to lines to edges; neurons higher up might prefer a moving contour. Still higher are those that respond to faces and other familiar objects. On top are those that project to pre-motor and motor structures in the brain, where they fire the neurons that initiate such actions as speaking or avoiding an oncoming automobile.

Chalmers believes, as we do, that the subjective aspect of an experience must relate closely to the firing of the neurons corresponding to those aspects (the neural correlates). He describes a well-known thought experiment, constructed around a hypothetical neuroscientist, Mary, who specializes in color perception but has never seen - a color. We believe the reason Mary does not know what it is like to see a color, however, is that she has never had an explicit neural representation of a color in her brain, only of the words and ideas associated with colors.

In order to describe a subjective visual experience, the information has to be transmitted to the motor output stage of the brain, where it becomes available for verbalization or other actions. This transmission always involves re-encoding the information, so that the explicit information expressed by the motor neurons is related, but not identical, to the explicit information expressed by the neurons associated with color experience, at some level in the visual hierarchy.

It is not possible, then, to convey with words and ideas the exact nature of a subjective experience. It is possible, however, to convey a difference between subjective experiences-to distinguish between red and orange, for example. This is possible because a difference in high-level visual cortical area will still be associated with a difference in the motor stages. The implication is that we can never explain to other people the nature of any conscious experience, only its relation to other ones.

The other two questions, concerning why we have conscious experiences and what leads to specific ones, appear more difficult. Chalmers proposes that they require the introduction of 'experience' as a fundamental new feature of the world, relating to the ability of an organism to process information. But which types of neuronal information produce consciousness? And what makes a certain type of
information correspond to the blueness of blue, rather than the greenness of green? Such problems seem as difficult as any in the study of consciousness.

We prefer an alternative approach, involving the concept of 'meaning.' In what sense can neurons that explicitly code for a face be said to convey the meaning of a face to the rest of the brain? Such a property must relate to the cell's projective field a pattern of synaptic connections to neurons that code explicitly for related concepts. Ultimately, these connections extend to the motor output. For example, neurons responding to a certain face might be connected to ones expressing the name of the person whose face it is and to others for her voice, memories involving her and so on. Such associations among neurons must be behaviorally useful, in other words, consistent with feedback from the body and the external world.

Meaning derives from the linkages among these representations with others spread throughout the cortical system in a vast associational network, similar to a dictionary or a relational database. The more diverse these connections, the richer the meaning. If, as in our previous example of prosopagnosia, the synaptic output of such face neurons were blocked, the cells would still respond to the person's face, but there would be no associated meaning and, therefore, much less experience. A face would be seen but not recognized as such.

Of course, groups of neurons can take on new functions, allowing brains to learn new categories (including faces) and associate new categories with existing ones. Certain primitive associations, such as pain, are to some extent inborn but subsequently refined in life.

Information may indeed be the key concept, as Chalmers suspects. Greater certainty will require consideration of highly parallel streams of information, linked-as are neurons-in complex networks. It would be useful to try to determine what features a neural network (or some other such computational embodiment) must have to generate meaning. It is possible that such exercises will suggest the neural basis of meaning. The hard problem of consciousness may then appear in an entirely new light. It might even disappear.

---

**The Author**

David J. Chalmers studied mathematics at Adelaide University and as a Rhodes Scholar at the University of Oxford, but a fascination with consciousness led him into philosophy and cognitive science. He has a Ph.D. in these fields from Indiana University and is currently in the department of philosophy at the University of California Santa Cruz. Chalmers has published numerous articles on artificial intelligence and the philosophy of mind. His book *The Conscious Mind*, which elaborates many of the ideas in this article, is forthcoming from Oxford University Press.

Introduction

The problem of consciousness is perhaps the largest outstanding obstacle in our quest to scientifically understand reality. The science of physics is not yet complete, but it is well-understood. The science of biology has explained away most of the mysteries surrounding the nature of life. Where there are gaps in our understanding of these fields, the gaps do not seem intractable; we at least have some idea of the direction in which solutions might lie. In the science of mind, things are not quite so rosy. Much progress is being made in the study of cognition, but consciousness itself is as much of a problem as it ever was.

The term "consciousness" often serves as a catch-all for all that is mysterious about mentality. When using the term, one must therefore be careful not to collapse important distinctions. The most important distinction in the study of consciousness bears upon the approach we take to studying it: we may take either the first-person or the third-person approach. We might say that the third-person approach treats consciousness as a scientific problem, while the first-person approach treats it as a metaphysical problem. These two different viewpoints that we can adopt lead to very different treatments of the phenomenon, each of which can supply crucial insights. But the reconciliation of the viewpoints seems to be a difficult matter. Frequently, proponents of the two approaches seem to be talking past each other. In this paper, I will try to explicate carefully the relation between the two approaches, and to argue that they are not so irreconcilable as they might seem.

The third-person approach

The third-person approach has much to recommend it. On this view, consciousness is treated as a problem of science, just like heat, life, or nuclear physics, and amenable to the same methods of inquiry. Researchers in the new discipline of cognitive science have had much success in taking this approach to
the study of mental processes in general. It is natural to hope that it might shed some light on the problems of consciousness, too.

The raw materials of cognitive science are much the same as those of any science - data gathered from external observation. These data can take a number of different forms. The most obvious kind of observable data are behavioral, and the study of human behavior is concentrated in the field of psychology. Another source of data, less accessible than behavior but extremely useful for the third-person approach, is observation of brain structure and function. The field of neuroscience is beginning to have significant success in explaining how the brain supports cognition. A third, less direct method in cognitive science is that of cognitive modeling - the construction of models, usually computational, that cohere to some extent with behavioral or neurophysiological data. The field of artificial intelligence is concerned with producing such models, and researchers in psychology and neuroscience often use computational models in their work.

This tripartite investigation of behavior, brain function and cognitive models has led to a significant increase in our understanding of diverse aspects of cognition, such as vision, memory and language comprehension. It is not surprising that these third-person methods might also be used to investigate consciousness. Such an approach to consciousness is urged by Dennett (1978; 1991), who goes so far as to sketch cognitive models for the phenomenon. Another third-person approach has been taken by Jackendoff (1987) (although Jackendoff explicitly recognizes that a third-person approach will not necessarily tell the whole story). Besides these philosophers, some psychologists (e.g., Johnson-Laird 1983) and computer scientists (e.g., Hofstadter 1979) have tried their hand at reining in the mysteries of consciousness with third-person accounts.

At the heart of the third-person approach is the philosophical position of functionalism. Roughly stated, this is the view that the correct way to understand mental processes is to perform causal analyses, revealing the abstract causal structure behind brain function. Such causal structure can be understood in objective terms, and duplicated in quite different materials (including, perhaps, in computers). Central to this approach is the view of mind as system. Insofar as this view addresses consciousness, it takes it to be a particular aspect of the function of a complex system; for example, it might be taken to be that process whereby a system is able to scan its own processing. The view of mind as system is certainly attractive, and it is a view that I share. The question is whether this approach taken alone is enough to explain the deepest mysteries of consciousness.

The first-person approach

Despite the attractiveness of the third-person approach, there is a feeling that it is side-stepping the really hard problems. The truly difficult questions only seem to arise when we take the first-person approach - when we consider, as Nagel famously put it, what it is like to be who we are, and what it might be like to be something quite different: another human, a bat, or a computational system. It is with these subjective questions that the deepest questions arise. Why is being me like anything at all? And why is it the way that it is? These questions are the real content of the problem of consciousness. There may be other senses of the term "consciousness", but in the sense in which it is most commonly used, to refer to the
real mysteries of mentality, it is these first-person questions that are being raised.

It is still easy to fall into confusion or to equivocate when talking of "consciousness", so here I will divide the first-person problem into three parts: the problems of sensory qualia, subjective mental content, and the existence of subjective experience.

(1) The problem of sensory qualia

Qualia are the qualitative aspects of our mental states, most obviously of our sensations. The paradigm qualia are those of color sensations; other favorites are the taste of chocolate, the sound of middle C, pleasure and pain. All of these are poorly understood. When we look at a red patch, this sets off a particular pattern of neural firings in our brain. Why should this physical process be accompanied by a rich, subjective sensation? Given that it is accompanied by a sensation, why is it this sort of sensation (the red sort) rather than that sort (the green sort)? There are two issues here: why qualia exist at all, and why particular qualia accompany particular processes. Is the correspondence of qualia to processes arbitrary, or is there some systematicity that we do not understand?

Jackson (1982) has provided the most recent reminder of the qualia mystery, with a sharpening of the argument of Nagel (1974) before him. A future scientist, living in a time when neuroscience is completely understood, might learn everything there is to know about physical brain-processes. But if she has lived all her life in a black-and-white room, she will still not know what it is like to see red; when she sees red for the first time, she will learn something. It seems that the third-person approach, at least as currently understood, cannot tell us about the nature of qualia.

(2) The problem of subjective mental content.

When I think about a lion, something takes place in my subjective experience that has something to do with lions. Again, a straight physical account gives no reason to believe that such an experience should take place. What should a pattern of neural firings have to do with lions? But somehow, my thoughts are about something; they have subjective mental content. It is easy to make attributions of mental content to a system, justified perhaps by causal relations with the external world, but for subjective mental content we need something stronger. We need brain-states to carry intrinsic content, independent of our systems of external attribution; there must be a natural (in the strongest sense, i.e., defined by nature) mapping from physical state to content.

The problem of subjective mental content is not entirely different in kind from that of sensory qualia - the experience of content is itself qualitative, in a way. The main difference is that sensory qualia usually arise during external perception, whereas this sort of mental content arises during thought. (There is also a third-person problem of mental content, which has been raging for years, centering on the question of how we can assign propositional attitudes, such as beliefs and desires concerning the world, to systems and persons. In some ways this is an easier problem, as it may rely on human-defined systems of attributions; these contents may have the status of theoretical entities, rather than states that are presented
to us directly. In other ways, the first-person problem is easier, as it may not have to deal with the problem of reference. When I think of a lion, my phenomenology bears some relation to a lion, but the relationship seems more like shared pattern than reference.)

(3) The existence of subjective experience

The two items above are concerned with the nature of our subjective states - why they are one way rather than another. But it is just as deep a problem why subjective states should exist in the first place. Why should it be like anything to be me? If I did not know that subjective states existed, it would seem unreasonable to postulate them. This is perhaps the deepest question of all, and no current theory has come close to dealing with it.

Not many people believe in zombies - humans with normal behavior but without any subjective mental states. These may be logically possible, but it seems implausible that there could be such things in the actual world. At least some people believe there could be functional zombies, however: beings which duplicate the functional organization of humans, perhaps computationally, without being conscious at all (e.g. Searle 1980, Block 1980). The question "what sort of entities can be subjects of experience?" is of great popular interest. For example, is every entity exhibiting intelligent behavior conscious? Could an appropriately programmed computer be conscious? I will argue, by combining first-person and third-person considerations, that the possible existence of functional zombies is implausible.

There are some other commonly-raised first-person problems not explicitly listed above. The problem of self-consciousness (or self-awareness) I take to be a subset of the problem of awareness, of which the difficult aspects are covered by (1) and (2). The problem of personal identity is a separate issue and a very deep one; but Parfit's exhaustive analysis (1986), which combines the first-person and third-person approaches to great effect, gives reason to believe that our first-person intuitions here may be mistaken. It is the three problems listed above that seem to be the residual content of the traditional mind-body problem. I will be using the term "consciousness" broadly to cover the phenomena of all of these problems. If you prefer, replace every occurrence of "consciousness" with "the subjective experience of qualia and mental content."

One difficulty with talking about first-person problems is that for every first-person (conscious) mental state, there is a corresponding third-person (functionally definable) mental state. (Perhaps there are not two different mental states, but simply two different ways of viewing one state; this is unclear. In any event, it is uncontroversial that for every subjective mental event there is a corresponding physical event; the physical event may be viewed via functional abstraction as a third-person mental event). For every subjective sensation there corresponds an objectively characterizable perception. This dichotomy in (ways of looking at) mental states makes things a little confusing, but it will be useful later on.

The relationship between the approaches

Of course, the first-person approach and the third-person approach are not entirely independent of each
other. Indeed, I will be arguing that much insight can come through considering them not singly, but juxtaposed. Before doing this, it is necessary to enumerate a few facts about the two approaches.

(1) The third-person approach is sufficient, in principle, to yield a complete explanation of human behavior.

This follows from the explanatory completeness of physical laws - a hypothesis that is relatively uncontroversial. Physical phenomena have physical explanations, and behavior is a physical phenomenon. There is no reason to believe that human behavior is any different in this regard from hurricanes, rivers or stars. With a complete understanding of the laws of physics, and a good understanding of the way physical entities combine into systems, behavior will be understood.

This is an extremely strong conclusion, of course, and it goes a long way towards explaining the dominance of the third-person approach to the study of mentality. Cognitive science is doing its best to break down the removable barrier implied by the "in principle", and there is no reason to believe that within a few centuries it should not succeed. If it does not, it will probably be because of problems of complexity rather than any deep metaphysical barrier. We might trivially restate (1) as

(1a) The first-person approach is not needed to explain anything about human behavior.

Of course, the first-person approach may well prove to be a useful short-cut in explaining behavior, and a powerful tool, but the point is that it is not necessary - it is in principle dispensable, as far as behavior is concerned.

(2) The third-person approach (as currently conceived) is not sufficient to explain all first-person phenomena.

Statements (1) and (1a) make a powerful argument for the primacy of the third-person approach. Nevertheless, this approach cannot tell the whole story. Consciousness, the subjective experience of qualia and mental content, is simply not explained by a third-person account. No amount of neuroscience and cognitive modeling explains the qualitative nature of a sensation of red, or even why such a subjective sensation should exist.

This statement is surely the most natural view, but it is not undisputed. Those who have spoken the loudest in dispute of (2) include Dennett (1982, 1988, 1991) and P. M. Churchland (1986). I believe their arguments to be flawed, but will not argue the issue here; it has been eloquently argued by others. Those who disbelieve (2) may choose to stop reading here, then, in the belief that consciousness is not really a special problem. They might however read on, to find an account of first-person problems which is motivated by third-person issues at every point, or at worst to find a reductio ad absurdum of the first-person position. The remainder - those who believe that the mind-body problem is still a real problem - may continue undisturbed.
It should be noted that (2) refers to the third-person approach as currently conceived—that is, the study of the brain as a physical system with the usual physical ontology, abetted by cognitive models and functional analyses. I would not like to rule out the possibility of an eventual "objective phenomenology", to use Nagel's term, but it is difficult to see what it would look like. At the least, new constructs would be needed, and our ontology would need to be expanded. To get from the physical and the functional to the subjective, we would need metaphysical bridging principles. It does not seem impossible, however, that these could be stated from a third-person viewpoint. The beginnings of such an approach will be outlined later in this paper. In the meantime, we can restate (2) as

(2a) The third-person approach is not sufficient, in the absence of extra metaphysical bridging principles, to explain all first-person phenomena.

The need for such a bridge is put nicely by Jackendoff (1987), who says that computational/functional accounts of mind may have solved the Mind-Body Problem, but what we need to do now is solve the "Mind-Mind Problem". This would provide a bridge from the "computational mind" to the "phenomenological mind" (in the terms I have used, from third-person mental events to first-person mental events). That computational and functional accounts may have already got us halfway there is a point that will resurface later.

(3) Our claims about consciousness are a fact of human behavior.

This is trivially true. (If you interpret "claim" as an irreducibly subjective term, then replace it by "utterance" or something more neutral.) When I say "I'm conscious, and I'm totally baffled by it," that is a fact of human behavior. When somebody writes "The ineffable sensation of red is inexplicable by physical premises", that is a fact of human behavior. This is harmless enough, until combined with (1) to yield

(4) The third-person approach is in principle sufficient to explain our claims about consciousness

or worse,

(4a) The first-person approach is not needed to explain our claims about consciousness.

Everything that we say about consciousness is, in principle, amenable to the usual kind of physical/functional analysis. There is no need to appeal to any mysterious metaphysical constructs to explain the things we say. On this account, the last 2000 years of debate over the Mind-Body Problem would have gone exactly the same in the absence of subjective experience (if such a thing were possible). In particular, our sense of bafflement about the first-person problems manifests itself in numerous third-person ways - the things we say, the things we write, even the things we think, if regarded in terms of neural processes - and is thus amenable to the methods of cognitive science[1]. The correct cognitive-science explanation of why we claim to be conscious might be a little while coming, but there should be
no deep metaphysical problems. This leads us to an important principle:

*[[McGinn (1989) requests an explanation of why it is so difficult to clearly articulate the problems of consciousness. I believe that the reason is closely tied up with (4) and (4a). Everything we can say about consciousness is physically caused, and somehow, at the back of our minds, we are aware of this. So when the words come out of our mouths, we are aware of how easy it might be to explain our claims without invoking any great mysteries. Further, our words can easily be taken as referring to third-person mental states: perception rather than sensation, and so on. Our claims seem very inadequate to do justice to the real phenomenon.]]

**The Mystery Principle:** Consciousness is mysterious. Claims about consciousness are not.

This can equivalently be stated as

**The Surprise Principle:** Although consciousness should surprise us, claims about consciousness should not.

Most people will agree that consciousness is a surprising phenomenon. If it were not for the fact that first-person experience was a brute fact presented to us, there would seem to be no reason to predict its existence. All it does is make things more complicated. By contrast, the things we say about consciousness are common-or-garden cognitive phenomena. Somebody who knew enough about brain structure would be able to immediately predict the likelihood of utterances such as "I feel conscious, in a way that it seems no physical object could be", or even Descartes' "Cogito ergo sum". In short, our bafflement about consciousness can be understood purely as a problem for cognitive science. There are very rich pickings awaiting anybody who takes this path. I believe that it is not as difficult a path as it might seem, and towards the end of this paper I will give a very brief account of why we might expect such bafflement.[*]

*[[There are other reasons why claims about consciousness should not surprise us. It seems plausible that any system which (in a purely functional sense) "perceives" aspects of the world and further has sophisticated linguistic capacity might profess perplexity about the nature of its perception; one might expect puzzlement at both the "qualitative" and "indexical" aspects. And if such a system has the capacity to "think about what it is thinking about" (a functional notion, once again), it might very well claim full-blown self-consciousness. No metaphysics needs to be invoked in our analysis of such a situation. (Computer A: "I know I'm just a collection of digital circuits, but I can't explain this strange feeling I have of having thoughts of my own." Computer B: "Yes, I'm inclined towards dualism myself.") This point deserves further development.]]

The situation with which we are now faced seems to border on the absurd. If everything we say, write and even think about consciousness is explainable by cognitive science, why is there a need to posit any great mystery about consciousness in the first place? Why not concede that the appearance of great metaphysical mystery is simply an illusion, and regard consciousness itself as a cognitive process, on much the same level as memory or learning? It becomes a third-person high-level term, playing a similar role in cognitive science as "heat" does in thermodynamics. As for this weird "first-person experience", then insofar as it is not a purely cognitive phenomenon, it simply does not exist. This is the approach taken by Dennett and others, and there are powerful arguments in its favor, as evidenced above. But this
paper is based on the premise that the mind-body problem is still a real problem. We are not yet prepared to concede that (2) is false, and that the third-person approach as currently conceived is sufficient to explain all of the first-person mysteries. As first-person loyalists, we have to bite this bullet and struggle on, trying to produce a coherent account of the matter. I believe that the pressures on a first-person account produced by (4) and (4a), and the third-person constraints that are thus acquired, are of great value in shaping a solution that might be acceptable to partisans of both the first-person and third-person approaches.

This is the low point for the first-person partisan. This is as bad as it gets. But we have to confront the problem posed by (4) and (4a) head on. This has rarely been done in the literature. "Qualia freaks" (Jackson's term) have generally been content to argue for the autonomy of first-person phenomena, from independent considerations, or more frequently to simply assume it. But if we do not take (4) and (4a) seriously, then any account that we produce is open to question. The question which faces us, put slightly differently, is

(4b) How can first-person experience have any bearing on what we say about first-person experience?

or more simply

(4c) How can consciousness have any bearing on what we say about consciousness?

I believe that in the proper understanding of this question lies the seed of a solution to the mind-body problem. All the same, it is surprising how rarely the question has been considered in the literature. (The more general question of how the mental can affect the physical of course a perennial favorite. Question (4c) is much more specific, and raises a different set of problems.) It has been touched on occasionally in various forms, however, with various different reactions. The choices in answering the question spread themselves out as follows.

(A) We might reject premise (1), and deny that the third-person approach can even give a full account of human behavior. This is the approach taken by Elitzur (1989), who argues from the fact that we talk about consciousness to the conclusion that consciousness plays an active role in determining human behavior, and deduces that the laws of physics must therefore play an incomplete role in determining behavior. This is certainly an interesting argument, but it is implausible and should be regarded as a last resort. The laws of physics are too important to us to be given up so easily. (A similar account of the matter would presumably be given by interactionist dualists from Descartes to Eccles.)

(B) We might answer (4c) by saying, simply, "It doesn't." This is the answer that might be given by Jackson (1982), who argues that qualia are completely epiphenomenal, playing no causal role (although he does not explicitly consider utterances about consciousness). Now, epiphenomenal qualia are already unparsimonious under general considerations, but considered in the context of question (4c) their implausibility increases. Are we to say that our claims about consciousness are completely independent
of the fact of our consciousness? That any similarity manifested between our claims and the actual facts are mere coincidence? While this conclusion cannot be completely ruled out, it certainly seems inelegant. It fails what I will call, later, the "Coherence Test" - its explanations of (1) consciousness and (2) claims about consciousness fail completely to cohere with each other.

I think there may nevertheless be a grain of truth in epiphenomenalism, but it needs to be spelt out more carefully. If we can explicate just how consciousness is an epiphenomenon of physical processing, then question (4c) may admit a more parsimonious answer. I will be defending a kind of "double aspect" theory that bears some similarity to epiphenomenalism, while at the same time being more palatable, I hope, to those with a naturalistic view of the world.

(C) We may deny premise (2), and argue that in fact the third-person approach tells us everything there is to know. By denying that consciousness is essentially a first-person phenomenon, we deny that question (4c) poses any problem. If there is anything at all called "consciousness" that plays a causal role, then it does so in exactly the same way that centers of gravity play a causal role in physics, or that temperature plays a causal role in thermodynamics: as a convenient third-person abstraction. This is presumably the approach that the likes of Dennett and Churchland would take.

The consideration of questions like (4c) has been used as an explicit argument for the third-person approach in a few places. For example, Foss (1989), arguing against the Nagel/Jackson arguments, argues that a "Super Neuroscientist" could in principle know everything that a being would say about its qualia-experience, and everything that it might say. From this, he draws the conclusion that the Super Neuroscientist would know everything that there is to know about qualia.

Clearly questions like (4c) are a goldmine for third-person arguments, but these analyses seem too simplistic. They "solve" the Mind-Body Problem by denying that there is a problem. This runs counter to our premise that there is a substantial problem to be solved. Nevertheless, I believe there is a grain of truth in these arguments. There is perhaps some sense in which qualia are physical. There is perhaps some sense in which consciousness is understandable from the third-person viewpoint. What must be explicated is the nature of this sense. The arguments above do not solve the Mind-Body Problem, but they do indicate that it might be soluble. However, there is more work to be done. A flat statement of physicalism is in no sense a complete solution. We need to know how physicalism could be true. The nature of the work that remains to be done will be outlined shortly.

Before we leave this section, we should note that a well-known argument of Shoemaker (1975) bears some resemblance to the arguments in (C). Shoemaker argues against the possibility of "Absent Qualia", or functional zombies. Some have argued that this possibility refutes functionalism, by demonstrating that we might duplicate any given functional process without any accompanying subjective experience. Shoemaker responds by arguing that we know about qualia; our knowledge is caused by the existence of these qualia; therefore qualia play some causal role. The conclusion is that Absent Qualia are impossible, as removing qualia would change the causal structure. This is generally construed as an argument for the third-person approach (for functionalism, in particular). Nevertheless, I am sympathetic with this argument and with functionalism, and believe that Absent Qualia are impossible. However, what needs to
be explained is why Absent Qualia are impossible, and how qualia could play a causal role. This question is not addressed by functionalism. Again, more work remains to be done. Both functionalism and epiphenomenalism have plausible aspects, but neither gives a complete account of the problems of consciousness. I will suggest that a correct theory of consciousness shares aspects of both functionalism and epiphenomenalism, and that the correct answer to question (4c) lies somewhere between (B) and (C).

The Coherence Test

The Coherence Test is a test that any completed theory of mind must pass. It is motivated directly by questions like (4c).

The Coherence Test:
A completed theory of mind must provide
(C1) An account of why we are conscious.
(C2) An account of why we claim to be conscious; why we think we are conscious.
Further (C3), accounts (C1) and (C2) must cohere with each other.

It should be noted that (C1) is a completely first-person matter; it involves answering the metaphysical question of how subjective experience is possible. (C2), on the other hand, is understandable on strictly third-person terms - it is, in principle, a matter for cognitive science. (If, again, in your vocabulary "think" and "claim" are irreducibly subjective terms, then replace them by appropriate third-person terms that deal with behavior and brain function.) Another way in which to phrase (C2) might be "An account of why consciousness seems so strange to us." Viewed appropriately, this is also in principle understandable by a cognitive science approach. Anyway, it is the coherence condition (C3) that is the most important here. This ensures that completely independent accounts under (C1) and (C2) will be ruled out; that the accounts must bear a substantial relationship to each other. This provides a vital link between the first-person and third-person approaches.

Another way of putting the Coherence Test is that we need accounts of
(C1a) The mind that we experience (a first-person question); and
(C2a) The mind that the system perceives (a third-person question).

One would hope that these "minds", on any completed account, would bear a very close relationship to each other. If the relationship is not strict identity, it should at least be a very close correspondence.

It is not possible to "prove" that a correct theory of consciousness must pass the Coherence Test, but it certainly seems extremely plausible. While it is logically possible that an account of why we are conscious could be completely independent of a cognitive account of why we believe we are conscious, it seems inelegant and unlikely. If the Coherence Test in fact fails for a correct completed theory of mind, then we are living in a world where the things we say about consciousness and the Mind-Body Problem bear at best a coincidental relation to the way these things actually are. Faced with the possibility of this complete unreliability of our verbal reports, it would probably be better to join the third-person camp and
regard the mysterious nature of "subjective experience" as a mere illusion.

Given that we accept the Coherence Test, a correct third-person account of cognitive processes puts severe constraints on possible first-person accounts, and possibly vice versa. Of course, we have not explicitly defined the notion of coherence. Instead, I think it is better to go ahead and apply it on a case-by-case basis, and let some understanding of the notion emerge.

Applying the Coherence Test

Functionalism is a controversial doctrine when applied to first-person aspects of mentality. But for the third-person study of mental processes, it reigns supreme. Few people these days doubt that the correct way to analyze human behavior and to explain the workings of the brain is in functional terms. All remotely satisfactory accounts of learning or memory, say, explain these via causal analyses of systems with many interacting parts. Indeed, it is difficult to see what other kind of account there could be. So when it comes to explaining the things we \textit{say} (and even \textit{believe}) about consciousness, there is little doubt that a functional analysis will be the way to go. We may enshrine this doctrine as

\begin{quote}
(5) The fact that we claim to be conscious holds in virtue of certain functionally specifiable properties of the brain.
\end{quote}

Of course, we are not sure exactly what those functional properties \textit{are}, yet - this is part of the reason why functionalism alone is not a completed theory of consciousness. But we are almost certain that the properties will be functional ones, considered at the most parsimonious level. And there is no doubt that if we make the correct functional abstraction from the brain, then duplicating this functional specifications will produce the same kind of claims about consciousness.

We may now use this uncontroversial claim, together with the Coherence Test, as an argument against certain theories of mind.

\textit{Theory 1: We are conscious in virtue of low-level biochemical processes.}

Such a view of mind is held by at least a few writers on the subject (e.g. Searle 1980, Block 1980). These writers have generally been arguing against functionalism as a theory of mind, or at least as a theory of the first-person aspects. Of course, almost everybody agrees that neurophysiological processes give rise to consciousness in the human case; but that view alone is compatible with functionalism, as these processes might give rise to consciousness precisely in virtue of their functional properties. Proponents of the present view take a stronger stand, suggesting that biochemical properties are \textit{directly} responsible for consciousness. On this view, \textit{only} a system with the relevant biochemical properties could be conscious; a silicon isomorph might lack consciousness entirely. Block, for example, claims that qualia might be a consequence of physiological facts which need not appear in a functional account. Searle thinks it very plausible that the "causal powers" of the brain (meaning those powers sufficient to cause consciousness) lie at the biochemical level.
This view, however, runs a great risk of failing the Coherence Test. If, as according to (5), our claims of consciousness are consequences of certain functional properties of the brain, then the statement that consciousness is inherently neurophysiological suggests that reason we make the claims is largely independent of the reason we are conscious. This would seem strange. A possible reply by neurophysiological partisans might be to claim that the neurophysiological locus of consciousness is specifiable functionally, albeit at a very low level. The connectionist movement in cognitive modeling has recently made popular the idea that a correct functional account may inhere at a low level of abstraction. But if we accept that neurophysiological accounts can also be functional, then this is no longer an argument against functionalism per se - a consequence that Block and Searle would be loath to accept. Insofar as our theory holds that the sources of consciousness are not specifiable functionally, then it is a theory that fails the Coherence Test. If consciousness does not arise from the functional, then our claims are independent of consciousness.

In reply to a related argument by Shoemaker (1975), Block (1980) suggests that qualia can be independent of any given functional account but still make a causal difference. But such a difference will by definition not bear on any aspect of our functional account. Given that our account is specifically constructed to include our claims of consciousness as a relevant aspect, this reply fails. If qualia are independent of this functional account, then qualia cannot make a difference to our claims. Horgan (1984) makes a similar move in defending the claim that qualia are neurophysiological. Considering the case of Martians functionally identical to us but physiologically different, he claims that the issue of whether or not they have qualia might be resolved by observing whether they manifest the same kind of puzzlement about qualia that we do. But of course they will manifest similar puzzlement, as this is determined by their functional architecture. Therefore such observation will tell us nothing more than we already knew.

For similar reasons, even if we hold that the underpinnings of consciousness are specifiable functionally, it may be dangerous to go to too low a level. It may well be that when an account of the processes which lead to our consciousness-claims is found, it will be specifiable at a level higher than the biochemical. If we insist that consciousness itself inheres at a lower level than this, then the source of consciousness is independent of the source of our consciousness-claims, and our theory fails the Coherence Test. It may be possible that certain aspects of qualia are determined at a lower level than the level of our qualia-claims. Such aspects could not make any causal difference relevant to our claims. For instance, the difference between red-sensations and green-sensations is very difficult to articulate, and so the precise nature of these sensations might be dependent on certain low-level facts. But the existence of such qualia must be dependent on the higher-level functional account, if the correct theory of mind is Coherent.

We may conclude that theories which place the source of consciousness at too low a level are implausible. A similar argument will apply to any theory which does not satisfy Functional Supervenience: the principle that replicating certain relevant functional processes, even in a different substrate, is sufficient to guarantee first-person mental states. (This is a weaker principle than the Functional State Identity Theory, which holds that mental states are functional states.) If consciousness exists in virtue of some fact which is quite independent of any functional account, then our claims of
Consciousness do not reflect the fact of our consciousness. This argument parallels Shoemaker's argument against Absent Qualia in some ways, although unlike Shoemaker I do not wish to argue for the truth of the Functional State Identity Theory. But the argument establishes that if there could exist beings which duplicate our relevant causal structure (perhaps in a quite different substrate), but which do not possess subjective states - in other words, if there could exist functional zombies - then the correct theory of mind is fundamentally Incoherent. [*]

*[[It should be noted that the implausibility of functional zombies does not necessarily imply the impossibility of computational zombies. It just might be possible to be a functionalist without believing that computational specifications can ever capture the appropriate causal structure. (Harnad (1989), for instance, believes that the requisite function is inherently analog.) Church's Thesis diminishes the plausibility of such a position - it seems likely that a non-computational causal account always supervenes on a lower-level computational account - and in practice functionalism and computationalism tend to stand and fall together.]]

**Theory 2: Epiphenomenalism.**

On the face of it, this view does not come close to satisfying the Coherence Test. It holds that we are conscious in virtue of certain dualistic principles which yield mental states as a consequence of physical states. Such principles would seem to be quite independent of the relatively straightforward functional sources of our claims that we have "qualia" and "subjectivity". All parsimony is thrown out the window. The facts that we (a) have qualia, and (b) claim to have qualia, are related only by coincidence.

I do not think that all forms of epiphenomenalism are ruled out, however. It might be possible to have a principled epiphenomenalism, where the mysterious "dualistic principles" above are replaced by something more concrete, showing that mental states arise in virtue of specific, functionally specifiable physical states. If this were done, then it is possible that the Coherence Test might after all be satisfied: we would be conscious and claim consciousness in virtue of similar functional accounts. But all that this possibility shows, for now, is that epiphenomenalism would need a great deal of development to be a plausible theory of mind.

**Theory 3: Identity Theories, Functional and Physical**

I have been rather sympathetic to functionalism in the preceding discussion, but it is not close to a completed theory of mind. It performs well on part (C2) of the Coherence Test. The source of our consciousness-claims is undoubtedly functionally specifiable. True, the flat statement of functionalism gives no insight into just which functional properties of the brain are responsible for our consciousness-claims, so there is more work to be done on that point - but we might set that aside as a mere technical difficulty, a matter for cognitive scientists. A more profound difficulty with functionalism is that it does not come close to dealing with (C1). It has often been noted (recently by Searle 1989) that functionalism is not a theory which is motivated by the existence of first-person mentality; rather, conscious mental states are viewed as an obstacle for functionalism to deal with (witness all the Absent Qualia and Inverted Spectrum objections). It is possible that functionalism is compatible with a correct theory of consciousness, but taken alone it is not that theory.
Functionalism gives very little insight into why consciousness exists. It is one thing to baldly state "subjective experience arises in virtue of our functional organization"; it is another to give an account of why. Functionalism, in this way, is not unlike its predecessor, the Identity Theory, which stated "mental states are brain states". The flat statement alone gives us no insight into how it could be true. There was, of course, some kernel of truth to the Identity Theory: this was that conscious mental states are indeed supervenient on brain states (that is, reproducing a brain state will reproduce the same corresponding mental state). In a similar way, Functionalism contains a kernel of truth: it is very plausible that conscious mental states supervene on certain functional states. By going from the loose notion of "physical state" to the more specific notion of functional state, functionalism has brought us closer to the goal, but it certainly has not achieved it.

So both functionalism and the Identity Theory pass over the key question of just why we are conscious in the first place. And of course, the fact that it fails on (C1) implies automatic failure on (C3) - without giving an account of the existence of subjectivity, it cannot give an account of coherence. Nevertheless, I believe that functionalism is a valuable theory, of which many aspects are worth retaining. Something simply needs to be added. The account that I will give below might be characterized as "functionalism plus something".

To satisfy the Coherence Test, and thus be a candidate for the title of "completed theory of mind", a theory must provide three things, on my estimation:

1. A metaphysical account of how subjective experience is possible. This will almost certainly include some new metaphysical construct, over and above physical laws.

2. A functional account of why we think and claim that we are conscious. This will presumably be in the idiom of cognitive science.

3. An account of functional-metaphysical coherence, which shows how (1) and (2) cohere with each other.

As we have seen, theories that consciousness is biochemical pass the buck on (2) and fail miserably on (3). Epiphenomenalism makes a start on (1), but as it stands has no chance on (3). And functionalism, as currently conceived, does not deal at all with (1), and therefore with (3). I hope that I have demonstrated just how far short currently conceived theories fall of yielding a solution to the Mind-Body Problem. The mode will now switch from pessimism to optimism. The three requirements above sound daunting, but I believe that they might be satisfied. In the next section, I will outline the beginnings of a speculative theory which has a chance of satisfying (1), (2) and (3) above. This theory alone will not be a solution to the Mind-Body Problem, but I hope that it points in the right direction.

Mind, pattern, information
The theory I am going to suggest is an example of what is known as a "double aspect" theory. That is, it holds that first-person mental states and third-person mental states are two different aspects of the same thing. Double aspect theories have been attractive to others (e.g. Nagel 1986), but they have usually foundered because we cannot say exactly what those aspects might be. The simple idea "double aspect theory" explains very little. But before I go on to elaborate on this particular theory, it might be useful to say a couple of words about why double aspect theories are so attractive. In short, this is because double aspect theories are at the same time almost epiphenomenalism and almost identity theories, combining the virtues of both with the vices of neither. The theory I will propose is almost an identity theory (by this term I include both "Brain State" and "Functional State" Identity Theories, though the proposed theory is nearer to the latter than the former), in that it holds that first-person and third-person states are the same thing - but different aspects of the same thing, a crucial difference. (You might say: an identity theory that takes subjective states seriously.) It is almost a version of epiphenomenalism, as we can imagine the subjective aspects "hanging off" the non-subjective aspects, allowing the complete autonomy of the physical - while at the same time allowing that subjective states can be causally efficacious, as they are but another aspect of the objective states. (You might say: an epiphenomenalism where mind can matter.)

The two different "aspects" that I propose are pattern and information. Wherever they occur, pattern and information occur together. All information is carried by some pattern in the physical world; all patterns carry some information. I speculate that they should be regarded as two different aspects of the same thing, which for want of a better term we may call "pattern/information."

My proposal is that third-person (objectively analyzable) mental events are patterns in the brain, while the corresponding subjective (first-person) mental events are information. On the above view of pattern/information, this implies that first-person and third-person mental events are indeed two different aspects of the same thing, the underlying pattern/information. (This has the advantage of not expanding our ontology too far.)

The idea that third-person mental events can be regarded as patterns should not be too controversial. A commitment very much like this is already made by functionalism, though it is not always emphasized. When we give a functional account of a system, we are necessarily abstracting away from many superficial details, and highlighting particular patterns in the physical substrate. When the functionalist says that a mental state is a functional state, she is committing herself to the notion that a mental state is an abstraction - and every abstraction is an abstraction of a pattern. (Of course, not every pattern is a functional pattern, but these are a very important subset.)

It is rarely made clear just what ontological claims a functionalist would wish to make, though. Are they committed to patterns as part of their natural ontology? They might not necessarily have to take this step, as if we are considering mental events only from the third-person viewpoint, then it is not clear that we have to admit them into our ontology anymore than we have to admit centers of gravity - both might be "convenient fictions", in Dennett's terminology. But I am prepared to bite the bullet, and reify patterns. Given that we believe that the mind and conscious experience are part of the basic ontology of things,
then some concession is necessarily -- we have to posit some metaphysical construction of the kind mentioned in the previous section. Admitting patterns into our ontology is a surprisingly painless way of doing this - and once it is done, we get minds for free.

Of course, we have done a little more than reify pattern: we have reified pattern/information. I claim that this is a reasonable step, given that they always go together. Put it this way: if there is any chance that a double aspect theory might be the right theory - and as we have seen and will see, there is very much that is attractive about them - then it is hard to imagine two more natural candidates for the "aspects" than pattern and information. To say that "mental events arise from a double aspect" is to say very little, unless we want to admit the mental as a primitive member of our ontology. Instead, by positing pattern/information, we have a much more natural primitive in our ontology, from which the double-aspect nature of mentality is inherited.

Once we have made this posit, then conscious mentality falls out. Third-person mental events are patterns in the brain: the corresponding conscious mental events are the information that these patterns carry. _Qualia are just information._ (A nice way of putting this is "information is what pattern is like from the inside". I am not quite sure what this means, but it certainly sounds good.) Anyway, conscious mentality arises from the one big pattern that I _am_. That pattern, at any given time, carries a lot of information - that information is my conscious experience. Incidentally, given any physical substrate there are many different ways of abstracting patterns from it. In my brain, there will be some patterns that do not correspond to mental states at all, and some which correspond to unconscious states. This is not a problem for the theory; there will be more on this later.

**Why we think we are conscious**

The last few paragraphs may strike the reader as wanton ontological extravagance. But apart from any inherent elegance the theory might have, it is also motivated by the fact that it can pass the Coherence Test. In fact, the above is at least in part motivated by an functional account of why we think we are conscious, and why consciousness seems strange. Logically, the functional account ought to come first, but it makes sense to present the metaphysical theory up front. But what follows can be read independently of what went before. This will be a purely functional account, in the tradition of cognitive science. So at least temporarily, all the metaphysical baggage may be thrown away.

Very briefly, here is what I believe to be the correct account of why we think we are conscious, and why it seems like a mystery. The basic notion is that of _pattern processing_. This is one of the things that the brain does best. It can take raw physical data, usually from the environment but even from the brain itself, and extract patterns from these. In particular, it can discriminate on the basis of patterns. The original patterns are in the environment, but they are transformed on their path through neural circuits, until they are represented as quite different patterns in the cerebral cortex. This process can also be represented as _information flow_ (not surprisingly), from the environment into the brain. The key point is that once the information flow has reached the central processing portions for the brain, further brain function is not sensitive to the original raw data, but only to the pattern (to the information!) which is embodied in the neural structure.
Consider color perception, for instance. Originally, a spectral envelope of light-wavelengths impinges upon our eyes. Immediately, some distinctions are collapsed, and some pattern is processed. Three different kinds of cones abstract out information about how much light is present in various overlapping wavelength-ranges. This information travels down the optic nerve (as a physical pattern, of course), where it gets further transformed by neural processing into an abstraction about how much intensity is present on what we call the red-green, yellow-blue, and achromatic scales. What happens after this is poorly-understood, but there is no doubt that by the time the central processing region is reached, the pattern is very much transformed, and the information that remains is only an abstraction of certain aspects of the original data.

Anyway, here is why color perception seems strange. In terms of further processing, we are sensitive not to the original data, not even directly to the physical structure of the neural system, but only to the patterns which the system embodies, to the information it contains. It is a matter of access. When our linguistic system (to be homuncular about things) wants to make verbal reports, it cannot get access to the original data; it does not even have direct access to neural structure. It is sensitive only to pattern. Thus, we know that we can make distinctions between certain wavelength distributions, but we do not know how we do it. We've lost access to the original wavelengths - we certainly cannot say "yes, that patch is saturated with 500-600 nm reflections". And we do not have access to our neural structure, so we cannot say "yes, that's a 50 Hz spiking frequency". It is a distinction that we are able to make, but only on the basis of pattern. We can merely say "Yes, that looks different from that." When asked "How are they different?", all we can say is "Well, that one's red, and that one's green". We have access to nothing more - we can simply make raw distinctions based on pattern - and it seems very strange.

So this is why conscious experience seems strange. We are able to make distinctions, but we have direct access neither to the sources of those distinctions, or to how we make the distinctions. The distinctions are based purely on the information that is processed. Incidentally, it seems that the more abstract the information-processing - that is, the more that distinctions are collapsed, and information recoded - the stranger the conscious experience seems. Shape-perception, for instance, strikes us as relatively non-strange; the visual system is extremely good at preserving shape information through its neural pathways. Color and taste are strange indeed, and the processing of both seems to involve a considerable amount of recoding.

The story for "internal perception" is exactly the same. When we reflect on our thoughts, information makes its way from one part of the brain to another, and perhaps eventually to our speech center. It is to only certain abstract features of brain structure that the process is sensitive. (One might imagine that if somehow reflection could be sensitive to every last detail of brain structure, it would seem very different.) Again, we can perceive only via pattern, via information. The brute, seemingly non-concrete distinctions thus entailed are extremely difficult for us to understand, and to articulate. That is why consciousness seems strange, and that is why the debate over the Mind-Body Problem has raged for thousands of years.

The above account is far too brief, and is almost certainly wrong in many important aspects.
Nevertheless, I believe there is a kernel of truth in there. Even if the above account needs to be thoroughly revised, I think this fact will remain: the facts that we think we are conscious, we claim to be conscious, and consciousness seems strange all hold true in virtue of the fact that the brain is a sophisticated pattern-processor (is a sophisticated information-processor).

Further, this account should not surprise us. Things have to be this way. Any being which "perceives" the world must do so in virtue of pattern/information processing. Once the processing has reached the heart of the cognitive system, further processing can only be sensitive to the information distinctions embodied there. When the being tries to articulate the nature of its perception, it will be reduced to talk of "qualitative distinctions". Similarly, if a being has any reflective access to its internal processing, it will only be in terms of high-level patterns. We should expect such beings to be baffled by this "consciousness". The Surprise Principle is vindicated: Consciousness should surprise us, claims about consciousness should not.

The above account, of course, did not rely on any ontological commitment to pattern and information - it merely used them as "convenient fictions." This was a completely functional account. If I were a third-person aficionado, who believed that the Mind-Body Problem is only a pseudo-problem, I might stop now, and say "See! Consciousness is just an illusion." But I am not, and this account was intended not to explain away consciousness but to cohere with it.

So now, we may run the Coherence Test. We claim that we are conscious in virtue of the brain's ability as a pattern-processor (as an information-processor). We in fact are conscious in virtue of the patterns (information) embodied by the brain. These explanations seem to cohere rather well. Of course, there is no pattern-processing without patterns. It is precisely the same patterns which are at the crux of the pattern processing (those at the heart of our processing system, from which all distinctions are made), which are also the patterns which are our mental states. (I occasionally use "pattern" as a shorthand for "pattern/information". No great harm is done.) One could not ask for better coherence than this. The reason we talk about mental states is that our processing is sensitive to precisely those patterns which are our mental states.

Another, slightly over-simplified way to put this is: (1) The brain perceives itself as pattern. (2) The mind (that we experience) is pattern. Therefore (3) The brain perceives itself as the mind.

Patterns in pattern-processors

On this account, there are two criteria for being a conscious entity: a metaphysical (first-person) and a functional (third-person) criterion. The metaphysical criterion is that one must be a pattern. All patterns exist, presumably. It would seem strange to reify some patterns but not others. But not all patterns are conscious. To be a conscious pattern, one must be part of the right kind of pattern processor, bearing an appropriate relation to it.

An interesting and difficult question concerns the status of patterns which are not part of pattern
processors. Such patterns may still carry information; is there anything it is like to be them? My answer is a tentative "yes". But it would not resemble what it is like to be a human being, for such patterns are not conscious, in the appropriate functional sense. They are not parts of pattern-processors, so they cannot be aware. This incidentally seems to demonstrate that we should separate the purely first-person notion of "be-ability" from the partially third-person notion of "consciousness". Consciousness itself is dependent on certain functional criteria, but it seems implausible that such third-person criteria should impose restrictions on metaphysical be-ability. Being the number 5 might be like something; if only like being asleep, without the excitement of dreaming.

On the other hand, there are pattern processors which are not embodied in human brains. Might such processors (or the patterns therein) have subjective experience? A connectionist network, for instance, is a pattern processor par excellence. A typical feed-forward network might have served as a perfect simplified example in the above account of the kind of pattern/information-processing that goes on in the human brain. Networks are sensitive to certain patterns in environmental data; they recode these patterns as they pass down the information-processing chain, until output is sensitive only to a certain kind of pattern in the inputs. Do connectionist networks have qualia? My answer is "yes!" This may seem very counter-intuitive at first, but I believe that upon reflection it becomes plausible. There is no principled distinction between the kind of pattern-processing performed by such a network and that performed by a brain, except one of complexity. And there is no reason to believe that complexity should make such a great difference to the existence of qualia. Certainly human qualia will be more complex and interesting, reflecting the more complex processing; but then, even considering our processing of "redness", there is no evidence that much more complex processing goes into this than goes into a typical large connectionist network. Pattern-processing leads to qualia in humans, and there seems no reason to deny that pattern-processing leads to qualia in networks also. (Of course networks cannot as yet reflect on the fact that they have qualia, let alone talk about it, but this is not the point.)

Then there is that old favorite, the thermostat. Do thermostats have qualia? It is not entirely clear that thermostats do the right kind of pattern-processing, but if they do, their qualia are remarkably simple. For thermostats process all physical inputs down to three states: too hot, too cold, and just right. It is not clear just what three-valued qualia would be like. But if we are ever to understand qualia, this is a good test case.

Connectionist networks help illustrate another point: that patterns may supervene on functional descriptions. The relevant pattern in networks are patterns of activation over a number of units, where units and their activations are of course functionally specifiable. It may not be the case that all patterns supervene on functional descriptions (that is, are specifiable relative to functional descriptions, and duplicating the functional system in another substrate allows duplicating the pattern), but it seems plausible that all patterns that represent first-person mental states should. The plausibility lies in the fact that patterns need to be processed for us to be aware of them, and processing is a functional notion. The current account is thus compatible with functionalism of a certain variety. You might say that it takes functionalism as a starting point, and adds what is necessary to deal with the problems of consciousness.[*]
No theory of mind worth its salt would pass up the chance to attack Searle's "Chinese Room" problem. For our theory, the explanation is straightforward. When we have a homunculus manipulating symbols on paper, there are two quite distinct sets of patterns: patterns carried by the head of the homunculus, and patterns carried by the complex system of symbols on pattern. The patterns in the paper may well support their own mind. Even if we assume the homunculus could internalize the rules (which would require vastly more memory than any human has), then there would still be two sets of quite distinct patterns, both of which are present in the homunculus's head. It is a fundamental fact that there can be many different patterns present in a given substrate. Thus, in a single head, there might be two quite distinct phenomenologies, without any overlapping first-person mental states.]

Loose ends

Moving away from the more cognitive aspects to the more metaphysical aspects, we are yet to explicitly answer our original question (4c): how can consciousness have any bearing on what we say about consciousness? On the present account, this is easy. Conscious experience is identified with the "information" aspect of certain pattern/information states. This information can certainly make a difference. It is just another aspect of the pattern, and there is no question that the pattern plays a causal role. Changing the information changes the pattern, and changing the pattern changes many consequences. In fact, as we have seen, our claims about consciousness reflect precisely that pattern/information in which our mental states consist. Consciousness is thus causally efficacious. At the same time, it is quite possible to analyze third-person mental states and thus behavior without ever needing to invoke consciousness, if we so desire. It is possible to cast everything in terms of pattern, without invoking information.

This answer corresponds to none of the answers (A), (B) or (C) given originally. Our options were in fact not quite so limited as they seemed. This again shows the advantages of a double aspect theory - an identity theory which takes consciousness seriously.

It might be noted that this is not quite a double aspect theory in the traditional sense, where the two aspects are the physical and the mental. This theory holds instead that the two aspects are first-person and third-person mental states - both of them mental, though in different senses. We are able to use the resources of theories like functionalism to get us past the first stage, from the physical to third-person mental states, which may be functional states, computational states, or some other patterns. All that is left is Jackendoff's "Mind-Mind" Problem - the bridge from third-person patterns (the "Computational Mind") to first-person mental states (the "Phenomenological Mind"). This is precisely what our posited pattern/information duality achieves.

Finally, it must be glaringly obvious that I have said very little about a very important topic: the relationship between pattern and information. Is this merely a primitive posited relation, or can it somehow be explicated? Some might claim that a given pattern can be interpreted as carrying any information you like. I believe that this is using a different sense of the word "information" to mine. The kind of information I have dealt with here is not "information that" - it does not need to refer. The kind of information I believe in is intrinsic. In this sense, there is a natural mapping from pattern to information.
Exactly what the nature of this mapping is is very difficult to say. This is why the current theory is not yet a solution to the Mind-Body Problem. It may be the case that the pattern/information relation is a brute fact, in much the same way that the laws of physics are brute facts. We have a certain amount of knowledge about their nomological connection, via our subjective experience. This may or may not be enough to understand all the facts perfectly. If it is not, then it may be the case that we can never know precisely what it is like to be an alien being (or a connectionist network), as we will not understand precisely the nature of the information that their patterns carry. The outlook is not necessarily so pessimistic, though, and perhaps a better analysis of the nature of pattern and information will tell us everything there is to know. (If pressed for an informal opinion, I would guess that at least nine tenths of the pattern/information relationship will be understandable analytically, with the last tenth up for grabs. If we are not able to understand precisely what it is like to be a bat, we will be able to come very close.)

This account has not removed the Mind-Body Problem. Nevertheless, my minimal hope is that it shows what the beginnings of a solution might look like. My maximal hope is that it has removed much of the confusion surrounding the problem, and localized the mystery at one key, primitive locus: the relationship between pattern and information.

References

I'm going to talk about one aspect of the role that neuroscience plays in the search for a theory of
consciousness. Whether or not neuroscience can solve all the problems of consciousness singlehandedly,
there is no question that it has a major role to play. We've seen at this conference that there's a vast
amount of progress in neurobiological research, and that much of it is clearly bearing on the problems of
consciousness. But the conceptual foundations of this sort of research are only beginning to be laid. So I
will look at some of the things that are going on from a philosopher's perspective and will see if there's
anything helpful to say about these foundations.

We've all been hearing a lot about the "neural correlate of consciousness". This phrase is intended to
refer to the neural system or systems primarily associated with conscious experience. I gather that the
catchword of the day is "NCC". We all have an NCC inside our head, we just have to find out what it is.
In recent years there have been quite a few proposals about the identity of the NCC. One of the most
famous proposals is Crick and Koch's suggestion concerning 40-hertz oscillations. That proposal has
since faded away a little but there are all sorts of other suggestions out there. It's almost got to a point
where it's reminiscent of particle physics, where they have something like 236 particles and people talk
about the "particle zoo". In the study of consciousness, one might talk about the "neural correlate zoo".
There have also been a number of related proposals about what we might call the "cognitive correlate of
consciousness" (CCC?).

A small list of suggestions that have been put forward might include:

- 40-hertz oscillations in the cerebral cortex (Crick and Koch 1990)
- Intralaminar nucleus in the thalamus (Bogen 1995)
- Re-entrant loops in thalamocortical systems (Edelman 1989)
On the Search for the Neural Correlate of Consciousness

- 40-hertz rhythmic activity in thalamocortical systems (Llinas et al 1994)
- Nucleus reticularis (Taylor and Alavi 1995)
- Extended reticular-thalamic activation system (Newman and Baars 1993)
- Anterior cingulate system (Cotterill 1994)
- Neural assemblies bound by NMDA (Flohr 1995)
- Temporally-extended neural activity (Libet 1994)
- Backprojections to lower cortical areas (Cauller and Kulics 1991)
- Neurons in extrastriate visual cortex projecting to prefrontal areas (Crick and Koch 1995)
- Neural activity in area V5/MT (Tootell et al 1995)
- Certain neurons in the superior temporal sulcus (Logothetis and Schall 1989)
- Neuronal gestalts in an epicenter (Greenfield 1995)
- Outputs of a comparator system in the hippocampus (Gray 1995)
- Quantum coherence in microtubules (Hameroff 1994)
- Global workspace (Baars 1988)
- Activated semantic memories (Hardcastle 1995)
- High-quality representations (Farah 1994)
- Selector inputs to action systems (Shallice 1988)

There are a few intriguing commonalities among the proposals on this list. A number of them give a central role to interactions between the thalamus and the cortex, for example. All the same, the sheer number and diversity of the proposals can be a little overwhelming. I propose to step back a little and try to make sense of all this activity by asking some foundational questions.

A central question is this: how is it, in fact, that one can search for the neural correlate of consciousness? As we all know, there are problems in measuring consciousness. It's not a directly and straightforwardly observable phenomenon. It would be a lot easier if we had a way of getting at consciousness directly; if we had, for example, a consciousness meter.

If we had a consciousness meter, searching for the NCC would be straightforward. We'd wave the consciousness meter and measure a subject's consciousness directly. At the same time, we'd monitor the underlying brain processes. After a number of trials, we'd say OK, such-and-such brain processes are correlated with experiences of various kinds, so that's the neural correlate of consciousness.

Alas, we don't have a consciousness meter, and there seem to be principled reasons why we can't have one. Consciousness just isn't the sort of thing that can be measured directly. So: What do we do without a consciousness meter? How can the search go forward? How does all this experimental research proceed?

I think the answer is this: we get there through principles of interpretation. These are principles by which we interpret physical systems to judge whether or not they have consciousness. We might call these *pre-experimental bridging principles*. These are the criteria that we bring to bear in looking at systems to say (a) whether or not they are conscious now, and (b) what information they are conscious of, and what information they are not. We can't reach in directly and grab those experiences and "transpersonalize"
them into our own, so we rely on external criteria instead.

That's a perfectly reasonable thing to do. But in doing this we have to realize that something interesting is going on. These principles of interpretation are not themselves experimentally determined or experimentally tested. In a sense they are pre-experimental assumptions. Experimental research gives us a lot of information about processing; then we bring in the bridging principles to interpret the experimental results, whatever those results may be. They are the principles by which we make inferences from facts about processing to facts about consciousness, so they are conceptually prior to the experiments themselves. We can't actually refine them experimentally (except perhaps through first-person experimentation!), because we don't have any independent access to the independent variable. Instead, these principles will be based on some combination of (a) conceptual judgments about what counts as a conscious process and (b) information gleaned from our first-person perspective on our own consciousness.

I think we are all stuck in this boat. The point applies whether one is a reductionist or an anti-reductionist about consciousness. A hard-line reductionist might put some of these points slightly differently, but either way, the experimental work is going to require pre-experimental reasoning to determine the criteria for ascription of consciousness. Of course such principles are usually left implicit in empirical research. We don't usually see papers saying "Here is the bridging principle, here are the data, and here is what follows." But it's useful to make them explicit. The very presence of these principles has some strong and interesting consequences in the search for the NCC.

In a sense, in relying on these principles we are taking a leap into the epistemological unknown. Because we don't measure consciousness directly, we have to make something of a leap of faith. It may not be a big leap, but nevertheless it suggests that everyone doing this sort of work is engaged in philosophical reasoning. Of course one can always choose to stay on solid ground, talking about the empirical results in a neutral way; but the price of doing so is that one gains no particular insight into consciousness. Conversely, as soon as we draw any conclusions about consciousness, we have gone beyond the information given, so we need to pay careful attention to the reasoning involved.

So what are these principles of interpretation? The first and by far the most prevalent such principle is a very straightforward one: it's a principle of verbal report. When someone says "Yes, I see that table now", we infer that they are conscious of the table. When someone says "Yes, I see red now", we infer that they are having an experience of red. Of course one might always say "How do you know?" -- a philosopher might suggest that we may be faced with a fully functioning zombie - but in fact most of us don't believe that the people around us are zombies, and in practice we are quite prepared to rely on this principle. As pre-experimental assumptions go, this is a relatively "safe" one - it doesn't require a huge leap of faith - and it is very widely used.

So the principle here is that when information is verbally reported, it is conscious. One can extend this slightly, as no-one believes that an actual verbal report is required for consciousness; we are conscious of much more than we report on any given occasion. So an extended principle might say that when
information is directly available for verbal report, it is conscious.
