Burge's arguments show only that context-ascription is pragmatically sensitive to context, depending on the epistemic predicament of the ascriber.
Content itself is still internal.

Argues that the extension of 'water' is the same on earth and twin earth, using arguments from isotopes and scientific development. Molar properties determine classification. Remarks on historicism and the division of labor.

2.2b Externalism and Psychological Explanation (Burge, Fodor)

Buller, D.J. 1997. Individualism and evolutionary psychology (or: In defense of "narrow" functions). Philosophy of Science 64:74-95.

Reply to Fodor 1982, clarification of position.

Psychology should be and is done non-individualistically, i.e. with reference to environment. Examples from vision, e.g. Marr.

Advocates a different sort of "active externalism", based on the role of the environment in actively driving cognition. Beliefs can extend into an agent's immediate environment (e.g. a notebook) in this way.

Argues that extrinsic properties can play a respectable role in scientific explanation; e.g. the histories of plants, animals, and devices are relevant in explaining their current behavior.

Maybe, maybe not. Contra Fodor: science can be non-individualistic. Contra Burge re oblique ascriptions and Marr.

Should do psychology without reference to the external world. What counts for psychology is in the head; who cares about truth, reference, and the rest?

Twin Earth isn't a problem for cognitive science. Intents of utterances, de re/de dicto, etc. Truth conditions aren't in the head, but that's no problem.

Methodological solipsism implies epistemological solipsism.

   Argues against Stich, Fodor, Block: use different taxonomies (narrow/wide) for different purposes. Both are OK, functionalism *and* content survive.

   Relates the individualism debate to Roschian prototype research.

   MS doesn't rule out all use of content, just of wide content. Narrow content is OK. With remarks on folk psychology and computation.

   Various problems for computational psychology handling content. It shares the problems of a naturalistic psychology.

   Object-dependent thoughts are redundant in psychological explanation, as an explanation applying to a hallucinator will work as well. But this needn't defeat externalism in general. With remarks on self-knowledge.

   Uses examples to argue that in explaining behavior we often ascribe beliefs in an individualistic way, even in cases where individual and community use diverge. These contents are at least sometimes expressible.
Developmental psychologists attribute concepts individualistically.

Externalist states are required for the explanation of relational properties. Counters objections from conceptual connections and dormitive-virtue worries, and applies to teleology, self-knowledge, etc.

Argues that behavior is often individuated widely for explanatory purposes, so that wide content is relevant, and that there is more to causation than local causation, so Stich's autonomy principle fails.

2.2c Externalism and Mental Causation
-------------------------------------

Argues contra Fodor that broad contents can be explanatory -- if they can't, no relational properties can. Fodor's "no-conceptual-connection" and "cross-context" tests for causal powers fail to do the job.

Arguments for the causal significance of broad content. Physical twins can
differ in causal powers; broad content figures in (ceteris paribus) causal generalizations; can make twin arguments against narrow content too. Hmm.

Contra Fodor: psychological processes can play differing causal roles, despite being physically identical.

Fodor's modal argument for narrow content rests on a false analogy between cases concerning thoughts and those concerning planets.

On when a difference in effects amounts to a difference in causal powers: when the effects are connected contingently, not conceptually, to the causes. Differences in wide content don't satisfy this, so aren't causal powers.

Mental content can be extrinsic and efficacious. Narrow content strategies don't work, as observation concepts are still extrinsic. One can't screen of the intrinsic part from the rest. Thought-experiments are inconclusive.

Reconciling Twin Earth with the causal relevance of content. Historical factors can be causally relevant.

Argues that externalist content is not causally efficacious, but is relevant to causal explanations of behavior indirectly, via the cognitive activities of others external to the system.

Epistemology requires the causal relevance of content, and the relevant content is narrow. On how various architectures might support this causal relevance, by being realized by more specific intrinsic features.

Against some arguments for internalism: local causation doesn't imply local type-individuation, as distal relations affect distal causes and effects; and processes can have access to semantic properties via formal properties.

Science frequently appeals to relational and historical taxonomies, so either causal powers can be non-intrinsic or science needn't taxonomize by causal powers. With remarks on causal properties and conceptual connections.

Arguments from causal powers beg the question, either on whether relational properties can have causal powers or on whether science taxonomizes by causal powers, as relational properties are common in scientific explanation.

2.2d Externalism and the Theory of Vision

Psychology should be and is done non-individualistically, i.e. with reference to environment. Examples from vision, e.g. Marr.

Contra Burge, Marr's theory is individualistic. Intentional contents therein are neutral between twins' environments; nothing grounds a more specific attribution.

Contra Segal, Marr's theory is non-individualistic even though it may classify twins together. Computational-level task descriptions rather than behavior guide content ascription, so the environment plays a crucial role.

2.2e Externalism and Computation

Winograd's SHRDLU doesn't support individualism: its concepts are anchored (to a fictional world) via its programmer, and it could have made errors.

Syntax is extrinsically determined, as well as semantics. So if broad content is irrelevant to psychology, syntax is too.

2.2f Externalism and Self-Knowledge

   We can't know our thought-contents by inference (circular), by introspection (because they're relational), or directly, so we can't know them at all.

   Contra McKinsey 1991, anti-individualism doesn't lead to a priori knowledge. The belief that water is wet doesn't conceptually entail facts about the external world (e.g. H2O), although it may metaphysically necessitate them.

Knowledge of our thoughts is compatible with externalism: its content is self-referential and self-verifying. We needn't be able to explicate the content or its enabling conditions, or rule out twin possibilities.

Gallois, A. & O'Leary-Hawthorne, J. 1996. Externalism and skepticism. Philosophical Studies 81:1-26. Externalist anti-skeptical arguments fail as they require us to know a priori that our terms designate natural kinds, and also because they require us to know a priori that externalism is true. A thorough analysis.

Subjectivism and environmentalism seem to clash on knowledge of content, but it's OK: under environmentalism we still know our contents w/o evidence.

Argues that cases of switching between language communities are quite common, so that Warfield's case for externalist self-knowledge doesn't work.

On reconciling externalism with the non-evidential character of first-person knowledge.

Argues that we can know the meaning of our words a priori. Analyzes twin earth cases by separating propositional meaning from linguistic meaning, which is indexical, fixes reference, and is knowable a priori.

Contra Burge: if there are conceptual connections between wide contents and
and the external world, then we can't know wide contents a priori, as otherwise we could know a priori that the world exists.

Reply to Brueckner 1992: The claim that belief metaphysically necessitate external facts is trivial. Almost all states do that, for Kripkean reason.

2.2g The Status of Narrow Content
---------------------------------

Traces and criticizes Fodor's position on narrow content. Argues that narrow content isn't content, and doesn't explain behavior. Fun but arguable.
Argues that problems with names don't require an appeal to narrow content in explanation. Broad content plus associated descriptions will do the job.

Representational cognitive science has no need for narrow content -- wide contents and formal properties can do all the work. Argues that the semantics of mental expressions needn't mirror the semantics of language.

Argues that type-identical functional states can differ in narrow content, so methodological solipsism fails. Uses the example of identical programs for playing chess and arms negotiations.

Some implausible twin cases trying to show that mental life can vary wildly while preserving physical/computational state. Bizarre.

Lots of arguments against narrow content. Very stimulating, though wrong.

Contra Loar 1988, the contents of "that"-clauses often reflect psychological content, even if it sometimes does not. We don't need narrow content.

There are big problems specifying the "mapping" and the relevant contexts for Fodor's theory noncircularly. Narrow content either collapses into syntax or is too coarse-grained. Nontrivial narrow content must be holistic.

Criticizes the "bracketing" strategy of Stich and Walker, and argues that intrinsic belief state should be individuated according to how it embeds in different environments. With a comparison with Fodor's related theory.

Argues for a two-dimensional intensional theory, with different kinds of intensions constituting notional and relational content. Notional content governs the dynamics of thought and behavior, and is primary in explanation.

Comments on Fodor 1987. Fodor doesn't make a conclusive case against externalism; but narrow content may be promising, and inexpressibility doesn't pose any real problems. With comparisons to neo-Fregean theories.

What matters are not propositional attitudes but notional attitudes; but it's hard to calibrate notional worlds. Very nice.

   Not syntactic psychology nor wide psychology, but narrow psychology.

   Science taxonomizes by causal powers, which are locally supervenient, so psychology needs a narrow notion of content. Proposes that a relativized notion -- a function from context to extension -- can do the job. Nice.

   Argues that folk psychology needs a notion of narrow content to provide robust predictive behavioral generalizations that covers doppelgangers. If not, then some behavioral patterns would be flukey.

   There's no good way to construe narrow content. Phenomenologist strategy is intrinsically wide, and indexicalist strategy can't specify content.

   Uses examples to argue that psychological content is not fixed by the content of "that"-clauses in belief ascription, and vice versa. We require a subtler kind of narrow content to capture what's going on.

   Contests the "provoked/aggravated assault" example of Baker 1986. If they're doppelgangers, then their narrow content can't differ.

   Narrow beliefs are de re beliefs about our inputs and outputs.

   Against perceptual-prototype and conceptual-role accounts of narrow content.

   Can't get a 'mode of presentation' account of narrow content to work, either through description theory or prototypes. Psych should be non-individualist.
   There are levels of narrowness, varying by whether independence is of actual or normal environment. Argues that this can be consistent with externalism.

Segal, G. 2000. _A Slim Book about Narrow Content_. MIT Press.

   On some problems with narrow content, contra Loar 1987. Narrow content is hard to spell out with "diagonal" propositions. Loar doesn't show that psychological content is narrow. With some remarks on privileged access.

   Argues that narrow content is still too coarse-grained for explanation, classifying psychologically distinct states together. Use syntax instead.

   Argues that the partial character construal of narrow content is not interestingly semantic. It collapses into syntax or phenomenology.

   Uses a "fraternal twin earth" thought experiment to show that even de dicto attributions don't supervene on narrow role, and that narrow content can't be explicited descriptively unless it collapses into phenomenalism.

   Replies to Burge/Stich arguments by introducing partial character -- a function from context to content, analogous to Kaplan's character -- as the semantic property determined by functional state and relevant to explanation.

   Argues for an account of narrow content in terms of notional worlds, by considering "objective optimality" across worlds. This allows for a sort of narrow radical interpretation. With arguments against Stalnaker.

   Narrow content theories can't handle the normativity of content. In-depth treatment of Burge cases and of the failures of causal and conceptual-role accounts. Normativity is fundamentally social. A long, interesting paper.

2.2h Miscellaneous

------------------

   An entertaining fable about a swampthing doppelganger of a murder witness. Does he have content? With plot twists about personal identity.

   Argues that a swampthing isn't intelligent or intentional, with different physiological processes and no sensations, as these are functional kinds.

   Should construe functionalism broadly rather than narrowly; then can handle the problem of broad content.

   Anti-intensional arguments are not independent but a series of dominos. Quine/Quine/Davidson/Putnam/Burge rise and fall together.

   Belief content has two distinct elements, one causal-explanatory, the other truth-related.

   Supplements externalist "locking" theories of content with an account of
internal "conceptions" by which thoughts lock onto environmental kinds, with that aid of dthat operators, thus solving various philosophical problems.

Contra Owens 1987: wide intentional descriptions and molar bodily descriptions don't exhaust the options. A bracketing strategy gives a narrow intentional taxonomy of mental states.

2.3 Causal Theories of Content
----------------------------------

2.3a Information-Based Accounts (Dretske, etc)
-----------------------------------------------

Defending information against Fodor 1986. Information is objective but relational, and depends on the relevant constraints between representation and environment. Circumstances play a vital role.

From material (formal) info to semantic info via teleology; from semantic information to representation via internal structure. Cute. With a good reply by Israel, and a terse reply by Dretske.

Uses information theory to analyze misrepresentation. A signal represents what it carries most information about, not what it correlates best with. Treating some signals as noise can increase information content.

Defines knowledge content in terms of information-flow from events, and
applies to various aspects of psychology.

Behavioral and Brain Sciences 6:55-90.
A summary of the book, with commentary and replies.

Dretske, F. 1990. Putting information to work. In (P. Hanson, ed)
_Information, Language and Cognition_. University of British Columbia Press.
On the causal role of information (as opposed to meaning). Information is
causally efficacious if considered with respect to learning. With
commentary by Brian Smith.

Logic 27.
Transmission of information is no good without the encoding of information.
With criticisms of associative networks, which transmit without encoding,
and criticism of Barwise & Perry's account of attunement to a relation.

Synthese.

Grandy, R. 1987. Information-based epistemology, ecological epistemology
and epistemology naturalized. Synthese 70:191-203.
Shannon's notion of information is more useful for naturalized epistemology
than Dretske's.

Philosophical Psychology 7:367-82.

We need to analyze indication in terms of "close enough" worlds; the
relevant conditionals are "might"-conditionals.

Israel, D. & Perry, J. 1990. What is information? In (P. Hanson, ed)
_Information, Language and Cognition_. University of British Columbia Press.

Jackendoff, R. 1985. Information is in the mind of the beholder. Linguistics
and Philosophy 8:23-33.
Argues that a representationalist theory of semantics beats a realist one.

Dretske has problems with ruling out alternative possibilities; and there is
a gap between information-caused belief and knowledge.

Makes a distinction between absolute information and information that's
relative to other knowledge.

Sayre, K.M. 1986. Intentionality and information processing: An alternative

Synthese 70:247-69.
On problems with a computational approach to content: computers process
info(t), the non-semantic content of communication theory, not info(s), or
semantic content. Get info(s) from efficient processing of mutual info(t).

2.3b Asymmetric Dependence (Fodor)
----------------------------------

Defends and refines a causal theory, using the notion of asymmetric dependence of a token upon the world.

Defending the asymmetric dependence theory against various objections.

Fodor's theory has counterexamples and can't explain its counterfactuals; but we can save it by borrowing from Dretske's account of misrepresentation.

2.3c Causal Accounts, General

-----------------------------

2.3d Teleological Approaches (Millikan, etc)
-----------------------------------------------

   Argues that a teleological account can resolve content indeterminacies, by an appeal to counterfactuals in examining what properties were selected for.

   Defends evolutionary theories of content against Fodor.

   Attacks original intentionality (Fodor/Burge/Dretske/Searle/Kripke) -- our intentionality, if anything, is derived through evolution, and so is as indeterminate as that of an artifact.

   Tries to deal with misrepresentation by appealing to function.

   Truth conditions are "entry conditions" for belief under "normal function". Later repudiated.

   Teleological solutions can't work, because of underdetermination and so on.

An evolutionary account of thought, content, and various intentional phenomena, appealing to proper functions and adaptational role to individuate contents.

The content of a desire is its adaptational Proper Function; the content of a belief is its Normal Condition for success.

Representation content is determined by the consumption of a representation, not its production. The representation-world correspondence is best taken as a normal condition for the consumer's function.

Contrasting positions on the role of representation production and consumption; also on the role of reliability, articulateness, and learning.

A reply to some of Fodor's criticisms of teleological theories in _Psychosemantics_ and elsewhere. With some remarks on Fodor's asymmetric dependence theory.

Millikan, R.G. 1993. _White Queen Psychology and Other Essays for Alice_. MIT Press,

A collection of papers on teleological semantics and other issues about psychology and mental content.

It's not unreasonable to deny a swampthing beliefs: swampcows aren't cows and swamphearts aren't hearts. Semantic norms are plausibly grounded in
biological norms and so in history.

Contra Dennett 1988, designed creatures can have intrinsic (if not original)
intentionality. Overall purpose is dependent on designer's goals, but
specific contents need not be.

Papineau, D. 1984. Representation and explanation. Philosophy of Science
51:550-72.
A teleological theory of belief/want contents: the satisfaction conditions
for a desire are those effects for which it was selected; truth conditions
for a belief are circumstances resulting in satisfaction of desires.

Papineau, D. 1990. Truth and teleology. In (D. Knowles, ed) _Explanation and
its Limits_. Cambridge University Press.
Best theory is combination of a success-guaranteeing account of
truth-conditions with a teleological account of desire.

Aristotelian Society 65.

Philosophy 76:1-14.

Papineau, D. 2001. The status of teleosemantics, or how to stop worrying about

University, Cognitive Science Research Paper 140.
Combining the analysis-relative and historical accounts of function, and
using these to give an account of intentionality: representation are produced
by conditional productive functions. Argues against Fodor on indeterminacy.

Philosophical Quarterly 73:267-82.
Millikan's theory has an implausible consequence: creatures' belief contents
can involve properties which they cannot discriminate. With examples.

Journal of Philosophy 32:393-419.

Rountree, J. 1997. The plausibility of teleological content ascriptions: A
reply to Pietroski. Pacific Philosophical Quarterly 78:404-??.

biology chase causality? Southern Journal of Philosophy
37:113-140.

Philosophical Quarterly 31:63-72.

Shapiro, L. 1996. Representation from bottom to top. Canadian Journal of
Philosophy 26:523-42.

Teleosemantics has big problems with indeterminacy, holism, false belief, and "psychophysical normalcy" in causation. So do all naturalistic stories.

2.3e Conceptual Role Approaches
-------------------------------
An in-depth program for conceptual-role semantics, and its role in a two-factor account of meaning. Also a defense of narrow content.

A defense of functional role semantics, and an account of its relation to truth-conditional factors. A two-factor theory will handle wide content.

No matter how we understand the denial of the analytic/synthetic distinction, the falsity of inferential-role semantics does not follow. The meaning-constitutive inferences needn't be the analytic inferences.

CRS conflates representation content and attitude content (which depends on a representation's "target"), so can't handle representation content; it makes all content-based explanations vacuous; and it can't handle error properly.

Explicates conceptual role in terms of conditional probability, and analyzes meaning as conceptual role plus reference. With remarks on truth, descriptions, and synonymy.

Conceptual role semantics isn't compatible with compositional semantics and the denial of an analytic/synthetic distinction, as full conceptual roles aren't compositional, and there's no way to specify a relevant subset.

Meaning and content is determined by the role of symbols in thought (e.g. inference and perception). With remarks on indeterminacy, context-dependence,
the linguistic division of labor, qualia, speech acts, and more.

   On the relation between conceptual role and truth-conditions. Contra Harman, truth-conditions are to an extent independent of conceptual role.

   Contra Harman 1982, truth-conditions are central to a semantic theory.

   Argues against Putnam 1987 that conceptual role plays an important role in determining meaning. Appeals to the induction theory of Holland et al.

   Contra Fodor and Lepore, meanings can be compositional even if inferential roles are not, as long as meanings only supervene on inferential role.

2.3f Theories of Content, Misc
-----------------------------

   On "translational" (conceptual) and "calibrational" (referential) content. Relation of content issues to computational issues.

   Critiques other views, offers interpretational semantics.

   On the ways in which meanings can come to cohere with their causal roles: learning, natural selection, and design. Criticizes Dretske for undervaluing the latter two: all three are in the same boat.

   On the reference and content of representations. Reference is determined by causation; content, i.e. representation "as", is determined by functional role, when functioning normally in natural habitat.

Stalnaker, R. 1991. How to do semantics for the language of thought. In (B. Loewer & G. Rey, eds) _Meaning in Mind: Fodor and His Critics_. Blackwell. On some tensions in Fodor's view of content: e.g. narrow content must be dependent on functional role, which seems to lead to holism. The role of denotational semantics as a defense is unclear.

2.4 Representation (General) [see also 4.2]
----------------------------

Because paramecia can't respond to non-nomic properties of the stimulus. Perceptual categories vs. sensory manifolds.

On the philosophical (inward-out) vs. psychological (outward-in) approaches to the mind-world relation; the psychological approach is more useful in understanding representation. Internal reality is an imperfect construction.

On different senses of "representation" -- external, experiential, mental locus, substrate of meaning, mediating functions, technicalpsychological.

On the distinction between representation and representation-use.

2.5 The Explanatory Role of Content (Dretske, etc)
-----------------------------------

On Dretske's account of the causal role of content. Addresses some objections: Dennett's worries about intrinsic intentionality, Fodor's about external causal powers, and some worries about syntax.

A critique of Fodor. Semantics per se doesn't cause. Also, Fodor's is an account of the what, not the how, of semantics. Somewhat bizarre.

Criticizes Dretske's account of the role of content, especially because of its dependence on an organism's history; also, it may not cohere with work in cognitive science. Argues for an interpretational, not a causal account.

Devitt, M. 1991. Why Fodor can't have it both ways. In (B. Loewer & G. Rey, eds) _Meaning in Mind: Fodor and his Critics_. Blackwell.

Content must explain why (not how) an internal state caused a certain output. The explanation is given in terms of what a state has historically indicated. With thermostats and sea-snails as examples. Comments by Cummins, and reply.

Distinguishes three problems of mental causation (extrinsic factors, exclusion of the nonphysical, anomalism). Criticizes Dretske's theory (can't handle unlearnt or here-and-now reasons), offers a counterfactual account.

We must individuate mental states by semantics, not just by function, as we need representation to capture generalizations about behavior; particularly due to the information-sensitivity and stimulus-independence of behavior.

2.6 Concepts
------------

Connectionism builds up concepts from the nonconceptual level. From nonconceptual content (e.g. perceptual experiences) to the emergence of objectivity.

Millikan, R.G. 1997. A common structure for concepts of individuals, stuffs, and kinds: More mama, more milk, and more mouse. Behavioral and Brain

A symposium on the book, with comments by Heal, Rey, Papineau.

On the significance of psychological work on concepts for philosophical conceptual analysis -- simple, precise analyses do not exist in general.

On concepts as abilities, and on construals of abilities that lead to internalism and externalism. Maybe the relevant abilities are characterized externally but determined internally. Remarks on Putnam, Davidson, Burge.

2.7 Meaning Holism

Uses Putnam's "Ruritania" example to argue that narrow content, if it exists, is holistic. Twins in different communities start with same narrow content, diverge by acquiring new beliefs; so belief change affects narrow content.

Rebutting arguments for meaning holism: those based on confirmation holism (Quine), normativity of interpretation (Davidson, Dennett, Lewis), and functional-role semantics (Block, Field, Churchland).

A discussion of _Holism_ with comments by Devitt, Rey, McLaughlin, Brandom, and Churchland, and a reply by Fodor and Lepore.

A critique of Fodor and Lepore. Distinguishes versions of holism, and argues for a weak version. Real thinkers are subjects, which imposes constraints on the interrelations of thoughts. Science fiction is irrelevant here.

Contra Fodor, meaning holism is compatible with intentional psychology. Most psychological generalizations quantify over contents, rather than appealing to specific contents.

A nice criticism of Fodor and Lepore's arguments that holism implies (a) the nonexistence of intentional laws and (b) the nonlearnability of language.

The argument from anatomism and the failure of the analytic/synthetic distinction to holism fails. On the many different interpretations of holism and anatomism: there is a reasonable molecularist position.

2.8 Mental Content, Misc

------------------------

Morris 1991 is wrong: formal individuation is easy, and objectively determinate content isn't needed. External grounding is also irrelevant.

Engel, P. 2000. Wherein lies the normative dimension in meaning and mental

Intentionality around the diamond: neoCartesianism, neobehaviorism, neopragmatism. 1B=Fodor/Pylshyn, 2B=Dennett/Quine, 3B=Heidegger/Sellars. SS=Wittgenstein. RF=Searle, CF=Skinner, LF=Rorty/Derrida. Lots of fun.

There can be no non-stipulative content to non-semantically individuated tokens. Mostly a critique of Cummins; also Fodor and Dennett.

Remarks on a number of aspects of mental content -- narrow, propositional, qualitative -- with respect to functionalism and the language of thought. With comments by Baker.

On the tacit theories underlying the folk psychology of belief: beliefs are states associated with typical causal patterns. With remarks on ambiguity, content identity and similarity, and environmental dependence.

Argues that a failure to "naturalize" intentionality won't lead to disasters such as irrealism, irrelevance, or non-science, whether naturalization is understood as analysis, property identity, supervenience, or whatever.

There's no deep problem of naturalism about intentionality, as we know it's true already. The real puzzle is that of finding a mechanism to close the gap, e.g. via analysis or essentialism. But naturalism doesn't require that.

--

3.1 Supervenience

---

3.1a Psychophysical Supervenience (Kim, etc)

---

Contra Papineau 1989: the assumption of completeness is false or trivial.
Maybe the mental is part of a complete physics. With response by Papineau.

42:129-43.
Various objections to Kim's arguments for supervenience. Not all internal
states relevant to I/O relations are psychological states. Strange.

Midwest Studies in Philosophy 4:31-49.
Supervenience of the mental on the physical is what is required to make
mental causation possible. Very nice.

Internal mental states (i.e. ones that are not rooted outside) supervene on
synchronous internal physical states, and internal states are all that is
relevant in the explanation of behavior.

and Brain Theory 5:129-47.
Distinguishes weak (within-world) vs strong (across-worlds) supervenience.
Relates to reduction, internal/external mental states, and various theories.

On some problems with supervenience, the relation between supervenience and reduction, and on reasons for accepting psychophysical supervenience. Loose.

If mental properties are supervenient but irreducible to physical/functional properties, we can't confirm them. Confirmation requires an indispensable explanatory role, which irreducibility precludes. With comments by Schiffer.

Psychophysical supervenience follows from completeness of physical laws.

3.1b Supervenience and Physicalism [see also 3.3a]

Argues that everything is logically supervenient on the physical. Considers classes, possibilities, numbers, universals, and objects of thought.

Supervenience is all we need for materialism. Various materialist arguments (unity, "nothing but", history, fear of darkness, simplicity, law) don't support physical exhaustion & token identity, over and above supervenience.

Some applications of the earlier treatment: examples of determination without reduction; the status of properties and universals; the mental; the life sciences; modalities and essentialism; theoretical equivalence.

Some remarks on determination, physicalism, model theory, and logical truth.

Argues that the generality of physics should be a supervenience thesis, not token physicalism. Fodor's token physicalism is untenable but might be saved with an appropriate view of events.

An account of how all facts supervene on microphysical facts, and how all intrinsic facts supervene on intrinsic microphysical facts.

Laplacean demon's job: number crunching, plus cosmic hermeneutics to explain high-level truths. All high-level truths follow from low-level by meaning constraints. Application to theoretical/mentalistic/everyday terms. Nice.

Supervenience is neither necessary nor sufficient for materialism. With various (contentious) counterexamples. So we need a different formulation.

Argues for strict implication rather than supervenience as a formulation of "minimal physicalism" (unless supervenience is formulated just right).

Formulates a definition of materialism: among worlds where no natural properties alien to our worlds are instantiated, no two differ without differing physically. With a lot of other material on universals.

How can supervenience, as a relationship between ontologically distinct properties, be explained? Modal realism and grand-properties don't work. Eliminativism about supervenient properties is the only possibility.

Defines physicalism in terms of claims that microphysical entities constitute everything and that microphysical laws govern everything. With a reply by Crane.

Seager, W.E. 1988. Weak supervenience and materialism. Philosophy and
Weak supervenience provides a more tenable form of materialism than strong supervenience, because of inverted spectrum possibilities, etc.

A construal of materialism in terms of constitution, not identity. Discusses the entailment between physical properties and mental properties; considers a nonreductive physicalism and a primitive dualism.

3.1c Technical Issues in Supervenience
--------------------------------------

A modal-logic analysis of the relations between various notions of supervenience. Most concepts of supervenience entail necessary co-extension, under certain closure assumptions for properties.

A model-theoretic treatment of supervenience, in terms of relations between theories. Supervenience turns out to be equivalent to reduction.

A nonreductive supervenience hypothesis: supervenient properties are properties of properties, e.g intrinsic goodness is a property of an object's nature.

On dependency supervenience (B properties determine A properties) versus determination supervenience (A properties need B properties).

Humberstone, I.L. 1992. Some structural and logical aspects of the notion of

Distinguishes weak and strong supervenience. A mistaken proof that strong and global supervenience are equivalent. Strong supervenience implies a kind of reduction, but not an explanatorily useful reduction.

Reasons why global supervenience doesn't entail strong supervenience, and trying to rescue global supervenience as a useful notion. Suggests a similarity-based notion of global supervenience.

How properties in one domain can supervene on properties in another, with or without co-ordination between domains. Relation to global supervenience.

Supervenience doesn't entail reducibility, as necessary coextension doesn't suffice, and is incompatible with reducibility, due to ontological asymmetry.

Distinguishes modal-operator and possible-worlds versions of supervenience, and explicates global supervenience and its relation to weak and strong. With remarks on multiple-domain supervenience and the relation to reduction.

Argues that global supervenience has epistemological problems -- how could we ever know that it holds, and that certain worlds are impossible?

Closure under resplicing makes supervenience both too narrow and too wide. Weak supervenience is generally too weak to capture the dependence relation.

Gives a proof of the distinction between strong and global supervenience that improves on Petrie's, and argues contra Kim that global supervenience is a perfectly reasonable dependence relation for physicalism.

Petrie, B. 1987. Global supervenience and reduction. Philosophy and
Defending global supervenience: it's weaker than strong supervenience, as base properties of other individuals are relevant. It doesn't entail type or token reducibility. On the relation to implicit definability and reduction.

Properties in supervenience relations shouldn't be closed under negation or resplicing, due to bad consequences. With reply by Bacon on resplicing.

3.1d Supervenience, General
---------------------------

On the incompatibility of weak supervenience without strong supervenience and realism. With discussion of various strengths of necessity involved in supervenience claims, and application to moral realism and anomalous monism.

How social facts supervene on the totality of individual facts. Application to belief, etc.

Supervenience is too weak to function as a dependency relation, as e.g. it can hold in two directions at once.

Reply to Miller 1990. Miller underestimates the modal force of supervenience and invokes irrelevant dispositional properties.

Horgan, T. 1993. From supervenience to superdupervenience: Meeting the demands of a material world. Mind 102:555-86.
An overview of supervenience, with focus on the problem of explaining supervenience relations. With remarks on mental causation, emergence, physicalism, and reduction.

Developing and motivating the notion of supervenience. Investigating the relationship to reducibility and definability (equivalence, under certain
conditions), and to microphysical determination.

On weak/strong supervenience, and high-level causation via supervenience.

A nice overview of supervenience and covariance.

A collection of articles on supervenience and causation in metaphysics and the philosophy of mind, with some added postscripts.

Supervenience doesn't entail reducibility, which is epistemological. The problem's not just huge disjuncts, but also the sharing of bases, no local correlations, and base-properties presupposing supervenient properties.

Argues that lower-level theories can explain supervenient but irreducible higher-level theories, but only under certain conditions, as low-level accounts don't have the relevant kind terms.

On supervenience as an ontological relation (via metaphysical necessity) or as an ascriptive relation (via conceptual necessity). The first doesn't preclude the second. Moral realism and mental realism are in the same boat.

On a number of issues: possible worlds vs modal notions, explicating global supervenience, the relation between weak/strong/global supervenience, multiple-domain supervenience, and implications for reduction.

If supervening properties can make arbitrarily fine distinctions, then physical properties supervene on moral/aesthetic/mental properties.

Contra Blackburn 1984 on the possibility of weak supervenience without strong supervenience, even with metaphysical necessity; using Nozick's concept structures, or indexical definitions. With application to moral realism.

Distinguishes "reductionist" and "metaphysical" conceptions of supervenience. Also discusses the relation between strong and global supervenience, degrees of necessity, and the explanatory role of supervenience.

Compares the Hellman/Thompson notion of determination with Kim's development of supervenience. Uses these to investigate the concept of materialism, and argues that materialism isn't contingent.

3.2 Reduction
-------------

3.2a Reduction and Multiple Realizability
---------------------------------------

On species-specific reductions. These can't reduce standard psychological properties, and problems with intra-species multiple realization can't be circumvented without giving up property reduction for token event identity.

The anti-reductionist argument assumes that functional properties aren't physical properties (not even extrinsic physical properties). This, not multiple realizability, does the work.

Multiple realization is compatible with reductionism. Jade (= jadeite or nephrite) isn't a scientific kind, and neither are multiply realizable mental properties. So there's no global psychology, just lots of local reductions.

Some comments on Wilson 1985: some special-science properties may be relevantly different in kind from his expanded physical properties.

Argues contra Fodor and Block that neurological equipotentiality doesn't refute type materialism. Mental states may not be anatomically defined neural states, but they may be more abstract neural holograms.

Argues for type-type identities and for an expanded view of the physical, as properties from physics exhibit the same sort of multiple realizability as functional properties. Sophisticated, with many interesting examples.

3.2b Nonreductive Materialism [see also 3.5d]

Beckermann, A. 1992. Reductive and nonreductive physicalism. In (A. Beckermann, H. Flohr, & J. Kim, eds) _Emergence or Reduction?: Prospects for
Nonreductive Physicalism_. De Gruyter.
On varieties of physicalism with respect to reduction: semantic physicalism, identity theory, supervenience, and the denial of emergence. Advocates a version on which physical states realize mental states.

Arguing for a pluralistic conception. With criticism of Churchland's reductionism, Davidson's token identity, and more generally reverential "scientism". Reductionist explanation is not the general rule.

Psychological kinds can't be reduced to physical kinds, due to cross-classification, although token physicalism still holds. How to maintain the generality of physics without a reductionist unity of science.

Gives four constraints on interlevel connections, and some arguments against reductionism and for the autonomy of psychology. Argues that supervenience fact are themselves in need of explanation.

Classifying psychophysical theories by the status (necessary, lawful, anomalous, false) of psychophysical/psychological generalizations. Defending autonomous monism: nonreductive materialism with psychological laws.

Somewhat loose arguments that non-reductive physicalist realism is untenable. Anomalous monism makes the mental irrelevant, functionalism is compatible with species-specific reduction, and supervenience is weak or reductive.

Argues that nonreductive materialism implies downward causation (as the mental has more causal powers than the physical alone), and that downward causation violates the causal closure of the physical.

Kim, J. 1992. "Downward causation" in emergentism and nonreductive physicalism. In (A. Beckermann, H. Flohr, & J. Kim, eds) _Emergence or

Argues that nonreductive materialism is just like 1930s emergentism, with the mental contributing new causal powers, and so implies downward causation.

Contra Kim, physicalists can avoid reduction by embracing strict implication.

Non-reductive physicalism is a mystery unless we invoke teleology.

Explicating anti-reductionism: mental causal powers are constituted of physical causal powers, but aren't type- or token-identical to them. Against arguments from local reduction, neuroscience, explanatory exclusion, etc.

A careful discussion of how to characterize physicalism, in terms of identity or supervenience, and argues that physicalism must reduce (bowdlerize) qualia to something they are not, as physicalism requires topic-neutral analyses.

On how a nonreductive materialism can handle problems about mental causation, psychophysical dependencies, and qualia. A teleofunctionalist view with different conceptual frameworks, but mental properties physically realized.

3.2c Reduction in Psychology
--------------------------------

Argues that cognitive theories have already been reduced to neurobiology in some domains, such as associative learning.
Psychology shouldn't be autonomous from natural science. By analogy with biology, nature provides (a) conceptual insight, and (b) real constraints, e.g. thermodynamic ones. Biology and psychology are continuous.

The relationship between psychology and neuroscience is best characterized not by reduction but by explanatory extension, where each field is enriched by the other. With a number of examples from recent empirical work.

Anti-reductionism needn't be ad hoc (contra Churchland). Although evolution provides some pressure for 1-1 psychophysical mappings, there are significant countervailing forces, e.g. in vision, memory, learning, and language use.

Reduction comes to supervenience plus expicability. Thus biconditionals, multiple realizability, etc, are irrelevant. Biology is already reduced (mostly via functional explanation), and psychology looks promising. Nice.

On the links between supervenience, reduction, and explanation. Supervenience is compatible with reductive explanation of a localized variety. We don't need laws, but explanatory links.

Contra Richardson 1979, a purely functional psychology is irreducible. The genetics analogy is misleading; multiple realizations can't explain high-level laws.

Mind is not reducible to body, but societies reduce to individuals. Multiple realization is in tension with predictability. Natural selection resolves the tension for the mental, but cannot for the social.

Argues that functionalism is compatible with reductionism, by analogies. Genetics has multiple realization and multiple function; reduction doesn't require biconditionals. With remarks on the de facto autonomy of psychology.

Response to Kitcher 1980. Reductions are usually domain-specific, and high-level regularities are indeed explained.

Excellent coverage of the notion of level and its applicability to mind.

3.3 Other Psychophysical Relations
----------------------------------

3.3a Physicalism [see also 1.3, 1.7b, 3.1b, 3.2b, 3.5]
-------------

If there are no contingent psychophysical laws, then there are no mental properties. So physicalism/supervenience is false; God had extra work to do.

Physical sciences have no ontological authority over the mental. Considers and dismisses arguments from laws, causation, reduction, supervenience.

Holder-Pichler-Tempsky. On why materialism requires conceptual analysis to locate mental properties in the natural world. Even a posteriori necessary connections have to be backed by a priori links. With remarks on supervenience. A nice paper.

If every physical event has a physical explanation, and the mental is causally efficacious, then mental facts are strictly implied by physical facts. A nice argument.

Materialism doesn't need a identity thesis. The requirement that mental facts are entailed by physical facts plays the role played by Kripke's requirement of necessary identity, and is more reasonable.

Nothing in the arguments of Crane and Mellor 1990 count against a physicalism based on strict implication.

On the problems posed for materialism by intentionality, autonomy, awareness, and indexicality. Tentatively advocates a Cartesian position.

Melynky, A. 1994. Being a physicalist: How and (more importantly) why. Advocates "realization physicalism": all properties are either physical or functional properties realized by physical ones. This achieves unity between sciences better than alternatives, and avoids overdetermination.

Discusses two formulations of physicalism: requiring high-level properties to be disjunctions of physical states, or to be functional properties realized physically. Tentatively endorses the latter.

Physicalism is the claim that (1) There are microphysical entities, (2) Microphysical entities constitute everything, (3) There are microphysical
regularities, (4) Microphysical regularities govern everything.

3.3b Token Identity [see also 3.5b, 3.5d]

We individuate mental events by their causal role, but we can't individuate causes uniquely. So each mental event has multiple physical correlates, and token identity doesn't hold.

Supervenience doesn't imply token identity, and Davidson's argument for token identity equivocates on "event". But weak supervenience (mentally discernible worlds are physically discernible) is all we need. With nice examples.

Physical/psychological token identity is no good: you can't individuate physical events without psychological predicates.

Can't isolate the physical token of a belief, say, as it's always accompanied by other beliefs. Meaning doesn't come in discrete tokens.

3.3c Emergence

-------------

On varieties of supervenience and of emergence, and of what is required for reduction. Argues that reduction involves general explanatory connections, whereas emergence involves unique and ultimate bridge laws.

A defence of radical emergence against Spencer-Smith 1995.

Lovejoy, A.O. 1927. The meanings of "emergence" and its modes. In (E.S.
Brightman, ed) _Proceedings of the Sixth International Congress of Philosophy_. Longmans, Green, and Co.

Morgan, C.L. 1923. _Emergent Evolution_. Williams and Norgate.

An in-depth analysis of Sperry's views on consciousness. Sperry is not a dualist; he believes in "structural causation" based on emergent properties.

3.3d Dualism [see also 1.3f, 1.4e, 1.4f]
------------

Interactionism is compatible with conservation of energy and momentum: the mind exerts a non-physical force on the brain.

Various arguments about interactionism based on conservation of energy. C of E only applies to causally isolated systems, so objections beg the question.

Argues that there can be interaction without breaking physical laws: e.g. by basic psychic forces, or by varying physical constants, or especially by arranging fractal trees of physical causation leading to behavior.

Argues that interactionist dualism is compatible with the causal closure of the physical, if we allow causal overdetermination; and there is a strong case for the latter.

Dualism is an empty hypothesis. Everything must be matter, though we may have to expand the notion of matter.

3.3e Psychophysical Relations, Misc
-----------------------------------

Argues that mental kinds are not natural kinds, and don't have real essences but nominal essences. For this reason, there are no psychophysical laws. With remarks on psychological laws, and the role of behavior.

Physical completeness, mental causation, non-reductionism are inconsistent. Ryle and Putnam are closet dualists, and Davidson's an epiphenomenalist.

3.4 Functionalism [see also 1.8, 4.6]

3.4a Causal Role Functionalism (Armstrong/Lewis)
-----------------------------------------------

Mental states should be analyzed as states that are apt to bring about certain kinds of behavior. Analysis of all kinds of mental states as such. With comments on dualism, behaviorism, identity theory, and consciousness.

Mental states are internal states that are apt to cause certain behaviors. A synthesis between the "thesis" of idealism and the "antithesis" of behaviorism. With defense against objections from consciousness.

Psychofunctionalism can evade chauvinism by specifying different functional identifications within each species. Applying same mental terms to each is justified by theory similarity; but it still isn't analytic functionalism.

Against functionalism: experiences have intrinsic introspectible acausal properties, such as duration, felt location, and unpleasantness. Both analytic and empirical functionalism fail.

Formalizing versions of functionalism, and seeing which entail token physicalism and/or type physicalism. On the most plausible versions, we have token physicalism without type physicalism.

Functionalism is compatible with type identity, as e.g. "pain" designates the state-type that fills the right functional role in an organism at a given time, i.e. a brain state. Contra Kripke, pain is not a rigid designator.

Argues that Lewis's functionalism founders on the specification of behavior. Described intentionally => non-materialist; physically => chauvinist.

Causal roles are definitive of mental states. Since physical states fill these causal roles (by the explanatory adequacy of physics), mental states are physical states.

Mental states can be defined, via a Ramsey-sentence analysis of the plattitudes of folk psychology, as entities that fill causal roles specified by the analysis. These fillers turn out to be physical.

Accounting for both pains that don't play the usual causal role and for pains that are realized in different substances, by a mixed theory: pain is the physical state that typically occupies a certain causal role in a population.

Functionalism (reducing the mental to its effects on the physical) is no more plausible than phenomenalism (reducing the physical to its effects on the mental).

Lewis's original theory leads to Kripkean reference-fixing, so chauvinism.
Token functionalism can't deal with paralytics. Species-relative functionalism fails as pain is intrinsic, not extrinsic.

Fleshing out Ramsey-sentence functionalism; against Lewis's "mad pain" mixed theory; relating functionalism to the causal theory of properties. Empirical functionalism is chauvinistic so probably false. A terrific, in-depth paper.

Contra Lewis: Functionalism isn't compatible with type physicalism. There are intra-population difficulties with species-relative construals, and individual-relative construals can still have multiple fillers.

3.4b Machine Functionalism (Putnam) [see also 4.8]

The relationship between mental and physical states is just like that between logical and structural states of Turing Machines, so no great mystery. With comments on privacy and semantic analysis.

Why mental states are more likely to be functional states (in probabilistic automata) than brain states or behavioral dispositions.

On explaining behavior via TM states, e.g. explaining preference via utility functions. Logical behaviorism assumes rational preference functions. Functional organization is what matters, not physical make-up.

Psychological states aren't TM states after all: we have lots of psych states at once; they depend on learning/memory; disjunctions of TM states are no good. But functional organization rather than physics is still what counts.

Type functionalism isn't any better than type physicalism, as mental states can be multiply realized as functional states. With what in common?

On abstract vs. physical TMs: Putnam should say that mental states are physical TM states. But then functionalism is compatible with physicalism.

On the relation between Putnam's and Armstrong's functionalism.

If machine functionalism were true, a homunculus-head would have all the mental states of its homunculus (by the definition of "realization"), which is absurd.

Reply to Elugardo 1983: so how do you specify what count as inputs/outputs?

Criticism of Lycan 1979, and a re-making of the argument.

Lycan's New Lilliputian argument fails as inputs/outputs for the homunculus are not the same as inputs/outputs for the full system.

Kane, R.H. 1966. Turing machines and mental objects

Argues for mechanism rather than functionalism. Criticizes Putnam for hypostasizing mental states, which are disanalogous to mental states. Defending mechanism against Kalke's & Rorty's objections.

Logical states don't give us any understanding of mind over and above what the function/structure distinction gives us. In particular, it doesn't help with the understanding of privacy and incorrigibility.

Contra Putnam: logical states are not physical states, and utterances about them are not about physical states.

Contra Lycan: machine functionalism can handle Bolivia and CRT cases by a causal/counterfactual account, and Lilliputian case by assigning mental states to minds, not bodies.

3.4c Functionalism, Miscellaneous
---------------------------------

A formal argument showing that functional definitions are equivalent to behavioral definitions.

The functional level is the appropriate level for psychology, but neurophysiological facts constrain this level and are thus relevant.

Ten papers on functionalism. Originally was Philosophical Topics, volume 12.

Distinguishes varieties of functionalism, e.g. machine and Ramsey-sentence functionalism; and compares to behaviorism. With a historical overview, and arguments for why functionalism is incompatible with physicalism.

Distinguishes analytic and empirical functionalism. Both have problems with absent qualia, and inputs/outputs. Analytic functionalism has problems with paralytics, etc; empirical functionalism has problems with Martians.

Mental states are not physical or behavioral states; could they be functional states? With various arguments against type identity, and against machine-table functionalism.

Reprinted in (N. Block, ed) _Readings in the Philosophy of Psychology_ (MIT Press, 1980).

On the role of functional explanation versus other kinds of explanation. Functionalism applies an analytic, not subsumptive strategy.

On mental state as inferred theoretical entities, individuated according to their function (cf. valve-lifters). Psychology and neuroscience will mutually constrain each other, giving a relation more complex than reduction.

Argues that functional explanation are reducible to structural explanations.

There's no absolute functional/structural distinction, as it depends on how you choose boundaries and levels of abstraction.
   Pursue a multi-leveled homuncular functionalism, with mental states
   characterized as states of teleologically identified subsystems.  Even the
   identity theorist is a functionalist at a low level.

Malcolm, N. 1980.  'Functionalism' in philosophical psychology.  Proceedings

   Synthese 88:341-58.
   Scientific realism requires dispositions of kinds be explained by intrinsic
   properties.  Neural/functional properties won't work, because of reductionism
   and circularity.  Use intrinsic psychological properties instead.

Richardson, R.C. 1979.  Functionalism and reductionism.  Philosophy of Science
   46:533-58.
   Argues that functionalism is compatible with reductionism, by analogies.
   Genetics has multiple realization and multiple function; reduction doesn't
   require biconditionals.  With remarks on the de facto autonomy of psychology.

   _The Representation of Knowledge and Belief_.  University of Arizona Press.
   Against functionalism for beliefs.  Both common-sense functionalism and
   psychofunctionalism have problems with finding the right functional theory,
   distinguishing beliefs, perceptual input conditions, Twin Earth, etc.

   Philosophical Forum 4:500-12.

Sober, E. 1990.  Putting the function back into functionalism.  In (W. Lycan,
   Need teleological functionalism, not Turing Machine functionalism.

   Synthese 64:165-93.

van Gulick, R. 1982.  Functionalism as a theory of mind.  Philosophy Research
   Archives 185-204.
   The structure/function distinction is level-relative, so physiology might be
   relevant even under functionalism.  Problems with automata, and with causal
   connections to nonintentionally characterized behavior.

van Gulick, R. 1980.  Functionalism, information and content.  Nature and
   System 2:139-62.  Reprinted in (W. Lycan, ed) _Mind and Cognition (Blackwell,
   1990).

   Philosophical Topics 12:147-67.
   Functionalism may be appropriate for cognitive psychology but not for folk
   psychology, due to differing goals.  Neuroscience will play an important
   role in developing functional theories.

   Argues that the possibility of multiple realization has not been established,
   whether by arguments from imagination, concepts, or empirical facts.

3.5 Other Psychophysical Theories
---------------------------------
3.5a Logical Behaviorism (Ryle, etc)
------------------------------------

The ancestor of most contemporary philosophy of mind. Among other things,
argues that the "ghost in the machine" view of mind is a category mistake,
and presents dispositional analyses of many mental concepts.

Personalist 60:233-42.

Carnap, R. 1959. Psychology in physical language. In (Ayer, ed) _Logical
Positivism_. Free Press.

Carrier, L. 1973. Professor Shaffer's refutation of behaviourism. Mind
80:249-52.

Chisholm, R. 1955. A note on Carnap's meaning analysis. Philosophical
Studies.

Chisholm, R. 1952. Intentionality and the theory of signs. Philosophical
Studies.

Chisholm, R. 1958. Sentences about believing. Minnesota Studies in the
Philosophy of Science 2.

Dalrymple, H. 1977. Some logical muddles in behaviorism. Southwestern
Philosophical Studies 2:64-72.

Ewing, A.C. 1953. Professor Ryle's attack on dualism. Proceedings of the
Aristotelian Society 53:47-78.

Defends behaviorism as a scientific hypothesis, so that conceivability
arguments aren't relevant, and advocates "penetrability" behaviorism which
can appeal to internal physical states.

Hamer, C. 1970. Why Ryle is not a behaviourist. Philosophical Studies
(Ireland) 17:7-25.

Heidelberger, H. 1966. On characterizing the psychological. Philosophy and
Phenomenological Research.

3.5b Identity Theory (Smart, etc) [see also 1.3c, 1.4g, 3.3b]

-----------------------------

The idea that consciousness is a brain process is logically coherent. It's a scientific hypothesis, not a necessary truth. On the "is" of composition vs the "is" of definition, and the fallacy of the internal phenomenal field.

Defending the thesis that sensations are contingently identical to brain processes against various objections. Topic-neutral analysis of sensation reports. Materialism beats epiphenomenalism on grounds of simplicity.

The number of possible mental states is infinite (think of any number), whereas there are only finitely many brain states, so they're not identical.

Likens the anti-materialist position to the "headless woman" fallacy: "I'm not aware the mental states are physical", so "I'm aware that mental states are non-physical".

A prima facie case for materialism based on grounds of rational consensus, arising especially from common-sense and scientific evidence. Mental states exist (common-sense) but should be analyzed causally (evidence from science).

Honor of Herbert Feigl_. University of Minnesota Press.

Mental states are necessarily private, and so cannot be physical states, which are public. We have epistemological authority about our mental states.

Argues that phenomenal properties aren't needed to identify sensations with brain-states, and nor are topic-neutral analyses.

An anthology of central articles on the identity theory.

Arguing for an event-identity construal of the identity theory. Comparing the identity theory to the weaker "principle of simultaneous isomorphism". The only reason to accept the identity theory is ontological simplicity.

Argues that the identity theory is compatible with linguistic dualism, as the mental and the physical may differ in intensional properties only.

On problems with theories that leave the nature of mind open a priori: how can we even understand the possibilities?

Location of mental states by convention (Shaffer 1961) won't work, as it (a) makes mental states public, and (b) conflicts with connections to behavior.

Philosophical Forum 7:139-58.

On topic-neutral reports, after-images, and after-radishes. Such a report requires epistemic access to physical resemblance, which we don't have.

There's no empirical support for identity, over and above that for correlation; and unity of science gives no reason to accept identity. The only reason might be that of ontological simplicity.

Deal with phenomenal properties by allowing only mental events, and eliminating mental objects. Identity theories needn't suppose psychophysical laws. With defense against multiple realizability arguments.

Recasting the identity theory and functionalism, using Kripkean theories of reference, so mental states can refer to physiological or psychological states that we don't yet understand; and qualia problems are handled better.

Mental states are defined by their causal roles. So, by the completeness of physics, they must be physical states.

On how materialism, as opposed to a double aspect view, can handle mental features -- by moving them into the world via a realist theory of perception. Remarks on identification of states. After-images, etc, cause problems.

Using the special theory of relativity to show that if mental events have a temporal location, then they must have a spatial location.

The identity theory is meaningless, if identity is analyzed as spatiotemporal coincidence, as thoughts don't have location. Thoughts also require context. Even if identity holds, explaining brain doesn't imply explaining mind.

Sensations and processes have different logical type, so it is a priori impossible that they should be identical.

Identity requires explanation to be accepted, but Smart doesn't provide this. But one can deny identity without claiming dualism -- e.g. a "duck-rabbit" theory of mind/brain. With remarks on the completeness of descriptions.

Place, U.T. 1960. Materialism as a scientific hypothesis. Philosophical
Contra Smart 1959: Materialism is a scientific hypothesis, if we accept certain logical criteria for what a sensation is; otherwise it's just false.

Comparing contemporary materialism to Pace's 1956 variety. With remarks on whether the thesis is empirical or a priori, and on deciding the issue between materialism and epiphenomenalism.

Discusses a paper of Martin's and the genesis of the identity theory, with a focus on 'public' and 'private logic' and topic-neutral descriptions.

The identity theory must be false, as pain centers in vitro will not be pains. With a reply by G. Pearce and a rejoinder.

On the identity theory as a linguistic proposal, compatible with dualism; epiphenomenalism and parallelism must be false, leaving interactionism.

Mental states don't have a location, and brain processes do; but we could stipulate a location for mental states. With remarks on possible relations between mental and physical features, states, and concepts.

We identify mental events by noticing mental features that must be nonphysical, but still might be empirically reducible. Against topic-neutral definitions, and with response to Coburn 1963 on location.

Reply to Stevenson 1960: There are no irreducible mental properties; they reduce to physical properties via topic-neutral definitions.

Reply to Baier 1962: epistemological authority is compatible with materialism. Mental state reports are not completely incorrigible, though.

Defending topic-neutral analyses of mental reports, and arguing against Wittgensteinian behaviorism via brain-in-vat examples. With remarks on the appeal of materialism and on compatibility with ordinary language.

On some problems for the identity theory arising from the intensionality of mental states and from the appeal to properties, and on how to modify the translation form of the theory without embracing the disappearance version.

Identity theory implies nomological danglers, due to the irreducibility of defining mental properties.

The identity thesis isn't ontologically simpler than dualism: we still need a dualism of properties, and explanatory danglers. Not much turns on the issue, except in teleological explanation.

Contra Malcolm 1965: explaining brain will explain mind, if the explanation is conjoined with the identity statement. With rejoinder from Malcolm.

Property identity theses fail due to meaning differences, and event identity these fail due to a lack of entailment relations. Rebuts objections from weaker identity criteria and analogies with scientific identification.

76:404-15.

Suggests a theory in which neural states are components of, but not identical to, overall psychological states. This can accommodate raw feels if necessary as a further component, but is mostly materialistic.

3.5c Eliminative Materialism (Rorty, Feyerabend) [see also 1.4d, 1.7c, 2.1c]

Cam, P. 1978. "*Rorty revisited", or "Rorty revised"*. Philosophical Studies 33:377-86.

Doppelt, G. 1977. *Incorrigibility, the mental, and materialism*. Philosophy Research Archives.

Identity theory implies dualism, though its acceptance of mental properties. Instead we should eliminate talk of mental processes altogether, or redefine them in physiological terms.

3.5d Anomalous Monism (Davidson)

--------------------------------

Arguing for anomalous monism: no strict psychophysical laws, no strict
psychological laws, and token identity without type identity. Mental events can still cause, via subsumption under physical laws.

The psychological supervenes on the physical but is not reducible to it, because of the holistic nature of intentional attribution. So building a perfect physical model may not explain psychology.

On the differing constitutive standards of mental and physical concepts. Attribution of mental concepts is holistic, and presupposes a background of rationality, etc. With examples from decision theory.

A collection of papers on action, causation and the philosophy of psychology.

Criticism of Davidson's argument for rational causation. Reasons must cause in virtue of their rational properties. Token identities can't exist, due to normativity. Quinean psychology can't yield rational explanations.

Anomalism is compatible with supervenience, if it is construed as denying psychophysical laws useful for explaining behavior. It is incompatible with token identity, though. With much on the uncodifiability of rationality.

Davidson's argument equivocates on the term "physical": the physical events that mental events cause might not be subsumed under laws.

Anomalous monism implies that mental properties don't cause anything.

If anomalous monism is true, mental events may cause, but their mental properties aren't causally relevant.

Anomalous monism loses out to Australian materialism. It can't be a priori, it leads to exhaustive monism, it doesn't support a new view of free action, and it implies the causal irrelevance of the mental.

Davidson's view leads to epiphenomenalism about content, as it can't support the appropriate counterfactuals. Strong supervenience might be a way out, but that is inconsistent with anomalous monism.

How there can be psychophysical generalizations but no laws -- they might lack modal force. On the relation between psychophysical anomalism and psychological anomalism. Casting Davidson as a Kantian dualist.

Anomalous supervenience is consistent, at the cost of anti-realism about the mental. Supervenience is a constraint on interpretation, but needn't support counterfactuals as different interpretation schemes are possible.

Problems with holism and ceteris paribus laws aren't unique to psychology. One finds the same thing in the physical sciences. So rationality plays no special role, and psychological laws are as reasonable as physical laws.

Anomalous monism is not committed to epiphenomenalism, as even non-strict laws can ground counterfactuals and so support the causal relevance of mental properties.

A functionalist defense against anomalous monism. Psychofunctional laws
and psychological laws, though not psychophysical laws, may exist. Rebutting arguments from rationality, indeterminism, intensionality, etc.

Supervenience is compatible with anomalism: biconditional laws are ruled out by the disjunctive base, and the wideness of mental states rules out one-way psychophysical laws, as there's no single property in the base.

Elucidating Davidson's argument, focusing on the argument against strict psychophysical laws. Generalizations involve disjunctive kinds and so are heteronomic and not law-like.

Argues contra Kim that supervenience is compatible with anomalous monism: the disjunctive generalizations aren't lawlike, as they aren't confirmed by their instances.

Some comments on holism, indeterminacy, anomalism, and materialism.

Response to Honderich 1982: physical events are individuated as mental states by virtue of their causal role, so the mental is causally relevant.

Supervenience entails psychophysical principles, but this is compatible with anomalous monism. On what constitutes a strict psychophysical law.

Various: physics is indeterministic and intensional, animals have beliefs, psychology has derived laws, and decision-theory doesn't need speech.

Rationality constraints don't introduce an irreducibly normative element into intentional attributions. Rationality serves as a condition of adequacy for psychophysical theories, but it doesn't rule them out.

12 essays on Davidson, with replies.

3.6 Mental Causation [see also 2.2c]

Mental causation is incompatible with strong supervenience and causal closure of physics, as we can't distinguish high-level causes from non-causes. So reject the metaphysics and make explanation prior to causation.

Arguing for the causal efficacy and scientific respectability of higher-order states, such as functional-role states. To require appeal to particular physical states is to succumb to a "Tractarian" view of physical primacy.

Rescuing content from epiphenomenalism via functional role argument; but then functional roles aren't really causally efficacious (cf. dormitive virtue), so epi all over again? Roles vs fillers, causation vs explanation.

Mental causation is not a real worry, but the to-do shows that materialist metaphysics has shed little light on it. It needs to be understood at the mental level. With remarks on exclusion arguments and token identity.

How can a relation to a proposition (an abstract object) be causally efficacious? Analogy with numbers doesn't work: weight properties are only pseudo-relational, depending on units, but propositions are absolute.

Argues that anomalism and causal closure don't pose problems for mental causation as they are false, and that functional properties can efficacious. States with content may be efficacious, although content itself may not be.

Argues that mental causation is a deep problem for constitutive (but not identity) forms of physicalism. The only way out is to argue that it is a different variety of causation. But then what motivates physicalism?

Mental events are structuring causes of behavior; biological events are triggering causes, dependent on previous mental structuring. This allows extrinsic properties to play a causal role.

On various problems with mental causation, and the relationship between
psychology and philosophy.

Honderich, T. 1993. The union theory and anti-individualism. In (J. Heil &
A. Mele, eds) _Mental Causation_. Oxford University Press.
The identity theory and psychoneural correlation can't handle mental
causation; only the union theory can. Anti-individualism causes problems,
but should be rejected in any case.

How mental events are causally relevant qua mental: via an account of "qua"
causation in general, using counterfactuals on "pertinently similar worlds".

Perspectives 11:165-84.

_Mental Causation_. Oxford University Press.

A defense of functional role as a causally efficacious property of physical
states. With application to connectionism & eliminativism.

Analysis 50:107-17.

Jackson, F. 1995. Essentialism, mental properties, and causation. Proceedings
of the Aristotelian Society.
How can content properties be causes, given that content is a matter of
functional role and that functional properties are not causes? Defends a
type-identity answer against various objections.

A "state of the art" review paper, concentrating on problems posed by
autonomy, functionalism, and externalism, and advocating a sort of identity
theory. With discussion of a "map-system" view vs. a language of thought.

Kim, J. 1984. Epiphenomenal and supervenient causation. Midwest Studies in
Philosophy 9:257-70. Reprinted in _Supervenience and Mind_ (Cambridge
University Press, 1993).
Psychological causation, like all macrocausation, is supervenient
epiphenomenal causation.

Kim, J. 1992. The nonreductivist's trouble with mental causation. In (J. Heil
& A. Mele, eds) _Mental Causation_. Oxford University Press. Reprinted in
_Supervenience and Mind_ (Cambridge University Press, 1993).
Argues that nonreductive materialism implies downward causation (as the
mental has more causal powers than the physical alone), and that downward
causation violates the causal closure of the physical.

physicalism. In (A. Beckermann, H. Flohr, & J. Kim, eds) _Emergence or
Reduction?: Prospects for Nonreductive Physicalism_. De Gruyter.
Argues that nonreductive materialism is just like 1930s emergentism, with the
mental contributing new causal powers, and so implies downward causation.

Kim, J. 1993. Mental causation in a physical world. In (E. Villanueva, ed)
_Science and Knowledge_. Ridgeview.

Argues that the arguments of Fodor and LePore & Loewer don't succeed in defeating the threat of epiphenomenalism.

On the problems that irreducibility -- multiple realizability, normativity, and non-supervenience -- pose for mental causation. Criticizes Kim's supervenient causation and Fodor's causal powers, and looks to "quasation".

Physical comprehensiveness and mental/physical non-reductionism don't imply mental inefficacy; nor does anomalous monism. Non-physical types can still be causal, though they must be accompanied by physical causation.

On making sense of the causal efficacy of higher-level properties under naturalism. They're relevant at the program level, not quite in the way that basic properties are. With remarks on Macdonald's objections.

On Goldman's (1969) argument that dualism and causal closure are compatible with mental causation. Goldman establishes only hypothetical necessity, not causal necessity.

Intentionality is caused by the physical, and causes. More a 1P emphasis.

Interactionist dualism is out, supervenient causation is in. But there are problems with mental events' causal relevance qua mental, especially for anomalous monism. Cf: a loud shot causes death, but loudness isn't relevant.

On three arguments against mental causation, from strict laws, non-local supervenience, and especially exclusion. Mental properties are stable, recurring high-level patterns with their own causal relevance.

Argues that mental events/properties stand to physical events/properties as determinable to determinates, solving the exclusion problem. Some mental events are *better* candidates for the cause of action than physical events.

Argues that anomalous monism is compatible with mental causation: supervenience is necessary and sufficient for causal efficacy.

3.7 Personal Identity

4.1 Can Machines Think?
-----------------------

4.1a The Turing Test
----------------------

Proposes the Imitation game (Turing test) as a test for intelligence: If a
machine can't be told apart from a human in a conversation over a teletype,
then that's good enough. With responses to various objections.

Alper, G. 1990. A psychoanalyst takes the Turing test. Psychoanalytic Review
77:59-68.

self-knowledge in the cybernetic age. Journal for the Theory of Social
Behavior 17:19-46.

A look-up table could pass the Turing test, and surely isn't intelligent.
The TT errs in testing behavior and not mechanisms. A nice, thorough paper.

Bringsjord, S. 2001. Creativity, the Turing test, and the (better) Lovelace
test. Minds & Machines 11:3-27.

Crockett, L. 1994. _The Turing Test and the Frame Problem: AI's Mistaken
Understanding of Intelligence_. Ablex.

Oxford University Press.

Dennett, D.C. 1984. Can machines think? In (M. Shafto, ed) _How We Know_.
Harper & Row.
Defending the Turing test as a good test for intelligence.

1:29-39.

The Turing Test is too hard, as it requires not intelligence but human
intelligence. Any machine could be unmasked through careful questioning, but
this wouldn't mean that the machine was unintelligent.
Response to Jacquette 1993.

The Turing test is not broad enough: there's much more to thought than the ability to play the imitation game.

On the Total Turing Test (full behavioral equivalence) as a test for mind.

A dialogue on the Turing test.

Defending the Turing test against French 1990. Turing did not intend the test to provide a *necessary* condition for intelligence.

Turing's test is neutral about the structure of the machine that passes it, but it must be practical and reliable (thus excluding Searle's and Block's counterexamples).

The basis of the Turing test is not an operational definition of thinking, but rather an inference to the best explanation.

   Reply to Stalker 1978: Mechanistic and mentalistic explanations are no more incompatible than program-based and physical explanations.

   Some obscure remarks on lying, imitation, and the Turing test.

   A weak argument against Block: input/output function doesn't guarantee a capacity to respond sensibly.

   The Turing test presupposes a representational/computational framework for cognition. Not all phenomena can be captured in teletype communication.

   Contra Moor 1976: The best explanation of computer behavior is mechanistic, not mentalistic.

functions. Minds & Machines 11:53-76.

4.1b Godelian arguments (Lucas, Penrose)
----------------------------------------

Discusses and sharpens Lucas's arguments. Argues that the real consequence
is that if we are Turing machines, we can't know which.

Bowie, G. 1982. Lucas' number is finally up. Journal of Philosophy Logic,
11:279-85.
Lucas's very Godelization procedure makes him inconsistent, unless he has an
independent way to see if any TM is consistent, which he doesn't.

Quarterly 33:147-59.
Remarks on the various ways in which Lucas and a machine might be said to
"prove" anything, and the ways in which a machine might simulate Lucas.
The argument has all sorts of level confusions, and a bit of circularity.

Chari, C. 1963. Further comments on minds, machines and Godel. Philosophy
38:175-8.
Can't reduce the lawless creative process to computation.

Chihara, C. 1972. On alleged refutations of mechanism using Godel's
An analysis of the Lucas/Benacerraf argument. On various senses in which a
machine might come to know its own program.

Only mathematicians understand Godel, so Lucas's argument isn't general; and
Turing machines can go wrong. Weak.

Dennett, D.C. 1978. The abilities of men and machines. In _Brainstorms_. MIT
Press.
There is no unique TM which we are -- there could be many.

Edis, T. 1998. How Godel's theorem supports the possibility of machine
intelligence. Minds and Machines 8:251-262.

Lucas's argument applies only to deductive machines, not inductive ones.

George, A. & Velleman, D.J. 2000. Leveling the playing field between mind and

of Science 18:145-6.
Even humans can't Godelize forever. On ordinals and transfinite counting.

Good, I.J. 1969. Godel's theorem is a red herring. British Journal for the
Philosophy of Science 19:357-8.
Rejoinder to Lucas 1967: the role of consistency; non-constructible ordinals.

An analysis of Benacerraf 1967. Benacerraf's "paradox" is illusory; there are no strong consequences of Godel's theorem for mechanism.

Contra Lucas: we can't Godelize forever; and we're not formal on top level.

Hutton, A. 1976. This Godel is killing me. Philosophia 3:135-44.
Gives a statistical argument to the effect that we cannot know that we are consistent; so the Lucas argument cannot go through.

Contra Lewis 1979, Lucas can derive the consistency of M even without the premise that he is M. Hmm.

A nice analysis of Lucas's argument and the circumstances under which a machine might prove another's Godel sentences. There's no reason to believe that machines and humans are different here.

A machine will fail a Turing test if it's asked about Godel sentences.

Lucas's argument fails, as theorems by humans don't correspond to outputs of their formal systems.

Lucas needs a rule of inference from sentences to their consistency, yielding Lucas arithmetic. No machine can prove all of Lucas arithmetic, but there's no reason to suppose humans can either, as the rule is infinitary.

Reply to Lucas 1970: the dialectical argument fails, as the human's output depends on the premise that it is the machine (to derive M's consistency). With a similar premise, the machine itself can do equally well.

Humans can Godelize any given machine, so we're not a machine.

Reply to Good 1967: a human can trump any given machine, so the human is not the machine, whether or not the human is superior across the board.

Benacerraf 1967 is empty and omega-inconsistent. Reply to arguments based on difficulty of seeing consistency (e.g. Putnam). Fallacious but engaging.

Response to Lewis 1969 and Coder 1969. Lewis misses the dialectical nature of the argument.

Contra Hutton, we know -- even if fallibly -- that we are consistent.

Reply to Lewis 1979.

Addresses all the counterarguments. Fun.

Martin, J. & Engleman, K. 1990. The mind's I has two eyes. Philosophy 510-16.
Contra Hofstadter: Lucas can believe his Whitley sentence.

Maudlin, T. 1996. Between the motion and the act... Psyche 2:40-51.

We are non-algorithmic as we can see Godel sentences of any algorithm.

Much debate over the "non-algorithmic insight" in seeing Godel sentences.

An argument from the halting problem to the nonalgorithmicity of mathematical thought. Addresses objections: that the algorithm is unknowable, unsound, everchanging, environmental, or random. New physical laws may be involved.

A reply to Chalmers, Feferman, Maudlin, McDermott, etc.

A generalized Godelian argument: if our prescriptive inductive competence is formalizable, then we could not know that such a formalization is correct.

Penrose's argument depends on our knowledge of the validity of the algorithm we use, and here he equivocates between conscious and unconscious algorithms.

   General analysis; Lucas commits type/token error; self-ref paradoxes.

   Cogito was a diagonal argument; connection to Godel, Lucas, Minsky, Nagel.

   A machine could escape the Godelian argument by inductively ascertaining its own syntax. With comments on the relevance of ingenuity.

   Weak defense of Lucas; response to Putnam, Bowie, Dennett.

   Humans get trapped too: "Lucas cannot consistently assert this formula".

4.1c The Chinese Room (Searle)
-----------------------------

   Implementing a program is not sufficient for mentality, as someone could e.g. implement a "Chinese-speaking" program without understanding Chinese. So strong AI is false, and no program is sufficient for consciousness.

   Axiomatizes the argument: Syntax isn't sufficient for semantics, programs are syntactic, minds are semantic, so no program is sufficient for mind.

   More on the arguments against AI, e.g. the Chinese room and considerations about syntax and semantics. Mind is a high-level physical property of brain.

   On the status of the Chinese Room argument, ten years on.

   A procedural account of how computers might have understanding and semantics.
A fully functional Chinese room is impossible, as it (for instance) could not say what the time is.

A chess-playing machine embodied as a robot could have intentional states. Reference requires input/output, computation, and context.

Criticizes Searle's "conclusion" that brains are needed for intentionality, notes that even a homunculus has intentional states. A misinterpretation.

Arguing against Searle on a number of fronts, somewhat unconvincingly.

Gives an account of symbolic vs. subsymbolic computation, and argues that the latter is less vulnerable to the Chinese-room intuition, as representations there are not computational tokens.

Artificial mentality is possible, not through classical AI but through brain-like AI. Argues the syntax/semantics point using an analogy with electromagnetism and luminance.

Lots of thought experiments like Searle's, against Searle. Searle's argument is like Leibniz's "mill" argument, with similar level confusions. Nice but patchy.

In the Chinese room, neither the person nor the system understands: a virtual person does. This person isn't the system, just as a normal person isn't a body. Follows from the "Kornese" room, which has two distinct understanders.

Advocates the systems reply, and criticizes Searle's "Chinese Gym" response to connectionism: Searle (like those he accuses) confuses a simulation with the thing being simulated. Nice.

Argues with Searle on many points. A little weak.

The homunculus doesn't have access to the system's intentionality. The
syntax/semantics relation is like the neurophysiology/mind relation.

   Reply to Searle/Harnad: systems reply, level confusions, etc.

   Reply to Harnad 1990: symbols, other minds, physically embodied algorithms.

   Double's argument implies that the brain isn't the basis of intentionality.

   The Chinese room isn't even implementing a Turing machine, because it doesn't use proximal causation. With a reply by Searle.

   Argues that Searle is confused, and underestimates computers. Weak.

   Non-symbolic function is necessary for mentality. Trying hard to work out a theory of why the Chinese Room shows what it does. Nice but wrong.

   Reply to Dyer 1990: on the differences between real and as-if intentionality.

   A discussion about the Chinese room, symbol grounding, and so on.

   Searle is committing a level confusion, and understates the complexity of the case. We can move from the CR to a brain (with a demon) by twiddling knobs, and the systems reply should work equally well in both cases.

   Searle's view implies that intentional causation is not efficient causation.

   If we had microfunctional correspondence, the CR argument would fail. With points about the status of abstract/biological intentionality. A bit weak.

Jacquette misses the point of the argument. Also, biological and abstract intentionality are quite compatible.

Reply to Searle on CR, central control, biological intentionality & dualism.

Against Rapaport's Korean Room argument -- syntax isn't enough.

The Chinese room doesn't succeed as an argument about semantics. At best it might succeed as an argument about consciousness.

Defends Searle against all kinds of objections.

Computational systems must also meet performance criteria.

A program can possess intentionality, even if not consciousness.

Comments on Cole, and some general material on syntax and semantics.

Rey, G. 1986. What's really going on in Searle's 'Chinese Room'.
Philosophical Studies 50:169-85.
Recommends the systems reply, and a causal account of semantics. Discusses the relevance of wide and narrow notions of content, and the tension between Searle's positive and negative proposals.

In arguing against the relevance of the serial/parallel distinction to mental states, Searle becomes a formalist. A nice point.

Searle's presence in the room destroys the integrity of the system, so that it is no longer a proper implementation of the program.

A person running the program, with interpretations at hand, would understand. Point-missing.
Argues against Searle, but misses the point for the most part.

Slovan, A. 1986. Did Searle attack Strong Strong AI or Weak Strong AI? In (Cohn & Thomas, eds) _Artificial Intelligence and its Applications_. Chichester.

Story about homunculi within homunculi. Fun.

Get semantics computationally via induction and functional roles.

Searle-in-the-room isn't in a position to know about the system's first-person states. Intrinsic intentionality is an incoherent notion.

Defending Searle's position, with remarks on the "causal powers" argument.

4.1d Machine Consciousness, Misc [see also 1.8b]
-------------------

Response to Maudlin 1989. True computation needs active, not passive causation, so Maudlin's machine isn't really computing.

Dennett, D.C. 1994. The practical requirements for making a conscious robot.
Philosophical Transactions of the Royal Society A 349:133-46.

One could model brain states with monadic states and appropriate connections.

But surely that's not intelligent -- the causation has the wrong form. Nice.

Computational state is not sufficient for consciousness, as it can be instantiated by a mostly inert object. A nice thought-experiment, raising questions about the relevance of counterfactuals to consciousness.

Of course, as we are machines. But what *sort* of machines are conscious, and in virtue of what properties? Remarks on artefacts, life, functionalism, and computationalism. So far, we don't know what makes the brain conscious.

Machines can think but can't feel, so aren't persons.

Various arguments and counter-arguments re machine consciousness and civil liberties. Problems of machine consciousness are analogous to problems of human consciousness. The structural basis of the two may well be the same.

More on TMs: explaining their psychology via preference functions.

To speak of a conscious machine is to commit a semantic mistake. 
Consciousness presupposes life and non-mechanism. Later retracted.

Arguments that AI systems like Pollock's Oscar needn't be conscious. Blindsight 
tells us that complex perceptual processing can go on unconsciously.

Thompson, D. 1965. Can a machine be conscious? British Journal for the 
Philosophy of Science 16:36.
Accepting machine consciousness would have few philosophical consequences, 
whereas rejecting it would tend to commit one to epiphenomenalism.

van de Vete, D. 1971. The problem of robot consciousness. Philosophy and 

Of course robots can't think: they're not alive, so this gives us good reason 
not to rely on behavior. With replies by J.J.C. Smart, N. Smart.

4.1e Machine Thought, Misc
-------------------------------

Bringsjord, S. 1998. Cognition is not computation: The argument from 
irreversibility. Synthese.

Arguing that a finite deterministic automaton can perform all natural human 
functions. With remarks on the logical organization of computers.

Subservience to known or knowable rules is incompatible with mentality.

Copeland, B. J. 2000. Narrow versus wide mechanism: Including a re-examination 

Defends the Turing Test, among other things.

Dretske, F. 1985. Machines and the mental. Proceedings and Addresses of the 

Dretske, F. 1993. Can intelligence be artificial? Philosophical Studies 
71:201-16.
Intelligence requires not just action or thought, but the governance of 
action by thought, which requires a history. "Wired-up" systems lack the 
explanatory connection between thought and action, so are not intelligent.

Computers follow rules, people don't.

Hauser, L. 1993. Why isn't my pocket calculator a thinking thing? Minds and 
Machines 3:3-10.

Henley, T.B. 1990. Natural problems and artificial intelligence. Behavior and 
Philosophy 18:43-55.
On the philosophical importance of criteria for intelligence. With remarks 
on Searle, the Turing test, attitudes to AI, and ethical considerations.

and Machines 7:269-87.

   An expert system would lack Holmes' ability to raise the right questions, sort out relevant data, and determine what data are in need of explanation.

   Lucas, Searle, and Penrose all fall prey to "dual-description" fallacies.

   A machine could possess every characteristic of human thought: e.g. freedom, creativity, learning, understanding, perceiving, feeling.

4.2 Computation and Representation
----------------------------------

4.2a Symbols and Symbol Systems [see also 2.1a, 4.3e]
-----------------------------------------------

   AI symbols are empty and meaningless. They need to be "grounded" in something, e.g. sensory projection. Maybe connectionism can do the trick?

   On the limitations of symbol systems, and the potential for grounding symbols in sensory icons and categorical perception, e.g. with neural networks.

On computer science, AI, & the Physical Symbol System Hypothesis.

4.2b Computational Semantics
-----------------------------

Against procedural semantics; it's a rerun of verificationism.

On the virtues of denotational semantics for AI. Notation without denotation, as found in many AI systems, leads to castles in the air.

Criticism of McDermott's views on semantics, logic and natural language.

Woods, W. 1981. Procedural semantics as a theory of meaning. In (A. Joshi,
4.2c Implicit/Explicit Rules and Representations

Argues that we need explicit rules for flexibility, adaptability, and representational redescription. With remarks on eliminativism.

On various kinds of representation of knowledge or belief without explicit tokens: control-implicit, domain-implicit, and procedural information.
The key distinction is representation vs. execution of a rule.

Hadley, R.F. 1990. Connectionism, rule-following, and symbolic manipulation. Proc AAAI.
Some rules are learnt so quickly that representation must be explicit.

Kirsh, D. 1990. When is information explicitly represented? In (P. Hanson, ed) _Information, Language and Cognition_. University of British Columbia Press.

Cummins' account of inexplicit information fails, as even "executed" rules must be represented in the system. With remarks on the Chinese room.

4.2d AI without Representation?

We don't need explicit representation; the world can do the job instead.
Use embodied, complete systems, starting simple and working incrementally.

A discussion of anti-representationalism in situated robotics and the dynamic systems movement (Brooks, Beer, van Gelder). These arguments appeal to overly simple domains, and a modest notion of representation survives.

   Argues for a dynamic-systems conception of the mind that is non-computational
   and non-representational. Uses an analogy with the Watt steam governor to
   argue for a new kind of dynamic explanation.

4.2e Miscellaneous
------------------

   On the problems with context-free symbolic representation.

   On Searle's critique of computational explanation, contrasted with
   Gallistel's use thereof. The real issue is computation on indirect vs.
   direct representations; direct computationalism is an attractive view.

4.3 Philosophy of Connectionism
-------------------------------

4.3a Connectionism and Compositionality (Fodor/Pylyshyn)
--------------------------------------------------------

   Connectionist models can't explain cognitive systematicity and productivity,
   as their representations lack compositional structure. The allures of
   connectionism are illusory; it's best used as an implementation strategy.

   Fodor and Pylyshyn's argument is an invalid instance of inference to the best
   explanation, as there is much to explain than systematicity. Connectionism
   and classicism may be compatible even without implementation, in any case.

Connectionism can make do with unstructured representations, as long have they have the right causal relations between them.

Contra Chalmers 1993, F&P's argument doesn't apply at the implementational level. Contra Chater and Oaksford 1990, connectionism can't be purely implementational, but some implementational details can be relevant.

Argues against Clark on holism and the conceptual truth of systematicity.

An experimental demonstration that connectionist models can handle structure-sensitive operations in a non-classical way, transforming structured representations of active sentences to passive sentences.

Points out a structural flaw in F&P's argument, and traces the problem to a lack of appreciation of distributed representation. With some empirical results on structure sensitive processing, and some remarks on explanation.

Implementation can make a difference at the algorithmic level.

Smolensky's weak compositionality is useless; and tensor product architecture can't support systematicity, as nonexistent tokens can't play a causal role.

Argues that existing connectionist models do not achieve an adequate systematicity in learning; they fail to generalize to handle structures with novel constituents.

Localist connectionist models may not be able to handle structured presentation, but appropriate distributed models can.

A discussion of how connectionism might achieve "effective syntax" without implementing a classical system.

F&P deal a sucker bet: on their terms, connectionism could never give a non-implementational explanation of systematicity, as the notions are construed in a manner specific to classical architectures.

Against responses to Fodor and Pylyshyn claiming that cognitive theories needn’t explain systematicity. Contra Clark, the conceptual truth of systematicity won't help. Contra others, nor will evolution.

Arguments that no connectionist model so far has come close to explaining systematicity. Considers the models of Elman, Chalmers, and Smolensky.

Develops a connectionist architecture -- recursive auto-associative memory -- that can recursively represent compositional structures in distributed form.

F&P's argument confuses constituent structure with logical/sentential structure. Connectionism is a psychotechtonic project, whereas propositional description is a psychosemantic project.

F&P ignore distributed representation and interaction effects.

Develops a connectionist architecture that represents compositional structures as tensor products of distributed representations.

Connectionism can do compositionality its own way, including both weak compositionality (with context effects) or strong compositionality (via tensor products).

Connectionism can do compositionality functionally. All one needs is the right functional relation between representations; physical concatenation is not necessary.

On connectionism as a Kuhnian paradigm shift in cognitive science, with emphasis on the implications of functional compositionality and distributed representations.

4.3b Representation in Connectionism
------------------------------------

On some troubles connectionism has with higher-order knowledge. Contrasts Cussins, Karmiloff-Smith on development. Subsymbols without symbols are blind.

On the importance of representational redescription, and on the limits of connectionist networks in cross-domain knowledge transfer. What does a true believer need, above behavior: conceptual combination, real-world fluency?

Connectionism isn't really radical. There's no new concept of representation
or of learning, and cognition can still be the manipulation of semantically structured representations.

Connectionism builds up concepts from the nonconceptual level. From nonconceptual content (e.g. perceptual experiences) to the emergence of objectivity.

On correlational semantics and context-dependent representations.

Some remarks on psychology & physiology. Even connectionism uses psychological concepts.

Argues that talk of representations has no explanatory role in connectionist theory, and can be discarded. It can't be understood along the lines of the teleo-informational or classical frameworks.

Pictorialism isn't compatible with language of thought, but connectionism might be.

Argues that distributed representation is best analyzed in terms of superposition of representation, not in terms of extendedness.

4.3c Connectionism and Eliminativism

------------------------------------

Connectionism implies eliminativism, as connectionist systems do not have functionally discrete contentful states, and folk psychology is committed to functional discreteness of propositional attitudes.

Outlines the semantic view of scientific theories, and applies it to the connectionism/eliminativism debate. There's no reason why folk psychology shouldn't be reducible, in a homogeneous or heterogeneous way.

Distinguishes active from dispositional beliefs: the former are realized discretely in activation patterns, the latter nondiscretely in weights, which is all that folk psychology needs.

Commentary on Ramsey/Stich/Garon. Connectionism has symbols that interact, and has propositional modularity in processing if not in storage.

Connectionism needn't imply eliminativism, as higher levels may have a causal role, if not causal completeness. Also, it may not tell the whole story.

Responding to eliminativist challenge via cluster analysis and recurrence.

Argues that our conception of thought requires causal systematicity, which requires a language of thought. Connectionist systems are not causally systematic, so connectionism leads to eliminativism.

Contra Ramsey, Stich, and Garon, connectionist representations can be seen to be functionally discrete on an appropriate analysis of causal relevance.

A dispositional construal of beliefs and desires can distinguish the relevant active states (via counterfactuals) and is compatible with FP, so internals can't threaten FP. With remarks on Davidson, overdetermination, etc.

Upon examination, the model of Forster and Saïdelf 1994 does not exhibit features that are both distributed and causally discrete.

4.3d The Connectionist/Classical Debate
---------------------------------------

The distinction between programming languages and networks is neutral on rule-following, etc, so there's nothing really new about connectionism.

A detailed analysis purporting to show that connectionism and "logicism" are compatible, as Turing machines can do everything a neural network can. Entertaining, but misunderstands subsymbolic processing.

Distributed models are at the implementational, not computational, level.

Connectionism won't affect AI too much, as AI is concerned with the information-processing (task) level. With greater modularity, connectionism will look more like traditional AI.

Drawing the battle-lines: High Church Computationalism at the "East Pole", New Connectionism, Zen Holism, etc, at various locations on the "West Coast". With remarks on connectionism, and on AI as thought-experimentation.

Reitering the value of connectionism, especially biological plausibility.

4.3e Subsymbolic Computation (Smolensky)

Smolensky offers a complete account at the subsymbolic level, rather than an approximate account at the symbolic level.

Explicates the distinction between symbolic and subsymbolic computation, and argues that connectionism can better handle the emergence of semantics from syntax, due to the non-atomic nature of its representations.

AI needs statistical emergence. For real semantics, symbols must be decomposable, complex, autonomous -- i.e. active.

Argues with Smolensky: symbolic systems such as decision trees have all the positive features of neural networks (flexibility, lack of brittleness), and can represent concepts as sets of subconcepts. With a reply by Clark.

Rejects Smolensky's PTC, as the proper interaction of the microscopic and macroscopic levels would take a "miracle".

On connectionist networks as subsymbolic dynamic systems.

4.3f Philosophy of Connectionism, Misc.

---------------------------------------

On the relationship between connectionism, symbol processing, psychology and neuroscience.

Lots of questions about connectionism.

There's room for both styles within a single mind. The rule-based level needn't be autonomous; the connectionist level plays a role in pattern recognition, concepts, and so on.

An account of the shift from propositions to pattern recognition in the study of cognition: knowing-how, imagery, categorization, connectionism.

Argues that connectionism allows for a more plausible epistemology of perception, compatible with direct realism rather than representationalism. With remarks on Fodor and Pylyshyn's argument against Gibson.

Connectionism will revolutionize our review of scientific theories: From the deductive-nomological view to descent in weight-space. Some cute analogies.

We achieve explanatory understanding not through the manipulation of propositions but through the activation of prototypes.

Implications of connectionism and neuroscience for our concept of mind.

All kinds of stuff on connectionism and philosophy.

Connectionism separates processing from competence. Instead of hopping down Marr's levels (theory->process), connectionism goes (1) task (2) low-level performance (3) extract theory from process. Cute.

On computation and representation in AI and connectionism, and on problems for radical connectionism in reconciling these without denying representation or embracing mystery.

Explicates computationalism, and discusses ways in which connectionism might end up non-computational: if causal states cross-classify representational states, or if transitions between representations aren't computable.

Argues that connectionist networks don't have tacit knowledge of modular theories (as representations lack the appropriate structure, etc.).

4.3g Foundational Empirical Issues
----------------------------------

On how to get connectionist networks to learn about structured task domains.
Concentrates on incremental learning, and other developmental/scaffolding strategies. With remarks on systematicity.

Criticizes connectionism for not being sufficiently rooted in neuroscience, and for not being grounded in the world.

What's new to connectionism is not learning or representation but the way that learning and representation interact.

Addresses behaviorist/associationist charges. Connectionism needs recurrent circuits to support active symbols.

On the importance of variable binding, and why it's hard with connectionism.

Criticism of connectionist language models. They build in too much.

On the relationship between ND, PDP and AI. All are computational.

Connectionism is better at explaining empirical findings about mind.

Extremely thorough criticism of the R&M past-tense-learning model, with arguments on why connectionism can't handle linguistic rules.

4.4 Dynamical Systems
---------------------

Eliasmith, C. 1996. The third contender: A critical examination of the

Eliasmith, C. 1997. Computation and dynamical models of mind. Minds and
Machines 7:531-41.

Foss, J.E. 1992. Introduction to the epistemology of the brain: Indeterminacy,
micro-specificity, chaos, and openness. Topoi 11:45-57.
On the brain as a vector-processing system, and the problems raised by
indeterminacy, chaos, and so on. With morals for cognitive science.

and Behavior 18:291-304.

alternative to a symbolic mind. Philosophical Psychology 9:301-22.

Philosophical Psychology 11:303-315.

eds) _Mind as Motion_. MIT Press.

University Press.

Cognitive Neuroscience 4:299-310.

content and the metaphysics of organizational properties in nonlinear dynamic

11:27-43.

Synthese 101:305-45.

agents and as coupled dynamical systems: A criticism. Philosophical Psychology
9:323-46.

Sloman, A. 1993. The mind as a control system. In (C. Hookway & D. Peterson,

van Gelder, T. & Port, R. 1995. _Mind as Motion: Explorations in the Dynamics
of Cognition_. MIT Press.

van Gelder, T. 1995. What might cognition be if not computation? Journal of
Philosophy 92:345-81.
Argues for a dynamic-systems conception of the mind that is non-computational
and non-representational. Uses an analogy with the Watt steam governor to
argue for a new kind of dynamic explanation.

(M. Carrier & P. Machamer, eds) _Mindscapes: Philosophy, Science, and the
Mind_. Pittsburgh University Press.

4.5 Foundational Questions in AI
---------------------------------

4.5a The Nature of AI
---------------------

AI as detailed armchair psychology and as thought-experimental epistemology.
Implications for mind: e.g. a solution to the problem of homuncular regress.

No, AI is an a priori science that uses empirical methods; its status is similar to that of mathematics.

On the status of "medium AI", the study of intelligence in computational systems (not just humans). Contra to many, this is not an empirical science, but a combination of (experimental) mathematics and engineering.

4.5b Levels of Analysis (Marr, etc)
----------------------------------

Outlines a theory of the equivalence of algorithms.

Generalizes Marr's levels to: cognitive state-transitions, mathematical state-transitions, implementation. Discusses these with respect to connectionism, dynamical systems, and computation below the cognitive level.

On levels of organization vs. levels of analysis.

Defines computational, algorithmic and implementational levels.
On different kinds of level-shifts: organizational and contextual changes. There are more than three levels available.

With commentaries by Smith, Dennett.

Psychological explanation is typically somewhere *between* the computational and algorithmic levels.

4.5c The Frame Problem
-----------------------

General overview.

FP is an artifact of computational explicitness. Contrast human commonsense know-how, with relevance built in. Comparison to expert/novice distinction.

FP is Hamlet's problem: when to stop thinking. It's equivalent to the general problem of non-demonstrative inference.

The FP may be a consequence of the explicit/implicit rep distinction. Use "complicit" reps instead, and changes will be carried along intrinsically.

FP is a relatively narrow problem, Some, e.g. Fodor, wrongly equate FP with the "Generalized AI Problem".

Criticizes Dennett's, Haugeland's and Fodor's construals of the FP.

McDermott, D. 1987. We've been framed: Or, Why AI is innocent of the frame problem. In (Z. Pylyshyn, ed) _The Robot's Dilemma_. Ablex.

Lots of papers on the frame problem.

4.5d AI Methodology

AI must integrate perception and cognition in the interest of flexible representation. Current models ignore perception and the development of representation, but this cannot be separated from later cognitive processes.

AI should look at biology.

Micro-worlds don't test true understanding, and frames and scripts are doomed to leave out too much. Explicit representation can't capture intelligence.

History of AI (boo) and connectionism (qualified hooray). And Husserl/Heidegger/Wittgenstein. Quite nice.

Various AI approaches to belief: syntactic, propositional/meaning-based, information, tractability, discoverability, and degree of confidence.

Identifying the dividing lines: pre-eminence of knowledge, embodiment, language-like kinematics, role of learning, uniformity of architecture.

AI usually comes up with Type 2 (algorithmic) theories, when Type 1 (info processing) theories might be more useful -- at least if they exist.

Problems in AI methodology: wishful mnemonics, oversimplifying natural language concepts, and never implementing programs. Entertaining.

Criticism of logicism (i.e. reliance on deduction) in AI.

Lots of papers on various aspects of AI methodology. Quite thorough.

On the non-represented background to everyday activity, and environmental interaction in cognition. Criticizes cognitivism, connectionism, looks at Agre/Chapman/Brooks, ethology, anthropology for support.

10 papers on philosophy of AI, psychology and knowledge representation.

Defending limited rationalism: i.e. a theory of intelligence below the conceptual level but above the neuronal level.

4.6 Computationalism in Cognitive Science [see also 2.2e]

Overview of computationalism. Relationship to intentionality, LOT, etc.

Argues for theses of computational sufficiency and computational explanation, resting on the fact that computation provides an abstract specification of causal organization. With replies to many anti-computationalist worries.

On analog/digital, representational/nonrepresentational, direct/indirect.

What computationalism is, as opposed to computerism & cognitivism. Implies: intentionality isn't special, and we don't make decisions. With commentary.

Argues that computational explanation requires the attribution of semantic content. Addresses Stich's arguments against content, and argues that computers are not formal symbol manipulators.

Machines can't even add, let alone think, as the symbols they use aren't meaningful to them. They would need real information based on perceptual embodiment, and conceptual capacities, for meaning to play a real role.

Computationalism is false, as it can't distinguish the ability to solve a maze for the ability to solve it's mirror image. An embodied computational taxonomy is needed, rather than software alone.

Mellor, D.H. 1989. How much of the mind is a computer. In (P. Slezak, ed)

Argues contra Pylyshyn 1984 that finite state automata are good models for
cognitive science: they are semantically interpretable and process symbols.

Pylyshyn, Z.W. 1980. Computation and cognition: Issues in the foundation of

A thorough account of the symbolic/computational view of cognition.

Behavioral and Brain Sciences 1:98-128.

An overview of the computational view of mind. On symbols, levels, control
structures, levels of correspondence for computational models, and empirical
methods for determining degrees of equivalence.

Sterelny, K. 1989. Computational functional psychology: problems and
Various points on pros and cons of computational psychology.

Dialectica 50:37-52.

4.7 Computation and Physical Systems
-------------------------------------

4:391-402.
Gives an account of what it is for a physical system to implement a
computation: the causal structure of the system must mirror the formal
structure of the computation. Answers objections by Searle and others.

Chalmers, D.J. 1996. Does a rock implement every finite-state automaton?
Argues that Putnam's "proof" that every ordinary open system implements
every finite automaton is fallacious. It can be patched up, but an
appropriate account of implementation resists these difficulties.

and Machines 4:403-20.

3:283-312.
Many physically realized functions can't be computeted by Turing machines:
e.g. "mundane procedures" and continuous functions. So the C-T thesis is
false of these, and maybe even of number-theoretic functions.

Cleland, C.E. 1995. Effective procedures and computable functions. Minds and
Machines 5:9-23.

Adapts Goodman's notational systems to explicate computational information processing. What is/isn't a physical notational system (e.g. LOT, symbol systems, connectionism) and why. How to reconcile notational/mental content?

Pragmatic factors are vital in connecting the theory of computation with empirical theory, and particularly in determining whether a given system counts as performing a given computation.

Syntax isn't intrinsic to physics, so computational ascriptions are assigned by observer. Syntax has no causal powers. Brain doesn't process information.

Disputes Kripke's argument that there is no objective way of determining when a system computes a given function, due to infinite domains and unreliability. Stipulating normal background conditions is sufficient.

4.8 Philosophy of AI, Misc
--------------------------

12 papers on the foundations of AI and cognitive science.

Thagard 1986 is wrong: speed and the like make no fundamental difference.
With Thagard's reply: it makes a difference in practice, if not in principle.

A nice paper on the relationship between techniques of theory formation from machine learning and philosophical problems of induction and knowledge.

All about how the computer should change the way we think about the mind.

Parallelism does make a difference. Some somewhat anti-functionalist points.

A comparison of philosophical and AI approaches to explanation: deductive, statistical, schematic, analogical, causal, and linguistic.

---

5.3a Psychological Laws [13]
5.1 Issues in Cognitive Science
---------------------------------

5.1a Nativism (Chomsky, etc)
-----------------------------

Concepts are undefinable, so primitive, so innate (plus gloss).

Overview; poverty of stimulus, unobservable features => rationalism.

An excellent collection of papers & responses by Piaget, Chomsky and others.

Why learning is selective and not instructive. Biological analogies, linguistic evidence. Dispense with "learning" as a scientific term.

Contra nativism: disputes (1) surprising universals (2) explanation of universals (3) ease of learning (4) relevance of IQ-independence.

Identifies minimal nativism vs anti-empiricism vs rationalism. Considers the relevance of connectionist networks. Some nativist arguments may survive.

Concepts can be acquired without being learned by symbol-manipulation.

Explain universals via Popper/Simon empirical model.

Can take middle ground. Anti-empiricism doesn't imply rationalism.

5.1b Modularity (Fodor, etc)
---------------

Against Fodor: modules are smaller, interact strongly, not domain-specific.

Remarks on Shanon and Fodor.

Overview of the original studies on top-down effects in perception.

Churchland, P.M. 1979. _Scientific Realism and the Plasticity of Mind_. Cambridge University Press.

Our perception is deeply theory-laden, and potentially very plastic.

Contra Fodor 1984: observation is theory-laden (built-in or not); supported by neurophysiological evidence; perceptual systems have long-term plasticity.

Perception happens in informationally encapsulated, domain-specific modules. Central systems aren't encapsulated, and so may be impossible to understand.

Summary of MOM (with commentary and reply in the BBS printing).

Fodor, J.A. 1986. The modularity of mind. In (Z. Pylyshyn, ed) _Meaning and
Cognitive Structure_. Ablex.
Informal discussion of modularity. With commentaries by Fahlman, Caplan.

Argues for an observation/theory distinction, and against belief affecting perception.

Churchland is up the creek without a paddle.

A collection of papers on modularity in language and vision.

Fodor's arguments for unencapsulated central systems are no good; AI is possible after all.

Criticism of Fodor. Modularity is dynamic, and can be central.

'Direct perception' can't correspond to anything. Perception is inferential.

5.1c Mental Imagery [see also 6.2j]
-------------------
Psychological Review 85.

Schwartz, R. 1980. Imagery: There is more to it than meets the eye. Philosophy of Science Association 1980.

Tye, M. 1991. _The Imagery Debate_. MIT Press,

5.1d Rationality

----------------

Rust, J. 1990. Delusions, irrationality, and cognitive science. Philosophical
Psychology.

5.1e Embodiment [see also 2.2]
---------------

On the importance of embodiment of systems in cognition.

Advocates a sort of "active externalism", based on the role of the environment in actively driving cognition. Beliefs can extend into an agent's immediate environment (e.g. a notebook) in this way.

   Argues that the mind is not just embedded but intimately intermingled with the world.  With some systems-theoretic arguments arguing against a determinate interface.  Mind is not an inner realm.

   Argues against the contemporary "Cartesian" view of mind as an ontologically homogeneous inner representational realm that causes behavior, arguing for a holistic embodied view instead.  Mind is therefore safe from elimination.

Wilkerson, W.S. 1999.  From bodily motions to bodily intentions: the perception of bodily activity.  Philosophical Psychology 12:61-77.

5.1f Animal Cognition [see also 6.4c, 6.4d]
---------------------

Savage-Rumbaugh, S. & Brakke, K.E. 1996. Animal language: Methodological and

5.2 Aspects of Mind
-------------------

5.2a Pain and Pleasure
----------------------

Goldstein, I. 1999. Intersubjective properties by which we specify pain, pleasure, and other kinds of mental states. Philosophy.

5.2b Emotions
--------------

5.2c Dreams [see also 6.21]  

5.2d Memory [see also 2.2f, 3.7]  

5.2e Color [see also 1.3a, 1.7a, 1.7d]

----------

Philosophical Studies 93:21-44.

Watkins, M. 1999. Do animals see colors? An anthropocentrist's guide to animals, the color blind, and far away places. Philosophical Studies 94:189-209.

5.3 Philosophy of Psychology, General

5.3a Psychological Laws [see also 3.5d]

Fodor, J.A. 1991. You can fool some of the people all of the time, everything else being equal: Hedged laws and psychological explanation. Mind 100:19-34.

Ceteris paribus means that every realizing state has completing conditions. Even absolute exceptions are OK, as long as they're not across-the-board.

Non-strict psychological laws are compatible with the (nomologically sufficient) causal responsibility of mental properties. So there's no need for epiphobia. With comments on the relation between laws and mechanisms.

There are no ceteris paribus laws, as there's no satisfactory way to cash the "unless" cause. But psychology doesn't need laws, anyway.

5.3b Psychology and Neuroscience [see also 6.1i]

Arguing for the notion of functional architecture as a bridge whereby neural components can be components of cognitive processes.

Argues that we can understand the brain under the hypothesis that it is optimized to "save wire", due to bounded resources: organization predicts placement. With remarks on the relation between cognitive and neural levels.

Some cute examples of neurophysiological reductions using state-spaces.

Churchland, P.M. 1995. _The Engine of Reason, the Seat of the Soul: A Philosophical Journey into the Brain_. MIT Press.

The brain can tell us a lot about the mind. With examples.

All about neuroscience, philosophy and prospects for their interaction.

About how neuroscience and connectionism affect our conception of mind.

On paradigm shifts, biology, evolution, connectionism, etc.

The relationship between psychology and neuroscience is best characterized not by reduction but by explanatory extension, where each field is enriched by the other. With a number of examples from recent empirical work.

Wittgenstein wouldn't have liked the Churchlands, as neuro might be chaos, and too much neuro might undermine our self-conception nihilistically.

Incommensurable theories don't necessarily require elimination, if their relationship is synchronic/interlevel, rather than diachronic/intralevel.

Argues contra Fodor and Block that neurological equipotentiality doesn't refute type materialism. Mental states may not be anatomically defined neural states, but they may be more abstract neural holograms.

Argues that the mind is not identical with the brain -- at the very least, it's the central nervous system, and perhaps more. "Brain" does not denote a natural kind in neurophysiology.

of Philosophy 81:67-88.
Cognitive psychology can transmogrify itself, who needs neuroscience?

5.3c Explanation in Cognitive Science
-------------------------------------

Owens, J. 1998. Psychological explanation and causal deviancy. Synthese...
   Philosophy is autonomous: empirical considerations can't affect it.

   On the role of non-empirical advances in psychology: e.g. in theory construction, coherence analysis, conceptual innovation, with the aid of logically necessary truths and the contingent/pragmatic a priori.

A general overview.

An overview of the last 40 years of the philosophy of language and the philosophy of mind, covering many issues and trends.

An overview of everything, circa 1978: logical behaviorism, functionalism, the identity theory, qualia, meaning, and so on, with bibliography.

In praise of the "Ryle-Dennett" tradition, and the elimination of dualism from the philosophy of mind.

A pragmatist perspective on the recent history of the philosophy of mind, focusing on consciousness, intentionality, and mental representation, and on debates between Fodor, Dennett, Searle, Putnam, and Davidson.

Shaffer, J.A. 1964. _Philosophy of Mind_. Prentice-Hall.

Proofs that $p$

Davidson's proof that $p$:
Let us make the following bold conjecture: $p$

Wallace's proof that $p$:
Davidson has made the following bold conjecture: $p$

Grunbaum:
As I have asserted again and again in previous publications, $p$.

Putnam:
Some philosophers have argued that not-$p$, on the grounds that $q$. It would be an interesting exercise to count all the fallacies in this "argument". (It's really awful, isn't it?) Therefore $p$.

Rawls:
It would be nice to have a deductive argument that $p$ from self-evident premises. Unfortunately I am unable to provide one. So I will have to rest content with the following intuitive considerations in its support: $p$.

Unger:
Suppose it were the case that not-$p$. It would follow from this that someone knows that $q$. But on my view, no one knows anything whatsoever. Therefore $p$. (Unger believes that the louder you say this argument, the more persuasive it becomes).

Katz:
I have seventeen arguments for the claim that $p$, and I know of only four for the claim that not-$p$. Therefore $p$.

Lewis:
Most people find the claim that not-$p$ completely obvious and when I assert $p$ they give me an incredulous stare. But the fact that they find not-$p$ obvious is no argument that it is true; and I do not know how to refute an incredulous stare. Therefore, $p$.

Fodor:
My argument for $p$ is based on three premises:
1. $q$
2. $r$
and
3. $p$

From these, the claim that $p$ deductively follows. Some people may find the third premise controversial, but it is clear that if we replaced that premise by any other reasonable premise, the argument would go through just as well.

**Sellars' proof that $p$:**

Unfortunately limitations of space prevent it from being included here, but important parts of the proof can be found in each of the articles in the attached bibliography.

**Earman:**

There are solutions to the field equations of general relativity in which space-time has the structure of a four-dimensional Klein bottle and in which there is no matter. In each such space-time, the claim that not-$p$ is false. Therefore $p$.

**Goodman:**

Zabludowski has insinuated that my thesis that $p$ is false, on the basis of alleged counterexamples. But these so-called "counterexamples" depend on construing my thesis that $p$ in a way that it was obviously not intended -- for I intended my thesis to have no counterexamples. Therefore $p$.

Outline Of A Proof That $P$ (1):

Saul Kripke

Some philosophers have argued that not-$p$. But none of them seems to me to have made a convincing argument against the intuitive view that this is not the case. Therefore, $p$.

_____________________

(1) This outline was prepared hastily -- at the editor's insistence -- from a taped manuscript of a lecture. Since I was not even given the opportunity to revise the first draft before publication, I cannot be held responsible for any lacunae in the (published version of the) argument, or for any fallacious or garbled inferences resulting from faulty preparation of the typescript. Also, the argument now seems to me to have problems which I did not know when I wrote it, but which I can't discuss here, and which are completely unrelated to any criticisms that have appeared in the literature (or that I have seen in manuscript); all such criticisms misconstrue my argument. It will be noted that the present version of the argument seems to presuppose the (intuitionistically unacceptable) law of double negation.
But the argument can easily be reformulated in a way that avoids employing such an inference rule. I hope to expand on these matters further in a separate monograph.

**Routley and Meyer:**

If \((q \& \text{not-}q)\) is true, then there is a model for \(p\). Therefore \(p\).

**Plantinga:**

It is a model theorem that \(p \rightarrow p\). Surely its possible that \(p\) must be true. Thus \(p\). But it is a model theorem that \(p \rightarrow p\). Therefore \(p\).

**Chisholm:**

\(P\)-ness is self-presenting. Therefore, \(p\).

**Morganbesser:**

If not \(p\), what? \(q\) maybe?
A Universal Philosophical Refutation

A philosopher once had the following dream.

First Aristotle appeared, and the philosopher said to him, "Could you give me a fifteen-minute capsule sketch of your entire philosophy?" To the philosopher's surprise, Aristotle gave him an excellent exposition in which he compressed an enormous amount of material into a mere fifteen minutes. But then the philosopher raised a certain objection which Aristotle couldn't answer. Confounded, Aristotle disappeared.

Then Plato appeared. The same thing happened again, and the philosophers' objection to Plato was the same as his objection to Aristotle. Plato also couldn't answer it and disappeared.

Then all the famous philosophers of history appeared one-by-one and our philosopher refuted every one with the same objection.

After the last philosopher vanished, our philosopher said to himself, "I know I'm asleep and dreaming all this. Yet I've found a universal refutation for all philosophical systems! Tomorrow when I wake up, I will probably have forgotten it, and the world will really miss something!" With an iron effort, the philosopher forced himself to wake up, rush over to his desk, and write down his universal refutation. Then he jumped back into bed with a sigh of relief.

The next morning when he awoke, he went over to the desk to see what he had written. It was, "That's what you say."

[From Raymond Smullyan, 5000 B.C. and Other Philosophical Fantasies. St. Martin's Press, 1983]
Dean, to the physics department. "Why do I always have to give you guys so much money, for laboratories and expensive equipment and stuff. Why couldn't you be like the math department - all they need is money for pencils, paper and waste-paper baskets. Or even better, like the philosophy department. All they need are pencils and paper."
Philosophical Clerihews

By Dean Zimmerman

I've wasted an inordinate amount of time on the lowest verse form in existence, the Clerihew. Here's the cream or the dregs, depending on how you look at it.

The first one ever written (1890, by the 16-year-old E. Clerihew Bentley) went like this:

Sir Humphry Davy
Detested gravy.
He lived in the odium
Of having discovered Sodium.

Here's a really good one by Maurice Hare:

Alfred de Musset
Used to call his cat Pusset.
His accent was affected.
That was to be expected.

The Poet's Manual and Rhyming Dictionary of Frances Stillman defines the clerihew as "a humorous pseudo-biographical quatrain, rhymed as two couplets, with lines of uneven length more or less in the rhythm of prose. It is short and pithy, and often contains or implies a moral reflection of some kind. The name of the individual who is the subject of the quatrain usually supplies the first line."

Bentley himself wrote a few on philosophers. W. H. Auden has a book of clerihews with ones on Kierkegaard, Hegel, and a couple of others. Paul Horgan's book of clerihews has a few as well. By and large the ones on philosophers aren't very good. The best I know of are these:

Desiderius Erasmus
Suffered from one of the rare asthmas.
His worst wheezes
Were caused by over-ripe cheeses.

(Paul Horgan)

John Stuart Mill,
By a mighty effort of will,
Overcame his natural bonhomie
And wrote *Principles of Political Economy*.*

*-=‘With some of their Applications to Social Philosophy’.

It was a weakness of Voltaire’s  
To forget to say his prayers,  
And one which to his shame  
He never overcame.

Sir James Jeans  
Always says what he means;  
He is really perfectly serious  
About the Universe being Mysterious.

(all by Bentley)

But the largest batch of philosophical clerihews follows...

---

**Philosophical Clerihews**

**by Dean W. Zimmerman**

This form was evidently  
invented by E. Clerihew Bentley.  
He did nothing else well,  
but what the hell?

Moses Maimonides  
wrote vast quantities  
and stood for amity  
in an age of Kalamity.

G. E. Moore  
was a bit of a bore;  
more an old fossil
Philosophical Clerihews

than a Cambridge Apostle.

By ghosts, C.D. Broad
was not generally overawed;
but he looked a trifle haggard
after his Examination of McTaggart.

Fearing Wittgenstein was blotto,
Popper adopted the motto:
"I will not argue with a joker
who's brandishing a red-hot poker."

"Peter Geach!" said God,
"would it not be slipshod
were I to raise not the authentical
you, but someone relatively identical?"

Roderick Chisholm
was never accused of asceticism
by Roderick Firth,
who was equally down-to-earth.

Nicholas Rescher
is under no pressure
to write another book;
but look!

Edwin B. Allaire
prefers particulars bare;
he doesn't find them rude
Jaegwon Kim, writing poetry under a pseudonym, met with considerable inconvenience in rhyming "supervenience".

"I sneezed", explained Al Plantinga, "as I scaled the rockface, barely panting. 'Gesundheit!' said a voice; but not God's, inasmuch as that's German not Dutch."

If your battery's dead, don't ask Bradley to give you a jump. He'll say: "Gladly, I have jumper cables; but need another item: a cable to connect the cables" and so ad infinitum.

The British railroad was the ruin of C.E.M. Joad. Back then it wasn't cricket to be caught without a ticket.

Jose Benardete cooks large batches of spaghetti. His noodles make you full when you've eaten Aleph-null.

Alfred Freddoso thinks his own work's just so-so; he'd never go so far as
to compare it to Suarez's.

Sydney's David Malet
Armstrong had little palate
for Marxism;
and that'll spark schism.

Derek Parfit
wouldn't wear a scarf. It
made him more bold
to think someone else would catch cold.

G. H. von Wright
is not very strict.
He remains polite
when called "von Wright".

Here's a moral pilfered
from Wilfrid
Sellars: Have enough to drink
and all ice cubes look pink.

Wilfrid Sellars
abhorred poor spellers;
they made his blood congeal
and gave him a raw feel.

When he was younger,
the ignorance of Peter Unger
was vast;
but it didn't last.

A handy acronym invented by Colin McGinn explains why philosophers shouldn't even try.

There's no disputin' that Grigori Rasputin had more will to power than Schopenhauer.

Susan K. Langer liked instruments that twang. Her *Philosophy in a New Key* was dedicated to Paul Stookey.

Unfortunately, Thales never tried Bailey's. It's smoother than water, so better suited to be that of which all is constituted.

The metaphysics of Ernie Sosa has little in common with that of Spinoza, except for this: both claim to show all things are like a ball of snow.

Although it hurt Curt Ducasse to be kicked in the ass, he was filled with elation.
at the observability of the causal relation.

Escaping at night from the embalmer's,
The zombies sought help from Dave Chalmers.
Though their speech was mere echolalia,
He knew what they wanted: dancing qualia.

With parenthetical suggestions for cartoons:

*(Gritting his teeth, fingers twitching)*

Stephen Stich
wouldn't scratch an itch:
one mustn't accept the ontology
of common sense psychology.

*(Picture of a bat with Nagel's face, putting wing over face in vampire fashion to avoid looking at a bust of Hegel)*

Don't ask Thomas Nagel
to study Hegel;
he'd rather be a bat
than do that.

*(Dancing waltzily while sensing redly)*

Michael Tye,
while just a young guy,
had an enthusiasm for the adverbial
that was proverbial.

*(In Saturday Night Fever outfit at a disco, opening letter and looking depressed)*
In youth, Frege
could really shake a leg. A
correspondence with Russell
left him unable to do The Hustle.

And here are some by Brian Leftow:

Who better to get my first clerihew
Than Yale's new chair, Robert Merrihew
Adams? His job is one to admire. He
Should hire me.

Goodman trades classes
for all possible scattered masses:
No matter where the parts are from,
they are many, ergo sum.

Hobbes has no abstracta
Just entia tacta-
what isn't in chunks
flunks.

"To be or not to be?"
Said Parfit, "totally
redundant. Hamlet pushed the issue way too far.
What matters isn't B, but R."

That Alvin
Rhymes with Calvin
Is, in my estimation,
Proof of predestination.
Quine and Cartwright point with glee
to the 1992 *Times*, where we
read that Mr. Bobbitt
was for awhile a scattered object.

Richard Rorty
Wrote philosophy till forty.
Then midlife crisis hit
And he quit to write... pragmatism.

If reference is inscrutable
And ostension mutable
There's just no knowing
where Quine is going.

When reading David Lewis
One can't say what the thing to do is-
Gape? Guffaw? Collapse and fall?
Elsewhere some counterpart does them all.

G.W.F. Hegel
Is less nutritious than a bagel.
A bagel has just one hole in the dough-
Hegel's all holes, wherever you go.

Antony Flew
Wouldn't be caught dead in a pew.
A wiser head
Would worry that some day he'll be caught dead.
According to W.V. Quine
Any ontology's fine
And that's why I
Think he's a heckgavagai.

According to John Stuart Mill,
Better check whether 2+2 still
Make four. They did today,
But as for tomorrow - who can say?

Nietzsche thought that all events
Repeat themselves- which makes no sense.
Nietzsche thought that all events
Repeat themselves- which makes no sense.

One more by Tom Kirby-Smith:

Ludwig Wittgenstein
Hardly ever went out to dine.
Be the menu never so abundant,
He found "green leafy lettuce salad" tautological and redundant.
I Also Dated Zarathustra

Sharon Wahl

On the Dating Game

It's not the questions that count, and it's not exactly the answers. You ask a silly thing: "What kind of fruit would you be?" and you hope a voice on the other side of the dividing panel, one from the row of three men on stools the audience can see but you cannot, will reach through the make-up and studio laughter to give a sign that he knows, yes, this is stupid, but what we want is not stupid: who, after all, knows how to find the person he will love?

I had looked nearly everywhere else and decided that if necessary, and it seemed to be necessary, I would look here, too. I would sit in a tight short dress with my legs placed at an advantageous angle to the camera, crossed at the knees with one high heel dangling from my toes. It's a favorite pose and successful. The men I was quizzing couldn't see it but the cameraman was driven crazy. With each question I asked, he returned to dwell on the ankle and bare heel.

Well then. What kind of fruit would he be?

Bachelor Number One? "Something that will make a really great pie. And that's a promise. I am one dependable fruit."

Bachelor Number Two? "I'd be plums, I'd be sweet and red and very juicy. And honey, I'm always ripe."

Bachelor Number Three? "I am a north wind to ripe figs. I am a prophet of the lightning and a heavy drop from the clouds. I am an intoxicated sweet lyre-- a midnight lyre, a croaking bell which no one understands but which still must speak!"

I didn't move but I was suddenly aware of my thighs, of the insides of my arms. Bachelor Number Three had a voice like a cloud speaking, traces of roar and thunder and waves held together with honey-cello. But what did I know about him? He might be ridiculous, I thought. He might be sublime.

When a man is mysterious enough, when I have no idea which things will be good or bad or where the problems will be or even what will happen next, it makes me think that anything might be possible.

"Num Ber Two! Num Ber Two!" the female audience chanted during the Thinking Music.

Number One hugged and kissed me. Number Two slipped a note with the number of his hotel room down the front of my dress. Number Three stiffly bowed.
He was older than the others. His eyebrows were shaggy and his mustache needed trimming. He wore a long black coat, which would never, in the course of our acquaintance, be removed.

He bowed and shook my hand. Then, lifting his eyebrows, he peered at it: a hand, yes, in his hand, a hand attached to other parts of a fairly beautiful woman with whom he was about to spend a weekend in Las Vegas. That is where they were sending us, to the glittering neon desert, to try our luck.

"Ah," he said. "What a long and beautiful hand! It is the hand of one who has always distributed blessings. But now it holds fast him you seek, me, Zarathustra."

**On Love of the Strange, and of Men**

Oh, it's a love of aching things, not sweet things, a love of stars, long silences, birds that sing at night. A love like an old Victorian house that is almost empty: a winding staircase to a room paneled in dark wood, its worn polish dimly reflecting light from a chandelier with yellow bulbs, a few notes of Chopin played in another wing of the house by an overnight guest who does not speak. (I would love him, too, thin like a carved rail of the staircase, awkwardly holding a glass of wine at dinner so that you might think his hands hadn't comfortably mastered the world; and yet, the Chopin.) A love like stamps from a country whose name you don't recognize, exquisite writing in a script you can't read or a language you don't know.

I have never loved anything I've understood.

"All mousetraps of the heart have now again been set! And wherever I raise a curtain, a little night-moth comes fluttering out." I was on the balcony, standing in the hot sun looking out over the Nevada desert, where the bare mountains were made beautiful by shadows. Zarathustra, in the hotel room, stretched his hands to the blasting air conditioner and spoke to himself.

The strange are often the best defended; that is how they have kept themselves strange. "I am not on my guard against deceivers, I must be without caution," Zarathustra said. Their hearts are not guarded deliberately, but by being essentially impenetrable.

It's a love that is like loneliness.

**Of Balancing on Four Legs**

It was a warm night, with lots of neon. It was one of those nights when the world seemed to be made not of people, but of couples. Everywhere I looked bodies were paired together, connected at the hands or more tightly around the waist, awkward animals walking with a tilt and lean, off-balance, unsymmetrical. They reminded me of those children's books with the pages cut in three, each section the top, middle, or bottom of an animal, so that the normal old heads and legs and bellies could be made into sillier
creatures: a salamousowl, a girelephish, a pandazebrogator.

And yes, I wanted to be part of it all. Of course I did. Oh, to be damply interlaced at the palms. To be affectionately leashed, tethered in the crowded streets, appended. To make a wider obstacle on the sidewalk, a wandering self-absorption that others had to navigate, rather than this narrow thing that darts and slips politely by.

But Zarathustra understood nothing of this. He would walk between or duck under the arms of people clearly together, something I by instinct could not do. It was impossible to truly accompany him, to predict and accommodate his walking speeds or stopping places. He seemed to resent being tied down, even by gravity. He walked with high fast steps and frequently bumped into things. Really he couldn't see very well; until he was at arm's length he wasn't completely certain what he was looking at. This meant that everything out of reach was immensely interesting, and the things close by merely obstacles.

And so we wandered, over the Brooklyn Bridge, into the great pyramids. When he pushed people aside to get a better view of the volcano or the pirates, I apologized and petted them, winked and shrugged: he's hopeless, what can I do? And really most people didn't mind so much once they saw him. He was so completely taken over by the spectacle, so silly looking and so utterly happy, that often enough they ended up watching us instead.

If there were a Couple Game, a prize for the oddest match on the Vegas strip, we would have won. Zarathustra could have been my father. Or crazy. Perhaps he was extremely wealthy? Something the casinos had flown in. And surely I was being paid. Madmen didn't get girls with legs this long. The casino had hired me, to raise the stakes. Or he had hired me, for much the same function. Oh wasn't he a lucky man!

We just didn't look like we were on a date. I wondered if this was why the show had assigned us a chaperone-- to give Zarathustra a backup option, and to let me off the hook. Surely this odd man couldn't be my type?

"Perhaps you would like a game of poker?" the chaperone had suggested, after dinner.

"I have played dice with the gods at their table, the earth," said Zarathustra.

"Oh, really? And where was this?"

The chaperone was a motherly type. She was a mother-in-law on a honeymoon who wanted desperately to be a fairy godmother. We had tickets to a show, coupons for free drinks, a hundred dollars in betting tokens, all of which she had bestowed upon Zarathustra, all of which had entered the pockets of his coat, never to be seen again.

She had tried to take the coat from him back in the hotel room. It was thick black wool, buttoned from
his chest to his knees, and must have felt like wearing a portable oven. Still, it seemed possible that he had simply forgotten it was there. The chaperone suggested, coquettishly reaching for the top button, that she would make him more comfortable. Zarathustra said to her, "This is the tarantula's cave! Do you want to see the tarantula itself?" She didn't. She never mentioned it again.

I had said nothing. By then I'd come to enjoy the prospect of removing the coat myself, at the end of the night. I pictured my long arms snaking from behind, my bare skin on his black wool, undoing him button by button.

And what was Zarathustra thinking, when he looked at me? Did he like tall redheads? Did he wish I was wearing more? "You have the most lovely shoulders," as the chaperone put it, winking at Zarathustra, who missed his cue for a courtly compliment.

It was difficult to imagine either of them on a date. She needed to have always been married; he needed to be taken by the arm and gently steered, directed this way or that with no mention made of the change of pilot. Or so I had thought; that was an innocent time, early evening.

"Try your luck!" the chaperone said, giving each of us a quarter as we passed a row of slot machines. They jingled and blinked happily among themselves like well-fed babies in need of occasional burping.

Zarathustra fed the nearest one his quarter, and I dropped mine in after, doubling the bet. The dizzy smile started up, spinning to lock on cherry; cherry; cherry. Quarters poured out. It was a good sign, I thought.

Zarathustra picked up a quarter and gave it back to the chaperone, then walked on. The chaperone had a wordless fit: sputter! etc. She saw that yes, we really did intend to walk away. This was her chance. A thousand quarters: she looked hungrily at the pile, thinking that among so many there must be others that would win, she had only to find them, to kiss each frog and find the princes.

And so we left her. We didn't need a chaperone; we had his coat.

We walked for hours. The signs, the palm trees, the cars, the casinos, the people he passed on the street and the things they carried, all seemed to Zarathustra equally there for entertainment. The boy whose cotton candy he sampled (gazing in rapture at the pink cloud, plucking a wisp from it, licking tentatively at the barely there) had no right to scream at him, no, not when one possessed an object so delicious! Not when one possessed an object he wanted. I wasn't able to explain this to the boy or his father, but bought the boy another cone and a small teddy bear, hoping he wouldn't notice how much it resembled Zarathustra.

When I caught up again a uniformed chauffeur had handed Zarathustra a vividly illustrated brochure of a desert brothel, and was offering to drive him there. Zarathustra seemed confused that the pamphleteer was not, as he had naturally (so he insisted) assumed, a philosopher or revolutionary. Clearly anyone distributing printed material deserved his full attention.
"Ah," he said, standing in a bright spotlight to study the pamphlet. As he considered the transcendent ideologies of Daisy and Trixie, his shadow roamed over the side of a building across the street. He raised his arms and the shadow tried to climb through the window of a hotel room much too small for it. Two blonde teenaged girls approached and the arms went after them, straining for a squeeze, wiggling fingertips poked their knees and tried to trip them, the pamphlet waved madly over their bodies as they escaped unclutched. The shadow shrugged. Zarathustra shook his head at it disapprovingly. "I must keep it under stricter control-- otherwise it will ruin my reputation."

I pulled him away by the arm, and found a moth hole in the outside of his coatsleeve, which fit my little finger like a ring. Z didn't seem to notice, so I kept it there. By this time it was becoming quite clear how much he needed me.

**Of Dancing Things**

"Listen," said Zarathustra. "It is night: now do all leaping fountains speak louder." We were sitting side by side on the low concrete ledge of the fountains in front of our hotel.

"And what do they say?"

"They are deep but without thoughts, like little secrets, like after-dinner nuts."

Zarathustra had his hand in the shallow water, plucking it with his finger, a soft plink plink, plink plink.

I slipped off my shoes, and stepped in. My legs were a lovely blue in the reflected light. The pool was ankle deep, gently swirled and bubbled by the water spraying and tumbling in the middle.

Zarathustra scooped some pennies from the bottom of the pool, a few of the good luck pennies which were everywhere, and dropped them in again. They plopped straight back to the bottom, shy as frogs.

"I know what the water says. It says it's given up waiting for the pennies to swim, it wants people to throw goldfish, instead."

"Everything is asleep," Zarathustra said. "Even the water is asleep. Its eye looks at me drowsily and strangely. But it breathes; I feel it. And it is dreaming, look how it tosses and turns."

The air was warm, the water was warm. My feet were delighted. I walked through the shallow pool to the other side of the fountains on my blue legs, nudging pennies with my toes. Which felt better, stork steps, or fish steps? Which felt better, going from the air to the water, or the water to the air?

Zarathustra couldn't see it, but I was dancing. The water's hands slipped teasing through my fingers. My tall partners the palms swayed out-of-reach above me. The desert breezes came in now and then,
stretched across us like a chorus line. Each of us with our private shivers.

I thought it would be nice, on a night like this, to fly. So I left the water in a balletic leap, toes neatly pointed, one arm up, one to the side. But when I came down I slipped on the pennies. I slid into a sharp pain-- a bottlecap. My foot was cut. Zarathustra, in his brown leather boots and thick coat, came striding through the water to see what I was swearing at.

The cut wasn't deep; a small bleeding gouge on the side of my big toe. I dried it with tissue, and found a band-aid in my purse. But Zarathustra was at war: there were to be no bottlecaps among the pennies. He went down on hands and knees to search them out. His coat settled into the water reluctantly, floating and full of pocketed air, then sponging and swelling and sinking.

At first he was amusing, almost gallant. The eradication of sharp edges, the world made safer for toes. But. He kept on and on, crawling through the water, attacking nickels then releasing them, puzzling over gum wrappers and bits of palm leaf, banishing all manner of suspicious things to his wet pockets.

I wanted to go. I wanted a drink, and I said so. I wanted a cold, numbing, double margarita. Zarathustra ignored me, or maybe didn't hear. I said this louder. Putting on my shoes made my toe hurt more. "Come on," I said. Zarathustra tucked another bottlecap into his coat pocket. Probably they were falling back out again as he crawled. "This is ridiculous!" I shouted.

"All fish talk like that; what they cannot fathom is unfathomable," he said.

"I'm going inside," I said. At the hotel entrance I turned back to see if he had followed. He hadn't. He lay in the fountain stretched full length, legs spread, arms wide, his hands flapping and spanking the water, cooling his overheated addled brain and burbling.

**On the Compassion of the White Tigers**

Sometimes it helps to be drunk. One stiff margarita and I remembered how much I liked being wet, how charming I would look with my hair thoroughly soaked and shaken into ringlets. The fountain would tell me so itself, really, I was ready to hear all sorts of things. I was ready to sing along.

But Zarathustra had finished his bath. I found him wandering the main corridor of the hotel, waving his arms and spraying drops like a wet, happy dog.

I preceeded him at a safe custodial distance. He didn't notice me; being human was sufficient camouflage.

The corridor led past a large white room, the mountain-kingdom throne room of the resort's white tigers, and there Zarathustra came to a sudden, astounded stop. Two white tigers lay on the floor not far from him, gazing into a distance we were certainly no part of.
"Ah, my brothers! If only my lioness Wisdom had learned to roar fondly!"

He sat down on the floor of the marble walkway and spoke to them, earnestly, and at great length.

Their heads went slowly side to side, looking at everything as though they already knew it in their painted kingdom of empty white spaces and artificial things, snow in their minds. They both had beautiful intelligent expressions and seemed complete, resigned to a stable satisfaction, not requiring further enlightenment.

He told them everything. I leaned half-behind a marble pillar and listened.

"I have always wanted to caress every monster. A touch of warm breath, a little soft fur on its paw-- and at once I have been ready to love and entice it. Love is the danger for the most solitary man, love of any thing if only it is alive!"

With my eyes closed, without the dreadful evidence of the wet coat, without the spreading streams of water the other casino-goers were gingerly stepping around as they passed him, looking at him and also trying not to look, not to spoil the night's glitter, not to wet their shoes, but especially not to hear him, surely this was gibberish, a language they didn't share, an animal speaking to animals, they pretended he was grunting--

With my eyes closed there were only his words, his words like little spotted night moths, and his low voice. The most enticing sort of monster is a soul aching with ferocious tenderness.

"To be sure, I am a forest and a night of dark trees: but he who is not afraid of my darkness will find rosebowers too under my cypresses."

Did I think I could change him? Yes. Did I care what the others thought, the tip-toers, the avoiders of puddles? No. Did I think he would escort me through the dark cypresses into his rose bower? Yes. I pictured pale yellow climbing roses, a weathered bench strewn with fallen petals. I thought he had made the bower with its little bench so that I would have a place to sit.

"Ah, my friends, it is the evening that questions thus within me. Forgive me my sadness! We were made for one another, you gentle, strange marvels. And we have already learned so much with one another!"

He left them, much cheered and quieted, though still dripping, and followed me into the nearest bar.

On Learning to Drink from All Glasses

Zarathustra was fascinated by the little white and red striped straw that came with his margarita. It made
slurps in such a nice assortment, hollow air sucks, loud bubble-burble, liquid squishes. It suffered lime-pulp obstructions, it poked under cubes of ice, it vacuumed the last stray drops. He kept the straw in place between his lips and sipped liked a bird, lowering his head to the glass, tilting side to side, poking and hunting.

Finally the ice was sucked tasteless. But Zarathustra hadn't had nearly enough of the straw. Here and there on the empty tables were glasses left behind, some with enough color to be more than ice melt. Come to us, they called, we are diluting. The straw perked like a lower appendage. He couldn't resist. "He who does not want to die of thirst among men must learn to drink from all glasses," he said as he left me.

But most of these abandoned drinks were only drowned remains, melted ice and cherry stems and gnawed wedges of orange or pineapple. They were insufficiently alcoholic. He saw a fresh cocktail with a pink umbrella on another table, and with his straw, went directly to it. The woman who had ordered the drink was horrified. She stared at the glass as though a man had popped out of it, not into it. It might happen again, acrobats could leap from the glass and stick their daiquiri-flavored tongues into her open mouth.

The couple at the next table said that someone really ought to call security. So I told them, leaning over confidentially, that Zarathustra was a paid comedian. "Yes, it's part of his act," I said. And truly, this was a stroke of genius.

"Oh!" they said, of course, it all made sense, and then they excitedly told the next couple. The world is so much nicer when it's making sense. I could see the rumor navigate the bar, who had heard and who hadn't, by the shift from flinches to smiles, then even to competition for Zarathustra's attention. Men called him over to shock their wives, a giggly, safely titillating little shock, and women offered up their drinks to him as he passed.

Zarathustra was delighted. Here was the world as he had intended it to be, here he was understood! Drunk, he was the perfect entertainer, a cross between a host and a clown, offering toasts and renaming all the drinks. The Death of God! he pronounced. The Will to Power! Live Dangerously! Eternal Recurrence!

The names were a bit mystifying to the drinking folk, but they loved him. He leaned over to suck another drink and lost his balance in a plump, elderly lap. The plump woman laughed and tried to grab him. "O Earth, you have grown too round for me!" he cursed. "Live Dangerously!" they toasted. And to me, "He's good, isn't he? It's very clever."

Finally he came back to our table. He was merry and elated and fidgety, reaching out when fresh drinks passed, glazing over with alcohol and exhaustion. It was getting late. I was ready for a little gratitude. I moved my chair around the table very close to his. He still had the perky little straw in his mouth.
"You haven't yet tasted me," I said, and sucked on the end of his straw. It pinched his tongue, and he spat it out.

"Oh, your straw!" I said. It had fallen to the floor on the other side of his chair. I leaned over to get it, full across his lap, and while I was there I took the time to undo the two lower buttons of his cool damp wool cocoon. He was absolutely still. Inside and out. But he thanked me for the straw.

"Zarathustra," I said, sort of snuggling up to him but distracting him by pointing to a young couple kissing vigorously in a dark corner of the bar. "Look. What are they doing?"

"They are discovering new words."

"You mean, speaking with different tongues?"

"Before long they will be devising festivals!"

"I like it when they smile between kisses."

"Like cats they arch their backs, they purr."

"Well, look where his paw is..."

"You must not want to see everything."

"But I do. I think I do want to see everything, don't you?"

"For that you must have long legs."

"Let's see." I hooked my foot under his and stretched our legs out, to measure them side by side. "Mine is longer! I thought so."

"You are making this cave sultry and poisonous, you evil sorcerer!"

"Sorcerer!"

"If I may tickle you with this name."

"I would prefer fingers."

Someone had left a marble in the ashtray on our table, a milky blue color, which Zarathustra began to roll across the table. I said it was the moon's right eye, sent to spy on us.
"He is lustful and jealous, the monk in the moon," Zarathustra said.

"And what about you?"

"I am invulnerable only in my heels."

"Are you lustful? Do you like the girl over there, kissing?"

"One should speak about women only to men."

"Why? Tell me! What do you think of women?"

"They know how to blow horns and to go around at night and awaken old things that have long been asleep."

"Zarathustra," I said, "what are you hiding under your coat?"

"It is a little truth that I carry. But it is as unruly as a little child, and if I do not stop its mouth it will cry too loudly."

"Ah," I said. "Oh."

"You want to call it by a name and caress it. You want to pull its ears and amuse yourself with it."

"Yes," I said, "you're right, I do." I suggested that it was time to go back to the room.

Of an Introduction to the Ideal Woman

I led our trek from bar to bedroom through a small dense jungle, under waterfalls, over a green and gold wooden elephant, through beaded curtains into a dim red room painted with a harem scene. We leaned against the wall of bare-breasted dark-eyed women and pretended to choose a favorite, whispering to each other in the opium light, bumping and brushing hands in the purple shadows.

And then I found the perfect finale. On a pedestal advertising the week's performers was a classic chorus girl mannequin, leg kicked high, arms wide. What a fetching pose, I thought. I could do that, too. A private Vegas floor show for Zarathustra.

I climbed up and danced a can-can with her, kicking my equally long legs, my arm across her shoulders. She was so cute. She was terribly sweet and happy. And Zarathustra gave us just the look I wanted, he gazed adoringly, ecstatically at the two of us intertwined. He said exactly what I wanted him to say:
"Something unquenched, unquenchable, is in me, that wants to speak out. A craving for love is in me..."

Oh yes, finally, yes yes yes. I let her go, and he walked up and reached out his arms and took her face in his hands, and kissed her.

He kissed her again, on her nose and her cheeks, her chin, on the corners of her smiling lips. He kissed her very nicely, too; sweet lingering little pecks. "Who could behold her smile and not dissolve into tears?" he asked me. Ah, yes. Indeed. Tears.

Then he stepped back to admire her, to take in the full measure of his luck. That this, this, should be waiting here, just for him.

She had those long showgirl legs (well, so do I), enhanced breasts (mine are real) set off by feather boas, and she had big unblinking blue eyes that said you were just exactly what she had all her life been waiting for (mine blink). Furthermore, you knew immediately that she would always look at you that way. In fact I think it's safe to say that most of one's first impressions of her were entirely accurate. Her behavior was in no way misleading. She might disappoint you, but she would never let you down.

She was impeccably calm. Here was a woman who could face life's batterings and joys with the same unwavering expression: *Oh, how big and strong you are! J'adore!* She would never complain. She was patient and always willing to listen, but never intrusive. She was never jealous.

Now, I have softer breasts and better legs, and I am warm, I bend and squish and lick and sing, my mouth opens, my hands grip and stroke, I can dance a tango in spike high heels. But I couldn't compete.

Zarathustra whispered to her, something I couldn't hear, then looked into her eyes as if she had agreed, yes, between them there was perfect understanding. Well, perhaps there was. I am only jealous of perfection when I see it taking a man away from me.

"I will rescue you from all corners," he said, gently pushing down her kicking leg. "I will brush dust, spiders, and twilight away from you."

He hoisted her from the platform, knocked over everything, and dislodged most of her feathers. After some fidgetting they fitted together with her stiff welcoming arms hooked over his left shoulder. He grasped her by her sequined ass and carried her toward the exit sign. She smiled at me over his shoulder, apparently delighted, as she was with all things. She went with him into the night with her eyes wide open.

"Come, cold and stiff companion! Let me show you my nocturnal world and the big, round moon and the silver waterfalls by my cave. The dog howls, the moon is shining. Here are caves and thickets: we shall go astray! Give me your hand! Or just a finger! Where now do you take me, you unruly paragon?"

I never saw him again. Though I still hear his voice from time to time, at night, when the ocean mutters
to itself. Perhaps this was to be expected from a man who spent ten years in a cave, whose best friends were a serpent and an eagle. What other things could reach him, on his mountaintop? Even the serpent had to be flown there in the talons of the eagle.

Perhaps, if I had grown wings and thick talons, Zarathustra would have let me carry him away.

Note: All lines spoken by Zarathustra were assembled from Friedrich Nietzsche's Thus Spoke Zarathustra, in the translation by R. J. Hollingdale.
Zombies on the web

Compiled by David Chalmers

Zombies are hypothetical creatures of the sort that philosophers have been known to cherish. A zombie is physically identical to a normal human being, but completely lacks conscious experience. Zombies look and behave like the conscious beings that we know and love, but "all is dark inside." There is nothing it is like to be a zombie.

Varieties of zombies

There are actually three different kinds of zombies. All of them are like humans in some ways, and all of them are lacking something crucial (something different in each case).

- **Hollywood zombies.** These are found in zombie B-movies. Their defining feature is that they are dead, but "reanimated". They are typically rather mean, and fond of human flesh. The zombies pictured on this page are mostly Hollywood zombies (though I'm informed that the one at the bottom is really a ghost demon). An expert tells me that the name should be "Pittsburgh zombies", since the most important zombie movies were made in Pittsburgh, but somehow it doesn't have the same ring.

- **Haitian zombies.** These are found in the voodoo (or vodou) tradition in Haiti. Their defining feature seems to be that they lack free will, and perhaps lack a soul. Haitian zombies were once normal people, but underwent zombification by a "bokor" through spell or potion, and are afterwards used as slaves.

- **Philosophical zombies.** These are found in philosophical articles on consciousness. Their defining features is that they lack conscious experience, but are behaviorally (and often physically) identical to normal humans.

(There are also zombie cocktails, Unix processes, and pop groups, but three is enough for now. There are still more categories here.)
These three classes are distinct. Hollywood zombies and Haitian zombies are not philosophical zombies, since they typically have behavioral impairments (see how to identify a zombie) and may have some sensory experiences (e.g., there maybe something it tastes like when a Hollywood zombie eats flesh). Likewise philosophical and Haitian zombies aren't Hollywood zombies, since they don't eat flesh and are arguably alive (though some hold that Haitian zombies are dead). One might make the case that philosophical and Hollywood zombies lack free will and are thus a sort of Haitian zombie, although both claims would be controversial. In any case, many believe that Hollywood zombies are a sort of corruption of Haitian zombies.

Philosophical zombies

It is philosophical zombies that I'm most interested in here, since I'm a philosopher and they raise very interesting issues. The sort I'm most concerned with are zombies that are physically and behaviorally identical to a conscious human, but lack any conscious experience. As in this case-study of my own zombie twin, for example.

Most people doubt that zombies could exist in the actual world. (In philosophical terms, they are naturally impossible.) But many people think that they are at least logically possible - i.e. that the idea of zombie is internally consistent, and that there is at least a "possible world" where zombies exist. This logical possibility is sometimes used to draw strong conclusions about consciousness (e.g. in my book The Conscious Mind, and elsewhere).

For example:

- It can be used as a way of illustrating the "hard problem" of consciousness: why do physical processes give rise to conscious experience? This question might equally be phrased as "why aren't we zombies?". If any account of physical processes would apply equally well to a zombie world, it is hard to see how such an account can explain the existence of consciousness in our world.

- It can be used to raise questions about the function of consciousness: why did evolution bother to produce us if zombies would have survived and reproduced just as well? (As e.g. Flanagan and Polger [1995] have argued.)
• And it can even be used to argue against materialism. If there is a possible world which is just like this one except that it contains zombies, then that seems to imply that the existence of consciousness is a further, nonphysical fact about our world. To put it metaphorically, even after determining the physical facts about our world, God had to "do more work" to ensure that we weren't zombies.

The general point is that the logical possibility of zombies is one way of illustrating that there is no logical entailment from physical facts to facts about consciousness, whereas there is such an entailment in most other domains. Of course even the logical possibility of zombies is controversial to some (e.g. Dennett [1995]), as conceivability intuitions are notoriously elusive; and some scientists have been known to wonder whether anything important really follows from what is merely conceivable. I think that most arguments that use zombies can actually be rephrased in a zombie-free way, so that these arguments can be set aside if one prefers; but zombies at least provide a vivid and provocative illustration.

Related ideas

There are two related ideas that turn up elsewhere in the philosophical and psychological literature.

The first is that of a functional zombie, a non-conscious system physically different from but functionally isomorphic to a normal human. For example, a system with silicon chips instead of neurons. (This idea also goes by the more prosaic name of "absent qualia"). Some use the logical possibility of such a functional zombie to argue against reductive functionalist theories of consciousness (which hold that consciousness = functioning). Some go further and argue that functional zombies might even exist in the actual world, suggesting that any form of functionalism or artificial intelligence is doomed. Others (like me) deny that functional zombies could actually exist, so that AI is not threatened.

The other related idea is that of the zombie within, which has recently gotten some play in psychology and neuroscience. It turns out that quite a lot of human activity can be accomplished unconsciously -- e.g. unconscious perception, memory, and learning. And some (notably Milner and Goodale) have argued that there are major neural pathways devoted to unconscious processing of visual inputs that leads directly to motor action. This has led some to suggest that each of us contains a "zombie within" that unconsciously produces many of our motor responses, without our realizing it.
**History**

As far as I know, the first paper in the philosophical literature to talk at length about zombies under that name was Robert Kirk's "Zombies vs. Materialists" in *Mind* in 1974, although Keith Campbell's 1970 book *Body and Mind* talks about an "imitation-man" which is much the same thing, and the idea arguably goes back to Leibniz's "mill" argument. After Kirk's paper, there was hardly any explicit discussion of zombies in the philosophical literature for a long time (although there was quite a lot on "absent qualia", i.e. functional zombies). When I wrote my 1993 Ph.D. thesis, in which zombies played a central role, there was hardly anything out there. But for one reason or another, zombies have risen from the grave in the last few years; and they turn out to be unaccountably well-represented on the web, in particular.

So here are a few links for the zombieholic.

**Papers on zombies**

- Selmer Bringsjord (1995), *In defense of impenetrable zombies*  
  - A commentary on Moody 1995 (one can't really distinguish zombies and humans).

- Selmer Bringsjord (1996), *The zombie attack on the computational conception of mind*  
  - Using the possibility of zombies to draw out inconsistencies in Dennett's argument against Searle.

- David Chalmers (1993), *Self-ascription without qualia: A case-study*  
  - A commentary on a paper by Goldman, with a case-study of "Zombie Dave".

- David Chalmers (1995), *Absent qualia, fading qualia, dancing qualia*  
  - Thought-experiments about functional isomorphs, arguing that in the actual world such isomorphs will be conscious.

  - My book on consciousness, with all the zombie discussions you could ever ask for. Unfortunately most of the zombie stuff isn't available on the web.

- Allin Cottrell (1996), *Sniffing the camembert: On the conceivability of zombies*  
  - A thoughtful paper arguing that zombies as I describe them in my book may not really be conceivable.

- Daniel Dennett (1995), *The unimaginable preposterousness of zombies*  
  - Zombies aren't really imaginable

- Daniel Dennett (1999), *The zombic hunch: Extinction of an intuition?*  
  - On why we shouldn't trust our intuitions about zombies

- Owen Flanagan & Tom Polger (1995), *Zombies and the function of consciousness*  
  - Using zombies to question whether consciousness has a function.

- Stevan Harnad (1995), *Why and how we are not zombies*  
  - The epistemic possibility of zombies illustrates the limits of cognitive science.
Zombies on the web

- Larry Hauser (1995), "Revenge of the zombies"
  - Uses "good zombies" to fight the "evil zombies" of dualism & identity theory, yielding behaviorism.

- Jaron Lanier (1995), "You can't argue with a zombie"
  - Dennett & other consciousness skeptics and AI supporters must be zombies.

- Peter Marton (1998), "Zombies vs. materialists: The battle for conceivability"
  - Zombies are conceivable if and only if materialism is inconceivable.

- Todd Moody (1995), "Conversations with zombies"
  - Zombies will be distinguishable as they won't worry about consciousness.

- John Perry, "The zombie argument"
  - Argues that arguments for zombies presuppose epiphenomenalism, and that any reasonable zombie would behave differently from us.

- Tom Polger, Zombies
  - An overview of many different philosophical issues about zombies.

- Nigel Shardlow, "Zombies"
  - Zombie behavior would be coincidental or lying; the idea rests on a Cartesian conception of self-knowledge.

- Nigel Thomas (1996), "Zombie Killer"
  - Zombies would claim to be conscious, and this leads to an incoherence. Whether the claim is interpreted as true, false, or meaningless, trouble for the zombiephile results.

The papers here deal with various aspects of the foundations of artificial intelligence. Some deal with relatively abstract matters about the analysis of computation and its relation to cognition, or about the possibility of artificial intelligence. Others deal with more empirical matters concerning various sorts of artificial intelligence, including symbolic AI, connectionism, and artificial life.

**A Computational Foundation for the Study of Cognition (PS)**

This paper addresses some key questions about computation and its role in cognitive science. I give an account of what it takes for a physical system to implement a given computation (in terms of abstract patterns of causal organization), and use this account to defend "strong artificial intelligence" and justify the centrality of computational explanation in cognitive science. This paper is so far unpublished, though parts of it have appeared as "On Implementing a Computation" in *Minds and Machines* (1994).

**Does A Rock Implement Every Finite-State Automaton? (PS)**

In an appendix to his book *Representation and Reality*, Hilary Putnam "proves" that every ordinary open system implements every finite automaton, so that computation cannot provide a nonvacuous foundation for the sciences of the mind. I analyze Putnam's argument and find it wanting. The argument can be patched up to some extent, but this only points the way to a better definition of implementation (of combinatorial-state automata) that is invulnerable to such an objection. A couple of open questions remain, however. This paper appeared in *Synthese* 108: 309-33, 1996.

**Minds, Machines, and Mathematics**

This is a commentary on Roger Penrose's book *Shadows of the Mind*, focusing on his attempt to use Gödel's theorem to demonstrate the noncomputability of thought. I argue that the attempt is ultimately unsuccessful, but that there is a novel argument here that many commentators have overlooked, and that it raises many interesting issues. I also comment on his proposals concerning "the missing science of consciousness". This paper appears in *PSYCHE*, in a symposium on Penrose's book. Penrose replied in "Beyond the Doubting of a Shadow".

**High-Level Perception, Analogy, and Representation: A Critique of Artificial Intelligence Methodology**

(Co-authored with Bob French and Doug Hofstadter.) This paper argues that high-level perception is crucially involved in most cognitive processing. We mount a critique of the common approach of using "frozen", hand-coded representations in cognitive modeling (exemplified by Langley and Simon's BACON and Gentner's Structure-Mapping Engine), and argue for a different approach in which
representations are constructed and molded "on the fly". This paper appeared in the *Journal of Experimental and Theoretical Artificial Intelligence* in 1992, and also in Hofstadter's book *Fluid Concepts and Creative Analogies*. You can find a commentary by Morrison and Dietrich here.

**Syntactic Transformations on Distributed Representations.**

In this paper I demonstrate that a connectionist network can be used to perform systematic structure-sensitive transformations on compressed distributed representations of compositional structures. Using representations developed by a Recursive Auto-Associative Memory (a model of Jordan Pollack's), a feedforward network learns to move systematically from representations of an active sentence to that of a corresponding passive sentence, and vice versa. This paper appeared in *Connection Science* in 1990. This line of research has since been extended by a number of others, e.g. in Lonnie Chrisman's "Learning Recursive Distributed Representations for Holistic Computation".

**Connectionism and Compositionality: Why Fodor and Pylyshyn Were Wrong.**

I point out some structural problems with Fodor and Pylyshyn's arguments against connectionism, and trace these to an underestimation of the role of distributed representation. I discuss some empirical results (from the paper above) that have some bearing on Fodor and Pylyshyn's argument. This paper was published in *Philosophical Psychology* in 1993 (an earlier version was in the 1990 *Proceedings of the Cognitive Science Society*). See Murat Aydede's "Connectionism and the Language of Thought" for some discussion.

**The Evolution of Learning: An Experiment in Genetic Connectionism.**

I combine genetic algorithms and neural networks to show how learning mechanisms might evolve in a population of organisms that initially have no capacity to learn. The dynamics of a neural network's cross-time development are specified in a genome, and phenotypes are selected for their ability to learn various tasks across a lifetime. Over many generations, sophisticated learning mechanisms are developed, including on occasion the well-known delta rule. This paper appeared in the *Proceedings of the 1990 Connectionist Summer School Workshop*. See here for more models of evolution and learning.

**Subsymbolic Computation and the Chinese Room.**

In this paper I analyze the distinction between symbolic and subsymbolic computation, and use this to shed some light on Searle's "Chinese Room" argument and the associated argument that "syntax is not sufficient for semantics". I argue that subsymbolic models may be less vulnerable to this argument. I no longer think this paper is very good, but perhaps the analysis of symbolic vs. subsymbolic computation is worthwhile. It appeared in *The Symbolic and Connectionist Paradigms: Closing the Gap*, edited by John Dinsmore, published by Lawrence Erlbaum in 1991.

SHORT ABSTRACT

Computation is central to the foundations of modern cognitive science, but its role is controversial. Questions about computation abound: What is it for a physical system to implement a computation? Is computation sufficient for thought? What is the role of computation in a theory of cognition? What is the relation between different sorts of computational theory, such as connectionism and symbolic computation? This article develops a systematic framework that addresses all of these questions. A careful analysis of computation and its relation to cognition suggests that the ambitions of artificial intelligence and the centrality of computation in cognitive science are justified.

LONG ABSTRACT

Computation is central to the foundations of modern cognitive science, but its role is controversial. Questions about computation abound: What is it for a physical system to implement a computation? Is computation sufficient for thought? What is the role of computation in a theory of cognition? What is the relation between different sorts of computational theory, such as connectionism and symbolic computation? In this paper I develop a systematic framework that addresses all of these questions.

Justifying the role of computation requires analysis of implementation, the nexus between abstract computations and concrete physical systems. I give such an analysis, based on the idea that a system implements a computation if the causal structure of the system mirrors the formal structure of the computation. This account can be used to justify the central commitments of artificial intelligence and computational cognitive science: the thesis of computational sufficiency, which holds that the right kind of computational structure suffices for the possession of a mind, and the thesis of computational explanation, which holds that computation provides a general framework for the explanation of cognitive processes. The theses are consequences of the facts that (a) computation can specify general patterns of causal organization, and (b) mentality is an organizational invariant, rooted in such patterns. Along the way I answer various challenges to the computationalist position, such as those put forward by Searle. I close by advocating a kind of minimal computationalism, compatible with a very wide variety of
empirical approaches to the mind. This allows computation to serve as a true foundation for cognitive science.

**Keywords**: computation; cognition; implementation; explanation; connectionism; computationalism; representation; artificial intelligence.

## 1 Introduction

Perhaps no concept is more central to the foundations of modern cognitive science than that of computation. The ambitions of artificial intelligence rest on a computational framework, and in other areas of cognitive science, models of cognitive processes are most frequently cast in computational terms. The foundational role of computation can be expressed in two basic theses. First, underlying the belief in the possibility of artificial intelligence there is a thesis of *computational sufficiency*, stating that the right kind of computational structure suffices for the possession of a mind, and for the possession of a wide variety of mental properties. Second, facilitating the progress of cognitive science more generally there is a thesis of *computational explanation*, stating that computation provides a general framework for the explanation of cognitive processes and of behavior.

These theses are widely held within cognitive science, but they are quite controversial. Some have questioned the thesis of computational sufficiency, arguing that certain human abilities could never be duplicated computationally (Dreyfus 1974; Penrose 1989), or that even if a computation could duplicate human abilities, instantiating the relevant computation would not suffice for the possession of a mind (Searle 1980). Others have questioned the thesis of computational explanation, arguing that computation provides an inappropriate framework for the explanation of cognitive processes (Edelman 1989; Gibson 1979), or even that computational descriptions of a system are vacuous (Searle 1990, 1991).

Advocates of computational cognitive science have done their best to repel these negative critiques, but the positive justification for the foundational theses remains murky at best. Why should *computation*, rather than some other technical notion, play this foundational role? And why should there be the intimate link between computation and cognition that the theses suppose? In this paper, I will develop a framework that can answer these questions and justify the two foundational theses.

In order for the foundation to be stable, the notion of computation itself has to be clarified. The mathematical theory of computation in the abstract is well-understood, but cognitive science and artificial intelligence ultimately deal with physical systems. A bridge between these systems and the abstract theory of computation is required. Specifically, we need a theory of *implementation*: the relation that holds between an abstract computational object (a "computation" for short) and a physical system, such that we can say that in some sense the system "realizes" the computation, and that the computation "describes" the system. We cannot justify the foundational role of computation without first answering the question: What are the conditions under which a physical system implements a given computation? Searle (1990) has argued that there is no objective answer to this question, and that any given system can be seen to implement any computation if interpreted appropriately. He argues, for instance, that his wall
can be seen to implement the Wordstar program. I will argue that there is no reason for such pessimism, and that objective conditions can be straightforwardly spelled out.

Once a theory of implementation has been provided, we can use it to answer the second key question: *What is the relationship between computation and cognition?* The answer to this question lies in the fact that the properties of a physical cognitive system that are relevant to its implementing certain computations, as given in the answer to the first question, are precisely those properties in virtue of which (a) the system possesses mental properties and (b) the system's cognitive processes can be explained.

The computational framework developed to answer the first question can therefore be used to justify the theses of computational sufficiency and computational explanation. In addition, I will use this framework to answer various challenges to the centrality of computation, and to clarify some difficult questions about computation and its role in cognitive science. In this way, we can see that the foundations of artificial intelligence and computational cognitive science are solid.

**2 A Theory of Implementation**

The short answer to question (1) is straightforward. It goes as follows:

A physical system implements a given computation when the causal structure of the physical system mirrors the formal structure of the computation.

In a little more detail, this comes to:

A physical system implements a given computation when there exists a grouping of physical states of the system into state-types and a one-to-one mapping from formal states of the computation to physical state-types, such that formal states related by an abstract state-transition relation are mapped onto physical state-types related by a corresponding causal state-transition relation.

This is still a little vague. To spell it out fully, we must specify the class of computations in question. Computations are generally specified relative to some formalism, and there is a wide variety of formalisms: these include Turing machines, Pascal programs, cellular automata, and neural networks, among others. The story about implementation is similar for each of these; only the details differ. All of these can be subsumed under the class of *combinatorial-state automata* (CSAs), which I will outline shortly, but for the purposes of illustration I will first deal with the special case of *simple finite-state automata* (FSAs).

An FSA is specified by giving a set of input states \( I_1, \ldots, I_k \), a set of internal states \( S_1, \ldots, S_m \), and a set of output states \( O_1, \ldots, O_n \), along with a set of state-transition relations of the form \((S, I) \mapsto (S', O')\), for each pair \((S, I)\) of internal states and input states, where \(S'\) and \(O'\) are an internal state and an output state.
respectively. $S$ and $I$ can be thought of as the "old" internal state and the input at a given time; $S'$ is the "new" internal state, and $O'$ is the output produced at that time. (There are some variations in the ways this can be spelled out - e.g. one need not include outputs at each time step, and it is common to designate some internal state as a "final" state - but these variations are unimportant for our purposes.) The conditions for the implementation of an FSA are the following:

A physical system $P$ implements an FSA $M$ if there is a mapping $f$ that maps internal states of $P$ to internal states of $M$, inputs to $P$ to input states of $M$, and outputs of $P$ to output states of $M$, such that: for every state-transition relation $(S, I) \rightarrow (S', O')$ of $M$, the following conditional holds: if $P$ is in internal state $s$ and receiving input $i$ where $f(s)=S$ and $f(i)=I$, this reliably causes it to enter internal state $s'$ and produce output $o'$ such that $f(s')=S'$ and $f(o')=O'$.[1]

This definition uses maximally specific physical states $s$ rather than the grouped state-types referred to above. The state-types can be recovered, however: each corresponds to a set $\{s \mid f(s) = S_i\}$, for each $S_i \in M$. From here we can see that the definitions are equivalent. The causal relations between physical state-types will precisely mirror the abstract relations between formal states.

There is a lot of room to play with the details of this definition. For instance, it is generally useful to put restrictions on the way that inputs and outputs to the system map onto inputs and outputs of the FSA. We also need not map all possible internal states of $P$, if some are not reachable from certain initial states. These matters are unimportant here, however. What is important is the overall form of the definition: in particular, the way it ensures that the formal state-transitional structure of the computation mirrors the causal state-transitional structure of the physical system. This is what all definitions of implementation, in any computational formalism, will have in common.

2.1 Combinatorial-state automata

Simple finite-state automata are unsatisfactory for many purposes, due to the monadic nature of their states. The states in most computational formalisms have a combinatorial structure: a cell pattern in a cellular automaton, a combination of tape-state and head-state in a Turing machine, variables and registers in a Pascal program, and so on. All this can be accommodated within the framework of combinatorial-state automata (CSAs), which differ from FSAs only in that an internal state is specified not by a monadic label $S$, but by a vector $[S^1, S^2, S^3, ...]$. The elements of this vector can be thought of as the components of the overall state, such as the cells in a cellular automaton or the tape-squares in a Turing machine. There are a finite number of possible values $S_j^i$ for each element $S^i$, where $S_j^i$ is the $j$th possible value for the $i$th element. These values can be thought of as "substates". Inputs and outputs can have a similar sort of complex structure: an input vector is $[I^1, I^2, I^3, ...]$, and so on. State-transition rules are determined by specifying, for each element of the state-vector, a function by which its new state depends on the old overall state-vector and input-vector, and the same for each element of the output-vector.

Input and output vectors are always finite, but the internal state vectors can be either finite or infinite.
The finite case is simpler, and is all that is required for any practical purposes. Even if we are dealing with Turing machines, a Turing machine with a tape limited to $10^{200}$ squares will certainly be all that is required for simulation or emulation within cognitive science and AI. The infinite case can be spelled out in an analogous fashion, however. The main complication is that restrictions have to be placed on the vectors and dependency rules, so that these do not encode an infinite amount of information. This is not too difficult, but I will not go into details here.

The conditions under which a physical system implements a CSA are analogous to those for an FSA. The main difference is that internal states of the system need to be specified as vectors, where each element of the vector corresponds to an independent element of the physical system. A natural requirement for such a "vectorization" is that each element correspond to a distinct physical region within the system, although there may be other alternatives. The same goes for the complex structure of inputs and outputs. The system implements a given CSA if there exists such a vectorization of states of the system, and a mapping from elements of those vectors onto corresponding elements of the vectors of the CSA, such that the state-transition relations are isomorphic in the obvious way. The details can be filled in straightforwardly, as follows:

A physical system $P$ implements a CSA $M$ if there is a vectorization of internal states of $P$ into components $[s^1, s^2, ...]$, and a mapping $f$ from the substates $s^j$ into corresponding substates $S^j$ of $M$, along with similar vectorizations and mappings for inputs and outputs, such that for every state-transition rule $([I^1, ..., I^k], [S^1, S^2, ...]) \rightarrow ([S'^1, S'^2, ...], [O^1, ..., O^l])$ of $M$: if $P$ is in internal state $[s^1, s^2, ...]$ and receiving input $[i^1, ..., i^n]$ which map to formal state and input $[S^1, S^2, ...]$ and $[I^1, ..., I^k]$ respectively, this reliably causes it to enter an internal state and produce an output that map to $[S'^1, S'^2, ...]$ and $[O^1, ..., O^l]$ respectively.

Once again, further constraints might be added to this definition for various purposes, and there is much that can be said to flesh out the definition's various parts; a detailed discussion of these technicalities must await another forum (see Chalmers 1996a for a start). This definition is not the last word in a theory of implementation, but it captures the theory's basic form.

One might think that CSAs are not much of an advance on FSAs. Finite CSAs, at least, are no more computationally powerful than FSAs; there is a natural correspondence that associates every finite CSA with an FSA with the same input/output behavior. Of course infinite CSAs (such as Turing machines) are more powerful, but even leaving that reason aside, there are a number of reasons why CSAs are a more suitable formalism for our purposes than FSAs.

First, the implementation conditions on a CSA are much more constrained than those of the corresponding FSA. An implementation of a CSA is required to consist in a complex causal interaction among a number of separate parts; a CSA description can therefore capture the causal organization of a system to a much finer grain. Second, the structure in CSA states can be of great explanatory utility. A description of a physical system as a CSA will often be much more illuminating than a description as the
corresponding FSA. Third, CSAs reflect in a much more direct way the formal organization of such familiar computational objects as Turing machines, cellular automata, and the like. Finally, the CSA framework allows a unified account of the implementation conditions for both finite and infinite machines.

This definition can straightforwardly be applied to yield implementation conditions for more specific computational formalisms. To develop an account of the implementation-conditions for a Turing machine, say, we need only redescribe the Turing machine as a CSA. The overall state of a Turing machine can be seen as a giant vector, consisting of (a) the internal state of the head, and (b) the state of each square of the tape, where this state in turn is an ordered pair of a symbol and a flag indicating whether the square is occupied by the head (of course only one square can be so occupied; this will be ensured by restrictions on initial state and on state-transition rules). The state-transition rules between vectors can be derived naturally from the quintuples specifying the behavior of the machine-head. As usually understood, Turing machines only take inputs at a single time-step (the start), and do not produce any output separate from the contents of the tape. These restrictions can be overridden in natural ways, for example by adding separate input and output tapes, but even with inputs and outputs limited in this way there is a natural description as a CSA. Given this translation from the Turing machine formalism to the CSA formalism, we can say that a given Turing machine is implemented whenever the corresponding CSA is implemented.

A similar story holds for computations in other formalisms. Some formalisms, such as cellular automata, are even more straightforward. Others, such as Pascal programs, are more complex, but the overall principles are the same. In each case there is some room for maneuver, and perhaps some arbitrary decisions to make (does writing a symbol and moving the head count as two state-transitions or one?) but little rests on the decisions we make. We can also give accounts of implementation for nondeterministic and probabilistic automata, by making simple changes in the definition of a CSA and the corresponding account of implementation. The theory of implementation for combinatorial-state automata provides a basis for the theory of implementation in general.

2.2 Questions answered

The above account may look complex, but the essential idea is very simple: the relation between an implemented computation and an implementing system is one of isomorphism between the formal structure of the former and the causal structure of the latter. In this way, we can see that as far as the theory of implementation is concerned, a computation is simply an abstract specification of causal organization. This is important for later purposes. In the meantime, we can now answer various questions and objections.

Does every system implement some computation? Yes. For example, every physical system will implement the simple FSA with a single internal state; most physical systems will implement the 2-state cyclic FSA, and so on. This is no problem, and certainly does not render the account vacuous. That would only be the case if every system implemented every computation, and that is not the case.
Does every system implement any given computation? No. The conditions for implementing a given complex computation - say, a CSA whose state-vectors have 1000 elements, with 10 possibilities for each element and complex state-transition relations - will generally be sufficiently rigorous that extremely few physical systems will meet them. What is required is not just a mapping from states of the system onto states of the CSA, as Searle (1990) effectively suggests. The added requirement that the mapped states must satisfy reliable state-transition rules is what does all the work. In this case, there will effectively be at least $10^{1000}$ constraints on state-transitions (one for each possible state-vector, and more if there are multiple possible inputs). Each constraint will specify one out of at least $10^{1000}$ possible consequents (one for each possible resultant state-vector, and more if there are outputs). The chance that an arbitrary set of states will satisfy these constraints is something less than one in $(10^{1000})^{10^{1000}}$ (actually significantly less, because of the requirement that transitions be reliable). There is no reason to suppose that the causal structure of an arbitrary system (such as Searle's wall) will satisfy these constraints. It is true that while we lack knowledge of the fundamental constituents of matter, it is impossible to prove that arbitrary objects do not implement every computation (perhaps every proton has an infinitely rich internal structure), but anybody who denies this conclusion will need to come up with a remarkably strong argument.

Can a given system implement more than one computation? Yes. Any system implementing some complex computation will simultaneously be implementing many simpler computations - not just 1-state and 2-state FSAs, but computations of some complexity. This is no flaw in the current account; it is precisely what we should expect. The system on my desk is currently implementing all kinds of computations, from EMACS to a clock program, and various sub-computations of these. In general, there is no canonical mapping from a physical object to "the" computation it is performing. We might say that within every physical system, there are numerous computational systems. To this very limited extent, the notion of implementation is "interest-relative". Once again, however, there is no threat of vacuity. The question of whether a given system implements a given computation is still entirely objective. What counts is that a given system implements a computation is still entirely objective. What counts is that a given system does not implement every computation, or to put the point differently, that most given computations are only implemented by a very limited class of physical systems. This is what is required for a substantial foundation for AI and cognitive science, and it is what the account I have given provides.

If even digestion is a computation, isn't this vacuous? This objection expresses the feeling that if every process, including such things as digestion and oxidation, implements some computation, then there seems to be nothing special about cognition any more, as computation is so pervasive. This objection rests on a misunderstanding. It is true that any given instance of digestion will implement some computation, as any physical system does, but the system's implementing this computation is in general irrelevant to its being an instance of digestion. To see this, we can note that the same computation could have been implemented by various other physical systems (such as my SPARC) without it's being an instance of digestion. Therefore the fact that the system implements the computation is not responsible for the existence of digestion in the system.

With cognition, by contrast, the claim is that it is in virtue of implementing some computation that a
system is cognitive. That is, there is a certain class of computations such that any system implementing that computation is cognitive. We might go further and argue that every cognitive system implements some computation such that any implementation of the computation would also be cognitive, and would share numerous specific mental properties with the original system. These claims are controversial, of course, and I will be arguing for them in the next section. But note that it is precisely this relation between computation and cognition that gives bite to the computational analysis of cognition. If this relation or something like it did not hold, the computational status of cognition would be analogous to that of digestion.

What about Putnam's argument? Putnam (1988) has suggested that on a definition like this, almost any physical system can be seen to implement every finite-state automaton. He argues for this conclusion by demonstrating that there will almost always be a mapping from physical states of a system to internal states of an FSA, such that over a given time-period (from 12:00 to 12:10 today, say) the transitions between states are just as the machine table say they should be. If the machine table requires that state $A$ be followed by state $B$, then every instance of state $A$ is followed by state $B$ in this time period. Such a mapping will be possible for an inputless FSA under the assumption that physical states do not repeat. We simply map the initial physical state of the system onto an initial formal state of the computation, and map successive states of the system onto successive states of the computation.

However, to suppose that this system implements the FSA in question is to misconstrue the state-transition conditionals in the definition of implementation. What is required is not simply that state $A$ be followed by state $B$ on all instances in which it happens to come up in a given time-period. There must be a reliable, counterfactual-supporting connection between the states. Given a formal state-transition $A \rightarrow B$, it must be the case that if the system were to be in state $A$, it would transit to state $B$. Further, such a conditional must be satisfied for every transition in the machine table, not just for those whose antecedent states happen to come up in a given time period. It is easy to see that Putnam's system does not satisfy this much stronger requirement. In effect, Putnam has required only that certain weak material conditionals be satisfied, rather than conditionals with modal force. For this reason, his purported implementations are not implementations at all.

(Two notes. First, Putnam responds briefly to the charge that his system fails to support counterfactuals, but considers a different class of counterfactuals - those of the form "if the system had not been in state $A$, it would not have transited to state $B". It is not these counterfactuals that are relevant here. Second, it turns out that Putnam's argument for the widespread realization of inputless FSAs can be patched up in a certain way; this just goes to show that inputless FSAs are an inappropriate formalism for cognitive science, due to their complete lack of combinatorial structure. Putnam gives a related argument for the widespread realization of FSAs with input and output, but this argument is strongly vulnerable to an objection like the one above, and cannot be patched up in an analogous way. CSAs are even less vulnerable to this sort of argument. I discuss all this at much greater length in Chalmers 1996a.)

What about semantics? It will be noted that nothing in my account of computation and implementation invokes any semantic considerations, such as the representational content of internal states. This is precisely as it should be: computations are specified syntactically, not semantically. Although it may
very well be the case that any implementations of a given computation share some kind of semantic content, this should be a consequence of an account of computation and implementation, rather than built into the definition. If we build semantic considerations into the conditions for implementation, any role that computation can play in providing a foundation for AI and cognitive science will be endangered, as the notion of semantic content is so ill-understood that it desperately needs a foundation itself.

The original account of Turing machines by Turing (1936) certainly had no semantic constraints built in. A Turing machine is defined purely in terms of the mechanisms involved, that is, in terms of syntactic patterns and the way they are transformed. To implement a Turing machine, we need only ensure that this formal structure is reflected in the causal structure of the implementation. Some Turing machines will certainly support a systematic semantic interpretation, in which case their implementations will also, but this plays no part in the definition of what it is to be or to implement a Turing machine. This is made particularly clear if we note that there are some Turing machines, such as machines defined by random sets of state-transition quintuples, that support no non-trivial semantic interpretation. We need an account of what it is to implement these machines, and such an account will then generalize to machines that support a semantic interpretation. Certainly, when computer designers ensure that their machines implement the programs that they are supposed to, they do this by ensuring that the mechanisms have the right causal organization; they are not concerned with semantic content. In the words of Haugeland (1985), if you take care of the syntax, the semantics will take care of itself.

I have said that the notion of computation should not be dependent on that of semantic content; neither do I think that the latter notion should be dependent on the former. Rather, both computation and content should be dependent on the common notion of causation. We have seen the first dependence in the account of computation above. The notion of content has also been frequently analyzed in terms of causation (see e.g. Dretske 1981 and Fodor 1987). This common pillar in the analyses of both computation and content allows that the two notions will not sway independently, while at the same time ensuring that neither is dependent on the other for its analysis.

What about computers? Although Searle (1990) talks about what it takes for something to be a "digital computer", I have talked only about computations and eschewed reference to computers. This is deliberate, as it seems to me that computation is the more fundamental notion, and certainly the one that is important for AI and cognitive science. AI and cognitive science certainly do not require that cognitive systems be computers, unless we stipulate that all it takes to be a computer is to implement some computation, in which case the definition is vacuous.

What does it take for something to be a computer? Presumably, a computer cannot merely implement a single computation. It must be capable of implementing many computations - that is, it must be programmable. In the extreme case, a computer will be universal, capable of being programmed to compute any recursively enumerable function. Perhaps universality is not required of a computer, but programmability certainly is. To bring computers within the scope of the theory of implementation above, we could require that a computer be a CSA with certain parameters, such that depending on how these parameters are set, a number of different CSAs can be implemented. A universal Turing machine could be seen in this light, for instance, where the parameters correspond to the "program" symbols on
the tape. In any case, such a theory of computers is not required for the study of cognition.

Is the brain a computer in this sense? Arguably. For a start, the brain can be "programmed" to implement various computations by the laborious means of conscious serial rule-following; but this is a fairly incidental ability. On a different level, it might be argued that learning provides a certain kind of programmability and parameter-setting, but this is a sufficiently indirect kind of parameter-setting that it might be argued that it does not qualify. In any case, the question is quite unimportant for our purposes. What counts is that the brain implements various complex computations, not that it is a computer.

3 Computation and cognition

The above is only half the story. We now need to exploit the above account of computation and implementation to outline the relation between computation and cognition, and to justify the foundational role of computation in AI and cognitive science.

Justification of the thesis of computational sufficiency has usually been tenuous. Perhaps the most common move has been an appeal to the Turing test, noting that every implementation of a given computation will have a certain kind of behavior, and claiming that the right kind of behavior is sufficient for mentality. The Turing test is a weak foundation, however, and one to which AI need not appeal. It may be that any behavioral description can be implemented by systems lacking mentality altogether (such as the giant lookup tables of Block 1981). Even if behavior suffices for mind, the demise of logical behaviorism has made it very implausible that it suffices for specific mental properties: two mentally distinct systems can have the same behavioral dispositions. A computational basis for cognition will require a tighter link than this, then.

Instead, the central property of computation on which I will focus is one that we have already noted: the fact that a computation provides an abstract specification of the causal organization of a system. Causal organization is the nexus between computation and cognition. If cognitive systems have their mental properties in virtue of their causal organization, and if that causal organization can be specified computationally, then the thesis of computational sufficiency is established. Similarly, if it is the causal organization of a system that is primarily relevant in the explanation of behavior, then the thesis of computational explanation will be established. By the account above, we will always be able to provide a computational specification of the relevant causal organization, and therefore of the properties on which cognition rests.

3.1 Organizational invariance

To spell out this story in more detail, I will introduce the notion of the causal topology of a system. The causal topology represents the abstract causal organization of the system: that is, the pattern of interaction among parts of the system, abstracted away from the make-up of individual parts and from the way the causal connections are implemented. Causal topology can be thought of as a dynamic
topology analogous to the static topology of a graph or a network. Any system will have causal topology at a number of different levels. For the cognitive systems with which we will be concerned, the relevant level of causal topology will be a level fine enough to determine the causation of behavior. For the brain, this is probably the neural level or higher, depending on just how the brain's cognitive mechanisms function. (The notion of causal topology is necessarily informal for now; I will discuss its formalization below.)

Call a property $P$ an organizational invariant if it is invariant with respect to causal topology: that is, if any change to the system that preserves the causal topology preserves $P$. The sort of changes in question include: (a) moving the system in space; (b) stretching, distorting, expanding and contracting the system; (c) replacing sufficiently small parts of the system with parts that perform the same local function (e.g. replacing a neuron with a silicon chip with the same I/O properties); (d) replacing the causal links between parts of a system with other links that preserve the same pattern of dependencies (e.g., we might replace a mechanical link in a telephone exchange with an electrical link); and (e) any other changes that do not alter the pattern of causal interaction among parts of the system.

Most properties are not organizational invariants. The property of flying is not, for instance: we can move an airplane to the ground while preserving its causal topology, and it will no longer be flying. Digestion is not: if we gradually replace the parts involved in digestion with pieces of metal, while preserving causal patterns, after a while it will no longer be an instance of digestion: no food groups will be broken down, no energy will be extracted, and so on. The property of being tube of toothpaste is not an organizational invariant: if we deform the tube into a sphere, or replace the toothpaste by peanut butter while preserving causal topology, we no longer have a tube of toothpaste.

In general, most properties depend essentially on certain features that are not features of causal topology. Flying depends on height, digestion depends on a particular physiochemical makeup, tubes of toothpaste depend on shape and physiochemical makeup, and so on. Change the features in question enough and the property in question will change, even though causal topology might be preserved throughout.

### 3.2 The organizational invariance of mental properties

The central claim of this section is that most mental properties are organizational invariants. It does not matter how we stretch, move about, or replace small parts of a cognitive system: as long as we preserve its causal topology, we will preserve its mental properties.

An exception has to be made for properties that are partly supervenient on states of the environment. Such properties include knowledge (if we move a system that knows that $P$ into an environment where $P$ is not true, then it will no longer know that $P$), and belief, on some construals where the content of a belief depends on environmental context. However, mental properties that depend only on internal (brain) state will be organizational invariants. This is not to say that causal topology is irrelevant to knowledge and belief. It will still capture the internal contribution to those properties - that is, causal topology will contribute as much as the brain contributes. It is just that the environment will also play a
The central claim can be justified by dividing mental properties into two varieties: psychological properties - those that are characterized by their causal role, such as belief, learning, and perception - and phenomenal properties, or those that are characterized by way in which they are consciously experienced. Psychological properties are concerned with the sort of thing the mind does, and phenomenal properties are concerned with the way it feels. (Some will hold that properties such as belief should be assimilated to the second rather than the first class; I do not think that this is correct, but nothing will depend on that here.)

Psychological properties, as has been argued by Armstrong (1968) and Lewis (1972) among others, are effectively defined by their role within an overall causal system: it is the pattern of interaction between different states that is definitive of a system's psychological properties. Systems with the same causal topology will share these patterns of causal interactions among states, and therefore, by the analysis of Lewis (1972), will share their psychological properties (as long as their relation to the environment is appropriate).

Phenomenal properties are more problematic. It seems unlikely that these can be defined by their causal roles (although many, including Lewis and Armstrong, think they might be). To be a conscious experience is not to perform some role, but to have a particular feel. These properties are characterized by what it is like to have them, in Nagel's (1974) phrase. Phenomenal properties are still quite mysterious and ill-understood.

Nevertheless, I believe that they can be seen to be organizational invariants, as I have argued elsewhere. The argument for this, very briefly, is a reductio. Assume conscious experience is not organizationally invariant. Then there exist systems with the same causal topology but different conscious experiences. Let us say this is because the systems are made of different materials, such as neurons and silicon; a similar argument can be given for other sorts of differences. As the two systems have the same causal topology, we can (in principle) transform the first system into the second by making only gradual changes, such as by replacing neurons one at a time with I/O equivalent silicon chips, where the overall pattern of interaction remains the same throughout. Along the spectrum of intermediate systems, there must be two systems between which we replace less than ten percent of the system, but whose conscious experiences differ. Consider these two systems, \(N\) and \(S\), which are identical except in that some circuit in one is neural and in the other is silicon.

The key step in the thought-experiment is to take the relevant neural circuit in \(N\), and to install alongside it a causally isomorphic silicon back-up circuit, with a switch between the two circuits. What happens when we flip the switch? By hypothesis, the system's conscious experiences will change: say, for purposes of illustration, from a bright red experience to a bright blue experience (or to a faded red experience, or whatever). This follows from the fact that the system after the change is a version of \(S\), whereas before the change it is just \(N\).
But given the assumptions, there is no way for the system to notice these changes. Its causal topology stays constant, so that all of its functional states and behavioral dispositions stay fixed. If noticing is defined functionally (as it should be), then there is no room for any noticing to take place, and if it is not, any noticing here would seem to be a thin event indeed. There is certainly no room for a thought "Hmm! Something strange just happened!", unless it is floating free in some Cartesian realm. [3] Even if there were such a thought, it would be utterly impotent; it could lead to no change of processing within the system, which could not even mention it. (If the substitution were to yield some change in processing, then the systems would not have the same causal topology after all. Recall that the argument has the form of a reductio.) We might even flip the switch a number of times, so that red and blue experiences "dance" before the system's inner eye; it will never notice. This, I take it, is a reductio ad absurdum of the original hypothesis: if one's experiences change, one can potentially notice in a way that makes some causal difference. Therefore the original assumption is false, and phenomenal properties are organizational invariants. This needs to be worked out in more detail, of course. I give the details of this "Dancing Qualia" argument along with a related "Fading Qualia" argument in (Chalmers 1995).

If all this works, it establishes that most mental properties are organizational invariants: any two systems that share their fine-grained causal topology will share their mental properties, modulo the contribution of the environment.

### 3.3 Justifying the theses

To establish the thesis of computational sufficiency, all we need to do now is establish that organizational invariants are fixed by some computational structure. This is quite straightforward.

An organizationally invariant property depends only on some pattern of causal interaction between parts of the system. Given such a pattern, we can straightforwardly abstract it into a CSA description: the parts of the system will correspond to elements of the CSA state-vector, and the patterns of interaction will be expressed in the state-transition rules. This will work straightforwardly as long as each part has only a finite number of states that are relevant to the causal dependencies between parts, which is likely to be the case in any biological system whose functions cannot realistically depend on infinite precision. (I discuss the issue of analog quantities in more detail below.) Any system that implements this CSA will share the causal topology of the original system. In fact, it turns out that the CSA formalism provides a perfect formalization of the notion of causal topology. A CSA description specifies a division of a system into parts, a space of states for each part, and a pattern of interaction between these states. This is precisely what is constitutive of causal topology.

If what has gone before is correct, this establishes the thesis of computational sufficiency, and therefore the view that Searle has called "strong artificial intelligence": that there exists some computation such that any implementation of the computation possesses mentality. The fine-grained causal topology of a brain can be specified as a CSA. Any implementation of that CSA will share that causal topology, and therefore will share organizationally invariant mental properties that arise from the brain.
The thesis of computational explanation can be justified in a similar way. As mental properties are organizational invariants, the physical properties on which they depend are properties of causal organization. Insofar as mental properties are to be explained in terms of the physical at all, they can be explained in terms of the causal organization of the system.[4] We can invoke further properties (implementational details) if we like, but there is a clear sense in which they are not vital to the explanation. The neural or electronic composition of an element is irrelevant for many purposes; to be more precise, composition is relevant only insofar as it determines the element's causal role within the system. An element with different physical composition but the same causal role would do just as well. This is not to make the implausible claim that neural properties, say, are entirely irrelevant to explanation. Often the best way to investigate a system's causal organization is to investigate its neural properties. The claim is simply that insofar as neural properties are explanatorily relevant, it is in virtue of the role they play in determining a system's causal organization.

In the explanation of behavior, too, causal organization takes center stage. A system's behavior is determined by its underlying causal organization, and we have seen that the computational framework provides an ideal language in which this organization can be specified. Given a pattern of causal interaction between substates of a system, for instance, there will be a CSA description that captures that pattern. Computational descriptions of this kind provide a general framework for the explanation of behavior.

For some explanatory purposes, we will invoke properties that are not organizational invariants. If we are interested in the biological basis of cognition, we will invoke neural properties. To explain situated cognition, we may invoke properties of the environment. This is fine; the thesis of computational explanation is not an exclusive thesis. Still, usually we are interested in neural properties insofar as they determine causal organization, we are interested in properties of the environment insofar as they affect the pattern of processing in a system, and so on. Computation provides a general explanatory framework that these other considerations can supplement.

### 3.4 Some objections

A computational basis for cognition can be challenged in two ways. The first sort of challenge argues that computation cannot do what cognition does: that a computational simulation might not even reproduce human behavioral capacities, for instance, perhaps because the causal structure in human cognition goes beyond what a computational description can provide. The second concedes that computation might capture the capacities, but argues that more is required for true mentality. I will consider four objections of the second variety, and then three of the first. Answers to most of these objections fall directly out of the framework developed above.

**But a computational model is just a simulation!** According to this objection, due to Searle (1980), Harnad (1989), and many others, we do not expect a computer model of a hurricane to be a real hurricane, so why should a computer model of mind be a real mind? But this is to miss the important point about organizational invariance. A computational simulation is not a mere formal abstraction, but
has rich internal dynamics of its own. If appropriately designed it will share the causal topology of the system that is being modeled, so that the system's organizationally invariant properties will be not merely simulated but \textit{replicated}.

The question about whether a computational model simulates or replicates a given property comes down to the question of whether or not the property is an organizational invariant. The property of being a hurricane is obviously not an organizational invariant, for instance, as it is essential to the very notion of hurricanehood that wind and air be involved. The same goes for properties such as digestion and temperature, for which specific physical elements play a defining role. There is no such obvious objection to the organizational invariance of cognition, so the cases are disanalogous, and indeed, I have argued above that for mental properties, organizational invariance actually holds. It follows that a model that is computationally equivalent to a mind will itself be a mind.

\textbf{Syntax and semantics.} Searle (1984) has argued along the following lines: (1) A computer program is syntactic; (2) Syntax is not sufficient for semantics; (3) Minds have semantics; therefore (4) Implementing a computer program is insufficient for a mind. Leaving aside worries about the second premise, we can note that this argument equivocates between programs and implementations of those programs. While programs themselves are syntactic objects, implementations are not: they are real physical systems with complex causal organization, with real physical causation going on inside. In an electronic computer, for instance, circuits and voltages push each other around in a manner analogous to that in which neurons and activations push each other around. It is precisely in virtue of this causation that implementations may have cognitive and therefore semantic properties.

It is the notion of implementation that does all the work here. A program and its physical implementation should not be regarded as equivalent - they lie on entirely different levels, and have entirely different properties. It is the program that is syntactic; it is the implementation that has semantic content. Of course, there is still a substantial question about how an implementation comes to possess semantic content, just as there is a substantial question about how a \textit{brain} comes to possess semantic content. But once we focus on the implementation, rather than the program, we are at least in the right ball-park. We are talking about a physical system with causal heft, rather than a shadowy syntactic object. If we accept, as is extremely plausible, that brains have semantic properties in virtue of their causal organization and causal relations, then the same will go for implementations. Syntax may not be sufficient for semantics, but the right kind of causation is.

\textbf{The Chinese room.} There is not room here to deal with Searle's famous Chinese room argument in detail. I note, however, that the account I have given supports the "Systems reply", according to which the entire system understands Chinese even if the homunculus doing the simulating does not. Say the overall system is simulating a brain, neuron-by-neuron. Then like any implementation, it will share important causal organization with the brain. In particular, if there is a symbol for every neuron, then the patterns of interaction between slips of paper bearing those symbols will mirror patterns of interaction between neurons in the brain, and so on. This organization is implemented in a baroque way, but we should not let the baroqueness blind us to the fact that the causal organization - \textit{real}, physical causal organization - is there. (The same goes for a simulation of cognition at level above the neural, in which
the shared causal organization will lie at a coarser level.)

It is precisely in virtue of this causal organization that the system possesses its mental properties. We can rerun a version of the "dancing qualia" argument to see this. In principle, we can move from the brain to the Chinese room simulation in small steps, replacing neurons at each step by little demons doing the same causal work, and then gradually cutting down labor by replacing two neighboring demons by one who does the same work. Eventually we arrive at a system where a single demon is responsible for maintaining the causal organization, without requiring any real neurons at all. This organization might be maintained between marks on paper, or it might even be present inside the demon's own head, if the calculations are memorized. The arguments about organizational invariance all hold here - for the same reasons as before, it is implausible to suppose that the system's experiences will change or disappear.

Performing the thought-experiment this way makes it clear that we should not expect the experiences to be had by the *demon*. The demon is simply a kind of causal facilitator, ensuring that states bear the appropriate causal relations to each other. The conscious experiences will be had by the system as a whole. Even if that system is implemented inside the demon by virtue of the demon's memorization, the system should not be confused with demon itself. We should not suppose that the demon will share the implemented system's experiences, any more than it will share the experiences of an ant that crawls inside its skull: both are cases of two computational systems being implemented within a single physical space. Mental properties arising from distinct computational systems will be quite distinct, and there is no reason to suppose that they overlap.

**What about the environment?** Some mental properties, such as knowledge and even belief, depend on the environment being a certain way. Computational organization, as I have outlined it, cannot determine the environmental contribution, and therefore cannot fully guarantee this sort of mental property. But this is no problem. All we need computational organization to give us is the *internal* contribution to mental properties: that is, the same contribution that the brain makes (for instance, computational organization will determine the so-called "narrow content" of a belief, if this exists; see Fodor 1987). The full panoply of mental properties might only be determined by computation-plus-environment, just as it is determined by brain-plus-environment. These considerations do not count against the prospects of artificial intelligence, and they affect the aspirations of computational cognitive science no more than they affect the aspirations of neuroscience.

_Is cognition computable?_ In the preceding discussion I have taken for granted that computation can at least _simulate_ human cognitive capacity, and have been concerned to argue that this counts as honest-to-goodness mentality. The former point has often been granted by opponents of AI (e.g. Searle 1980) who have directed the fire at the latter, but it is not uncontroversial.

This is to some extent an empirical issue, but the relevant evidence is solidly on the side of computability. We have every reason to believe that the low-level laws of physics are computable. If so, then low-level neurophysiological processes can be computationally simulated; it follows that the function of the whole brain is computable too, as the brain consists in a network of neurophysiological
parts. Some have disputed the premise: for example, Penrose (1989) has speculated that the effects of quantum gravity are noncomputable, and that these effects may play a role in cognitive functioning. He offers no arguments to back up this speculation, however, and there is no evidence of such noncomputability in current physical theory (see Pour-El and Richards (1989) for a discussion). Failing such a radical development as the discovery that the fundamental laws of nature are uncomputable, we have every reason to believe that human cognition can be computationally modeled.

**What about Gödel's theorem?** Gödel's theorem states that for any consistent formal system, there are statements of arithmetic that are unprovable within the system. This has led some (Lucas 1963; Penrose 1989) to conclude that humans have abilities that cannot be duplicated by any computational system. For example, our ability to "see" the truth of the Gödel sentence of a formal system is argued to be non-algorithmic. I will not deal with this objection in detail here, as the answer to it is not a direct application of the current framework. I will simply note that the assumption that we can see the truth of arbitrary Gödel sentences requires that we have the ability to determine the consistency or inconsistency of any given formal system, and there is no reason to believe that we have this ability in general. (For more on this point, see Putnam 1960, Bowie 1982 and the commentaries on Penrose 1990.)

**Discreteness and continuity.** An important objection notes that the CSA formalism only captures discrete causal organization, and argues that some cognitive properties may depend on continuous aspects of that organization, such as analog values or chaotic dependencies.

A number of responses to this are possible. The first is to note that the current framework can fairly easily be extended to deal with computation over continuous quantities such as real numbers. All that is required is that the various substates of a CSA be represented by a real parameter rather than a discrete parameter, where appropriate restrictions are placed on allowable state-transitions (for instance, we can require that parameters are transformed polynomially, where the requisite transformation can be conditional on sign). See Blum, Shub and Smale (1989) for a careful working-out of some of the relevant theory of computability. A theory of implementation can be given along in a fashion similar to the account I have given above, where continuous quantities in the formalism are required to correspond to continuous physical parameters with an appropriate correspondence in state-transitions.

This formalism is still discrete in time: evolution of the continuous states proceeds in discrete temporal steps. It might be argued that cognitive organization is in fact continuous in time, and that a relevant formalism should capture this. In this case, the specification of discrete state-transitions between states can be replaced by differential equations specifying how continuous quantities change in continuous time, giving a thoroughly continuous computational framework. MacLennan (1990) describes a framework along these lines. Whether such a framework truly qualifies as computational is largely a terminological matter, but there it is arguable that the framework is significantly similar in kind to the traditional approach; all that has changed is that discrete states and steps have been "smoothed out".

We need not go this far, however. There are good reasons to suppose that whether or not cognition in the brain is continuous, a discrete framework can capture everything important that is going on. To see this,
we can note that a discrete abstraction can describe and simulate a continuous process to any required
degree of accuracy. It might be objected that chaotic processes can amplify microscopic differences to
significant levels. Even so, it is implausible that the correct functioning of mental processes depends on
the precise value of the tenth decimal place of analog quantities. The presence of background noise and
randomness in biological systems implies that such precision would inevitably be "washed out" in
practice. It follows that although a discrete simulation may not yield precisely the behavior that a given
cognitive system produces on a given occasion, it will yield plausible behavior that the system might
have produced had background noise been a little different. This is all that a proponent of artificial
intelligence need claim.

Indeed, the presence of noise in physical systems suggests that any given continuous computation of the
above kinds can never be reliably implemented in practice, but only approximately implemented. For the
purposes of artificial intelligence we will do just as well with discrete systems, which can also give us
approximate implementations of continuous computations.

It follows that these considerations do not count against the theses of computational sufficiency or of
computational explanation. To see the first, note that a discrete simulation can replicate everything
essential to cognitive functioning, for the reasons above, even though it may not duplicate every last
detail of a given episode of cognition. To see the second, note that for similar reasons the precise values
of analog quantities cannot be relevant to the explanation of our cognitive capacities, and that a discrete
description can do the job.

This is not to exclude continuous formalisms from cognitive explanation. The thesis of computational
explanation is not an exclusive thesis. It may be that continuous formalisms will provide a simpler and
more natural framework for the explanation of many dynamic processes, as we find in the theory of
neural networks. Perhaps the most reasonable version of the computationalist view accepts the thesis of
(discrete) computational sufficiency, but supplements the thesis of computational explanation with the
proviso that continuous computation may sometimes provide a more natural explanatory framework (a
discrete explanation could do the same job, but more clumsily). In any case, continuous computation
does not give us anything fundamentally new.

4 Other kinds of computationalism

Artificial intelligence and computational cognitive science are committed to a kind of computationalism
about the mind, a computationalism defined by the theses of computational sufficiency and
computational explanation. In this paper I have tried to justify this computationalism, by spelling out the
role of computation as a tool for describing and duplicating causal organization. I think that this kind of
computationalism is all that artificial intelligence and computational cognitive science are committed to,
and indeed is all that they need. This sort of computationalism provides a general framework precisely
because it makes so few claims about the kind of computation that is central to the explanation and
replication of cognition. No matter what the causal organization of cognitive processes turns out to be,
there is good reason to believe that it can be captured within a computational framework.
The fields have often been taken to be committed to stronger claims, sometimes by proponents and more often by opponents. For example, Edelman (1989) criticizes the computational approach to the study of the mind on the grounds that:

An analysis of the evolution, development, and structure of brains makes it highly unlikely that they could be Turing machines. This is so because of the enormous individual variation in structure that brains possess at a variety of organizational levels. [...] [Also,] an analysis of both ecological and environmental variation, and of the categorization procedures of animals and humans, makes it highly unlikely that the world (physical and social) can function as a tape for a Turing machine. (Edelman 1989, p. 30.)

But artificial intelligence and computational cognitive science are not committed to the claim that the brain is literally a Turing machine with a moving head and a tape, and even less to the claim that that tape is the environment. The claim is simply that some computational framework can explain and replicate human cognitive processes. It may turn out that the relevant computational description of these processes is very fine-grained, reflecting extremely complex causal dynamics among neurons, and it may well turn out that there is significant variation in causal organization between individuals. There is nothing here that is incompatible with a computational approach to cognitive science.

In a similar way, a computationalist need not claim that the brain is a von Neumann machine, or has some other specific architecture. Like Turing machines, von Neumann machines are just one kind of architecture, particularly well-suited to programmability, but the claim that the brain implements such an architecture is far ahead of any empirical evidence and is most likely false. The commitments of computationalism are more general.

Computationalism is occasionally associated with the view that cognition is rule-following, but again this is a strong empirical hypothesis that is inessential to the foundations of the fields. It is entirely possible that the only "rules" found in a computational description of thought will be at a very low level, specifying the causal dynamics of neurons, for instance, or perhaps the dynamics of some level between the neural and the cognitive. Even if there are no rules to be found at the cognitive level, a computational approach to the mind can still succeed. Another claim to which a computationalist need not be committed are "the brain is a computer"; as we have seen, it is not computers that are central but computations).

The most ubiquitous "strong" form of computationalism has been what we may call symbolic computationalism: the view that cognition is computation over representation (Newell and Simon 1976; Fodor and Pylyshyn 1988). To a first approximation, we can cash out this view as the claim that the computational primitives in a computational description of cognition are also representational primitives. That is to say, the basic syntactic entities between which state-transitions are defined are themselves bearers of semantic content, and are therefore symbols.

Symbolic computationalism has been a popular and fruitful approach to the mind, but it does not exhaust the resources of computation. Not all computations are symbolic computations. We have seen that there
are some Turing machines that lack semantic content altogether, for instance. Perhaps systems that carry semantic content are more plausible models of cognition, but even in these systems there is no reason why the content must be carried by the systems' computational primitives. In connectionist systems, for example, the basic bearers of semantic content are distributed representations, patterns of activity over many units, whereas the computational primitives are simple units that may themselves lack semantic content. To use Smolensky's term (Smolensky 1988), these systems perform subsymbolic computation: the level of computation falls below the level of representation.[5] But the systems are computational nevertheless.

Note that the distinction between symbolic and subsymbolic computation does not coincide with the distinction between different computational formalisms, such as Turing machines and neural networks. Rather, the distinction divides the class of computations within each of these formalisms. Some Turing machines perform symbolic computation, and some perform subsymbolic computation; the same goes for neural networks. (Of course it is sometimes said that all Turing machines perform "symbol manipulation", but this holds only if the ambiguous term "symbol" is used in a purely syntactic sense, rather than in the semantic sense I am using here.)

Both proponents and opponents of a computational approach have often implicitly identified computation with symbolic computation. A critique called What Computers Can't Do (Dreyfus 1972), for instance, turns out to be largely directed at systems that perform computation over explicit representation. Other sorts of computation are left untouched, and indeed systems performing subsymbolic computation seem well-suited for some of Dreyfus's problem areas. The broader ambitions of artificial intelligence are therefore left intact.

On the other side of the fence, Fodor (1992) uses the name "Computational Theory of Mind" for a version of symbolic computationalism, and suggests that Turing's main contribution to cognitive science is the idea that syntactic state-transitions between symbols can be made to respect their semantic content. This strikes me as false. Turing was concerned very little with the semantic content of internal states, and the concentration on symbolic computation came later. Rather, Turing's key contribution was the formalization of the notion of mechanism, along with the associated universality of the formalization. It is this universality that gives us good reason to suppose that computation can do almost anything that any mechanism can do, thus accounting for the centrality of computation in the study of cognition.

Indeed, a focus on symbolic computation sacrifices the universality that is at the heart of Turing's contribution. Universality applies to entire classes of automata, such as Turing machines, where these classes are defined syntactically. The requirement that an automaton performs computation over representation is a strong further constraint, a semantic constraint that plays no part in the basic theory of computation. There is no reason to suppose that the much narrower class of Turing machines that perform symbolic computation is universal. If we wish to appeal to universality in a defense of computationalism, we must cast the net more widely than this.[6]

The various strong forms of computationalism outlined here are bold empirical hypotheses with varying
degrees of plausibility. I suspect that they are all false, but in any case their truth and falsity is not the issue here. Because they are such strong empirical hypotheses, they are in no position to serve as a foundation for artificial intelligence and computational cognitive science. If the fields were committed to these hypotheses, their status would be much more questionable than it currently is. Artificial intelligence and computational cognitive science can survive the discovery that the brain is not a von Neumann machine, or that cognition is not rule-following, or that the brain does not engage in computation over representation, precisely because these are not among the fields' foundational commitments. Computation is much more general than this, and consequently much more robust.[7]

5 Conclusion: Toward a minimal computationalism

The view that I have advocated can be called minimal computationalism. It is defined by the twin theses of computational sufficiency and computational explanation, where computation is taken in the broad sense that dates back to Turing. I have argued that these theses are compelling precisely because computation provides a general framework for describing and determining patterns of causal organization, and because mentality is rooted in such patterns. The thesis of computational explanation holds because computation provides a perfect language in which to specify the causal organization of cognitive processes; and the thesis of computational sufficiency holds because in all implementations of the appropriate computations, the causal structure of mentality is replicated.

Unlike the stronger forms of computationalism, minimal computationalism is not a bold empirical hypothesis. To be sure, there are some ways that empirical science might prove it to be false: if it turns out that the fundamental laws of physics are noncomputable and if this noncomputability reflects itself in cognitive functioning, for instance, or if it turns out that our cognitive capacities depend essentially on infinite precision in certain analog quantities, or indeed if it turns out that cognition is mediated by some non-physical substance whose workings are not computable. But these developments seem unlikely; and failing developments like these, computation provides a general framework in which we can express the causal organization of cognition, whatever that organization turns out to be.

Minimal computationalism is compatible with such diverse programs as connectionism, logicism, and approaches focusing on dynamic systems, evolution, and artificial life. It is occasionally said that programs such as connectionism are "noncomputational", but it seems more reasonable to say that the success of such programs would vindicate Turing's dream of a computational intelligence, rather than destroying it.

Computation is such a valuable tool precisely because almost any theory of cognitive mechanisms can be expressed in computational terms, even though the relevant computational formalisms may vary. All such theories are theories of causal organization, and computation is sufficiently flexible that it can capture almost any kind of organization, whether the causal relations hold between high-level representations or among low-level neural processes. Even such programs as the Gibsonian theory of perception are ultimately compatible with minimal computationalism. If perception turns out to work as the Gibsonians imagine, it will still be mediated by causal mechanisms, and the mechanisms will be
expressible in an appropriate computational form. That expression may look very unlike a traditional computational theory of perception, but it will be computational nevertheless.

In this light, we see that artificial intelligence and computational cognitive science do not rest on shaky empirical hypotheses. Instead, they are consequences of some very plausible principles about the causal basis of cognition, and they are compatible with an extremely wide range of empirical discoveries about the functioning of the mind. It is precisely because of this flexibility that computation serves as a foundation for the fields in question, by providing a common framework within which many different theories can be expressed, and by providing a tool with which the theories' causal mechanisms can be instantiated. No matter how cognitive science progresses in the coming years, there is good reason to believe that computation will be at center stage.

References

Notes

1. I take it that something like this is the "standard" definition of implementation of a finite-state automaton; see, for example, the definition of the description of a system by a probabilistic automaton in Putnam (1967). It is surprising, however, how little space has been devoted to accounts of implementation in the literature in theoretical computer science, philosophy of psychology, and cognitive science, considering how central the notion of computation is to these fields. It is remarkable that there could be a controversy about what it takes for a physical system to implement a computation (e.g. Searle 1990, 1991) at this late date.

2. See Pylyshyn 1984, p. 71, for a related point.

3. In analyzing a related thought-experiment, Searle (1991) suggests that a subject who has undergone silicon replacement might react as follows: "You want to cry out, `I can't see anything. I'm going totally blind'. But you hear your voice saying in a way that is completely out of your control, `I see a red object in front of me'" (pp. 66-67). But given that the system's causal topology remains constant, it is very unclear where there is room for such "wanting" to take place, if it is not in some Cartesian realm. Searle suggests some other things that might happen, such as a reduction to total paralysis, but these suggestions require a change in causal topology and are therefore not relevant to the issue of organizational invariance.

4. I am skeptical about whether phenomenal properties can be explained in wholly physical terms. As I
argue in Chalmers (forthcoming c), given any account of the physical or computational processes underlying mentality, the question of why these processes should give rise to conscious experience does not seem to be explainable within physical or computational theory alone. Nevertheless, it remains the case that phenomenal properties depend on physical properties, and if what I have said earlier is correct, the physical properties that they depend on are organizational properties. Further, the explanatory gap with respect to conscious experience is compatible with the computational explanation of cognitive processes and of behavior, which is what the thesis of computational explanation requires.

5. Of course there is a sense in which it can be said that connectionist models perform "computation over representation", in that connectionist processing involves the transformation of representations, but this sense is too weak to cut the distinction between symbolic and subsymbolic computation at its joints. Perhaps the most interesting foundational distinction between symbolic and connectionist systems is that in the former but not in the latter, the computational (syntactic) primitives are also the representational (semantic) primitives.

6. It is common for proponents of symbolic computationalism to hold, usually as an unargued premise, that what makes a computation a computation is the fact that it involves representations with semantic content. The books by Fodor (1975) and Pylyshyn (1984), for instance, are both premised on the assumption that there is no computation without representation. Of course this is to some extent a terminological issue, but as I have stressed in 2.2 and here, this assumption has no basis in computational theory and unduly restricts the role that computation plays in the foundations of cognitive science.

7. Some other claims with which computationalism is sometimes associated include "the brain is a computer", "the mind is to the brain as software is to hardware", and "cognition is computation". The first of these is not required, for the reasons given in 2.2: it is not computers that are central to cognitive theory but computations. The second claim is an imperfect expression of the computationalist position for similar reasons: certainly the mind does not seem to be something separable that the brain can load and run, as a computer's hardware can load and run software. Even the third does not seem to me to be central to computationalism: perhaps there is a sense in which it is true, but what is more important is that computation suffices for and explains cognition. See Dietrich (1990) for some related distinctions between computationalism, "computerism", and "cognitivism".
Does a Rock Implement Every Finite-State Automaton?

David J. Chalmers

chalmers@arizona.edu

ABSTRACT

Putnam has argued that computational functionalism cannot serve as a foundation for the study of the mind, as every ordinary open physical system implements every finite-state automaton. I argue that Putnam's argument fails, but that it points out the need for a better understanding of the bridge between the theory of computation and the theory of physical systems: the relation of implementation. It also raises questions about the classes of automata that can serve as a basis for understanding the mind. I develop an account of implementation, linked to an appropriate class of automata, such that the requirement that a system implement a given automaton places a very strong constraint on the system. This clears the way for computation to play a central role in the analysis of mind.

1 Introduction

The theory of computation is often thought to underwrite the theory of mind. In cognitive science, it is widely believed that intelligent behavior is enabled by the fact that the mind or the brain implements some abstract automaton: perhaps a Turing machine, a program, an abstract neural network, or a finite-state automaton. The ambitions of artificial intelligence rest on a related claim of computational sufficiency, holding that there is a class of automata such that any implementation of an automaton in that class will possess a mind. A similar claim is often made about many specific mental properties, including properties characteristic of human mentality: that is, it is claimed that there exists a class of automata such that any implementation of an automaton in that class will have the mental property in question. In this way, it is hoped that computation will provide a powerful formalism for the replication and explanation of mentality.

In an appendix to his book *Representation and Reality* (Putnam 1988, pp. 120-125), Hilary Putnam argues for a conclusion that would destroy these ambitions. Specifically, he claims that *every ordinary open system realizes every abstract finite automaton*. He puts this forward as a theorem, and offers a detailed proof. If this is right, a simple system such as a rock implements any automaton one might imagine. Together with the thesis of computational sufficiency, this would imply that a rock has a mind, and
possesses many properties characteristic of human mentality. If Putnam's result is correct, then, we must either embrace an extreme form of panpsychism or reject the principle on which the hopes of artificial intelligence rest. Putnam himself takes the result to show that computational functionalism cannot provide a foundation for a theory of mind. [[Searle (1990) argues for a similar conclusion, although his argument is much less detailed than Putnam's. I comment on it briefly toward the end of the paper.]]

In what follows I will argue that Putnam's argument does not establish such a conclusion, and that the foundations of artificial intelligence are not in danger. His argument nevertheless points to the need for a better understanding of implementation, the relation that connects the theory of computation with the theory of physical systems. (Putnam calls this relation `realization'.) An analysis of Putnam's argument leads us to a better understanding of implementation, as well as to insights into the class of automata that are relevant in computational theories of cognition. As objections are raised and modifications are made, the discussion that follows will touch on a number of formalisms in the theory of computation and various constraints on implementation, before settling on a formalism and an account of implementation that avoid the most serious problems.

2 Putnam's Argument

Putnam precedes his proof with discussion of some physical principles. There is a Principle of Physical Continuity, which is not important for our purposes (it plays a minor role in the argument in an application I will accept), and a more central Principle of Noncyclical Behavior. The latter principle holds that every ordinary system is in different maximal states at different times. (A "maximal" state is a total state of the system, specifying the system's physical makeup in perfect detail). Putnam argues for this on the basis that every such system is exposed to electromagnetic and gravitational radiation from a natural clock. I will accept the principle in the discussion that follows. Even if it does not hold across the board (arguably, signals from a number of sources might cancel each other's effects, leading to a cycle in behavior), the more limited result that every noncyclic system implements every finite-state automaton would still be a strong one.

Putnam is centrally concerned with finite-state automata, or FSAs, and in particular FSAs without input or output, or inputless FSAs. (He extends his results to FSAs with inputs and outputs later.) Such an FSA is specified by a set of formal states \( \{S_1, ..., S_n\} \), and by a set of state-transition relations which specify for each state the state that must follow. He does not offer an explicit account of the conditions under which a physical system implements an FSA, but from his discussion it is clear that he requires something like the following.

A physical system implements an inputless FSA in a given time-period if there is a mapping \( f \) from physical states of the system to formal states of the FSA such that: if the system is in physical state \( p \) during the time-period, this causes it to transit into a state \( q \) such that formal state \( f(p) \) transits to formal state \( f(q) \) in the specification of the FSA.

I will later argue that this account is not quite right, but it captures the central facet of the notion of
implementation: the requirement that in order for a physical system to implement a formal automaton, causal relations among states of a physical system must mirror formal relations among states of the automaton.

Putnam considers an arbitrary system $S$ - say, a rock - over an arbitrary time period, such as from 12:00 to 12:07. Using the expression $St(S,t)$ to denote the maximal state of $S$ at $t$, he defines states of $S$ in the following way.

Let the beginnings of the intervals during which $S$ is to be in one of its stages [...] be $t_1$, $t_2$, ..., $t_n$ (in the example given, $n=7$, and the times in question are $t_1 = 12:00$, $t_2 = 12:01$, $t_3 = 12:02$, $t_4 = 12:03$, $t_5 = 12:04$, $t_6 = 12:05$, $t_7 = 12:06$). The end of the real-time interval during which we wish $S$ to "obey" this table we call $t_{n+1}$ (= $t_8 = 12:07$, in our example). For each of the states $t_i$ to $t_{i+1}$, $i = 1, 2, ..., n$, define a (nonmaximal) interval state $s_i$ which is the "region" in phase space consisting of all the maximal states $St(S,t)$ with $t_i \leq t < t_{i+1}$. (I.e., $S$ is in $s_i$ just in case $S$ is in one of the maximal states in this "region". Note that the system $S$ is in $s_1$ from $t_1$ to $t_2$, in $s_2$ from $t_2$ to $t_3$, ..., in $s_n$ from $t_n$ to $t_{n+1}$. (Left endpoint included in all cases but not the right - this is a convention to ensure the "machine" is in exactly one of the $s_i$ at a given time.) The disjointness of the states $s_i$ is guaranteed by the Principle of Noncyclical Behavior. (pp. 122-123.)

The states are defined, then, so that the system goes through states $s_1$, $s_2$, ..., $s_n$ in succession, in time intervals following $t_1$, $t_2$, ..., $t_n$ respectively.

We can choose an arbitrary (inputless) FSA for the purposes of the argument. Putnam chooses (claiming no loss of generality) an FSA that transits back-and-forth between two states $A$ and $B$, which is therefore required to go through the sequence $ABABABA$ in the time-period in question.

The argument that the system implements the FSA is straightforward. We simply define physical state $a$ to be the disjunction $s_1 \lor s_3 \lor s_5 \lor s_7$, and state $b$ to be $s_2 \lor s_4 \lor s_6$, and we define the mapping $f$ so that $f(a)=A$ and $f(b)=B$. (Putnam's presentation does not distinguish between physical states $a$ and $b$ and formal states $A$ and $B$; I introduce the distinction for clarity.) It is easy to see that during the period in question, the physical system cycles through the states $abababa$, corresponding to formal states $ABABABA$ as required.

Putnam further argues that the system's being in state $a$ causes it to transit into state $b$ and vice versa, using the Principle of Continuity to show that given that the system was in state $a$ at a time $t$ with $t_{[n-1]} \leq t < t_n$ (and given boundary conditions at $t$), it was determined that the system would be in state $b$ at times $t$ with $t_n \leq t < t_{[n+1]}$. I will postpone discussion of this part of the argument.

The argument is general. Given any inputless FSA and any noncyclic physical system, we can map physical states of the system over an arbitrarily long period of time to formal states of the FSA by the
same method. We associate the initial physical state of the system with an initial state of the FSA and associate subsequent physical states of the system with subsequent states of the FSA, where the FSA state-evolution is determined by its state-transition rules. The implementation mapping is determined by taking the disjunction of associated physical states for each state of the FSA, and mapping that disjunctive state to the FSA state in question. Under this mapping, it is easy to see that the evolution of the physical states precisely mirrors evolution of the FSA states. Therefore every noncyclic physical system implements every (inputless) FSA.

3 Analysis

Some object to this argument on the grounds that it requires "unnatural" physical states, involving arbitrary disjunctions. It is difficult to make this objection precise, however, as there does not seem to be an objective distinction between "natural" and "unnatural" states that can do the relevant work; and an objective distinction is needed, if having a mind is to be an objective matter. I will not pursue this line, as I think the problems lie elsewhere. It is also sometimes objected that Putnam employs "time-varying" states, but this is based on a misreading of the argument. The states themselves are quite invariant over time. Time has simply been used to fix reference to these atemporal states.

The problem, I think, is that Putnam's system does not satisfy the right kind of state-transition conditionals. The conditionals involved in the definition of implementation are not ordinary material conditionals, saying that on all those occasions in which the system happens to be in state p in the given time period, state q follows. Rather, these conditionals have modal force, and in particular are required to support counterfactuals: if the system were to be in state p, then it would transit into state q. This expresses the requirement that the connection between connected states must be reliable or lawful, and not simply a matter of happenstance. It is required that however the system comes to be in state p, it transits into state q (perhaps with some restriction ruling out extraordinary environmental circumstances; perhaps not). We can call this sort of conditional a strong conditional.

It is not quite clear whether Putnam intends his conditionals to have this sort of modal force. He requires that the relation be a causal relation, and goes to some lengths to argue that his construction indeed satisfies the causal relation by arguing that its being in state a fully determines its transition into state B, so he may have some such requirement in mind. In any case, I will argue that his system does not satisfy the strong conditionals in the way that implementation of an automaton requires. There are two ways in which Putnam's system fails to satisfy the strong conditionals. The first concerns the state-transitions that are actually exhibited. The second concerns unexhibited state-transitions.

To see the first point, consider the transition from state a to state b that the system actually exhibits. For the system to be a true implementation, this transition must be reliable. But Putnam's system is open to all sorts of environmental influences by its very definition as an open system (indeed, Putnam exploits this fact to establish his Principle of Noncyclical Behavior). It follows that if environmental circumstances had been slightly different, the system's behavior would have been quite different. Putnam's construction establishes nothing about the system's behavior under such circumstances. The construction is entirely...
specific to the environmental conditions as they were during the time-period in question. It follows that
his construction does not satisfy the relevant strong conditionals. Although on this particular run the
system happened to transit from state $a$ to state $b$, if conditions had been slightly different it might have
transited from state $a$ to state $c$, or done something different again.

In particular, it is quite possible for Putnam's system to be in state $a$ at all times between $t_{n-1}$ and $t_n$, while failing to be in state $b$ at all times between $t_n$ and $t_{n-1}$. If environmental conditions had been slightly different at and after time $t_n$, the system might have been buffeted into an entirely different state well before $t_{n+1}$. The relevant strong conditionals are therefore not satisfied. It will not do to argue
that the system counts as being in state $b$ if it is in that state at the beginning of the relevant time-interval. If so, then the same goes for state $a$, and a similar argument can be given. We only need to note the
possibility of environmental buffeting soon after $t_{n-1}$, so that although the system counts as being in
state $a$ in the given interval, it is never in state $b$ in the following interval.

Putnam argues (p. 123) that the system's being in state $a$ throughout the first interval determines the
transition into state $b$ in the next interval, but his argument falls short of establishing what is required. In
particular, he only establishes that:

...given the information that the system was in state $A$ at $t$, and given that the boundary
condition at $t$ was $B_t$, a mathematically omniscient being can determine from the Principle
of Continuity that the system $S$ must have been in $St(S,t)$, and can further determine, given
the boundary conditions at subsequent times and the other laws of nature, how $S$ evolves in
the whole time interval under consideration. (p. 123)

What is important here is the clause "given boundary conditions at subsequent times". This is illegitimate
information for the omniscient being in question to use. What is required is that together with the laws of
nature, the state (and perhaps boundary conditions) during the first interval determines the state during
the next interval. It is illegitimate to appeal to the boundary conditions throughout the next interval. To be
sure, if we can independently specify these conditions, then the next state will be entirely fixed, as there
will be no room for external buffeting, but this is no more interesting than noting that if we fix the
physical state during the next time interval, the physical state will be fixed. This argument therefore fails
to establish what is required, and the strong conditional is unsatisfied.

The second failure of the conditionals is perhaps more interesting. To qualify as an implementation, it is
not only required that the formal state-transitions that are manifested on this run (say, the transitions from
$A$ to $B$ and back) are mirrored in the structure of the physical system. It is required that every state-
transition be so mirrored, including the many that many not be manifested on a particular run. It may be,
for instance, that the FSA in question is specified by the state-transitions $A \rightarrow B$, $B \rightarrow A$, $C \rightarrow D$, $D \rightarrow E$, and so on. In this case, we require that the unmanifested features of the machine-table are reflected in the
physical structure of the system, so that it will be the case that if the system had been in state $C$, it would
have transited to state $D$, and so on.

Perhaps it might be objected that there is little point having such extra states when the machine eternally
cycles between two states and will never reach the other states. However, an FSA will often specify the machine's behavior for more than one initial state; and more importantly the fact that there is a cycle in the state-space is a contingent feature of Putnam's example, and his argument is supposed to be perfectly general. Generally, a finite-state machine that is of practical interest will not exhaust all its states in a given run, nor will it cycle.

The requirement that unmanifested state-transitions also be reflected in the physical structure of the machine requires a slight change to our definition of implementation. It should read:

A physical system implements an inputless FSA in a given time-period if there is a mapping \( f \) from physical states of the system onto formal states of the FSA such that: for every formal state-transition \( P \rightarrow Q \) in the specification of the FSA, if the physical system is in a state \( p \) such that \( f(p) = P \), this causes it to transit into a state \( q \) such that \( f(q) = Q \).

The changes are (1) the requirement that the mapping map physical states onto all states of the FSA, and (2) the requirement that a conditional be satisfied for each state-transition in the FSA. If these conditions are not satisfied, there is a very clear sense in which the FSA is not fully implemented.

It is clear that Putnam's construction does not satisfy this stronger condition. In fact, for any formal state \( P \) that does not appear in the sequence manifested in a given run, his construction leaves undefined the physical states that map onto \( P \). Even if we pick arbitrary uninstantiated physical states to map onto \( P \), there is no reason to believe that these will satisfy the requisite state-transition conditionals. (If the conditional in the definition of implementation is read as a material conditional, then it turns out that these conditionals are satisfied vacuously - every instance of \( p \) transits to \( q \), because there are no instances of \( p \). Again, the conditional needs to be read modally.)

To put the point slightly differently: from the fact that any system that implements a given FSA must go through a sequence \( abababa \) in real time, the converse does not follow. We cannot infer that any system that goes through the sequence \( abababa \) implements the FSA. In effect, Putnam has failed to ensure that his system reflects the structure of the FSA. All he has done is ensure that a particular trace of the FSA - that is, the states it goes through on a particular run - is reflected by the system's behavior.[*] But much more is required. There are all sorts of inherent possibilities in an FSA that are not reflected in a given trace.

*[[I owe this observation to Joseph O'Rourke.]]

In the body of his book (pp. 96-98), Putnam responds briefly to the charge that his construction does not satisfy a certain kind of counterfactual: in particular, the requirement that if the system had not been in state \( a \), it would not have transited into state \( b \) (this is a requirement on causation according to the analysis in Lewis 1973). His response is that these counterfactuals are dependent on the vague notion of a similarity metric over possible worlds (at least on Lewis' analysis), and that the notions of similarity and possible worlds are even vaguer than what we are trying to explicate.
The counterfactuals that I require do not have this problem. All that my account of implementation requires is that if the system is in state $a$, it will transit into state $b$, however it finds itself in the first state. This is in no way a similarity-based counterfactual. It requires that in all (or perhaps most) situations in which the system is in state $a$, it will transit into state $b$, no matter how similar or dissimilar that situation is from the actual one. This class of counterfactuals is much less vague than the other kind, and is therefore not open to a similar objection. It simply corresponds to the requirement that the transition be lawful. What makes the law of gravity a law is that under any circumstances, if two bodies have an appropriate mass, there will be such-and-such a force exerted. If it only happens between 12:00 and 12:07 today, due to unusual environmental conditions, it does not count.

4 A Possible Reply

It turns out that the above objections can be met fairly easily. To ensure that the physical systems satisfies the relevant strong conditionals as well as the material conditionals, we need only require that the system satisfies a pair of undemanding constraints. It remains the case that problems with strong conditionals undermine Putnam's general thesis, but we will have to wait a while to see why.

To overcome the first objection, it is sufficient to require that the system reliably transits through a sequence of states $s_1$, $s_2$, ..., irrespective of environmental conditions. (To simplify, I will hereafter assume that time is discrete. Nothing will depend on this.) This is not a difficult requirement: most clocks satisfy it, for instance. Probably most physical systems satisfy such a requirement; perhaps we might find reliable sequences like this in patterns of radiation decay. In any case, let us say a physical system contains a clock if it has a subsystem that reliably transits through a sequence like this.

A system containing a clock will circumvent the first objection. If we define the states $s_1$, $s_2$, ... of the system as those states containing the relevant states of the clock, then the transition from $s_n$ to $s_{n+1}$ will be reliable. If disjunctive states $a$, $b$, and so on are defined appropriately, then the transitions between these will satisfy the appropriate strong conditionals.

To reply to the second objection we need to make sure that the system has sufficient extra states to map onto formal states that are not manifested on a given run. We can do this by ensuring that the system contains a dial: that is, a subsystem with an arbitrary number of different states, such that when it is put into one of those states it stays in that state come what may. Most physical systems will contain a dial - think of states corresponding to marks on rocks, for instance.

Claim: Every physical system containing a clock and a dial will implement every inputless FSA.

Proof: Label physical states of the system $[i,j]$, where $i$ corresponds to a clock state and $j$ to a dial state. If the system starts in state $[1,j]$ it will reliably transit through states $[2,j]$, $[3,j]$ and so on.

Assume the physical system on the actual run has dial state 1. The initial state of the system will be $[1,1]$; we associate this state with an initial state of the FSA. We associate states $[2,1]$, $[3,1]$ and so on with
subsequent states of the FSA in the obvious way. If at the end of this process some FSA states have not
come up, choose an unmanifested state $P$, and associate state $[1,2]$ with it. We associate states $[2,2], [3,2]$
and so on with the states that follow $P$ in the evolution of the FSA. If this does not exhaust the states of
the FSA, choose an unmanifested state and associate state $[3,1]$ with it, and so on. Eventually all the
states of the FSA will be exhausted. For each state of the FSA, there will be a non-empty set of associated
physical states $[i,j]$. To obtain the implementation mapping, the disjunction of these states is mapped to
the FSA state.

It is easy to see that this system satisfies all the strong conditionals in the strengthened definition of
implementation. For every state of the FSA, if the system is (or were to be) in a state that maps onto that
formal state, the system will (or would) transit into a state that maps onto the appropriate succeeding
formal state. So the result is demonstrated.

There are minor problems with the states $[n,i]$ that come up at the end of the run, where $t_n$ is the final
time-step. We need to satisfy conditionals of the form "if it were in state $[n,i]$, it would transit
appropriately" - that is, $[n,i]$ would transit to a physical state that maps onto a successor of $f([n,i])$ - but
we have established nothing about the physical successors to $[n,i]$. We can get around this problem by
assuming the clock has an infinite sequence of states, mapping all the states in each sequence, and
mapping an infinite disjunction onto each formal state. This is not an especially unrealistic assumption;
there are probably such infinite clocks in most continuous systems.

Thus Putnam's result is preserved in only a slightly weakened form. But there is still no problem for the
computationalist about the mind. All this has demonstrated is that inputless FSAs are an inappropriate
formalism. The structure of an inputless FSA is quite trivial, and it is entirely the wrong sort of thing to
describe or specify a mind. Inputless FSAs are almost never invoked in the theory of computation,
precisely because of this triviality.

To see the triviality, note that the state-space of an inputless FSA will consist in a single unbranching
sequence of states ending in a cycle, or at best in a finite number of such sequences. The latter possibility
arises if there is no state from which every state is reachable. It is possible that the various sequences will
join at some point, but this is as far as the "structure" of the state-space goes. This is an completely
uninteresting kind of structure, as indeed is witnessed by the fact that it is satisfied by a simple
combination of a dial and a clock.

This suggests that we need a more interesting formalism than inputless FSAs. In particular, to put stronger
constraints on structure we need to move to FSAs with input and perhaps with output. The addition of
input changes the formalism from trivial to non-trivial. Where there is input, there can be branching
behavior. A formal state can be succeeded by various different formal states, depending on the input.
Furthermore, the presence of input gives the formalism a kind of combinatorial structure. Later states
depend not just on a single state, but on a combination of state and input.

This formalism is much more appropriate for capturing the dynamics of cognitive systems. Humans do
not have a single path of states along which their lives are determined. Even if they do, as some fatalistic
views might suggest, this path does not exhaust their description. For any given sequence of states that a human goes through, it remains the case that if things in the world had gone slightly differently, they would have functioned in an interestingly different way. Omitting this potentiality leaves out a vital part of the description of human functioning.[*] A wind-up toy or perhaps a videotape of my life could go through the same sequence of states, but it would not be a cognitive system. Cognition requires at least the possibility of functioning in more than one way.

*Maudlin (1989) raises some very interesting questions about along these lines, questioning the relevance of counterfactual-involving conditionals to conscious experience. For instance, if one blocks the connection that supports some counterfactual conditional in a currently static part of the system, is it plausible that this could change or remove the system's conscious experience? Maudlin suggests that it could not. We have seen, however, that such conditionals are constitutive of computational organization. Using an elaborate construction, Maudlin makes an argument along these lines to the conclusion that cognition is not based in computation. This argument requires an in-depth treatment in its own right.[*]

It might be objected that there are or might be people who have effectively no capacity for input and outputs - blind, deaf paralytics for instance -- who nevertheless have minds, and are cognitive systems in a quite reasonable sense. According to this objection, such people cannot be cognitive in virtue of implementing an automaton with input or output, for they have no such input or output themselves.

I think this would be to misdescribe the situation, however. These people can be seen to implement an automaton with input and output. It remains the case when they are in a given state that if they were to receive a given input, then their state would transit appropriately. It is just that they are currently not receiving any inputs (at best they are receiving a single "null" input) due to the malfunctioning of their sensory apparatus. Of course this means that the inputs in question have to be understood as stimulations of the optic nerve, or of the visual cortex or some other internal system, rather than as patterns of photons (mutatis mutandis for other sensory modalities), but this is no problem. It simply moves the boundary inward. The malfunctioning of their sensory system means that their visual cortex does not often get stimulated, but if it were to be stimulated, their internal state would change in interesting ways. We can deal with outputs in a similar way.

It is this very sensitivity or potentiality that demonstrates that there is a cognitive system present. If there were only one sequence of states along which a system could "work", it would not be a person but a wind-up toy. The sensitivity to change shows that real cognitive mechanisms are present.

An alternative way to handle this sort of case will be outlined later, in terms of automata with internal combinatorial structure. Either way, it turns out that structureless FSAs without input or output are inadequate for the specification of a cognitive system.

5 Finite-State Automata with Input and Output

Putnam extends his result to the case of FSAs with input and output. He notes that there is no hope of
extending the universal realization result to this case. To implement an FSA with input and output, a
physical system must at least have the capacity for input and output. Furthermore, it must have something
like the right kind of input and output, and of input/output dependencies. Putnam notes (p. 124) that inputs
and outputs to physical systems cannot map to inputs and outputs of automata arbitrarily, as is the case
with internal states. There are generally restrictions on the mapping, depending on our purposes.

Instead, Putnam puts forward a more limited result that is still significant. He argues that a finite-state
automaton with input and output is realized by every physical system with the right input/output
dependencies. That is, if the physical system gets the input and output right, it gets the FSA right.

To see that this is still significant, note that there are vastly different FSAs with the same input/output
pattern. Think of an FSA that outputs zero on every input, for instance, and an FSA that upon receiving an
input \( n \) goes into an exhaustive calculation to determine whether the number is prime, outputs zero if it is
prime, and zero if it is not (it also outputs zero on each step during its calculation). These FSAs have
precisely the same input/output dependencies. Nevertheless, one would think that most simple systems
that implement the first machine certainly do not implement the second, with its vastly more complex
internal structure.

Putnam also notes that if this result is correct, then (computational) functionalism about mentality will
imply behaviorism about mentality. If mentality is dependent on implementing the right automaton, and if
an automaton is implemented by any system with the right input and output, then mentality is dependent
only on input/output patterns. But functionalism is generally taken to stand in contrast to behaviorism,
and to lack many of behaviorism's problems. If Putnam's result is correct, functionalism is no better off.
As he summarizes:

Thus we obtain that the assumption that something is a "realization" of a given automaton
description (possesses a specified "functional organization") is equivalent to the statement
that it behaves as if it had that description. In short, "functionalism", if it were correct,
would imply behaviorism! If it is true that to possess mental states is simply to possess a
certain "functional organization", then it is also true that to possess mental states is simply
to possess certain behavior dispositions! (pp. 124-125)

Putnam's argument for this conclusion is a straightforward variation of his earlier argument. Given an
arbitrary FSA, take a system \( S \) with the right input/output dependencies. For the usual reasons \( S \) will go
through a sequence of states \( s_1, s_2 \), and so on. Associate \( s_1 \) with the relevant initial state of the FSA,
and associate \( s_2 \) and subsequent physical states with the relevant subsequent formal states (that is, those
FSA states determined by the earlier states and inputs in question). To every FSA state, we map the
relevant disjunction of associated physical states. The system therefore goes through relevant states \( a, b, c \)
that correspond under this mapping to FSA states \( A, B, C \); these states transit appropriately given the
previous state and the input, and appropriate output is produced at each step. So, Putnam argues, the
system implements the FSA.

To evaluate this claim, we need to spell out conditions of implementation for an FSA with inputs and
outputs. An FSA with input and output is specified by a set of states, a set of inputs, a set of outputs, and a set of state-transitions \((I,S) \rightarrow (S',O)\) for each input/state pair \((I,S)\), specifying the next state \(S'\) and the output \(O\) that will be produced by that state and input. (Perhaps the output should depend only on the previous state and not on the input, but the generalization does not hurt.) We can then straightforwardly extend our previous account of implementation as follows. Of course, we require that the relevant strong conditionals are satisfied.

A physical system implements an FSA (with input and output) in a given time-period if there is a mapping \(f\) from physical states of the system onto formal states of the FSA and from inputs and outputs to the system onto inputs and outputs of the FSA such that: for every formal state-transition \((I,S) \rightarrow (S',O)\) in the specification of the FSA, if the physical system is in a state \(s\) and receiving input \(i\) such that \(f(s) = S\) and \(f(i) = I\), this causes it to transit into a state \(s'\) such that \(f(s') = S'\) and to produce output \(o\) such that \(f(o) = O\).

(There will generally be some further restrictions on the mapping from inputs to inputs and outputs to outputs, but I will not go into this here.)

Does Putnam's construction satisfy this definition? It will have trouble with reliability and with uninstantiated formal states, of course, but as before we can stipulate that it contains a clock and a dial to avoid that problem. There is still a serious problem. We have established that the system transits appropriately in response to the inputs and outputs that it receives. However, we have no guarantee of its transition behavior if the inputs and outputs had been different. Again, in order to satisfy the strong conditionals, it is necessary that if it had been in a state/input pair that did not come up in the given run, then it would have transited appropriately.

Nothing in Putnam's construction ensures that this condition is satisfied. In fact there is every reason to believe that it will not be. If the sequence of internal states \(s_1, s_2, \ldots\) is deterministic or reliable in itself, as it will be in the clock/dial case and as nothing in Putnam's stipulation rules out, then the system will produce precisely the same transition behavior for any inputs. There is none of the sensitivity that an FSA with input and output is required to have.

Once again, the strong conditionals go unsatisfied. Once again, this is because the structure of the FSA is not fully reflected in the structure of the physical system. All that is represented are a few state-transitions, those that come up on the run in question. If a state-transition in the machine table is not play a role in that run, then it will correspond to nothing in the structure of the physical system. The system therefore fails to implement the FSA.

Because of the combinatorial nature of these state-transitions, it is not as easy to get around this failure as it was before. We cannot simply disjoin states to our heart's content. For every state that takes part in such a disjunction, it is required that for every input, it transits appropriately. We cannot simply map the new physical state that follows a given state and input onto the requisite formal state, as it will often be the case that the same physical state can be produced as the result of two distinct state/input pairs. Because of this, the iterative mapping procedure described above will not be well-defined.
Still, this suggests yet another maneuver that might salvage something of Putnam's argument. If we require that for every initial physical state and every sequence of inputs, the system goes into a distinct physical state, the mapping above will be well-defined. Furthermore, this condition is not too hard to satisfy. It is satisfied by a system that keeps a record of all its inputs, for instance.

Let us say a physical system contains a input memory if it has a subsystem that goes into a distinct state for every possible sequence of inputs (think of it as keeping a list of the inputs so far, perhaps). It then turns out that every physical system with an input memory and a dial implements every FSA with the right input/output dependencies.

To see this, denote states of the physical system by labels \([j, i_1, \ldots, i_n]\) (where \(n\) can take any value from zero up). The dial state is represented by \(j\), and the sequence of inputs in the recorder is represented by the sequence \(i_1, \ldots, i_n\). To construct the mapping, assume the dial is in fact set to 1, and associate state \([1]\) with the appropriate state \(S\) of the FSA. For every possible input sequence \(i_1, \ldots, i_n\), we associate physical state \([1, i_1, \ldots, i_n]\) with the FSA state that we get by starting at state \(S\) and feeding inputs \(i_1, \ldots, i_n\) (or the formal correlates of these) to the FSA. If there are FSA states that are not reached anywhere in this "tree", we pick such a state, associate it with physical state \([2]\), and start the process again, and repeat until FSA states are exhausted. We map disjunctions of physical states to formal states in the obvious way, and the construction is complete.

It is easy to see that under this mapping, all the relevant strong conditionals are satisfied. If the system is in a physical correlate of a given formal state, and receives some input, it will always transit appropriately. As long as we require that the system has the right input/output dependencies (and not just the right input/output patterns in a particular run), then the system will also satisfy the right strong conditionals concerning outputs. It follows that the system implements the automaton.

By requiring the addition of an input memory, we have moved well beyond universal realization, but the result is still troubling. Input memories are not difficult to instantiate. A system that retains a separate mark for every input will achieve it, for instance. It follows for instance that any implementation of a simple zero-outputting FSA, supplemented with a dial and a input memory, will implement the complex primality-testing FSA. This result is quite counterintuitive, but it seems that we are stuck with it.

It also means that if AI is dependent on this FSA formalism, then functionalism still almost reduces to behaviorism. We know that everybody with the right behavior will realize a given automaton as long as they carry a videocamera to record inputs and a dial in their pocket. If so, the functionalist premise implies that any two behaviorally equivalent people will be mentally equivalent, as long as they are carrying input memories and dials. The caveat is not much help for non-behavioristic functionalism.

(There is an interesting alternative argument for the reduction of functionalism to behaviorism that Putnam does not mention. There is a plausible general principle about the computational basis of cognition:
If a cognitive system implements two FSAs $F$ and $G$ both of which are sufficient to produce the system's behavioral function, and $G$ implements $F$, then the cognitive properties of the system arise in virtue of its implementing $F$ (as the added structure of $G$ is just irrelevant implementational detail).

However, by the minimization principle for finite-state automata (Hopcroft and Ullman 1979, p. 67), any two FSAs with the same input/output dependencies implement a common simpler FSA with the same dependencies. Take any two behaviorally equivalent cognitive systems whose cognitive properties arise by virtue of implementing an FSA. By the reduction theorem and $(++)$, these will have the same cognitive properties. It follows that if functionalism is not to reduce to behaviorism, we must either reject $(++)$ or reject FSAs as the basis for cognition.

It is true that we are no longer in danger of panpsychism, as most systems will not even have the right behavior. However, the result may imply that every FSA will be implemented by a "giant lookup table" (see Block 1981) consisting of a tree with an output listed for each series of inputs. The matter is slightly unclear, as any such tree in our world will be finite; whether a finite tree implements the FSA depends on whether we allow the state-transition conditionals to fail for states at the end of a given time-period (that is, at the outer edge of the tree). But is a human being with a finite lifetime any better off? In any case, even the result that an infinite lookup-table would be as conscious as you and me is troubling.

6 Combinatorial State Automata

It might be tempting to respond to this construction by arguing that somehow these inputs, states, and outputs do not have the right sort of connections between them. After all, there is a reasonable sense in which the state of the recorder is causally irrelevant to the system's function; one might try to introduce some causal relevance condition, or some other requirement on the relation between states. I am not sure that this would work, however; there would be problems with FSAs that always output zero despite complex calculations, for example. I leave the possibility open, because otherwise we are left with the counterintuitive result that the zero-outputter with a dial and a recorder implements the prime-tester, but I will focus here on another way to handle the matter.

The real moral of the above discussion is that even simple FSAs with inputs and outputs are not constrained enough to capture the kind of complex structure that computation and cognition involve. The trouble is that the internal states of these FSAs are monadic, lacking any internal structure, whereas the internal states of most computational and cognitive systems have all sorts of complex structure. Generally these states are divisible into components which interact locally and globally according to complex principles. Just as the structure of the system is not captured by a monadic state description, neither are the state-transitions captured by a monadic state-change. There may be all sorts of local dependencies that go into the functioning of such a system.

Turing machines and cellular automata are good examples of computational devices whose states have internal structure. In cognition, it is obvious that the brain has a highly complex structure, with its
functioning consisting in a complex pattern of interaction among billions of neurons and other parts. There is also plausibly complex structure in cognitive processing at coarser levels, structure that is central to the explanation of human thought and behavior.

To capture all this, I will introduce the notion of a *combinatorial state automaton*, or CSA. A CSA is much like an FSA, except that its states have combinatorial structure. An internal state of a CSA is a vector \([S^1, S^2, ..., S^n]\), where the \(i\)th component of the vector can take on a finite number of different values, or *substates*. The components of the vectors can be thought of by analogy with squares in a Turing machine or cells in a cellular automaton. The substates correspond to symbols in those squares or particular values for the cells. Inputs and outputs can also have a complex structure if this is desired. State-transition rules are determined by specifying for each component of the state vector a function by which its new substate depends on the old overall state vector and input vector (it will frequently depend on only a few "nearby" components of these vectors), and the same for each element of the output vector. The vectors involved may be finite or infinite, but I will stick to the finite case.

The conditions for implementation of a CSA are analogous to those for an FSA, with appropriate modifications. The main change is that internal states of the physical system must be specified as vectors, where each element of the vector corresponds to an independent element of the physical system. I will stipulate that each element in such a decomposition corresponds to a distinct physical region in the system, although there are other alternatives. The same goes for the complex structure of inputs and outputs, if required. The definition of implementation is as follows:

A physical system implements a given CSA if there is a decomposition of its internal states into substates \([s^1, s^2, ..., s^n]\), and a mapping \(f\) from these substates onto corresponding substates \(S^j\) of the CSA, along with similar mappings for inputs and outputs, such that: for every formal state transition \(((I^1,...,I^k),[S^1,...,S^n]) \rightarrow ([S'^1,...,S'^n],[O^1,...,O^l])\) of the CSA, if the system is in internal state \([s^1,...,s^n]\) and receiving input \([i^1,...,i^n]\) such that the physical states and inputs map to the formal states and inputs, this causes it to enter an internal state and produce an output that map appropriately to the required formal state and output.

Often the state-transitions of a CSA will be defined in terms of *local* dependencies, as when a substate depends only on a few neighboring substates and perhaps on a few inputs rather than on the entire previous state and input vectors (this will be so for cellular automata and Turing machines, for instance). In this case, we can require that the appropriate restricted conditional holds: that is, if the physical system is in the (few) specified previous substates and receiving the specified inputs, this causes it to transit appropriately.

It will be observed that (finite) CSAs are no more powerful that FSAs. For every CSA, there is an FSA that can simulate it. However, the implementation conditions for CSAs are much more constrained than those for the corresponding FSA. A implementation of a CSA is required to consist in a complex causal interaction among a number of separate parts. Not only do states have to be subdivisible, but the many state-transition conditionals imply that the system must have fine-grained causal structure than an
Because of these constrained implementation conditions, CSAs are much less vulnerable to Putnam-style objections that FSAs. Unlike FSA implementations, CSA implementations are required to have complex internal structure and complex dependencies among their parts. For a complex CSA, the right sort of complex structure will be found in very few physical systems. What does the work is precisely the combinatorial nature of the states, through the requirement that the parts of an internal state are independently variable. This imposes a constrained structure of dependencies on the system that arbitrary systems have no hope of passing.

The CSA formalism also provides another solution to the problem of the blind and deaf paralytic mentioned earlier. A non-trivial computational basis for cognition in this case may be specified by a CSA description, where the CSA need not have inputs and outputs. Even if a CSA lacks inputs and outputs, its combinatorial structure enables it to evade Putnam's objections. We can therefore argue that it is in virtue of implementing this CSA that the person possesses mentality. Certainly such a person will still have complex combinatorial structure in their brain, and there will be all sorts of dependencies such as "if this neuron were in a different state, then...". The complexity and sensitivity implied by this formalism can therefore go a long way toward capturing the complex inner life of such a person.

CSAs are a plausible candidate for principles of computational sufficiency, then, due to the fine-grained causal structure they impose on an implementation. They are also much more appropriate for the purposes of cognitive explanation than FSAs. Where an FSA description of a process will consist in an unenlightening sequence of monadic states, a CSA description of the same process will provide detailed information about the internal structure and about patterns of interaction between various parts, giving the potential for a much better understanding of the process in question.

CSAs, more than many other computational formalisms, directly reflect certain properties of cognitive dynamics that such a formalism must handle, in order to provide a foundation for a theory of mind. Unlike monadic FSAs but like natural cognitive systems, their internal states have complex structure. Unlike Turing machines and cellular automata (at least as these are most commonly understood), these can take in input and produce output at every time-step, and area therefore quite suitable for the modeling of ongoing situated cognitive function. Nevertheless, the CSA framework is perfectly general. An FSA, a Turing machine, or a cellular automaton can be straightforwardly described as a CSA.

Given an account of implementation for CSAs, it is easy to derive an account of implementation for Turing machines, cellular automata, and so on. We simply have to translate one of these machines into the CSA formalism, which is straightforward. For an implementation of the machine in question, we simply require implementation of the corresponding CSAs. We can derive implementation conditions for programs in languages such as LISP and C by similar methods. Here the translation into the CSA formalism is more complex, but there is no problem in principle.

7 Open questions
The above account of what it is to implement a CSA is useful but not perfect. There are two problems that I can see: the first is that it lets in a few too many systems; the second is that it may let in too few. Neither of these problems are debilitating for the account, but both points suggest the need for a future, more perfect account. Here, I leave both of these as open questions for future work.

1. It turns out that even the CSA framework lets in some Putnam-style false implementations - of a sort. The false implementations here include no systems that we are ever likely to encounter, but they include certain astronomically large systems. Thus we still have counterexamples within the realm of logical possibility, if not within the realm of practical possibility. I give details in what follows.

In attempting to construct Putnam-style counterexamples, one might first try an extension of the "input memory" strategy, by building in an input memory into every component state. For a three-component FSA, for example, one might try an implementation that sends state \([a,b,c]\) with input \(I\) into state \([aI, bI, cI]\) (where \(a, b, c\) are strings, and \(aI\) is a concatenation of \(a\) and \(I\)); then, we map the strings \(aI, bI, cI\) onto the appropriate CSA substates, depending on the substates that \(a, b,\) and \(c\) mapped to. But it is easy to see that this "implementation" fails to have the requisite combinatorial structure. When we recombine component states here with other component states, we will get the wrong results. For example, \(\text{any state of the form } [a,-,-]\) will transit into one of the form \([aI,-,-]\), but the CSA state-transitions will almost certainly require a different first component in the resulting state depending on the other components in the original state.

For a Putnam-style counterexample to be possible, every component state must be sensitive to every previous component state. The most straightforward way to do this is as follows: build an implementation in which state \([a,b,c]\) with input \(I\) transits into state \([abcI, abcI, abcI]\) (where \(abcI\) is a concatenation of \(a, b, c,\) and \(I\)). Now, we are assured that for every resultant component state, there is a unique candidate for the preceding state and input. Then we can construct the natural mapping from strings \(abcI\) (in various positions) onto substates of the CSA, without fear of troubles with recombination. A recombined state such as \([a,b',c']\) will transit into a new state with unique component states in every position, each of which can be mapped to the appropriate CSA substate.

But this sensitivity comes at a price. A system like this will suffer from an enormous combinatorial explosion, getting three times bigger at every time-step. If the strings that make up each component have length \(L\) at one point, within 100 time-steps they will have length \(3^{100}L\), which is about \(5.10^{47}\) times larger. In a very short time, the system will be larger than the known universe! CSAs that are candidates to be bases for cognition will have many more than three components, so the situation there will only be worse. Here, the "implementing" system will reach the boundaries of the universe in number of steps corresponding to a fraction of a second in the life of a brain. So there is no chance that any realistic system could ever qualify as an implementation in this manner.

It is easy to see that any Putnam-style implementation will suffer from such an explosion. To achieve the requisite sensitivity "blindly", every component state must be sensitive to the value of every preceding component state. If a system had step \(t\) has \(n\) components each with \(k\) possible values, then at \(t+1\) each
component must be able to carry $k^n$ possible values, at $t+2$ each component must be able to carry $k^{n^2}$ possible values, and so on. Given that encoding $k^m$ values takes a system whose size is proportional to $m$, we can see that the size of the system must increase by a factor of $n$ at every time step.

No practically possible system has this structure, and it is likely that no physically possible system has it either, as this sort of unbounded explosion is probably incompatible with the physical structure of the universe. It follows that the threat of vacuity and of panpsychism have long since disappeared; the only physically possible systems that implement a non-trivial CSA will do so in virtue of having the right sort of fine-grained causal structure among their components. If the CSA is complex enough to be a plausible basis for mentality, the implementations will themselves be complex enough to be plausible candidates for mentality.

Still, the mere logical possibility of these false implementations is troubling. Intuitively, it seems that the exponentially-increasing system, for all its size, lacks the right sort of specific structure to count as really implementing the corresponding computation. Of course, one might bite the bullet and say that in a system that large, there is enough going on that we can truly find all computations implemented, just as one can find all possible books in Borges' Library of Babel. It might or might not follow that the corresponding minds could be found there too, depending on whether one takes the sufficiency of computational structure for mentality to hold with logical necessity or natural necessity. If it is only a natural necessity, then no conclusions follow from the consideration of a mere logical possibility, but if it is a logical necessity, the stronger conclusion would follow.

On reflection, I think that these systems should be ruled out as implementations, on grounds of lacking the right sort of causal structure. But this means that the account I have given of implementing a CSA is imperfect as it stands. It needs some sort of revision or addition, specifying an additional constraint on causal structure. To find this constraint, we need to reflect upon and analyse the features that the false implementations intuitively lack. One way to cash out the intuitions might be to add a "uniformity" clause, specifying that underlying each formal state-transition of a CSA there needs to be a uniform causal mechanism, as opposed to the highly disjunctive causal mechanism found in the false implementations. Another might be to add a causal relevance clause along the lines suggested before. But it is not obvious just how these suggestions should be spelled out in detail, so I leave the project as a challenge for the future.

In the meantime, we can rest reasonably content with the knowledge that the account as it stands provides satisfactory results within the class of physically possible systems. If a physically possible system implements a CSA on this account, it will do so by virtue of having the right sort of systematic, non-trivial causal dependencies between its component states. But the difficulties in the realm of logical possibility remain something of a challenge.

2. The second worry concerns an area in which the implementation conditions seem not too weak, but too strong. I refer to the constraint that each component in a CSA's state-vector must correspond to a distinct region in the physical system. (This constraint arises from the stipulated definition of a decomposition of a physical system.) One might think that the constraint is somewhat arbitrary. Why cannot components of
a CSA be implemented by overlapping physical states, for example?

Some such independence condition on components is required, however. Otherwise, the conditions for implementing a CSA would collapse into the conditions for implementing the corresponding FSA, and the structure of the CSA would be lost. To see this, consider an arbitrary CSA with an \( n \)-element state vector, and the corresponding FSA obtained by collapsing each complex state into a single monadic state, with appropriate state-transitions. Let \( T \) be a system that implements the FSA under a mapping \( f \). To see that it implements the CSA under the unrestricted condition: let \( T^i_j \) be the substate of the CSA where the \( i \)th element takes on its \( j \)th value. Let \( t^i_1 \), \( t^i_2 \), ... will be the states of the physical system corresponding to substates \( T^i_1 \), \( T^i_2 \), ... of the CSA, and the implementation will hold under the appropriate mapping.

To see what is going on here, note that when the independence condition is left aside, a decomposition of internal states of a physical system into substates is just a set of non-maximal states \( t^i_1 \), \( t^i_2 \), ... (representing the various substates of the \( i \)th element) are mutually disjoint and together exhaustive of maximal states of the system, for each \( i \). We can think of these as states wherein a parameter has a particular value, with a separate parameter for each element of the vector. If we allow each value of each parameter to be determined by an arbitrary global mapping, we lose the sense that the system is functioning by interaction between independent components, and we therefore lose the extra structure that is vital to the nature of a CSA.

In order to have a true implementation of a CSA, we must require that the various parameters are in some strong sense *independent*, corresponding to separable components of a system. The easiest way to do this is to require that for a system to implement a CSA, the physical differences relevant to the variation in a given parameter - must be restricted to a limited physical region, with different physical regions for each element. That is, the values of a "parameter" supervene on a distinct region for each parameter.

It is possible, however, that a weaker "independence" condition could suffice. After all, not all existing computational systems have disjoint regions for each computational component. Witness systems with virtual memory, where the value of a given CSA "component" can be represented in various parts of the system depending on where there is free space, simply by using a pointer to the correct memory location. Cases such as this one might be handled in terms of more flexible independence conditions on components. An alternative would be to handle such cases by a two-stage definition of implementation, noting that the system implements some more complex CSA under the usual conditions, and the complex CSA bears an appropriate relation to the original CSA. The burden here would rest on the latter relation, but that could be analyzed purely mathematically (in terms of pointer values and the like), avoiding the problems with physical systems and causation.

In any case, the conditions that we have outlined provide at the very least *sufficient* conditions for the implementation of an automaton, admitting a wide class of devices that are appropriate, and excluding counterintuitive "implementations" such as Putnam's. The question of how far these conditions can be loosened without letting in inappropriate systems remains open.
8 Minds, Brains, and Programs

It is worth mentioning an argument by Searle for a thesis similar to Putnam's (Searle 1990). He argues that any physical system can be seen to implement any computation: computational properties are not intrinsic to physics, so that computational descriptions are observer-relative. Under the right interpretation, for example, his wall might be seen to implement the Wordstar program.

From what we have seen here, this argument fails. Whether or not computational properties are intrinsic to physics, the implementation relation between abstract automata and physical systems is perfectly objective. Even if there is a correspondence between states of the wall and states of the Wordstar program, and even if we do not worry about inputs and outputs, it is almost certain that the wall states will not satisfy the relevant strong state-transition conditionals, as the wall will not possess the requisite causal organization. Implementation is a determinate matter, as we have seen, and it puts a very strong constraint on the relevant class of physical systems.

There is a weak sense in which computational descriptions are "observer-relative", however. This reflects the fact that most physical systems will implement more than one abstract automaton. Every system will implement a trivial 1-state CSA, for instance, most systems will implement a 2-state CSA, and so on. So an observer is free to choose between a number of different computational "descriptions" of a system. This poses no problems of vacuity, however. The question of whether or not a given system is accurately "described" by a given computational description remains an objective one. The vacuity problem would arise only if every system implemented every CSA, and that is not the case. A given complex CSA will only be implemented by a small fraction of physical systems.

Indeed, it is a commonplace idea that a given physical system can implement more than one abstract computation. A single computer can simultaneously implement a number of programs, for example. One can even have a situation where a program is indirectly implemented, by implementing one program that implements another in turn (where the implementation relation between programs is cashed out in the natural way). It is natural to expect that the brain implements a large number of different automata, depending on what part of the brain we are focusing on and on the level of detail we are concerned with. Descriptions of brain processes in terms of implementations of these automata remain both objective and informative, although which description we appeal to at a given time may depend on our purposes.

There may even be instances in which a single system implements two independent automata, both of which fall into the class sufficient for the embodiment of a mind. A sufficiently powerful future computer running two complex AI programs simultaneously might do this, for example. In this case, we would naturally expect two minds to arise, not one. This suggests that if minds arise in virtue of implementing CSAs, then mental properties should be ascribed to the (system, CSA) pair, rather than to the system alone. Alternatively, it might be more in line with AI terminology to redefine the term "system" to denote the pair in question, in order that a single object can support more than one system. Either way, a given physical hunk of matter can be associated with more than one mind.
This suggests a natural response to Searle's (1980) "Chinese Room" argument. In the Chinese room, where a human is simulating a computer program, there are two distinct CSAs being implemented. The causal organization of the human's brain supports one CSA, and the causal organization between the marks on paper supports another one. We should not let the fact that the human is facilitating the causal dynamics of the second implementation blind ourselves to the fact that the causal structure is there - there are counterfactual-supporting state-transition relations between the marks on paper, just as there are between silicon chips or neurons - and that this structure is quite distinct from the structure in the first CSA implementation. We therefore have a situation analogous to that in which a computer implements two independent programs. There are two distinct causal and computational systems here, and we should expect two distinct minds to be associated with them.

9 Conclusion

Computational descriptions of physical systems need not be vacuous. We have seen that there is a well-motivated formalism, that of combinatorial state automata, and an associated account of implementation, such that the automata in question are implemented approximately when we would expect them to be: when the causal organization of a physical system mirrors the formal organization of an automaton. In this way, we establish a bridge between the formal automata of computation theory and the physical systems of everyday life. We also open the way to a computational foundation for the theory of mind.

This is only half the story, of course, and the easy half. The harder part is to take advantage of this bridge, showing that the physical properties that a computational description fixes are the properties in virtue of which minds arise. It is not implausible that minds arise in virtue of causal organization, but neither is it obvious. It is also plausible but not obvious that the discrete CSA framework can capture the precise causal organization (perhaps continuous, perhaps even non-computable) on which mentality depends. This second half is likely to be a long story, although see Chalmers (1994b) for my own attempt at putting things together. In any case, an account of computation and implementation clears the way.[*]

Introduction

In his stimulating book SHADOWS OF THE MIND, Roger Penrose presents arguments, based on Gödel's theorem, for the conclusion that human thought is uncomputable. There are actually two separate arguments in Penrose's book. The second has been widely ignored, but seems to me to be much more interesting and novel than the first. I will address both forms of the argument in some detail. Toward the end, I will also comment on Penrose's proposals for a "new science of consciousness".

1. The First Argument

The best way to address Gödelian arguments against artificial intelligence is to ask: what would we expect, given the truth of Gödel's theorem, if our reasoning powers could be captured by some formal system $F$. One possibility is that $F$ is essentially unsound, so that Gödel's theorem does not apply. But what if $F$ is sound? Then we would expect that:

(a) $F$ could not prove its Gödel sentence $G(F)$;

(b) $F$ could prove the conditional "If $F$ is consistent, then $G(F)$ is true";

(c) $F$ could not prove that $F$ is consistent.

If our reasoning powers are capturable by some sound formal system $F$, then, we should expect that we will be unable to see that $F$ is consistent. This does not seem too surprising, on the face of it. After all, $F$ is likely to be some extremely complex system, perhaps as complex as the human brain itself, and there is no reason to believe that we can determine the consistency of arbitrary formal systems when those systems are presented to us.

There does not seem to be anything especially paradoxical about this situation. Many arguments from
Gödel's theorem, such as that given by Lucas, founder at just this point: they offer us no reason to believe that we can see the truth of our own Gödel sentence, as we may be unable to see the consistency of the associated formal system. How does Penrose's argument fare?

Penrose is much more cautious in his phrasing. In Chapter 2, he argues carefully for the conclusion that our reasoning powers cannot be captured by a "knowably sound" formal system. This seems to be correct, and indeed mirrors the analysis above. If we are a sound formal system $F$, we will not be able to determine that $F$ is sound. So far, this offers no threat to the prospects of artificial intelligence. The real burden of Penrose's argument is carried by Chapter 3, then, where he argues that the position that we are a formal system that is not "knowably sound" is untenable.

One position that an advocate of AI might take is to argue that our reasoning is fundamentally unsound, even in an idealization. I will not take this path, however. For a start, I have some sympathy with Penrose's idea that we have an underlying sound competence, even our performance sometimes goes astray. But further, it seems to me that to hold that this is the only problem in Penrose's argument would be to concede too much power to the argument. It would follow, for example, that there are parts of our arithmetical competence that no sound formal system could ever duplicate; it would seem that our unsoundness would be essential to our capacity to see the truth of Gödel sentences, for example. This would be a remarkably strong conclusion, and does not seem at all plausible to me. So I think that the deepest problems with Penrose's argument must lie elsewhere.

I will concede to Penrose that we are fundamentally sound, then. As before, the natural position for an advocate of AI is that our powers are captured by some sound formal system $F$ that cannot demonstrate that $F$ is sound. What is Penrose's argument against this position? He has two sub-arguments here, depending on whether we can know that $F$ captures our reasoning.

If we could know that $F$ captures our reasoning, Penrose's argument would be very straightforward:

(1) We know that we are sound;

(2) We know that $F$ captures our reasoning;

so (3) We know that $F$ is sound.

One might question premise (1) - I will raise some problems with it later - but it does have a certain plausible quality. Certainly, it seems antecedently more plausible than the much stronger position that we know that $F$ is sound. But all this is irrelevant, as premise (2) is so implausible. There is very little reason to believe that if our reasoning is captured by $F$, then we could know that fact.

It might seem plausible that we could know that $F$ underlies our processing - why couldn't we just investigate our underlying brain processes? But to do this would be to change the game. It is of no help to Penrose if we can know using external resources (such as perception inputs) that $F$ captures our
reasoning. For to use external resources would be to go beyond the resources provided by $F$ itself. And there would be no contradiction in the supposition that $F$ could know, using external resources, that $F$ is consistent, and therefore that $G(F)$ is true. A contradiction would only arise if $F$ could know this wholly under its own steam.

For this argument to be at all relevant, then, we would need to know that $F$ captures our reasoning powers wholly using our internal resources - that is, the resources that $F$ itself provides. But there is not the slightest reason to believe that we could do this. If we are a formal system, we certainly cannot determine which formal system we are on the basis of introspection! So again, the advocate of artificial intelligence is in no danger. She need simply hold the unsurprising position that we are a formal system $F$, but that we can't tell through introspection that we are $F$.

To make his case, Penrose needs to argue that if we are a sound formal system $F$, then we could determine that $F$ is sound, independently of any knowledge that we are $F$. That is, he needs to make the case that if $F$ is presented to us, we could determine that it is sound through an analysis of $F$ alone. This is the burden that Penrose tries to meet in section 3.3. It is this section that effectively carries all the crucial weight; if it does not succeed, then this line of Penrose's argument simply fails.

How does Penrose argue that we could see that $F$ is sound? He argues in 3.3 that we can see $F$ as a system of axioms and inference rules. Clearly, we can see that each of the axioms is true: if $F$ can see their truth, so can we. Further, Penrose argues, we must be able to see that each of the basic inference rules is valid, as it is extremely implausible that our reasoning could rely on inference rules that we regard as "fundamentally dubious". And if we know that the axioms are true and that the inference rules are valid, then we know that $F$ is sound.

But why should we accept that $F$ consists of a set of axioms and inference rules? $F$, after all, is supposed to potentially correspond to any sort of computational system - it might be a simulation of the whole of the human brain, for example. This will not look anything like a neat logical system: we will not be able to decompose it into an underlying set of "axioms" and "rules of procedure". Rather, it will be a big computational system that churns away on a given statement as input, and eventually outputs "yes" or "no".

It is true that for any Turing machine that accepts a certain class of statements, we can find a corresponding axiom-plus-rules system that accepts the same class (or at least the closure of that class under logical consequence). There is a lemma by Craig to this effect; without it applications of Gödel's theorem to draw conclusions about Turing machines would not even get off the ground. But the "axiom-plus-rules" system that we end up with may be extraordinarily complex. In particular, the "inference rules" may be just about as complex as the original system - perhaps equivalent to a complex connectionist procedure for generating further theorems. And as before, there is no reason why we should be able to see that this sort of "rule" should be valid, any more than we could see from an analysis that an overall computational brain process is sound. This is not to say that we think we are relying on "fundamentally dubious" procedures - it is just that the procedures that govern the dynamics of our brain are too complex for us to analyse them as sound or otherwise.
In this section, Penrose seems to assume that the relevant class of computational systems are all something akin to theorem-provers in first-order logic, but of course there is no reason to make such an assumption. For his argument to have its full generality, proving that our physical processes could not even be simulated computationally, it must apply to any sort of computational process. Even within the realm of existing AI research, there are many computational procedures, such as connectionist networks, which are not decomposable into axioms and rules of inference.

(I suspect that even an advocate of logic-based AI might have a response to make here. It might be held, for example, that we may occasionally use certain complex inference rules (when we generate Gödel sentences by transfinite counting, for example), whose validity is not obvious to us on analysis, without this in any way impugning the reliability of our reasoning. We might soundly "use" a procedure despite its resistance to our analysis. This indeed is just what we might expect around the "outer limits" of Gödelization, which after all is really where Penrose's argument gains its force. There is no difficulty in the idea that the reasoning methods we use in everyday mathematics can be seen to be sound - Penrose's arguments really apply at the level of our unusual "Gödelizing" procedures, which rely on our ability to count transfinite ordinals. But to be able to see that some Gödelizing rule is valid would be akin to making that last step in a Gödelization procedure, the one that is just complex enough to be beyond us. But I leave these difficult issues aside for now.)

It is section 3.3 that carries the burden of this strand of Penrose's argument, but unfortunately it seems to be one of the least convincing sections in the book. By his assumption that the relevant class of computational systems are all straightforward axiom-and-rules system, Penrose is not taking AI seriously, and certainly is not doing enough to establish his conclusion that physics is uncomputable. I conclude that none of Penrose's argument up to this point put a dent in the natural AI position: that our reasoning powers may be captured by a sound formal system $F$, where we cannot determine that $F$ is sound.

2. Penrose's Second Argument

Hiding at the back of Chapter 3, however, Penrose has a new argument that escapes many of these problems. It is unfortunate that this argument was so deeply buried; most commentators seem to have missed it. Unlike the previous argument, this argument does not depend on the claim that we if we are a sound formal system $F$, we would be able to see that $F$ is sound. Because of this, it is a more novel and interesting argument, and more worthy of attention.

The argument is developed in a roundabout way (which may have led some readers astray), but is summarized in the fantasy dialogue with a robot mathematician in 3.23. The argument is given in a somewhat indirect form, involving complex procedures by which a given formal system might have evolved, but its basic structure is very simple. In a simplified and somewhat loose form, the argument goes as follows:

(1) Assume my reasoning powers are captured by some formal system $F$ (to put this more briefly, "I am
Minds, Machines, and Mathematics

Consider the class of statements I can know to be true, given this assumption.

(2) Given that I know that I am F, I know that F is sound (as I know that I am sound). Indeed, I know that the larger system F' is sound, where F' is F supplemented by the further assumption "I am F". (Supplementing a sound system with a true statement yields a sound system.)

(3) So I know that G(F') is true, where this is the Gödel sentence of the system F'.

(4) But F' could not see that G(F') is true (by Gödel's theorem).

(5) By assumption, however, I am now effectively equivalent to F'. After all, I am F supplemented by the knowledge that I am F.

(6) This is a contradiction, so the initial assumption must be false, and F must not have captured my powers of reasoning after all.

(7) The conclusion generalizes: my reasoning powers cannot be captured by any formal system.

Strictly speaking, the conclusion that must be drawn is that I cannot know that I am identical to a formal system F; in showing that I can see the truth of G(F'), we assumed not just that I am F but that I know I am F. But this is still a strong conclusion. For example, it would rule out even the possibility that we could empirically discover that we were identical to some system F - if we were to "discover" this, the reasoning would lead us to a contradiction. So even this would be threatening to the prospects of AI.

The power of this argument stems from the fact that it does not depend on one's ability to determine that a system F is sound, or to determine that we are F. Rather, it relies on the assumption that one is F to reach the relevant conclusions, thus contradicting the assumption. On the face of it one might have thought that making such an assumption would show only that the larger system F' could prove the Gödel sentence of the smaller system F, but the insight of the argument is that things can be bootstrapped into a situation where F' sees its own Gödel sentence, leading to trouble.

As far as I can determine, this argument is free of the obvious flaws that plague other Gödelian arguments, such as Lucas's argument and Penrose's earlier arguments. If it is flawed, the flaws lie deeper. It is true that the argument has a feeling of achieving its conclusion as if by magic. One is tempted to say: "why couldn't F itself engage in just the same reasoning?". But although there are various directions in which one might try to attack the argument, no knockdown refutation immediately presents itself. For this reason, the argument is quite challenging. Compared to previous versions, this argument is much more worthy of attention from supporters of AI.

On reflection, I have come to believe that the greatest vulnerability in this argument lies in the assumption that we know (unassailably) that we are consistent. This assumption seems relatively innocuous, compared to the previous strong claim that we could determine that F is consistent; on the
face of it, it does not seem vastly stronger than the assumption that we are consistent. But I think that in fact, it is this assumption, and not the assumption that we know we are \( F \), that carries the central responsibility for generating the contradiction. I have largely become convinced of this through discussions with Daryl McCullough, and the central argument below (an adaptation of a result of Lob’s) was suggested by him.

The best way to see this is to show that the assumption that we know we are consistent already leads to a contradiction in its own right, even without the further assumption that we know we are \( F \). Specifically, we can argue that any system that "unassailably" believes in its own consistency will in fact be led to a contradiction (under certain plausible further assumptions). This can be done as follows.

In these matters, we are concerned with a system's reasoning about its own beliefs, as well as about mathematics. So we can assume it has a symbol \( B \), representing belief, where \( B(n) \) corresponds to the statement that it believes the statement with Gödel number \( n \). (Below, I abbreviate by writing "\( B(A) \)" instead of "\( B(\^A) \)", where \(^A\) is the Gödel number of \( A \).) And let us write \( |- A \) if the system has the power to "unassailably" assert \( A \). (By using this notation I do not intend to beg the question about whether the system is computational!) Then the following assumptions are reasonable (suppressing universal qualifiers):

1. If \( |- A \), then \( |- B(A) \).
2. \( |- B(A_1) \land B(A_1 \rightarrow A_2) \rightarrow B(A_2) \)
3. \( |- B(A) \rightarrow B(B(A)) \)

(1) says that if the system has the power to assert \( A \), it has the power to assert \( B(A) \). (2) says essentially that the system knows it has the power to reason by modus ponens. (3) says, in effect, that the system knows (1). All of these assumptions seem unproblematic. To these we add the key assumption:

4. \( |- \neg B(\neg) \)

which says that the system asserts that it is not inconsistent. It turns out that these assumptions, along with the assumption that the system has the resources to do Peano arithmetic, lead to a contradiction.

To see this, we simply construct a sentence \( G \) such that

5. \( |- G \leftrightarrow \neg B(G) \).

This is a standard diagonal construction, and does not rely on any assumptions about the system's computability. We define the function \( \text{diag} \) in Peano arithmetic so that \( \text{diag}(\^C(x)) \) is \( \^C(\^C(x)) \) for any predicate \( C \). (For clarity, I reintroduce the `\^` notation for Gödel numbering.) Then let \( G \) be the sentence \( \neg B(\text{diag}(\neg B(\text{diag}(x)))) \). It is straightforward to show that \( G \leftrightarrow \neg B(\^G) \). As long as the system
has at least the capacities of Peano arithmetic, it can replicate this reasoning, so that $|- G \leftrightarrow \neg B('G').$

$G$ is effectively a sentence that says "I do not believe $G", much like a standard Gödelian construction, but without any assumptions about computability. It is not hard to see how the contradiction arises. The system knows that if it believes $G$, it is unsound; so it knows that if it is sound, it does not believe $G$. But this is to say that it knows that if it is sound, $G$ is true. By assumption, it knows that it is sound, so it knows that $G$ is true. So now it must be unsound, as it has fallen into a contradiction. This reasoning is easily formalized:

(6) $|- B(G) -> B(\neg B(G))$ [from (5), (1), (2)]

(7) $|- B(G) -> B(B(G))$ [from (3)]

(8) $|- B(G) -> B(\text{false})$ [from (6), (7), (2)]

(9) $|- B(\text{false}) -> B(G)$ [from (2), along with $|- B(\text{false} -> G)$]

(10) $|- G \leftrightarrow \neg B(\text{false})$ [from (5), (8), (9)]

(11) $|- B(G)$ [from (10), (4), (1)]

(12) $|- B(\text{false})$ [from (12), (9)]

We can see, then, that the assumption that we know we are sound leads to a contradiction. One might try to pin the blame on one of the other assumptions, but all these seem quite straightforward. Indeed, these include the sort of implicit assumptions that Penrose appeals to in his arguments all the time. Indeed, one could make the case that all of premises (1)-(4) are implicitly appealed to in Penrose's main argument. For the purposes of the argument against Penrose, it does not really matter which we blame for the contradiction, but I think it is fairly clear that it is the assumption that the system knows that it is sound that causes most of the damage. It is this assumption, then, that should be withdrawn.

Penrose has therefore pointed to a false culprit. When the contradiction is reached, he pins the blame on the assumption that our reasoning powers are captured by a formal system $F$. But the argument above shows that this assumption is inessential in reaching the contradiction: A similar contradiction, via a not dissimilar sort of argument, can be reached even in the absence of that assumption. It follows that the responsibility for the contradiction lies elsewhere than in the assumption of computability. It is the assumption about knowledge of soundness that should be withdrawn.

Still, Penrose's argument has succeeded in clarifying some issues. In a sense, it shows where the deepest flaw in Gödelian arguments lies. One might have thought that the deepest flaw lay in the unjustified claim that one can see the soundness of certain formal systems that underlie our own reasoning. But in fact, if the above analysis is correct, the deepest flaw lies in the assumption that we know that we are sound. All
Gödelian arguments appeal to this premise somewhere, but in fact the premise generates a contradiction. Perhaps we are sound, but we cannot know unassailably that we are sound.

3. The Missing Science of Consciousness?

A reader who is not convinced by Penrose's Gödelian arguments is left with little reason to accept his claims that physics is noncomputable and that quantum processes are essential to cognition, although these speculations are interesting in their own right. But even if one accepts that human behavior can be accounted for computationally, there is still the question of human consciousness, which after all is Penrose's ultimate target.

Penrose is clear that the puzzle of consciousness is one of his central motivations. Indeed, one reason for his skepticism about AI is that it is so hard to see how the mere enaction of a computation should give rise to an inner subjective life. Why couldn't all the computation go in the dark, without consciousness? So Penrose postulates that we appeal to physics instead, and suggests that the locus of consciousness may be a quantum gravity process in microtubules. But this seems to suffer from exactly the same problem. Why should quantum processes in microtubules give rise to consciousness, any more than computational processes should? Neither suggestion seems appreciably better off than the other.

Although Penrose's quantum-gravity proposal might at least *conceivably* help explain certain elements of human behavior (if behavior turned out to be uncomputable, for example), it simply seems to be the wrong sort of thing to explain human consciousness. Indeed, Penrose nowhere claims that it does, and by the end of the book the "Missing Science of Consciousness" seems as far off as it ever was. As things stand, even by the end of Penrose's book, we seem to be left in Penrose's position $D$: these physical theories leave consciousness entirely unexplained.

This might seem odd, given that Penrose says he embraces position $C$, but in fact $C$ and $D$ are quite compatible. This is because Penrose's four positions run together a number of separate issues. For convenience, I repeat the positions here:

- **A**: All thinking is computation; in particular, feelings of conscious awareness are evoked merely by the carrying out of appropriate computations.

- **B**: Awareness if a feature of the brain's physical action; and whereas any physical action can be simulated computationally, computational simulation cannot by itself evoke awareness.

- **C**: Appropriate physical action evokes awareness, but this physical action cannot even be properly simulated computationally.

- **D**: Awareness cannot be explained by physical, computational, or any other scientific terms.

Note that $A$, $B$, and $C$ all concern how awareness is *evoked*, but $D$ concerns how awareness is *explained*. 
These are two very different issues. To see the contrast, note that almost everybody would accept that the brain *evokes* awareness - if we were to construct a duplicate brain, there would be conscious experience associated with it. But it is far from clear that a physical description of the brain can *explain* awareness - many people have argued that given any physical account of brain processes, the question of *how* those processes evoke conscious experience will be unanswered by the physical account.

To really clarify the positions in the vicinity, we have to distinguish three questions:

1. What does it take to simulate our physical action?
2. What does it take to *evoke* conscious awareness?
3. What does it take to *explain* conscious awareness?

In answer to each question, one might say that (a) Computation alone is enough, (b) Physics is enough, but physical features beyond computation are required, or (c) Not even physics is enough. Call these positions C, P, and N. So we have a total of 27 positions, that one might label CCC, CPN, and so on.

Question (1) is the question Penrose is concerned with for most of the book, and the issue that separates B and C above. He argues for position P-- over C--. Descartes might have argued for N--, but few would embrace such a position these days.

Question (2) is the issue at the heart of Searle's Chinese room argument, and the issue that separates A from B and C above. Searle argues for -P- over -C-, and Penrose is clearly sympathetic with this position. Almost everyone would accept that a physical duplicate of me would "evoke" consciousness, so position -N- is not central here.

Question (3) is the central question about the *explanation* of consciousness (a question that much of my own work is concerned with). Penrose's positions A, B, and C are neutral on this question, but D is solely concerned with it; so in a sense, D is independent of the rest. Many advocates of AI might hold --C, some neurobiologists might hold --P, whereas my own position is --N.

The four positions Penrose describes come down to CC- (A), CP- (B), PP- (C), and --N (D). Penrose seems to think that in arguing for position C (PP-) he is arguing against position D (--N), but it is clear from this analysis that this is not so. In the end, nothing in Penrose's book bears on question (3), which is a pity, though it is certainly understandable. It would be very interesting to hear Penrose's position on just how physical theories might or might not explain human consciousness.

Indeed, one might even combine positions A and D, as I do, embracing CCN. On this position, human-like behavior can be produced computationally, and indeed enacting the right computation will give rise to consciousness, but neither a computational account nor a physical account alone will explain consciousness. It might seem odd that computation should evoke but not explain consciousness, but this
is no more odd than the corresponding position that neurophysiology might evoke but not explain consciousness. In either case, consciousness emerges from some underlying basis, but we need a further element in the theory to explain just how and why it emerges.

One can have a lot of fun cataloging positions (Dennett is CCC; Searle may be CPP; Eccles is NNN; Penrose is PPP; I am CCN; some philosophers and neuroscientists are CPN or PPN; note that all these are "non-decreasing" in C->P->N, as we might expect), but this is enough for now. The main point is that Penrose's treatment runs together question (3) with questions (1) and (2), so that in the end the question of how consciousness might be explained is left to one side.

A true science of consciousness will have address all of these questions, and especially question (3). Penrose has produced an enormously enjoyable and challenging book, but it seems to me that for all his hard work, the science of consciousness is still missing.
The two-envelope paradox

- **The Two-Envelope Paradox: A Complete Analysis? (PS)**
  - You're given two envelopes, and are told that one contains twice the amount in the other, but you aren't told which is which. You tentatively decide to take envelope A, but then reason that there is a 50% chance that B contains twice A's amount and a 50% chance that it contains half A's amount, with an expected value of 1.25 times A's amount overall, so it is in your interests to switch. But of course the same holds in reverse. What is going on? I give a detailed analysis of this "two-envelope" paradox, including a few interesting subtleties that are sometimes overlooked. I didn't publish this as I now think the analysis is incomplete; in effect it solves the "numerical" paradox but not the "decision-theoretic" paradox.

- **The St. Petersburg Two-Envelope Paradox**
  - This is a much more recent short paper (2001) that fills in the gap in the paper above. It sets out a closely related scenario, which combines elements of the St. Petersburg paradox and the two-envelope paradox, and use this to diagnose where the decision-theoretic paradoxical reasoning goes wrong.

Old proto-papers

These are a few unfinished papers on a variety of subjects, mostly written around when I was graduate student at Indiana. I set these aside because I wasn't quite happy with them, or because I didn't think they were very significant, or because they evolved into something else, or because I am lazy, but looking at them now I quite enjoy them. My 1999 self may not endorse every youthful excess here, but there are some interesting bits and pieces.

- **The First-Person and Third-Person Views**
  - An early high-level overview of "first-person" and "third-person" issues about consciousness. This was Part I of a supposedly 3-part paper - the two remaining parts got turned into my paper "Consciousness and Cognition". This part doesn't reach any firm conclusions, but it captures something of the eternal internal struggle.

- **A Taxonomy of Cognitive Jokes**
This was my inner taxonomist at work. (See my bibliography for another example of this sad trait.) Following a workshop on humor at CRCC, during which innumerable jokes were told and dissected, this was my attempt to fit all of the jokes into a few basic templates. Unfortunately the jokes themselves are given only one-line summaries, so I wish you luck with recognizing them.

On Spaghetti-Sorters and the Powers of Analog Computation

This has a few jottings on the existence of "spaghetti-sorters" and other remarkable devices that seem to be able to compute certain functions faster than any standard computer (a spaghetti-sorter sorts a list of n numbers in order n time, for example, by cutting n pieces of spaghetti with the right lengths and banging them against a table).

How Cartesian Dualism Might Have Been True

On a not-too-far-fetched scenario, inspired by contemporary work in artificial life, in which a Cartesian interactive dualism would have turned out to be true. Indeed, many of the "simulated worlds" in artificial life are Cartesian in just this way.

Philosophical commentaries

These are a few commentaries I've given at philosophy conferences over the years. Often I don't write these up, but these may have enough in them to be worthwhile.

Connectionist Representation and Deep Systematicity
- A 1991 commentary on Andy Clark's "Theoretical Spaces". I think the idea of "deep systematicity" as the central virtue of connectionism is quite important, although I haven't got around to developing it in a real paper. There are also some remarks on the relationship between evolution and learning.

Determining the Moment of Consciousness?
- This was a 1993 commentary on Valerie Hardcastle's paper "On Determining the Moment of Consciousness" (recently published in Philosophical Psychology), which argues the neural level can help determine some "Orwell/Stalin" indeterminacies. Here I was in the unusual position of defending Dan Dennett; at the end Dennett was in the unusual position of agreeing with almost everything I said.

What is it Like to be a Thermostat?
- A 1994 commentary on Dan Lloyd's "What is it Like to be a Net?" Most people at the time thought I was joking.
In days gone by I posted to Usenet, and other mailing lists, quite a bit. There was an occasional very good discussion - at least one of my published papers resulted from this sort of thing, and I can see other traces here and there. Other postings were just intellectual curiosity or frivolity. The endless discussions of Chinese rooms and consciousness were too open-ended to excerpt here, but here are a few more specific topics.

- **"Pick a number between zero and infinity"**
  - About the time I stood on a street corner and asked just that.

- **Is the Continuum Hypothesis true, false, or neither?**
  - I asked this question in sci.math and got quite a few interesting responses. This message (which is now part of the sci.math FAQ) is a summary and discussion. Lots of information on the Continuum Hypothesis can be found [here](http://www.u.arizona.edu/~chalmers/misc-papers.html).

- **Thoughts on emergence**
  - An attempt at explicating the notion of "emergence" that is very popular in artificial life, complex systems theory, and other parts of contemporary science.

- **Does a rock implement every FSA?**
  - A comp.ai.philosophy discussion of Putnam's argument that every ordinary open system implements every finite automaton. A number of people contributed to this discussion, which has lots of interesting byways and raises plenty of deep questions about computation. My [paper](http://www.u.arizona.edu/~chalmers/misc-papers.html) of the same title descended from this.

- **Realms of cognitive science**
  - Someone else posted about various "realms" such as those of matter, representation, and consciousness; here I take the conceit and run with it, multiplying the realms and discussing various possible relations among them.

The Two-Envelope Paradox: A Complete Analysis?

David J. Chalmers

Department of Philosophy
University of Arizona
Tucson, AZ 85721

chalmers@arizona.edu

[[Doug Hofstadter introduced me to the two-envelope paradox in 1988. This paper corresponds to more or less the position I came up with then. I wrote this up in 1994 after a couple of papers on the subject appeared in Analysis. I never published it, partly because it came to seem to me that this treatment resolves only part of the paradox: it resolves the "numerical" paradox but not the "decision-theoretic" paradox. For a more recent treatment of the decision-theoretic paradox, see The St. Petersburg Two-Envelope Paradox.]]

A wealthy eccentric places two envelopes in front of you. She tells you that both envelopes contain money, and that one contains twice as much as the other, but she does not tell you which is which. You are allowed to choose one envelope, and to keep all the money you find inside.

This may seem innocuous, but it generates an apparent paradox. Say that you choose envelope 1, and it contains $100. In evaluating your decision, you reason that there is a 50% chance that envelope 2 contains $200, and a 50% chance that it contains $50. In retrospect, you reason, you should have taken envelope 2, as its expected value is $125. If your sponsor offered you the chance to change your decision now, it seems that you should do so. Now, this reasoning is independent of the actual amount in envelope 1, and in fact can be carried out in advance of opening the envelope; it follows that whatever envelope 1 contains, it would be better to choose envelope 2. But the situation with respect to the two envelopes is symmetrical, so the same reasoning tells you that whatever envelope 2 contains, you would do better to choose envelope 1. This seems contradictory. What has gone wrong?

The paradox can be expressed numerically. Let $A$ and $B$ be the amounts in envelope 1 and 2 respectively; their expected values are $E(A)$ and $E(B)$. For all $n$, it seems that $p(B>A|A=n) = 0.5$, so that $E(B|A=n) = 1.25n$. It follows that $E(B)=1.25E(A)$, and therefore that $E(B) > E(A)$ if either expected value is greater than zero. The same reasoning shows that $E(A) > E(B)$, but the conjunction is impossible, and in any case $E(A) = E(B)$ by symmetry. Again, what has gone wrong?

This problem has been discussed in the pages of Analysis by Jackson, Menzies and Oppy [2], and by Castell and Batens [1], but for reasons that will become clear I think that their analyses are incomplete and mistaken respectively, although both contain insights that are important to the resolution of the problem. I will therefore present my own analysis of the "paradox" below.
Some distractions inessential to the problem arise from the facts that in the real world, money comes in discrete amounts (dollars and cents, pounds and pence) and that there are known limits on the world's money supply. We can remove these distractions by stipulating that for the purposes of the problem, the amounts in the envelopes can be any positive real number.

There are a number of steps in the resolution of the paradox. The first step is to note (as do the authors mentioned above) that the amounts in the envelopes do not fall out of the sky, but must be drawn from some probability distribution. Let the relevant probability density function be $g$, where the probability that the smaller amount falls between $a$ and $b$ is $\int_a^b g(x) \, dx$. We can think of this distribution as either representing the chooser's prior expectations, or as the distribution from which the actual values are drawn. I will generally write as if it is the second, but nothing much rests on this. To fix ideas, we can imagine that our sponsor chooses a random variable $Z$ with probability density $g$, and then flips a coin. If the coin comes up heads, she sets $A=Z$ and $B=2Z$; if it comes up tails, she sets $A=2Z$ and $B=Z$.

Recognizing the existence of a distribution immediately shows us that the reasoning that leads to the paradox is not always valid, as Jackson et al note. For example, if the distribution is a uniform distribution over values between 0 and 1000, with amounts over 1000 being impossible, then if $A > 500$, it is always a bad idea to switch. It is therefore not true that for all distributions and all values of $n$, $p(B>A|A=n) = 0.5$. In general, $E(B|A=n)$ will not depend only on $n$; it will also depend on the underlying distribution.

In their analysis, Jackson et al are satisfied with this observation, combined with the observation that limitations on the world's money supply ensure that in practice the relevant distributions will always be bounded above and below. The paradox does not arise for bounded distributions, as we saw above. When $A$ is a medium value, there may be equal chances that $B$ is larger or smaller, but when $A$ is large $B$ is likely to be smaller, and when $A$ is small $B$ is likely to be larger, so the paradox does not get off the ground.

This practical observation is an insufficient response to the mathematical paradox, however, as Castell and Batens note. Unbounded distributions can exist in principle if not in practice, and in-principle existence is all that is needed for the paradox to have its bite. For example, it might seem that if the distribution were a uniform distribution over the real numbers, then $p(B>A|A=n) = 0.5$ for all $n$. This would seem to have paradoxical consequences for mathematics, if not for the world's money supply.

This leads to the second step in the resolution of the paradox, which is that taken by Castell and Batens. (We will see that this step is ultimately inessential to the paradox's resolution, but it is an important intermediate point of enlightenment.) There is in fact no such thing as a uniform probability distribution over the real numbers. To see this, let $g$ be a uniform function over the real numbers. Then $\int[k,k+1] g(x) \, dx$ is equal to some constant $c$ for all $k$. If $c=0$, then the area under the entire curve will be zero, and if $c>0$, then the area under the entire curve will be infinite, both of which contradict the requirement that the integral of a probability distribution be 1. At one point Jackson et al raise the possibility of infinitesimal probabilities, but if this is interpreted as allowing $c$ to be infinitesimal, the
suggestion does not work any better. To see this, note that if the distribution is uniform:

\[
\int[0, \infty] g(x) \, dx = \int[0,1] g(x) \, dx + \int[1,2] g(x) \, dx + \int[2,3] g(x) \, dx + \ldots
\]

\[
= \int[0,1] g(x) \, dx + \int[2,3] g(x) \, dx + \int[4,5] g(x) \, dx
\]

\[
= \frac{1}{2} \left( \int[0,\infty] g(x) \, dx \right)
\]

so that the overall integral must be zero or infinite. A uniform distribution over the real numbers can only be an "improper" distribution, whose overall integral is not 1.

The impossibility of a uniform probability distribution over the real numbers is reflected in the fact that every proper distribution must eventually "taper off": for all \( \epsilon > 0 \), there must exist \( k \) such that

\[
\int[k, \infty] g(x) \, dx < \epsilon.
\]

It is very tempting to suppose that this "tapering off" supplies the resolution to the paradox, as it seems to imply that if \( A \) is near the high end of the (proper) distribution, it will be more likely that \( B \) is smaller; perhaps sufficiently more likely to offset the paradoxical reasoning? This is the conclusion that Castell and Batens draw. They offer a "proof" that the distribution must be improper for the paradoxical reasoning to be possible.

Unfortunately Castell and Batens' proof is mistaken, and in fact there exist proper distributions for which the paradoxical reasoning is possible. The error lies in their assumption, early in the paper, that

\[
p(B>A|A=n) = \frac{g(n)}{g(n) + g(n/2)}.
\]

This seems intuitively reasonable, but in fact \( p(B>A|A=n) = \frac{2g(n)}{2g(n) + g(n/2)} \), which is significantly larger in general.

To see this, note that if \( A \) is in the range \( n \pm dx \), then \( B \) is either in the range \( 2n \pm 2dx \) or in the range \( n/2 \pm dx/2 \). The probability of the first, relative to the initial distribution, is \( g(n)dx \); the probability of the second is \( g(n/2)dx/2 \). The probabilities that \( B \) is greater or less than \( A \) therefore stand in the ratio \( 2g(n):g(n/2) \), not \( g(n):g(n/2) \), as Castell and Batens suppose.

For example, given a uniform distribution between 0 and 1000, if \( A \) is around 100, it is in fact twice as likely that \( B \) is around 200 than that \( B \) is around 50. To dispel any lingering counterintuitiveness, note that something like this has to be the case to make up for the fact that when \( A > 500 \), \( B \) is always less than \( A \). To find a distribution where the chances of a gain and a loss are truly equal for many \( n \), we should turn not to a uniform distribution but to a decreasing distribution, where \( g(n/2) = 2g(n) \) for many \( n \). An example is the distribution \( g(x) = 1/x \), where we cut off the distribution between arbitrary bounds \( L \) and \( U \), and normalize so that it has an integral of 1. This distribution will have the property that for all \( n \) such that \( 2L < n < U/2 \), \( p(B>A|A=n) = 0.5 \). To illustrate this intuitively, note that for such a decreasing distribution, the prior probability that the smaller value is between 4 and 8 is the same as the probability that it is between 8 and 16, and so on, if \( L \) and \( U \) are appropriate. Given the information that \( 8 < A < 16 \), it is equally likely that \( B \) is in the range above or below.

This flaw in Castell and Batens' reasoning nullifies their proof that a distribution must be improper for the paradoxical reasoning to arise, but it does not yet show that the conclusion is false. It remains open whether there is a proper distribution for which the paradoxical reasoning is possible. The bounded
distribution above will not work, as its bound will block the paradoxical reasoning in the usual fashion; and the unbounded distribution \( g(x) = 1/x \) is improper, having an infinite integral. But this can easily be fixed, by allowing the distribution to taper off slightly faster. In particular, the distribution \( g(x) = x^{-(1.5)} \), cut off below a lower bound \( L \) and normalized, allows the paradox to arise. The distribution has a finite integral, and even though for most \( n \), \( p(B > A | A=n) < 0.5 \), it is still the case that for all relevant \( n \), \( E(B|A=n) > n \). To see this, note that if \( n < 2L \), then \( E(B|A=n) = 2n \); and if \( n \geq 2L \), then

\[
p(B > A | A=n) : p(B < A | A=n) = 2g(n) : g(n/2) = 2n^{-1.5} : (n/2)^{-1.5} = 1:\text{sqrt}(2).
\]

The expected value \( E(B|A=n) \) is \((2n+\text{sqrt}(2)n/2)/(1+\text{sqrt}(2))\), which is about \(1.12n\). The paradox therefore still arises.

The distribution here may be unintuitive, but it is easy to illustrate a similar distribution intuitively. Take a distribution in which the probability of a value between 1 and 2 is \( c \), the probability of a value between 2 and 4 is just slightly less, say \( 0.9c \), the probability of a value between 4 and 8 is \( 0.81c \), and so on. This distribution has a finite integral, as the integral is the sum of a decreasing geometric series; and it is sufficiently close to the case in which the probability of a value between \( 2^k \) and \( 2^{(k+1)} \) is constant that the paradoxical reasoning still arises. Even though \( p(B < A | A=n) \) is now slightly less than 0.5, due to the incorporated factor of 0.9, it has decreased by a sufficiently small amount that \( E(B|A=n) \) remains greater than \( n \). The case \( g(x) = x^{-(1.5)} \) is just like this, except that the factor of 0.9 is replaced by a factor of \( 1/\text{sqrt}(2) \), which is around 0.7.

The paradox has therefore not yet been vanquished; there are perfectly proper distributions for which the paradoxical reasoning still applies. This leads us to the third and final step in the resolution of the paradox. Note that although the distributions above have finite integrals, as a probability distribution should, they have infinite expected value. The expected value of a distribution is \( \int_{0}^{\infty} xg(x)dx \). When \( g(x) = x^{-(1.5)} \) (cut off below \( L \)), the expected value is \( \int_{L}^{\infty} x^{-(0.5)} dx \), which is infinite. But if the expected value of the distribution is infinite, there is no paradox! There is no contradiction between the facts that \( E(B) = 1.12 E(A) \) and \( E(A) = 1.12 E(B) \) if both \( E(A) \) and \( E(B) \) are infinite. Rather, we have just another example of a familiar phenomenon, the strange behavior of infinity.[*]

[*][Castell and Batens note some similar consequences of infinite expected values in another context, in which the distribution is over a countable set. They say that infinite expected values are "absurd", but I do not see any mathematical absurdity.]]

To fully resolve the paradox, we need only demonstrate that for distributions with finite expected value, the paradoxical situation does not arise. To do this, we need to precisely state the conditions expressing the paradoxical situation. In its strongest form, the paradoxical situation arises when \( E(B|A=n) > n \) for all \( n \). However, it arises more generally whenever reasoning from \( B \)'s dependence on \( A \) leads us to the
conclusion that there is expected gain on average (rather than all the time) by switching A for B. This will hold whenever $E(K-A) > 0$, where $K$ is the random variable derived from $A$ by the transformation $x \rightarrow E(B|A=x)$. We therefore need to show that when $E(A)$ is finite, $E(K-A) = 0$.

Let $h$ be the density function of $A$. Then $h(x) = (g(x) + g(x/2)/2 = (2g(x)+g(x/2))/4$. (Note that $h \neq g$, as $g$ is the density function of the smaller value.) Then

$$E(K-A) = \int_{0}^{\infty} h(x) (E(B|A=x) - x) \, dx$$
$$= \int_{0}^{\infty} \frac{(2g(x)+g(x/2))/4 - x}{x/2 \cdot g(x/2)/4} \, dx$$
$$= \frac{\int_{0}^{\infty} 2xg(x)dx - \int_{0}^{\infty} 2yg(y)dy}{4}$$
$$= 0.$$

Note that the fourth and fifth steps above are valid only if $\int_{0}^{\infty} xg(x)dx$ is finite, which holds iff $E(A)$ is finite. (If $\int_{0}^{\infty} xg(x)dx$ is infinite, it is possible that $\int_{0}^{\infty} 2xg(x)-x/2 \cdot g(x/2)dx \neq 0$, even though $\int_{0}^{\infty} 2xg(x)dx = \int_{0}^{\infty} x/2 \cdot g(x/2) \, dx$.)

It follows that when $E(A)$ is finite, consideration of the dependence of $B$ on $A$ will not lead one to the conclusion that one should switch $A$ for $B$. A colollary of the result is that when $E(A)$ is finite, it is impossible that $E(B|A=n) > n$ for all $n$, so that the strong form of the paradox certainly cannot arise.

If $E(A)$ is infinite, this result does not hold. In such a case, it is possible that $E(A) = E(K)$ (both are infinite) but that $E(K-A) > 0$. Here, the "paradoxical" reasoning will indeed arise. But now the result is no longer paradoxical; it is merely counterintuitive. It is a consequence of the fact that given infinite expectations, any given finite value will be disappointing. The situation here is somewhat reminiscent of the classical St. Petersburg paradox: both "paradoxes" exploit random variables whose values are always finite, but whose expected values are infinite. The combination of finite values with infinite expected values leads to counterintuitive consequences, but we cannot expect intuitive results where infinity is concerned.[*]

The St. Petersburg Two-Envelope Paradox

David J. Chalmers

Department of Philosophy
University of Arizona
Tucson, AZ 85721.

chalmers@arizona.edu

The Two-Envelope Paradox: I am presented with two envelopes A and B, and told that one contains twice as much money as the other. I am given envelope A, and offered the options of keeping envelope A or switching to B. What should I do?

I reason: (1) For any x, if I knew that A contained x, then the odds are even that B contains either 2x or x/2, so the expected amount in B would be 5x/4. So (2) for all x, if I knew that A contained x, I would have an expected gain in switching to B. So (3) I should switch to B. But this seems clearly wrong, as my information about A and B is symmetrical.

It is widely accepted that one's reasoning in this scenario should depend on one's initial probability distribution for the amounts in the envelopes. It is also widely accepted that if this distribution has a finite expected value, (1) and (2) are false, so the reasoning goes wrong. However, it is well-known that there are certain distributions with infinite expected value such that although (1) is false, (2) is still true. For such distributions, the paradox seems to arise as strongly as ever, and there is no widespread agreement on how to handle it.[*]

[[For the existence of paradoxical distributions with infinite expected values, see Broome 1994. Chalmers 1994 gives a proof that the paradox does not arise for finite distributions, and notes the existence of infinite paradoxical distributions. I now think that the discussion there does not get to the bottom of the residual "paradox"; the current paper is a corrective.]]

To help diagnose the residual "paradox", I offer the following variant, obtained by mixing and matching two well-known scenarios:

The St. Petersburg Two-Envelope Paradox: I am presented with two envelopes, A and B. I am told that each of them contains an amount determined by the following procedure, performed separately for each envelope: a coin was flipped until it came up heads, and if it came up heads on the nth trial, $2^n$ is put into the envelope. This procedure is performed separately for each envelope. I am given envelope A, and offered the options of keeping A or switching to B. What should I do?

I reason: (0) Before opening the envelopes, the expected value in each is infinite. (1) For any x, if I knew that A contained x, then the expected value in B would still be infinite. So (2) for all x, if I knew that A
contained x, I would have an expected gain in switching to B. So (3) I should switch to B. But this seems clearly wrong, as my information about A and B is symmetrical.

What is going on here? Obviously the problem lies in the step from (2) to (3). When a distribution over finite amounts has an infinite expected value, any specific result will be disappointing. It will then always be in one's interest to do things over, if given the opportunity. But it does not follow from this that before knowing the result, it is in one's interest to do things over. The general moral can be put decision-theoretically or probabilistically.

Decision-theoretically, the moral is that dominance reasoning is not generally valid. Say one has two choices A and B, and a parameter C whose value is unknown, on which the utility of A or B may depend. An unrestricted dominance principle says that if, given any specific value of C, A is preferable to B, then A is preferable to B overall. The St. Petersburg two-envelope paradox (taking C as the value in envelope A, and A and B as the respective choices) shows us that this principle is false.

Probabilistically, the moral is that one cannot discharge certain universally quantified claims about conditional expected values. An initially plausible principle holds that given any two unknown quantities C and D, then if E(D|C=x) > 0 for all x, then E(D) > 0. The St. Petersburg two-envelope paradox (taking C = A, and D = B-A, where A and B are the amounts in the two envelopes, and allowing infinite positive and negative expected values) shows that this principle is false.

What applies to the St. Petersburg two-envelope paradox applies equally to the original two-envelope paradox. In both cases, the reasoning from (2) to (3) tacitly relies on a principle such as those above. These principles are false, so the reasoning is invalid.

Why do the principles fail in these cases? In both cases, the overall expected gain from switching (B-A) can be represented as the sum of an infinite series in which the sums of both the positive and the negative terms diverge. Such a series has an undefined sum, but can always be partitioned into a new series with only positive terms (each of which is a sum of terms in the original series) and also into a new series with only negative terms. (In the envelope cases, one obtains such new series via partitions that hold fixed the value of A and the value of B respectively.) When this instability under partitioning is present, it is to be expected that dominance reasoning and the principles above break down.

These principles may be true under certain restrictions: e.g., a restriction to cases involving only finite expected values and absolutely convergent series (setting aside Newcomb-style cases, in which C is not independent of one's decision between A and B). There may be weaker restrictions that suffice, since there are plausibly some cases involving infinite expected values where dominance reasoning is valid. Articulating the weakest possible restrictions here is an important open question; but for now, what matters is that the principles do not hold in general.

The upshot is a disjunctive diagnosis of the two-envelope paradox. The expected value of the amount in the envelopes is either finite or infinite. If it is finite, then (1) and (2) are false: the paradoxical reasoning
results from illicitly ignoring probability distributions. If it is infinite, then the step from (2) to (3) is invalid: the paradoxical reasoning relies on dominance principles or probabilistic principles that are false in the infinite case.[*]

[*][Apart from the illustration provided by the St. Petersburg two-envelope paradox, most of the issues discussed here have been discussed elsewhere: Dreier (forthcoming) discusses the breakdown of dominance reasoning; Norton (1998) discusses matters in the vicinity of the false probabilistic principle, and Clark and Shackel (2000) discuss the role of absolute convergence. Thanks to Michael Clark and Nicholas Shackel for comments and to Jamie Dreier for discussion.]]

The First-Person and Third-Person Views (Part I)

David J. Chalmers

[[An overview of "first-person" and "third-person" issues about consciousness, written when I was a first-year graduate student at Indiana in 1989. This was Part I of a supposedly 3-part paper - the two remaining parts got turned into "Consciousness and Cognition". This part doesn't reach any firm conclusions, but it captures something of the eternal internal struggle.]]

Organization, roughly.

- Intro to what "first-person" and "third-person" mean.
  - (outline the probs of the first person)
  - (convenience of third-person vs absoluteness of first-person)
  - (explain terminology)
- Dominance of third-person, reasons.
  - (embarassment with first person)
  - (division of reactions)
  - (natural selection - those who can make the most noise)
  - (analogy with behaviourism)
- Reductionism, hard-line and soft-line
- Appropriation of first-person terms by reductionists.
  - (mind, consciousness, first-person)
  - (correspondence of first-person to third-person)
- The problems of the first person
  - (problem of qualia, problem of mental content)
- The cult of the first person
- The reconciliation - what the third person can tell us about the first person

We CAN'T separate the first-person from the third-person. Even as I write this, it's my brain that is doing the thinking.

The First Person and the Third Person

Perhaps the most important duality in the philosophy of mind is that between the first-person and third-person views of mental events. Some might say that the fundamental duality is between mind and brain, or between subjective and objective - but all of these reduce to the first-person/third-person duality.

The first person is, at least to many of us, still a huge mystery. The famous "Mind-Body Problem," in these enlightened materialist days, reduces to nothing but the question "What is the first person, and how is it possible?". There are many aspects to the first-person mystery. The first-person view of the mental
The First-Person and Third-Person Views

encompasses phenomena which seem to resist any explanation from the third person. Such phenomena include some famous philosophical bugbears: subjective experience, qualia, consciousness, and even mental content (although see below. It is notoriously difficult to even talk about the first person without slipping into confusion, and these terms may have different connotations for different people.).

The distinguishing mark of the first-person view is the air of mystery which surrounds it. This feeling of mysteriousness has led many people to dismiss the first-person out of hand. It perhaps has 'spiritual' connotations not unlike those of the occult or religion. But the first-person is not to be dismissed so easily. It is indeed a glaring anomaly today, in the heyday of the scientific world-view. If it was not for the direct experience which all of us have of the first-person, it would seem a ridiculous concept. But it throws up too many problems to be neatly packaged away in the kind of third-person explanation which suffices for everything else in the scientific world. Pity.

The third-person view, by contrast, poses no deep metaphysical difficulties. The difficulties here, while not to be underestimated, are in a sense merely technical. From the third-person view, the human brain is (in principle at least) perfectly understandable. It is after all only a physical system - a tremendously complex one, without doubt, but a physical system nevertheless - which like all other such systems, is constituted at the bottom line by microscopic physical parts, obeying the laws of physics. Its behaviour would be totally analyzable and predictable if one had a detailed knowledge of physical principles. From the third person, there is no room for any mystery.

Of course, as with any complex system, a microscopic-level physical explanation may not tell the whole story, or at any rate it may not tell the story as elegantly and simply as it could be told. Purely reductionist explanations are not noted for their parsimony. So third-person theorizers are drawn into a search for the correct level of explanation, and for useful high-level predicates and properties which can be abstracted from the physical base. Some kinds of abstractions may prove to have great explanatory and predictive power, in which case they will be retained; others will not, and will thus be discarded. This is the way of the world in any sort of complex system analysis - whether it be in the field of biology, economics or psychology.

The kind of abstractions which have proved particularly interesting to third-person theorizers in the philosophy of mind include such diverse concepts as beliefs and desires, rationality, understanding,...; and occasionally even concepts like consciousness, sensation and experience (but importantly, these latter concepts have a subtly different emphasis when viewed from the third person to when viewed from the first person). Some of these have proved to have great explanatory power. But nevertheless, from the third person these remain (merely) convenient and useful abstractions. From the third person, no-one need ascribe any absolute 'reality' to these concepts, and more than is ascribed to any other abstraction. One might say that the distinguishing mark of the third-person view of the mental is convenience.

By contrast, first-person mental events seem to be something more than just convenient abstractions. When we talk of colour-sensations, or pains, or even consciousness, we are not doing this because of the need to make useful abstractions. We are doing this because they seem to have an absolute reality. From a totally 'objective' view, no-one would stop for a moment to think that there might really be something in
there experiencing those convenient abstractions which they had made; no third-person theorizer would believe that their elegant stipulations of mental content had any absolute truth behind them; nobody would believe that a mere physical system could really carry meaning; and yet there is, they do and it does. What would seem ridiculous from the objective view is almost self-evident from the subjective view. The first person is an anomaly, but it is forced upon us.

In recent years there has been a polarity between philosophical thinkers who take the third-person stance, and those who address the first-person issues. In a sense there seems to be an irreconcilable division. I will argue that this division is not as great as it seems to be. Unlike hard-line members of the third-person camp, I believe that the first-person does present us with major problems to be answered. Unlike hard-line members of the first-person camp, I believe that the third-person view can be the source of much wisdom. The third-person and first-person are inseparable - I try to outline why, and how.

In Part I of this paper, I outline some of the major differences between the first-person and third-person camps, and some of the subdivisions within these camps. In some ways the polarity between these camps is not surprising - I try to make a case for why.

In Part II, I take up the third-person position. I give arguments showing why it was perhaps ridiculous to ever suppose that the first-person could be separated from the third-person view. In particular, I try to investigate the possibility of a being which seems to have all the third-person attributes required for, say, consciousness, but which is nevertheless lacking a first-person 'experiencer.' More than one recent thinker seems to believe in such a possibility, but I show that if this could be the case, it would lead to strong consequences. In particular, it might mean that the Mind-Body Problem was insoluble.

By Part III, we will have seen the necessity for coherence between a first-person and a third-person theory of mind. I will try to present a framework for such a theory, which might explain the notion of the first person without dismissing it. This will involve the two fundamental (and inseparable) concepts of pattern and information. Without giving too much away, the fundamental thesis will be this: third-person is to first-person as pattern is to information.

A Note on Terminology

Readers of this paper may hear rather more of the terms "first-person" and "third-person" than they would like. I originally intended to use the word "consciousness" to represent the mysteries of the first-person, but this had two problems: the word has been often used to denote third-person viewable phenomena (the notion of a system which gets feedback from its own processing, to name just one aspect), and this could lead to much confusion; and secondly, I believe there is more to the first-person mystery than consciousness alone (the problem of qualia, for instance, does not fit easily into a framework shaped around consciousness).

Instead I have chosen to use the term "first-person", as a coverall for all the problems which we recognize when we take the first-person stance - that range of problems often subsumed under the somewhat
antiquated heading "Mind-Body Problem." The baffling problems of qualia, consciousness, and subjective experience are all part of the "first-person" mystery. What this term lacks in sparkle, it makes up in generality and accuracy.

Many mental events are viewable from the first person and from the third person. Take a pain, for instance: from the first-person we are interested in the particular qualitative sensation to which it gives rise; from the third-person, we are interested in the state of the brain at the time (including the famous firing of C-fibres), its causal effect on other parts of the brain, and the behaviour to which it gives rise. Obviously, these views of a pain are very much related. But when I want to make the distinction between these aspects of a pain, I will refer to "first-person pains" and "third-person pains," as a kind of shorthand. Similarly for other mental events. Even such a phenomenon as consciousness we can view in two ways, as "first-person consciousness" and "third-person consciousness."

This is a very useful distinction to make. Firstly, it avoids confusion. Secondly, it allows us to talk about mental events from the third-person without presupposing that there are true, first-person mental events 'going on inside.' This is very useful when, for instance, we want to speculate on the possibility of a robot being conscious. The first step is to take what Dennett would call the "intentional stance" towards it, and see what kind of third-person mental events we could ascribe. Hard-line members of the first-person camp, such as Searle and McGinn, would deny us even this.

And an apology to grammaticists. "First-person" is an adjective, not a noun. When I speak of "the first person," this is usually a shorthand for "the first-person view," or sometimes "phenomena viewable from the first-person view." I hope the intended usage is clear in context. I do not mean to beg the question of whether there is indeed a single, indivisible "first person." This question, the problem of the self, is a related but separate issue which has been discussed by thinkers from Hume to Dennett and Parfit, and I believe the jury is still out.

The Dominance of the Third-Person View

The third-person view has enjoyed a distinct primacy in the philosophy of mind of recent years. This is not least because philosophers have finally caught up with the scientific notion that the bottom line of all that exists is the physical universe. But there are other reasons. In this section I will present some of the reasons why we should expect the third-person program to be dominant and quite successful. None of these reasons are inconsistent with the view that there remains a great mystery about the first person.

It seems that many philosophers of mind find first-person questions a little embarrassing. Here we have a very sophisticated academic field, but still it seems we have trouble getting far with what most outsiders would see as our fundamental problem: the Mind-Body Problem. There are four typical reactions to this embarrassment:

(1) Ignore the first-person, and maybe hope that it will go away. If one is candid, admit one's embarrassment but lack of a solution. Work on other problems instead.
(2) Deny that there is any embarrassment at all. Claim that the mystery of the first-person was only ever a powerful illusion, perhaps a remnant of our Cartesian heritage. Attempt to demonstrate that a reductionistic (or eliminative) third-person analysis is enough to deal with the problems of the first-person. (This position is the Hard-Line Reductionist stance which I delineate below.)

(3) Admit the embarrassment, and spend one's time going around pointing out the problems. The only trouble with this approach is that without solutions to these problems, a new kind of embarrassment of one's own takes over. One can only point out the problems so many times without repeating oneself. The leading exponent of this stance has been Nagel. Searle's arguments have been a variation on this theme.

(4) Admit the embarrassment, and try to deal with the mystery of the first-person without denying its existence. This has been tried by many ambitious philosophers over the years, but no approach has met with universal approval. Many people recognize the problems of the first-person, but few seem satisfied with solutions that have been proposed. This makes attempting to resolve the first-person mysteries a somewhat quixotic enterprise. Consider this paper another addition to the canon.

Position (1) is the most common reaction. There is, after all, much interesting philosophy which can be done from the third-person stance. The sophistication of this domain contrasts hugely with the vagueness which surrounds the first-person. So we have today a proliferation of papers which deal with the third-person without taking a stance on the first person. Occasionally, authors explicitly admit to being baffled by the mysteries of the first person, but more often their position is left unstated. Some third-person philosophers par excellence include Fodor, Stich, ...

Position (2) is also not too uncommon, and is a not unexpected reaction to the apparent mystery of the first person. There exist many recent papers which take the third-person stance, give a detailed analysis of mental phenomena, and in doing so claim to have dismissed or explained seemingly first-person problems. This claim is usually the part most in need of examination. Sometimes it is supported with a great deal of careful argument (Parfit). More often, what is given is a purely third-person account, perhaps an account of the architecture or evolution of mental structures (Dennett, Churchland); and immediately thereafter the claim is baldly made that this account eliminates the first-person mysteries. Often, at least to the eyes of a member of the first-person camp, the argument given to support this claim seems a little thin.

One of the main difficulties with taking position (3) or (4) is that it is difficult to even talk about the first-person without confusion. Part of the reason for this is the huge intrinsic difficulty of the problem; another reason is the predominance of terminological confusion when talking about such things as "mind," "consciousness," "self" and other traditionally first-person concepts. Everybody uses these terms in their own way, and there is no general agreement about their domains of applicability (let alone about to what they refer!). I go into more detail about this problem below.

Given this difficulty with talking about first-person issues, it is not surprising that third-person philosophy
of mind should be prevailing, almost by default. Despite the fact that many people out there are hugely puzzled by the problems of the first-person (as they may admit off-the-record), it is difficult to make much noise about it without falling into both repetition and negativity. The third-person stance, by contrast, can yield many important insights about the mind, despite the fact that it does not usually deal with the Big Issues. Taking the third-person stance, one is able to make much more noise. So, almost by natural selection, the third-person stance becomes dominant, and the first-person stance is reduced to the status of a quirky domain for those who like to cause trouble.

**An Analogy with Behaviourism**

One might make an analogy with behaviourism in psychology, in the earlier part of this century. In those days, nobody had the slightest idea what was going on inside the brain. To speak of internal cognitive processes was to descend to the level of speculation. The only things which people could get a handle on were behavioural manifestations. It was natural that as a result, behaviour became by far the dominant area of research. Nobody even had a clear idea of what would be the correct language to talk about internal processes with.

One may presume that when the behavioural paradigm was just beginning, not many serious thinkers actually doubted the existence of internal processes. It was just that nobody knew quite how to study them, and that in even talking about them researchers felt like they were standing on quicksand, descending into vagueness. Little wonder they grasped at whatever surer ground they had available, the direct study of behaviour. And indeed the analysis of behaviour produced many important insights. These insights had a profound and often positive effect on psychology. All that believers in 'cognitive processes' could do was stand around and say "but this isn't all!".

A curious thing began to happen. Where once behaviourists had abjured the study of internal processes because of the difficulty of dealing with these, some now, following upon the great success of their research program, began to deny the existence of internal processes at all. When spelt out, the argument of these radical behaviourists went something like this:

1. We have had much success analyzing behaviour in terms of stimulus- -response mechanisms, without needing 'internal processes.'

2. Believers in 'internal processes' have had little success in reaching any concrete conclusions, and seem vague about what they are even talking about.

3. There may be a few problems with our view, such as certain arguments proposed by the 'cognitivists,' but these will go away with careful analysis.

Therefore

4. 'Internal processes' are an unnecessary hypothesis, and do not exist.
Looking upon this with the assistance of hindsight, there seems to be a monumental non sequitur there somewhere. To be sure, behaviourism had met with some success, but surely no-one had ever expected it to tell us *everything*? And did they completely doubt the evidence of their own introspection, about the existence of internal states? The arguments of the cognitivists, which seem so obvious to us today, surely must have given them cause for doubt?

But we should not be surprised. The argument was almost self-supporting, by natural selection. Believers in internal processes found it difficult to get beyond naysaying, to achieve concrete results, because these processes were still shrouded in mystery. So, to make a living these believers had to either join the behaviourist bandwagon, or more likely leave the field. The behaviourists were the ones who were making the noise, given the constraints of the current state of scientific knowledge, so the field acquired an unnatural bias in their direction. To be sure, many 'reasonable' behaviourists remained, who admitted that one day internal processes would have to be dealt with; but these comments were more often made in the protection of their homes, or their departmental tea-room. The point could only be made in print so many times, before repetition and negativity set in.

Sound familiar? I am sure that I do not need to spell out the analogy. These days, nobody has any problem believing in cognitive processes. They may not be totally understood, but progress has been made and a language for discussion has been developed. The bugbear these days is "subjective experience," and related first-person phenomena. We are simply not yet sophisticated enough to discuss these without encountering a fog of vagueness. As with the behaviourists, this leads to a understandable predominace of third-person analysis. And just as with the behaviourists, there are some 'radicals' who, to avoid the embarassment of problems we do not understand, claim that the problems do not exist, despite strong arguments to the contrary. We should not be surprised by this.

**Reductionism and the cult of the third-person**

The term "reductionism" is often a little vague in its application, especially in the philosophy of mind. Dawkins has said that "nobody is a reductionist in any sense worth being against." This may or may not be true in the philosophy of mind. I will divide reductionism into "hard-line" and "soft-line" varieties.

The Hard-Line Reductionist believes that to explain everything that is interesting about the mind, all we have to do is explain what is happening in the physical system that is the brain (and, perhaps, in the body and surrounding environment). Beyond this collection of third-person facts (they believe) there is *nothing more to explain*. Any claims of "but you've left out the most interesting part!" are not countenanced. These reductionists may allow certain abstractions from the physical base to be made, for the purposes of elegance and explanatory power, but these abstractions are made simply out of convenience, and they are not held to reflect any absolute truth.

Hard-line reductionists believe that questions of "subjective experience" and "qualia" and "phenomenology" are distracting chimeras, at best powerful illusions. A list of hard-line reductionists would include Ryle, Armstrong, and more recently, Dennett, Churchland and Parfit. These are people...
who take position (2) above, in reaction to first-person issues: they deny that there is any mystery. I believe that this is a sense of reductionism is worth being against.

In contrast, Soft-Line Reductionists are much more amenable to first-person questions. The soft-line reductionists believes that the cause of everything which is going on in the mind is the physical system, and this physical system is explainable from the third-person, but there may still be some emergent phenomena which are not captured by a purely physical, third-person description. Most hard-line reductionists probably regard soft-line reductionists as unbearably "wimpy," in rather the same way that an atheist would regard an agnostic, or that a communist would regard a social democrat.

Essentially, a soft-line reductionist is a materialist who nevertheless believes that the first-person is a great mystery; a hard-line reductionist believes there is no mystery at all. While the soft-liner may be dismissed by the hard-liner as "soft, squishy, and mystical," in this paper I intend to show that not only is soft-line reductionism a tenable position, but also that it does not inevitably lead to throwing up ones arms in frustrated wonder at the mystery of it all. I believe that a theory of the first-person can be developed which is coherent with a theory of the third-person, but which is not subsumed by a theory of the third-person.

The Appropriation of First-Person Terms

As I have said, the first-person is hard to talk about. One important reason is that every first-person concept has a corresponding third-person concept. The word "consciousness" has often been taken as a compact reference to all that is mysterious about the first-person; but obviously, there are some third-person aspects which are very relevant to the word. If consciousness means something like "awareness of self," then a third-person commentator can point to the properties of physical systems (like the brain) which are monitoring their own processing, and using this feedback to adjust their behaviour. "So," the reductionist will claim, "wasn't this just what you meant by the term?". The first-personite will of course reply "No, the problem is, how could a mere physical system experience this awareness." The reductionist will reply in character, and the two will go on, feeling that they are talking past each other. The two are talking about corresponding phenomena, but not necessarily about identical phenomena.

This direct correspondence between first-person and third-person phenomena is the cause of much of the confusion. It has led to a slippery terminological slope, where nobody is sure what words in the "mental" vocabulary are referring to at a given time. Increasingly, terms which were once reserved for first-person issues are now used to cover third-person issues also.

The word "mind" once stood for everything that was quintessentially first-person. Witness the phrase "mind-body problem," for instance. But over the years the emphasis of the term has changed, until now is now much more frequently used to refer to third-person phenomena. Terms in common parlance such as "the subconscious mind" bear witness to this fact. Cognitive science, which is essentially the third-person investigation of mechanisms of thought, is often described as the "study of mind." These days the word "mind" is a general coverall for abstractions from the brain, first-person or third-person.
The word "consciousness," even. People who talk of "the evolution of consciousness", and of its survival value, are obviously addressing third-person aspects of the problem. I don't mean to say that these aspects are uninteresting, but nevertheless these aspects are not what makes consciousness such a mysterious problem. It is a pity; for a while the word "consciousness" was a general indication that one was talking about the mysteries of the first-person. These days, this seems to be less often the case.

The cause of this confusion is of course the intimate relation that the first person has to the third person. We should never forget that the mind is caused by a brain, and that the brain is at the bottom line a physical system understandable from the third-person view. Although we do not know how, a first-person is emergent from a third-person-understandable substrate. A consequence of this is that much of interest from the first-person viewpoint corresponds directly to phenomena viewable from the third person. Even the thought which I am having now: "Wow, how could it be that a mere brain could experience this thought", is being supported by a pattern of neural activity in my brain.

Take "consciousness," for instance. Despite the fact that this word usually represents all that is mysterious about the first-person, it would be naive to expect that the phenomenon be completely separable from the third-person viewpoint. And indeed, there is much in the third-person viewpoint which gives us insight into consciousness. The third-person notion of a brain which is scanning itself, or observing (directly or indirectly) its own processing, for example, obviously has a lot to do with consciousness - it is an important part of the third-person substrate from which consciousness emerges.

But it would be a mistake to regard this view of consciousness as dissolving the first-person mysteries altogether (as is sometimes claimed). To make this distinction clear, I will always denote this view of consciousness as "third-person-consciousness", or in the interests of brevity, "3P-consciousness." (One should not confuse this third-person view of consciousness with "consciousness of the third person," which is a different matter entirely.) When I use the word "consciousness" alone I will always mean "first-person-consciousness", which I will sometimes abbreviate "1P-consciousness."

This direct correspondence (some might even say isomorphism) between first-person phenomena and (a certain subset of) third-person phenomena seems to be what often leads to confusion when discussing first-person issues. Many commentators, particularly those in the third-person camp, give the illusion of reducing first-person mysteries by appropriating the usual first-person words to refer to the third-person phenomena to which they correspond. It would be a final irony if this was to happen to the word "first-person" itself. I hereby issue a plea that this word be off-limits to the third-personites. If they wish, they may argue that the first-person does not exist; but they may not pretend to 'explain' the first-person by describing only third-person phenomena.

It would be nice if every article on 'mind' and 'consciousness' came with a caveat at the beginning, alerting the reader whether it is to be the first-person or the third-person phenomena that will be discussed. It is not unusual to find a paper which seems to be addressing the great first-person mysteries, only for the reader to find halfway through that it is doing no such thing. Sometimes even authors themselves seem confused as to which questions they are addressing.
It seems that there are only about three expressions which these days are still reserved only for first-person phenomena. These are "qualia," "phenomenology," and "subjective experience." But even these words (particularly the last) may begin to be appropriated by reductionists; and besides, each of these words has a fairly limited domain of application. I will always use the term "first-person" as a general term covering the whole area of this metaphysical mystery.

Of course there is also the old standby "Mind-Body Problem." This phrase has probably outgrown its usefulness, with the change in usage of the word "Mind" and the change in emphasis from "body" to "brain." But I will still use it from time-to-time; no other phrase has such universal first-person connotations.

The Mystery of the First-Person

As I have said, it is difficult to talk about the first-person without descending into vagueness. But what can be done, if it is done carefully, is to point out the mysteries, and ask how a third-person, physical theory could ever deal with these. I do not intend to do this in this paper - I take it that this has already been done most ably, by Nagel and others, and that reductionists have never given an adequate response. To re-present these arguments would be to go over old ground.

Instead, I intend to find out what the third-person can tell us about the first-person, and to present a first-person theory which coheres with the third-person view. Any hard-line reductionists reading this will of course not be convinced by my premise. They may read this paper perhaps for amusement, perhaps because these first-person ideas may give them some insight into their third-person ideas, and perhaps even to realize that not all believers in the first-person are as unreasonable as they had supposed.

I will, however, give a very brief account of some of the most difficult first person problems. Two of these stand out above the others.

(1) The problem of QUALIA.

Qualia are the qualitative aspects of subjective experience, particularly sensations such as colour, taste and pain. One can ask: how could a third-person theory begin to explain the sensation of seeing the colour red? Could a theory be given which enabled a being, as intelligent as ourselves but without the capacity for sight (or even a visual cortex), to truly understand the subjective experience of the colour red? Analogously, as Nagel asks, could we ever understand how it feels to BE a bat, or another creature with very different mental architecture.

It is extremely difficult to imagine how a physical explanation of brain architecture could solve these problems. If, in answer to the question "could a sightless being understand the sensation of red?", the reductionist answers "yes," then we have the right to ask "How, possibly?". I believe that no satisfactory answer to this has been given. If, on the other hand the reductionist answers "no," then the very least of her problems is a serious epistemological limitation.
(2) The problem of MENTAL CONTENT

This problem is harder to articulate than the previous one, but I believe that it is even more important. When we think, our thoughts have content. How is it possible that, in some absolute sense, patterns of neuronal activity in a small biological system support meaning? We can stipulate meaning to a physical system (as is done by Dennett's 'intentional stance', and perhaps by Fodor's 'language of thought'), but do these stipulations have any metaphysical reality? If it wasn't for the direct evidence of our introspection, the idea that a physical system could in an absolute sense carry meaning would be dismissed. And yet it happens.

There are other ways to articulate first-person problems. We could talk about the problem of "subjective experience," or of "consciousness," but we begin to tread on slippery terminological ground, which it is probably best to avoid if possible. In any case, all of the first-person mysteries are encapsulated in the term "Mind-Body Problem." People who think that this problem has been solved are surely in the minority.

Most writers on the subject of 'consciousness' recently have chosen to take a very third-person stance, talking about such things as the "Evolution" and "Architecture" of consciousness, while in fact talking about no such thing. They talk about fascinating third-person properties of thinking systems, which begin to explain why the systems produce these outlandish CLAIMS of consciousness and so on; and even explain how the ability of these systems to monitor themselves leads to the appearance of consciousness; but only very rarely is the bottom-line question of "how could ANY physical system support a first-person?" addressed.

One of the these of this article is that we should not be at all surprised at the success of these writers in explaining the "appearance" or evolution or "illusion" or architecture of consciousness - claims of consciousness are something we should expect every intelligent creature to make, and these claims by themselves are not inherently mysterious facts. There is plenty of fertile ground for Reductionists to give theor numerous explanations of the "fiction of the self" and the "evolution of consciousness". But the first-person, subjective question is still not answered. Only rarely do reductionists take more than a paragraph or two to address the true concerns of the first-personites, and when they do it is usually to say "Well, we've explained why a physical system might believe in these fictions, and that's all we need to do." But if they don't answer the question of how a physical system might have semantic content or subjective experience, then this is wasted effort. [Aaaargh, rephrase this.] One reductionist who does a great job of applying third-person thinking to yield though-out first-person conclusions is Parfit, but he is definitely in
Philosophers these days who argue for the mystery of the first-person view are often regarded as having a slightly anti-materialist bias. I try to show in this paper that this is not necessarily the case. I will present a materialist framework which, I believe, can *explain* the first person without *dismissing* it. One can be a materialist without being a hard-line reductionist.

I intend to present a framework for discussion of the first-person that still makes sense from a third-person view. The theory which I present is, as I see it, the only real alternative to the cult of the third-person. In fact I have a sneaking sympathy with the reductionists, and I believe they have a passing chance of being correct. Who knows, perhaps they are in fact right, and consciousness is just an incredibly powerful illusion. (Especially in view of the occasional really good argument such as that of Parfit). But this is far from demonstrated now. If a first-person theory is to have any chance of being coherent, I believe it must fit into the framework which I present.
A Taxonomy of Cognitive Jokes

David J. Chalmers (February 1989)

By a 'cognitive joke', I mean a joke whose humour seems to rely on higher-level, more abstract cognitive processing in the brain. These contrast with sexual, violent and other types of jokes which rely on our 'baser' and more instinctual reactions.

This is just a beginning categorization. I claim no 'objective correctness' for it. And of course the categories can be fluid, and the same joke can be a member of more than one category (and perhaps it will be funnier if it is). But thinking about the jokes which I can recall from the Humour Weekend, most seem to fall squarely into one or another category, indicating that perhaps this is a useful way of dividing jokes. It seems to me that the "causes of humour" in all 4 classes are different, coming from different parts of the brain.

The 4 basic classes...

(1) Allusive: Allusion to common situations or shared human foibles, producing a spark of recognition (from experience) when told.

(2) Interpretational (or Gestalt): 2 ways of interpreting exactly the same situation - or alternatively 2 situations that fit the same description. This is perhaps the largest category. It seems to arise from the power of the brain to interpret situations flexibly. This category is divided into many subclasses.

(3) Paradoxical: Typically, self-defeating statements or contradictory situations. Examples of this small class often have a flavour of mathematical logic.

(4) Inferential: The listener is forced to make an inference from information given in the joke (especially in the punch-line, which typically seems to "fall flat" for a moment), to reach a surprising conclusion. The pleasure seems to be mostly in the process of inference itself.

CATALOGUE

(1) Allusive

- Doonesbury, often (e.g. teaching strip, "everything about you")
- Russian "that reminds me of my cow" ;;this is also inferential
- Viola jokes
- Meaning of Liff
- Bohr "profound truth"
- Marriage jokes
● some ethnic jokes (good ones as opposed to generic ones)
● most political jokes

The humour here is usually in the recognition of a common experience from life, of a common type of person or event. (Often a peculiarity that is rarely commented on explicitly but recognized from everybody). Typically there is a 'spark' of recognition - "that is so true".

If the allusion is not recognized directly, then these can be taken as "information-conveying" jokes (Yan Zhao). In this case the jokes take on a mildly Inferential quality.

(2) Interpretational

There are various categories of interpretational jokes, perhaps the most common type of cognitive joke. All involve the notion that a situation can be matched to a description (or interpretation) in more than one way. This can happen in various ways: either the description or the situation can be given as the initial data, and the 'branching' can occur either in the step from situation to description or vice versa.

We classify these jokes by the order in which these events occur. Our classes are labelled SDS, DSS, SDD and SD.

SDS: These could also be called "Do this" jokes. A situation S1 is given, and typically somebody (in the joke) is required to perform the action in S1 themselves, in some sense. This is a kind of analogy problem, so a description of the situation must be formulated. Usually there is an obvious or expected interpretation D1, which would lead to situation S1' under analogy; but instead a surprising interpretation D2 is made, leading to an unexpected situation S2 (a 'false analogy').

(so SDS == situation -> (wrong) description -> unexpected situation).

1 - Garfield "do this"
2 - Copycat jokes
3 - lion-tamer joke

DSS: Here a linguistic description D of a situation is given. There is an obvious (to us) implementation of this description as situation S1. However, as it turns out, whether through stupidity or quirk of fate this description is actually implemented as a surprising situation S2. (DSS == description -> expected situation S1 AND surprising situation S2.)

4 - Poles changing lightbulbs
5 - Poles washing car-windows
6 - Alaska superconductor
7 - "wanted to look like Liz Taylor"
8 - Pearls and "The Meaning of Dreams"
These cases SDS and DSS are closely related. Both involve a situation S1 as expected implementation, and a surprising implementation S2 which occurs instead. The difference is whether the implementation is situation-based ("Do this", by analogy) or description-based.

There are some sub-categorizations which run across the border between these categories.

(1) The difference between the two situations S1 and S2 can be a reversal (figure-ground) relation (1, 3, 4, 5), a 'parallel slippage' relation (6, 7, 8), or neither (9, 10).

(2) Most of these cases are 'goal-directed' (except 8, 9). We can regard the description (or the "Do this") as a goal to be achieved. In all cases the goal is achieved in a surprising way. This can either be through stupidity (resulting in a harder than necessary solution) (4, 5, 10), through cleverness (resulting in an 'easy' solution) (1, 3, maybe 6, 7), or maybe through non-intentional quirk-of-fate, resulting in a 'different' and usually easier solution (6, 7). (Perhaps regarding 6 and 7 as goal-directed is stretching things somewhat.) (Incidentally, note the presence of Allusion in 6, 7, 9.)

We have to check how independent these variables are. (e.g. I believe SDS and parallel slippage may be incompatible, though this may be false.)

**SDD**: Here we start with a situation S, which has a correct or obvious interpretation D1, but which is instead perceived as the surprising interpretation D2 (usually mistakenly, else facetiously).

- "Is the doctor home?"
- Zero-legged frogs are deaf
- Pan-Am luggage labels.

These are closely related to SDS jokes. In both cases two descriptions are found to fit a situation. The difference is that in SDS jokes, these interpretations are implemented as analogical situations, whereas here the surprise is explicitly in the description.

**SD**: In this case we have a situation S which has NO obvious explanation until the punch-line. The punch-line supplies a weird but sense-making and 'correct' interpretation D.

- Superman at Empire State Building
- Sperm cell from mouth
- Bulldog, gorilla and shotgun.

These could possibly also be classed as Inferential jokes - see below. They are also quite closely related to SDD jokes. Also, some DSS jokes could be rephrased as SD jokes, by giving the surprising situation S2...
first and waiting for the explanation. ("Did you hear that Reagan is a juror for the North trial")

**DS:** Newsflash from the front! Here is a new, similar category DS. A description is given that seems difficult to satisfy, and then a weird implementation S, which satisfies the description, is given in the punch-line.

- Many riddles, e.g. "How do you sink an Irish submarine?"

These have a similar feel to SD jokes, with the same "Inferential" flavour. They are also quite related to DSS jokes.

So we have (at least) 5 categories of Interpretational jokes. These are SDS, DSS, SDD, SD and DS jokes. With SDS, DSS and DS jokes, the humour is in the unexpected implementation S2 or S, which is typically revealed in the punch-line. With SDD and SD, the humour is in the unexpected interpretation D2 or D, again typically revealed in the punch-line.

As we have seen, there is an intricate set of inter-relationships between the categories. This could be explored in more detail.

The humour in all categories seems to be based on the exceptionally flexible mechanisms which human beings have for matching interpretations to situations.

**(3) Inferential**

Here typically, when the punch-line is delivered, a situation is set up which at first seems unexplained and perhaps incomplete. For a moment the joke seems to fall flat - "is that it?". Then, after a moment the listener is forced to make an inference from information present in the text to form an explanation, which is often surprising or weird. The pleasure seems to lie mostly in the actual process of inference, and in the discovery of the explanation.

- Shostakovich = Beethoven backwards
- deaf genie (12-inch pianist)
- soldier cuts off his other arm
- self-referential kangaroo joke
- Local-Hero-type jokes
- Russian cow joke

These jokes are quite closely related to Interpretational SD jokes, which often need mild inference to explain a situation. The difference is one of degree; in SD jokes the inference is usually very easy upon the punch-line, and the humour lies mostly in the surprising nature of the interpretation. If the inference in Inferential jokes were less difficult, many could perhaps still be mildly funny SD jokes; but for me at least, it is the inference which gives these jokes their special quality, and makes them typically much
funnier than an ordinary Interpretational joke.

(4) Paradoxical

This is a smaller class of jokes, which seem to be based around self-defeating statements and paradoxes.

- "Individuals...I'm not"
- Cut off right arm to be ambidextrous
- 100000 times, don't exaggerate
- "Yesterday I could raise my arm THIS high"
- soldier who cuts off his second arm

Here the humour comes when we realize the contradiction. (Occasionally a process of inference is required, depending on how obvious the contradiction is, so this class is not totally disjoint from (3).) Perhaps the appreciation of these jokes comes from the "logical centers" of the brain, which have a relish for playing with paradox. Alternatively, the pleasure could be produced from the dissonance set up by the contradiction.

There are some other jokes with a somewhat logical framework.

- "Am I getting stronger or weaker?"
- God's stone - so heavy She can't lift it?
Analog vs. Digital Computation

David J. Chalmers (February 1989)

It is fairly well-known that certain hard computational problems (that is, 'difficult' problems for a digital processor to solve) can in fact be solved much more easily with an analog machine. This raises questions about the true nature of the distinction between analog and digital computation (if such a distinction exists). I try to analyze the source of the observed difference in terms of (1) expanding parallelism and (2) more generally, infinite-state Turing machines. The issue of discreteness vs continuity will also be touched upon, although it is not so important for analyzing these particular problems.

We find that to truly explain these problems we have to answer hard questions about the nature of the universe.

Analog solutions to hard computational problems. (e.g. NP-Complete ones).

Examples:

- 1) Spaghetti sorter - time \( n \) (as opposed to \( n \log n \))
  - Cut \( n \) pieces of spaghetti in proportional lengths, bang them against the table.

- 2) String shortest-path finder - constant time (?) (vs ?)
  - Cut strings of the appropriate length between free-floating "vertices", then tug on the two appropriate vertices until there's a straight line.

- 3) Cog-turner to solve NP complete problem (?) in time \( n \).
  - Described in Scientific American

These solutions all cheat by using PARALLEL computation, inherent in nature. But, you say: these problems can be shown to be just as hard on parallel machines as on serial machines (things just get speeded up by a constant factor).

But aha - there is something special going on here. Nature is not just providing us with an ordinary parallel computer. It is an EXPANDING parallel computer whose parallelism expands to meet our needs. In the spaghetti sorter, for instance, we essentially have \( n \) parallel processors, one for each stick of spaghetti. As \( n \) increases, so does the number of processors. This is unlike any typical digital computer in our experience.

Using natural parallelism, here is another, digital solution: Building \( n \) digital processors is only going to take time \( n \) (with a rather large constant factor). Once this was done then many of these hard problems would become easier. With a self-replicating machine, humans could even be taken out of the loop altogether!
Obviously both of these solutions are cheating mildly when compared with the original formulation. The original formulation only applied to nice, Turing-Machine-like algorithmic digital devices. The first solution uses "arbitrary" properties of the real world; and even the second "jumps out of the system" by physically fabricating new machines. But still... does this not mean that perhaps the original definition of 'algorithm' was a little restricted (Church and Turing turn in their graves)?

Anyway: the essence of the trick lies in EXPANDING PARALLELISM. We could give a formal definition of such machines and see what theorems apply to them.

*Question:* although we talk of (indefinitely) expanding parallelism, is it not the case that we start with one huge parallel machine to start with, namely the physical universe? We are not so much expanding our machine as making better and better use of its resources. If the universe is infinite, this is OK - improvement can go on indefinitely. But if the universe is huge but finite, then "expanding parallelism" is only an illusion. In the end we are going to exhaust all the spaghetti sticks in existence! This would be analogous to having a computer which was hard-wired to solve a problem extremely fast for \( n < 100 \), but which failed for all \( n \geq 100 \).

(General principle for all these analog 'solutions': Think hard about what happens for very large \( n \).)

Basic question: is the universe an infinite-state-machine or a finite-state-machine? If the second, then it is WEAKER than a Turing machine, so these analog solutions are essentially weak theoretically. If the first, then is it true that it is STRONGER than a Turing machine? At the very least, it seems that it has different theorems of computational complexity.

The only way a Turing machine can accomodate 'parallelism' is through its states. But as a TM has by definition only a finite number of states, then indefinitely expanding parallelism is out of the question. (Of course, such parallelism can be 'simulated' serially by use of its tape, but this is not helpful for questions of computational complexity, although this is good enough for questions of computability.)

If we have an infinite number of states, it seems that indefinitely expanding parallelism can be accomodated. As we've seen, this leads to better results for questions of computational complexity. It is an interesting question whether such a machine was more powerful computationally (in terms of the problems it could solve, independent of resource-use).

Presumably we have to specify our definition a little better. First: do we allow uncountable number of states? This might behave even better, but presumably this is outside the spirit of computation, which has it that algorithms must be well-defined and in a sense 'constructible'. The well-known inconstructibility of uncountable sets (or at least of most of their members) would seem to mean that such a machine is inherently "impractical".
OK, given a countable number of states - we'll index them by the positive integers. Next question: what do we allow as our transition functions? Do they have to be computable functions, or do we allow any function \(Z \times \ldots \rightarrow Z\) to be 'hard-wired'. This question does not arise for finite-state machines, because here any function is computable. My intuition here is that again, to be computationally 'reasonable', such functions must be computable and maybe even primitive recursive.

Incidentally, where does the physical universe fall into these classes? Assuming it is (a) infinite and (b) discrete (this is arguable) then I believe that, although the number of 'possible' states is uncountable (from a calculation like 2-to-the-infinity), the number of 'reachable' states (from constructible initial situations) is countable. And given that the laws of physics are reasonable, the transition function is computable and indeed primitive recursive (though it may be non-deterministic).

----

My basic idea of an infinite-state-machine is like this. As we already have an infinite number of states, we have no need for a tape - we can simply incorporate this into the states. One obvious way of specifying a state is by an infinite string of 0's and 1's. (Note that this gives an uncountable number of states, however). We simply require that every string at time \(t\) determines another string at time \(t+1\).

(In imagining this, we imagine ourselves 'outside' the system and determining its initial state, or at least a relevant portion of it. Of course in the case of the physical universe we are in fact INSIDE the system; but given the 'illusion' of free will we can treat it as if we were manipulating things from the outside).

The idea of having "reasonable" laws of physics corresponds to the idea of having a computable transition function. So I require that the digit at position \(P\) in the string be a primitive recursive function of the previous string. (To make this totally meaningful, we may have to make it determined LOCALLY; a digit \(P\) can only depend on its \(N\) nearest neighbours.)

This definition corresponds fairly closely to an infinite discrete universe. Another possibility would be the 'potentially infinite universe'. Here we require that all initial configurations consists of 0's outside some finite range. The 'local' nature of the laws dictate that information would always be contained within a finite range, but this finite range could be always expanding. Perhaps, given the Big Bang theory, this corresponds closest of all to our universe. The computational power here is not obvious. It seems that indefinitely expanding parallelism is still accommodatable in such a universe, but my intuition is that it should be computationally weaker.

Incidentally, the potentially infinite universe is nice also because it only requires a countable number of states. I believe that this can be shown to be equivalent to the infinite-state machine where states are indexed by integers (a few paragraphs above.)
If in fact it turns out that the universe is non-discrete, it would take a strong argument to convince me that this led to inherently different results to a discrete universe. Everything we have seen indicates that all interesting properties of non-discreteness can be simulated using low-level discreteness, especially using non-determinism. But I may be wrong here. A finite but non-discrete universe might be worth analysing. As we've seen, a finite discrete universe is equivalent only to a (rather big) finite state automaton, so that despite our initial illusion of powerfulness, it is in fact weaker than a Turing Machine. If the universe was finite and non-discrete (as may well in fact be the case), then on the face of it, this is a powerful infinite-state machine, more powerful than a Turing machine. The question is whether the continuity on smaller and smaller levels can even theoretically be utilized by us computationally, or whether (for instance) randomness, 'chaos' and noise would make this system no more powerful than the discrete case.

Summing up, we have a few cases.

Infinite discrete universe: this is an infinite-state machine, with an uncountable number of states. It seems that it can accommodate indefinitely expanding parallelism. Results in computational complexity here are less limitative than those about ordinary Turing machines. It is not initially obvious whether computability power is greater or equivalent.

Potentially infinite discrete universe: this is an infinite-state machine with a countable number of states. This probably can accommodate indefinitely expanding parallelism, although the computational power may be a little weaker than above.

Finite discrete universe: this is equivalent to a finite-state automaton, so it is weaker than a Turing machine despite the initial impression of computational power.

Finite continuous universe: harder to analyze. Perhaps equivalent to the finite discrete case, perhaps more powerful.

Infinite continuous universe: could this be more powerful than the infinite discrete case? This is hard to say. The discrete case was extremely powerful already. Perhaps once we have infinitude already, then continuity can give us nothing extra.

The question of whether continuity is inherently more powerful than discreteness is a fascinating one which needs to be analyzed. Here, however I have mainly been concerned with issues of finite vs. infinite, serial vs parallel - these are the issues which underlie the 'powerful' analog machines mentioned at the start. Discreteness vs continuity may be another important aspect of the analog vs digital issue, but there is no hard evidence for
How Cartesian Dualism Might Have Been True

David J. Chalmers (January, 1990)

We could have been characters in a huge computer simulation. It is a familiar idea that the whole world might be simulated on a computer, and things would seem exactly the same to us (and indeed, who is to say that we are not).

I imagine, though, a different sort of simulation, of the kind common in the fields of artificial intelligence and artificial life, where we have (1) a simulated environment and (2) simulated beings which are "moving" through this environment, according to a program that models these beings' thought processes and their decisions. Imagine a very complex project like this (like the vivarium, say), perhaps with genetic algorithms which get more and more complex and sophisticated, until eventually very sophisticated, rational beings evolve.

When they speculate about the world, they will find that the environment possess certain regularities, and this will lead them to laws of "physics" about their external world. This will lead them to speculate about whether they too, at the bottom line, are subject to the same laws. This might seem plausible...but of course it will not be the case! Their "mental" life obeys a completely different set of laws, and further these laws are off limits for direct observation. Their mental life takes place not within their world at all, but within in a computer in a completely different universe! When it comes to observing the "laws" of their behaviour, they will reach some dead end in looking for causal mechanisms. Unlike our world, such mechanisms are simply not "locally supported" by simple physical laws. I'm not quite sure what would happen next.

If they tried to "look inside their heads" (assuming they have at least vaguely coherent senses)... They'd just find an empty box. They'd ask "how can I do all this complex processing". The answer would have to be, well, I'm just kind of non-material mind. Of course, there would be a breakdown in the usual kind of physical causation around the "heads" of such a being, unlike our world.

Moral: Cartesian Dualism isn't quite so outlandish and conceptually problematic as tends to be supposed.

- For a non-Cartesian form of dualism see my Facing Up to the Problem of Consciousness.

Deep Systematicity and Connectionist Representation

David J. Chalmers

Commentary on Andy Clark, "Theoretical Spaces"

1. I think that by emphasizing theoretical spaces of representations, Andy has put his finger on an issue that is key to connectionism's success, and whose investigation will be a key determinant of the field's further progress. I also think that if we look at representational spaces in the right way, we can see that they are deeply related to classical phenomenon of systematicity in representation. I want to argue that the key to understanding representational spaces, and in particular their ability to capture the deep organization underlying various problems, lies in the idea of what I will call deep systematicity. This is closely related to classical systematicity, but I think that it may potentially be much more far-reaching.

So I'll spend a few minutes developing this point, starting with a look at classical systematicity.

If we look at the cluster of phenomena that Fodor and Pylyshyn emphasize in their discussion of the Classical approach - compositionality, systematicity of cognitive capacities, productivity - we can see that all these derive from one key property of Classical representation: that the semantic structure of what is represented is systematically reflected in the formal structure of the corresponding representation. This is the general property that I'll call Classical systematicity.

e.g. look at [example and explanation]. we can see how this systematicity of representation immediately buys the phenomena we were talking about, and most importantly of all, it buys a systematicity of functional role. Representations that have a relevantly similar semantic structure, will, by virtue of their systematic form, play a relevantly similar functional role. So the propositions "John loves Bill" and "John loves Mary" will play similar functional roles within the system, with any differences being a systematic reflection of the difference in one constituent; and these two propositions will play an entirely different functional role to that played by a proposition such as "The quarterback fainted last Saturday."

This is guaranteed precisely by the complex internal structure in each representation. If the representations were structurally atomic, any such systematicity of functional role would have to be arbitrarily imposed by external rules.

It's difficult to overemphasize the power of this idea, and it's been been at the root of much of the last century's work in formal logic and AI.

BUT...
are there semantic primitives?

classical atomic representations lack any internal structure

so there is no reflection of semantic similarity among such representations

inferences performed on such atomic representations are therefore quite unsystematic.

consequences include the well-known *brittleness* of symbolic AI models.

Reason: internal structure of a classical representation reflects at best the *compositional* properties of what is represented, but there are a lot more semantic properties out there.

2. This is where connectionism comes in, and connectionist representational spaces in particular. I think what ought to be regarded as the key philosophical commitment underlying connectionism is the following:

No structurally atomic representation.

Instead, in connectionist systems, *every* representation has complex internal form. This is made possible by the universal use of *distributed representation*, where the representation of any concept is spread over a number of separate computational units, none of which is a representation in its own right.

Once we allow every representation to have complex internal structure, then we have opened the door to what I will call *deep systematicity*, that is, the reflection of semantic properties of what is represented in the formal structure of the corresponding representation, *all the way down*.

In connectionist representational spaces, that's just what we find. After a period of learning, representations fall into a multi-dimensional vector space, such as the one depicted here (in a diagram lifted from PC). What we find is that the structure of this space is in no way arbitrary. Instead, objects that are semantically similar, in a way that is relevant to a given problem, have corresponding representations that are formally similar - lying close together in this vector space, for instance. In a connectionist network that classifies animals, for instance, the representations of "cats" and "dogs" will be much closer together than those of "cat" and "elephant". This is a direct consequence of the fact that relevant semantic properties of the "cat" concept are reflected directly in the structure of the vector that represents "cat".

Of course, this space here is just one of Andy's theoretical spaces, that, assuming it is successful, has developed in a way that captures the deep organizational structure of a given problem space. So theoretical spaces and deep systematicity are two sides of the same coin.

Now what does deep systematicity buy you:
(1) Firstly and most importantly, it buys the key property of *automatic generalization* that Andy has been stressing. If a representational space has been built up that handles cats and mice and elephants, and all of a sudden a hamster comes along, then deep systematicity causes the hamster to be slotted into a vectorial representation that is likely to be closer to the representation of "mouse" than that of "cat", and certainly than that of "elephant", though also different in relevant ways. Any actions to be taken will depend directly on this representational structure, so it is likely that if we've got the representation right, we should get the action about right too - and that's what we find in practice.

Other properties that come along with deep systematicity includes the ability of *context* to subtly influence the form of a representation, and therefore the consequent actions - something that is more difficult to achieve when objects are represented by simple primitives; and also the ability to interpolate between two different representations when appropriate.

Now, of course the existence of a deeply systematic representational space doesn't do *all* the work for you - you still need processes that will operate on the representations, allowing them to play appropriate functional roles. But the point is that (just as in the case of Classical systematicity), the systematicity in representational form provides a strong assurance of systematicity of functional role - i.e., a functional role that will cohere with the semantic properties of what is represented. In effect, deep systematicity tries to, as far as possible, take the responsibility for reflection of semantic regularities out of the rules, and into the representations.

Words on classical systematicity (tensor products, RAAM).

Now, to get back to the problems that Andy was worrying about, it seems to me that the central problem is just this: How can deep systematicity be *achieved*? Connectionism per se, through the introduction of distributed representation, *allows* the possibility of deep systematicity. But that potential needs to be backed up by ways of getting there - by actual mechanisms that develop deeply systematic representational spaces. So far, connectionism has developed just a few algorithms, that demonstrate the potential, but they're far from exhausting the possibilities.

In connectionism's most frequent incarnation to date, deep systematicity of representation is achieved through the use of the backpropagation algorithm. Now backpropagation is terrifically powerful, but Andy has criticized it, rightly I think, for being too tightly tied to first-order properties of the input and output spaces. If the relevant organizational properties of the relevant representational space can be straightforwardly extracted from the input and output spaces, then it will do fine, otherwise it tends to have trouble. The problem seems to me to lie in the fundamentally associationist nature of the algorithm. What is being learned is an input-output association, and the hidden representation in constrained to be a simple way station on the path from input to output. There is little room for the complex processing that might exploit more abstract properties of the input and output spaces when necessary.

Andy's response is to lean on the possibility of exploiting the sequential order in what is learnt. I think
this is an intriguing possibility, but that he may be overestimating it. For even incremental learning shares with traditional backpropagation a strong associationism - indeed backpropagation is the algorithm that Andy supposes is used throughout. So it seems to me that the associated problems will not so easily be avoided. It may well be that the right kind of incremental learning will provide a slight improvement over vanilla backpropagation, to speak somewhat figuratively an improvement of 20 or 30 percent; but it seems to me that it's not the kind of thing that will lead to a vast qualitative difference, on the order of 200 percent. Incremental learning or not, backpropagation remains strongly driven by the first-order properties of input and output spaces. The empirical evidence is not yet in, but I've heard of as many failures with incremental learning as successes, so I think there are grounds to be skeptical.

Andy's proposal shares with traditional connectionism the tendency to lean as strongly as possible on learning. There seems to be a deep suspicion in these circles of positing too many innate mechanisms. To some connectionists, to posit that a problem is solved by the use of innate mechanisms is something of a cheat, if it could be solved by learning instead. You might say that on this view, an organism has to earn its abilities.

I don't entirely agree with this attitude, but neither do I agree with the attitude that the only real explanation of systematicities must be due to innate architectural constraints, an attitude that is suggested by the work of Fodor and Pylyshyn. This view goes to the other extreme, arguing that innate mechanisms carry the real burden, and that so-called "learning" is just a matter of the triggering of the right innate mechanisms.

Instead I think there is a middle ground that allows the admission of strong innate mechanisms while retaining the connectionist emphasis on the importance of learning. This view, which I've objectively labeled "enlightened connectionism", sees our cognitive capacities as the result of the continuous adaptive processes of evolution and learning.

Of course there's nothing at all radical about this - it's just a way of looking at the development of cognitive capacity that causes all of the nativist vs. empiricist problems to seem relatively unimportant. It involves the recognition that evolution and learning are processes of adaption that are relevantly similar in kind: both process whereby organisms can climb up adaptive landscapes, improving their ability to deal with an environment. Evolution takes you so far, and learning gets you the rest of the way. That point that is so important to nativists and empiricists alike - that is, the question of what is built-in at birth - is reduced to the status of a relatively unimportant border where these two processes of adaptation meet. Furthermore, this line between evolution and learning is actually quite arbitrary. There are studies showing that what was once achieved by learning, some time in a species' past, can later be achieved by evolution. It's just a matter of which is more efficient.

With this view in hand, we can construct a view of cognitive development that is quite compatible with the spirit of connectionism, but which eschews any simple form of empiricism. For a start, the only tabula rasa are in the priordial soup. Everything since then has been the result of an adaptive process, and so is very much a product of its evolutionary environment, with mechanisms developed that are adapted
to that environment. On the other hand, we can't throw around innate mechanisms willy-nilly - on this methodology, there at least has to be some reasonable evolutionary explanation of how an innate mechanisms might have come about.

As a very rough rule of thumb, we can say that in the development of cognitive capacities, evolution may be likely to build mechanisms that exploit regularities that are robust across a number of different environments, to deal with problems that any member of a species is likely to have to handle; whereas learning is likely to handle regularities that are specific to the environment that an individual organism finds itself in. If we apply this to the case of the classical systematicity of cognitive capacities, as Andy considered at the end of his talk, we can see that it may be more plausible that the mechanisms responsible for this systematicity might be a product of evolution, precisely because it seems to reflect a similar robust systematicity in most environments. One doesn't just find trees to the left of lakes; one also finds lakes to the left of trees, and so on for a very large number of relations and objects, though by no means all of them. So it maybe more reasonable to suppose that classical systematicity would be sufficiently adaptive that it might be built in by an evolutionary process. Of course, as we've seen, the line is somewhat arbitrary - it is also quite possible that some of the job might be left to learning, as long as it was guaranteed that learning could do the job relatively quickly, and reliably across different environments. The latter suggestion might also help explain the gaps in systematicity that are purported to exist in at least some animals. But it does not seem to me that systematicity should entirely be a product of a difficult process of knowledge acquisition, as Clark suggests - that would seem to be a maladaptive way to deal with such a vital capacity.

All of this would come to very little if it were not for the fact that there exists a perfect computational tool to go along with this variety of connectionism, and that is the genetic algorithm.

[explanation goes here]

Now this can be combined very directly with the use of connectionist networks, e.g. to specify the modularity of a network, or the topology, as an initial state. Of course we only specify the state of an organism at the beginning of its life; we then allow learning to take over. Those organisms are most fit that are doing the best after a period of learning.

What we find is that individual organisms are selected that have a complex initial structure that allows them best to learn problems with given domains.

How does this relate to deep systematicity? Well, the explanatory burden need not fall entirely onto learning. Instead, we can find - and experiments have been done along each of these lines, that through an evolutionary process, we can develop innately:

- modular structures within network design
- biases upon the learning algorithms that networks use
- development of appropriate learning algorithms for appropriate domains
There have been various studies showing how connectionist learning and generalization can be improved by each of these techniques. These might seem to be "innate" mechanisms that a connectionist might like to rule out - Andy talks of building in "task-specific information" -- but in fact we are nowhere buying something for nothing. We need only suppose that a given task, or more likely a given class of tasks, has been around in an organism's evolutionary environment, and it is quite natural that mechanisms might develop that are specifically to handle certain classes of tasks, or even more likely, to enable the right organizing structure of given task domains to be picked up quickly and easily.

In this way we can step back from the empiricist/nativist debate, and admit a strong role for evolution in the development of such cognitive capacities as deep systematicity while still admitting the centrality of learning in cognitive explanation.
Determining the Moment of Consciousness?

David J. Chalmers

Commentary on Valerie Hardcastle, "Determining the Moment of Consciousness".

It's very interesting to see neurophysiological evidence brought to bear on the puzzling question of conscious experience. Many have observed that information-processing models of cognition seem to leave consciousness untouched; it is natural to hope that turning to neurophysiology might lead us to the Holy Grail. Still, I think there are reasons to be skeptical. There are good reasons to suppose that neurophysiological investigation contributes to cognitive explanation at best in virtue of constraining the information-processing structure of cognition. Of course this is a very large and significant role for it to play, but it may be over-optimistic to suppose that it can play some further explanatory role, taking us where information-processing theories cannot. If so, then neurophysiological accounts will be no more and no less successful at dealing with consciousness than information-processing accounts are.

I will elaborate these considerations later. For now, I will focus on the problem at hand: the difficult questions about the timing of conscious experience raised by Dennett and Kinsbourne. It seems to me that these considerations apply equally to this problem. If an information-processing account of cognition is insufficient to determine a fact of the matter about certain conscious experiences, then a neurophysiological account will not help us. If a neurophysiological account does the job, an information-processing account would have worked equally. In what follows, I'll examine the interesting data about evoked-response potentials that Hardcastle has presented, and see whether it helps in determining the various facts that Dennett and Kinsbourne claim are indeterminate.

First, it is useful to get clear on what is going on. There are two experimental scenarios that are relevant. In the first, a prime - say "CAT" - is presented for a lengthy period of 500 milliseconds, so that the subject is aware of having seen it, and shortly thereafter a target - say "DOG" is presented. The semantic relation between prime and target has a significant effect on reaction time, but more relevant for our purposes is an evoked-response potential that is consistently found to occur. This is the N400 evoked-response potential, starting about 300 msec after the presentation of the target. In the second scenario, a mask is presented followed by an extremely brief presentation of the prime, for only 33 msec, and then the target is presented. In these conditions, the subject is unaware of having seen the prime, but reaction time is still facilitated. Furthermore there is a separate anterior negative effect, the so-called "Ne" effect, around 200 msec after target presentation. In these experiments, the N400 potential is associated with access to explicit memory - that is, to information that a subject can explicitly recall - whereas the Ne is associated with implicit memory - information that a subject cannot explicitly recall, but which affects behavior in various subtle ways. These associations have appeared in other experimental conditions, leading many to suppose that N400 is associated with a separate system for explicit memory and that Ne is associated with a system for implicit memory system, perhaps specialized for lexical information.

Let us take this association of ERP's with memory systems as granted. What light does this shed on the
Determining the Moment of Consciousness?

difficult questions about conscious experience?

First, I take it that the importance of masked priming experiments to Dennett and Kinsbourne lies in the following question: was the masked prime consciously experienced? On the face of it, there are two possibilities: the so-called "Orwellian" hypothesis, that it was briefly experienced but then forgotten, and the "Stalinesque" hypothesis that it never made it to consciousness at all. Dennett and Kinsbourne claim that there is no way to decide between these hypotheses, and indeed that there is no fact of the matter between them. Do the results under consideration help?

It seems that they do not. The results are compatible with both the Orwellian or Stalinesque hypotheses. What we are told is that information about the masked prime is stored in an implicit memory system; one to which the subject has no conscious access. But this tells us, at best, that the memory is unconscious; it tells us nothing about whether the perception of the prime, way back when, was conscious. Perhaps it was consciously experienced but never made it into explicit memory, only into implicit memory; this is the Orwellian hypothesis. Perhaps it was never consciously experienced, but was perceived subliminally and found its way into the unconscious implicit memory system; this is the Stalinesque hypothesis. Either way, upon later presentation of the target we would expect activation of the implicit memory system but not the explicit memory system, leading to the observed evoked-response potentials. No results about the triggering of memories can possibly distinguish the Orwellian and Stalinesque hypotheses, which by their nature differ only on events around the time of perception. It follows that the neurophysiological timing of memory retrieval is irrelevant to this question, and that the experimental results do not distinguish between the Orwellian and Stalinesque hypotheses. Dennett and Kinsbourne's indeterminacy remains undetermined.

I take it that Hardcastle is not claiming that her results settle this indeterminacy; that is, that they settle no questions about the experience of the prime. Rather, the claim is that they settle some questions about the experience of the target. It is somewhat unclear just what the question to be settled is; certainly, there are no obvious Orwellian/Stalinesque mysteries hanging in the air for this case, in which the stimulus is perceived and remembered in a straightforward veridical manner throughout. The key claims that Hardcastle makes for the data are (1) that they suggest that implicit memory systems are activated before explicit memory systems, with a possible processing path from the first to the second, and (2) that they may allow us to determine the moment of consciousness in a fine-grained manner.

Looking at (1) first: Of course it is dangerous to infer from these localized measurements of potentials that implicit memory is activated before explicit memory, especially if both systems involve processes that are distributed in time and space; perhaps the potentials detect the tail end of the explicit memory retrieval, but the very beginning of implicit memory activation. But in any case, I don't think that isolating a processing flow from implicit to explicit memory systems would contradict any of Dennett and Kinsbourne's claims. As they say at the end of the BBS article:

There is nothing theoretically amiss with the goal of acquiring precise timing information on the mental or informational transactions in the brain. It is indeed crucial to developing a good theory of the brain's control functions to learn exactly where and when various informational streams converge, when
Determining the Moment of Consciousness?

"inferences" and "matches" and "bindings" occur. But these temporal and spatial details do not directly tell us about the contents of consciousness. The temporal sequence in consciousness is, within the limits of whatever temporal control window bounds our investigation, purely a matter of the content represented, not the timing of the representing.

The contents of our experience of the target, I take it, are not here a matter of dispute. This leaves as the remaining live issue the moment of our experience of the target, as the title of Hardcastle's paper suggests. I take it that Hardcastle's goal is to establish the time at which some content becomes conscious. It is not clear to me that "the moment of consciousness" is even meaningful, but even if it is, the present data fall well short of establishing it. At best, we have timed certain specific physical events associated with a conscious experience. Presumably there are many such events, distributed in space and time, so it is unclear why this one - a fairly arbitrary potential that happens to be accessible to our measurements - should qualify as the moment.

This is made even clearer when we think about just what these potentials represent. We have been led to suppose that they correspond to the activation of certain explicit and implicit memory systems, carrying information about past events; but what does the time of activation of these systems have to do with the time of consciousness of the present perception? Very little, it would seem. Perhaps activation of these precedes "the moment of consciousness"; perhaps it comes afterwards. We might as well measure the moment of retinal stimulation, or the moment of verbal report. Either way, the "moment of consciousness", even if it is determinate, remains undetermined.

It seems that the neurophysiological data under consideration do not help us in settling questions about the moment and content of consciousness. There are good reasons why we should have been skeptical all along. In general, when one sees neurophysiological properties invoked in cognitive explanation, they are generally invoked in virtue of their contribution to certain information-processing properties. It follows that the neurophysiological properties give us little in the way of extra explanatory grip. One can see this in various neurophysiological "theories" of consciousness that have been put forward. For instance, Crick and Koch put forward certain 40 Hz oscillations in the cerebral cortex as the secret to consciousness; but upon close examination, these oscillations are put forward only in virtue of the role they may play in the binding of certain represented contents.

If we don't know why binding gives rise to consciousness, telling a story about the oscillations does not help; the other way around, if we have a good explanation of why binding gives rise to consciousness, the neurophysiological details are just the icing on the cake.

In Hardcastle's discussion, certain evoked-response potentials are invoked as explanatorily relevant. Here, it turns out that these are invoked precisely in virtue of their association with implicit and explicit memory systems. A detailed information-processing account of implicit and explicit memory would have worked just as well or as badly in settling the problems at hand; the neural properties give us nothing extra. Presumably Dennett and Kinsbourne would claim that timing information about explicit and implicit memory systems doesn't solve the problems about the timing of consciousness. Information about the ERP's is relevant here at best for the information it gives us about the timing of such memory
Determining the Moment of Consciousness?

I'll conclude by considering the question of the "disappearance" of consciousness from information-processing accounts, and asking whether neurophysiology helps us at all. It seems to me that this "disappearance" comes to one of two things. First, the models provide no explanation of consciousness. Second, they provide no explanatory role for consciousness. I'm sympathetic with both these concerns, but I don't think that neurophysiology helps.

On the question of explanation, the problem is: whenever we are given an information-processing account of cognition, there always seems to be a further unanswered question: why should that sort of processing give rise to conscious experience? Nothing internal to the information-processing account answers this question, and consciousness therefore goes unexplained by such an account. This "explanatory gap" is not closed any further by a neurophysiological account. Given some neural correlate of consciousness, such as a N400 potential or a 40 Hz oscillation, we can always ask "why should that be accompanied by consciousness"? The only answer to this question that can usually be given appeals to the information-processing role that such a neural process plays - the role it plays in binding or in memory, for instance. But this gets us no further than before: the question of why that sort of information-processing should give rise to consciousness goes unanswered. It seems that on both the information-processing and neurophysiological accounts, we have at best an association between underlying properties and conscious experience, not an explanation.

The same goes for the question of the explanatory role of consciousness. Strange but true, it seems that information-processing accounts are providing good explanations of behavior even without their coming to grips with the mysteries of consciousness. To many, it seems that such accounts are logically compatible with the absence of consciousness. If so, then under certain natural assumptions, consciousness has no explanatory role to play in such accounts. This matter is controversial, but let us take the "disappearance" for granted, and ask again: does neurophysiology help? Again, it seems not. At best, neurophysiology will yield an association between neural processes and conscious experience. Perhaps we can take the questionable step of "identifying" the process and the experience, thus giving the experience an explanatory role by fiat; but again, this gives us nothing that an information-processing account could not. Certainly there are all sorts of associations between information-processing properties and conscious experience; take the association between consciousness and reportability, for instance. If we wanted to, we could identify consciousness with some associated information-processing property, thus giving it an explanatory role. The move is equally sound or equally dubious as it is in the neurophysiological case. I think there are good reasons why the move is unsatisfactory, but for present purposes we need only note that whether is is satisfactory or not, neurophysiological and information-processing accounts are on a par with each other.

Whichever way we cut the cake, consciousness seems to "disappear" from neurophysiological accounts of cognition no more and no less than it disappears from information-processing accounts. I conclude that the path to the Holy Grail lies elsewhere.
What is it like to be a Thermostat?

David J. Chalmers

Commentary on Dan Lloyd, "What is it Like to Be a Net?"

The project that Dan Lloyd has undertaken is admirable and audacious. He has tried to boil down the substrate of information-processing that underlies conscious experience to some very simple elements, in order to gain a better understanding of the phenomenon. Some people will suspect that by considering a model as simple as a connectionist network, Dan has thrown away everything that is interesting about consciousness. Perhaps there is something to that complaint, but I will take a different tack. It seems to me that if we apply his own reasoning, we can see that Dan has not taken things far enough. When we have boiled things down to a system as simple as a connectionist network, it seems faint-hearted to stop there, and perhaps a little arbitrary as well. So I will take things further, and ask what seems to be the really interesting question in the vicinity: what is it like to be a thermostat?

A quick glance at diagrams of the models shows that there are a lot of similarities between connectionist networks and thermostats. Both take an input, perform a quick and easy nonlinear transformation on it, and produce an output. Of course, there are a few extra units and connections in the connectionist network, but one wonders how relevant this whiff of complexity will ultimately be to the arguments about consciousness. Someone once said that there are no reasonable numbers between one and infinity. Once a model with five units, say, is to be regarded as a model of consciousness, surely a model with one unit will also yield some insight.

Indeed, if we apply Lloyd's own reasoning, the thermostat does very well as a model of consciousness. For a start: like NETTALK, it can be provided with an interpretation that also construes it as a model of the world. Specifically, it can be naturally construed as representing the world's temperature. Furthermore, it satisfies Lloyd's "coincidence condition", requiring a structural similarity between the world for the system and the world for us. Just as NETTalk captures salient distinctions in the world of English phonetics, the thermostat captures salient distinctions in the world of temperature. Indeed, it captures the single most salient such distinction, the distinction between hot and cold.

Now, to be sure, the thermostat does not use distributed representation, which Lloyd makes much of, and consequently it does not support the relevant superposition of information. To get around this disanalogy, we might relax our standards of simplicity just a touch and move to the "superthermostat", also known as the two-unit connectionist network. It seems to me that we could achieve the kind of distribution and superposition that Lloyd is interested in with this network, but I am inclined to suppose that we need not clutter our model with such needless complexity. After all, does it not seem that this rich superposition of information is an inessential element of consciousness? To be sure, in the glory of human consciousness we find this richness, as Lloyd illustrates with the manifold aspects of a Tudor cottage, but the aim of the current exercise is to simplify and abstract.
Surely, somewhere on the continuum between systems with rich and complex conscious experience and systems with no experience at all, there are systems with simple conscious experience. A model with superposition of information seems to be more than we need - why, after all, should not the simplest cases involve information experienced discretely? We might imagine a traumatized creature that is blind to every other distinction to which humans are normally sensitive, but which can still experience hot and cold. Despite the lack of superposition, this experience would still qualify as a phenomenology. So, just as a connectionist network qualifies as a model of superimposed phenomenology, the thermostat seems to qualify as a model of this basic kind of phenomenology. Indeed, if we accept Lloyd's approach, it seems to follow that in this model we have stripped down the substrate of phenomenology to its bare essentials. (They say that Euclid alone has looked on beauty bare, but surely this comes close.)

Having come this far this quickly, perhaps it is time to sit back and get some perspective. A thermostat, or indeed a simple connectionist network, as a model of conscious experience? This is indeed very surprising. Either there is a deep insight somewhere within Lloyd's reasoning, or something has gone terribly wrong. I am inclined to think that there is an element of truth in both these diagnoses of Lloyd's counterintuitive claim.

First, the insight. What Lloyd's approach brings out is that when we try to isolate the kind of processing that is required for conscious experience, the requirements are remarkably hard to pin down, and a careful analysis does not throw up processing criteria that are more than minimal. What are some reasonable-seeming functional criteria for conscious experience? One traditional criterion is reportability, but this is far too strong to be an across-the-board requirement. It seems reasonable to suppose that dogs and cats have conscious experience, even in the absence of an ability to report. A weaker criterion is introspectability: perhaps for a content to be experienced a system needs to be thinking about the content, or at least able to think about the content. I am sympathetic, though, with Lloyd's remarks that this sort of thing seems to be more symptomatic of reflective consciousness than of primary consciousness. On the face of it, it seems plausible that we can experience the fringes of our visual field without thinking about those experiences; and it is not implausible that a dog, say, might have visual experiences but entirely lack the conceptual capacity to monitor those experiences at a higher-level. I don't think the higher-order thought view of consciousness leads to an infinite regress, as Lloyd suggests - on such a view, a first-order thought will be conscious if it is accompanied by a higher-order thought, but the higher-order thought need not itself be conscious, so the regress is terminated - but it nevertheless seems more appropriate as an account of reflective rather than primary consciousness. Of course the issue is complex, but strong intuitions suggest that a system could be experiencing while only thinking about the world, not about its own mental states.

Sometimes it is suggested that conscious experience is a consequence of sufficient complexity, but this answer simply slides over the problem. Complexity is often relevant to the existence of some high-level phenomenon, but what is relevant is never complexity tout court, but the role that this complexity plays in a system. Life requires complexity, because complexity is required for adaptation and reproduction. If complexity is required for consciousness, it will be in virtue of some further functional property that this complexity enables, and we are seeing that this functional property is hard to pin down.
What is it like to be a Thermostat?

Indeed, on reflection it is hard to see why the intuitions that lead us to ascribe conscious experience to dogs and cats should prevent us from ascribing it to mice, or to flies, or to simpler systems. Such systems may lack such frills as language, a rich conceptual system, the ability to introspect, and perhaps even a concept of self, but why should experience require any of these? When we look at the kind of processes that give rise to experience in humans, such as the processes underlying color vision, what seems most essential is that the processes make certain discriminations, and make the relevant information available to the overall system in the control of behavior. This is a very basic sort of information processing, and is something that even a very simple system might share. It is this sort of reasoning that makes it seems just possible, after all, that there might be something it is like to be a net, or even a thermostat.

I confess that I was a little disappointed, though, after Dan's bold title, to see his nerve failing at the crucial juncture. Almost as an aside, he concedes that in fact NETTALK lacks experience, and that the answer to his title question is therefore "nothing". NETTALK, then, is not an instantiation of conscious experience; it is only a model of it.

This claim is weaker on the surface, but in fact I find it even harder to believe that NETTALK is a model of experience than that NETTALK has experience, counterintuitive though that second claim may be. For a model carries a particular burden: it must explain. And this leads us to what is perhaps the central worry about Lloyd's approach. On the face of it, this approach is put forward as a way of dealing with Nagel's worries about consciousness, where the central mystery is: why is there something it is like to be us at all? There is a huge prima facie mystery about how any sort of physical system could possess conscious experience. Lloyd holds out the promise that connectionist models might shed light on this question, but at the end of the day the models seem to leave the key explanatory question unanswered. Even if we were to go out on a limb and suppose that these simple systems are conscious, the question of explanation would still remain untouched.

What is it that these models might explain? On the face of it, they hold out the promise of explaining our abilities to make certain distinctions, and to exploit those distinctions in the control of behavior. We might ultimately see how the formation of a sophisticated world-model through information-processing enables a repertoire of actions that reflect the sophistication of that model. But where, in these models, is an explanation of experience? The problem in explaining experience is the apparent gulf between the brain and the quality of experience itself. A model might be expected to make this link more intelligible, but these models leave it as wide as ever. Why should this sort of processing be responsible for experience? There is no answer to be found my examining the models, or indeed within Lloyd's discussion. These are only models of processes, and they leave the gulf between process and experience as wide as ever.

Perhaps the best way to regard these models is as follows. We take the existence of experience for granted, and note that at least in familiar cases, there is a remarkable coherence between the structural properties of our experience and certain structural properties of our cognitive processes: the distinctions within phenomenology seem to parallel the distinctions made by our perceptual system, and so on. If we take this principle for granted, we can perhaps "model" the structure of consciousness indirectly by modeling the structure of our cognitive processing: so when Lloyd finds a certain superpositional
What is it like to be a Thermostat?

structure in a network, this suggests itself as a substrate for the superpositional structure of our experience. This is a worthy explanatory achievement, even though it leaves the key question unanswered: why is there experience at all? These "models" take the existence of experience as a brute fact. Indeed, to gain their explanatory purchase, they must assume wholesale some such principle of structural coherence between experience and processing. But surely, these assumptions are precisely what we want a theory of experience to ultimately explain. Perhaps the existence of experience and these principles of coherence will ultimately need to be taken as basic; but if so, what we will be left with is irreducibility and perhaps even a kind of dualism, rather than the kind of reductive explanation that Lloyd is searching for.

The value of these models, I think, is that they reduce the substrate of processing that underlies conscious experience to its most basic core. Once we get to that core, we find the explanatory gulf remains as wide as ever. Some will be tempted to respond by increasing the complexity of the models, but that ultimately misses the point. The problem with those models is not their simplicity - rather, it is the simplicity of the models that brings out the problems with any models of this kind. At the end of the day, a more complex model of processing will give us just more of the same. A processing model may yield a terrific explanation of functions, abilities, and capacities, but to explain experience, it is simply the wrong sort of thing. The moral that I draw is that for a theory of consciousness, we must look elsewhere. But that is a topic for another day.
Pick a Number between Zero and Infinity...

David J. Chalmers

Subject: Re: call for votes: most & least boring numbers
Date: 17 Jan 90 20:40:02 GMT

In article <18311.25b44848@merrimack.edu> ain14924@merrimack.edu writes:

Reminds me of a friend of mine who claims that the number 17 is "the most random" number. His proof ran as follows: pick a number. It's not really as good a random number as 17, is it? (Invariable Answer: "Umm, well, no...")

This reminds me of a little experiment I did a couple of years ago. I stood on a busy street-corner in Oxford, and asked passers-by to "name a random number between zero and infinity." I was wondering what this "random" distribution would look like.

The results: (most common numbers first, out of about 150 responses in all):

- 3 (11 people)
- 7 (9 people)
- 5 (8 people)
- 12 (6 people)
- 1, 4, 10, 77 (5 people each)
- 2, 47, infinity-1 (4 people each)
- 15, 17, 20, 27 (3 people each)
- 18, 23, 26, 30, 42, 99 (2 people each)
- 6, 13, 14, 19, 21, 22, 25, thirteen more 2-digit numbers, twenty 3-digit numbers, twelve 4-digit numbers, one 5-digit number, one 6-digit number, four 7-digit numbers, one 8-digit number, one non-integer (328.39), one huge number (9.265.10^10^10). (1 person each)

Of course a uniform distribution is a priori impossible so I couldn't have expected that :-). Even a logarithmic distribution is impossible (it has infinite integral). Interestingly enough, this distribution, taken coarsely, was quite close to logarithmic up to 1000 or so. There were roughly the same number of 2-digit responses as 1-digit responses, and a few less 3-digit responses. Then things fell off sharply, however.

Other interesting features:
Pick a number between zero and infinity...

- 17 wasn't quite as "random" as might have been predicted.
- Extreme frequency of the digit "7" all round.
- Especially notable are the good performances of 77 and 47.
- Poor performance of digit "8", also "6" and "9".
- Both "very prime" (e.g. 17) and "very composite" (e.g. 12) numbers did well.

Then I could tell you about the "random word" experiment I did on Sydney harbour...perhaps another time.
Thanks to all the people who responded to my enquiry about the status of the Continuum Hypothesis. This is a really fascinating subject, which I could waste far too much time on. The following is a summary of some aspects of the feeling I got for the problems. This will be old-hat to set theorists, and no doubt there are a couple of embarrassing misunderstandings, but it might be of some interest to non-professionals.

A basic reference is Gödel's "What is Cantor's Continuum Problem?", from 1947 with a 1963 supplement, reprinted in Benacerraf and Putnam's collection *Philosophy of Mathematics*. This outlines Gödel's generally anti-CH views, giving some "implausible" consequences of CH.

"I believe that adding up all that has been said one has good reason to suspect that the role of the continuum problem in set theory will be to lead to the discovery of new axioms which will make it possible to disprove Cantor's conjecture."

At one stage he believed he had a proof that $C = \aleph_2$ from some new axioms, but this turned out to be fallacious. (See Ellentuck, "Gödel's Square Axioms for the Continuum", Mathematische Annalen 1975.)

Two people pointed me to a recent paper by Maddy: "Believing the Axioms", Journal of Symbolic Logic 1988 (in 2 parts). This is an extremely interesting paper and a lot of fun to read. A bonus is that it gives a non-set-theorist who knows the basics a good feeling for a lot of issues in contemporary set theory.

Most of the first part is devoted to "plausible arguments" for or against CH: how it stands relative to both other possible axioms and to various set-theoretic "rules of thumb". One gets the feeling that the weight of the arguments is against CH, although Maddy says that many "younger members" of the set-theoretic community are becoming more sympathetic to CH than their elders. There's far too much here for me to be able to go into it in much detail.

Some highlights from Maddy's discussion, also incorporating a few things that other people sent me:
Continuum Hypothesis: True, False, or Neither?

(1) Cantor's reasons for believing CH aren't all that persuasive today.

(2) Gödel's proof of the consistency of CH shows that CH follows from ZFC plus the Axiom of Constructibility (V=L, roughly that the set-theoretic universe = the constructible universe). However, most set-theorists seem to find Constructiblity implausible and much too restrictive. It's an example of a "minimizing" principle, which tends to cut down on the number of sets admitted to one's universe. Apparently "maximizing" principles meet with much more sympathy from set theorists. Such principles are more compatible with ~CH than with CH.

(3) If GCH is true, this implies that aleph_0 has certain unique properties: e.g. that it's that cardinal before which GCH is false and after which it is true. Some would like to believe that the set-theoretic universe is more "uniform" (homogeneous) than that, without this kind of singular occurrence. Such a "uniformity" principle tends to imply ~GCH.

(4) Most of those who disbelieve CH think that the continuum is likely to have very large cardinality, rather than aleph_2 (as Gödel seems to have suggested). Even Cohen, a professed formalist, argues that the power set operation is a strong operation that should yield sets much larger than those reached quickly by stepping forward through the ordinals:

"This point of view regards C as an incredibly rich set given to us by a bold new axiom, which can never be approached by any piecemeal process of construction."

(5) There are also a few arguments in favour of CH, e.g. there's an argument that not-CH is restrictive (in the sense of (2) above). Also, CH is much easier to force (Cohen's method) than ~CH. And CH is much more likely to settle various outstanding results than is ~CH, which tends to be neutral on these results.

(6) Most large cardinal axioms (asserting the existence of cardinals with various properties of hugeness: these are usually derived either from considering the hugeness of aleph_0 compared to the finite cardinals and applying uniformity, or from considering the hugeness of V (the set-theoretic universe) relative to all sets and applying "reflection") don't seem to settle CH one way or the other.

(7) Various other axioms have some bearing. Axioms of determinacy restrict the class of sets of reals that might be counterexamples to CH. Various forcing axioms which are "maximality" principles (in the sense of (2) above), imply ~CH. The strongest (Martin's maximum) implies that C = aleph_2. Of course the "truth" or otherwise of all these axioms is controversial.

(8) Freiling's principle about "throwing darts at the real line" is a seemingly very plausible principle, not involving large cardinals at all, from which ~CH immediately follows. Freiling's paper (JSL 1986) is a good read. More on this at the end of this message.

Of course I've conspicuously avoided saying anything about whether it's even reasonable to suppose that CH has a determinate truth-value. Formalists will argue that we may choose to make it come out
whichever way we want, depending on the system we work in. On the other hand, the mere fact of its independence from ZFC shouldn't immediately lead us to this conclusion - this would be assigning ZFC a privileged status which it hasn't necessarily earned. Indeed, Maddy points out that various axioms within ZFC (notably the Axiom of Choice, and also Replacement) were adopted for extrinsic reasons (e.g. "usefulness") as well as for "intrinsic" reasons (e.g. "intuitiveness"). Further axioms, from which CH might be settled, might well be adopted for such reasons.

One set-theorist correspondent said that set-theorists themselves are very loathe to talk about "truth" or "falsity" of such claims. (They're prepared to concede that 2+2=4 is true, but as soon as you move beyond the integers trouble starts. e.g. most were wary even of suggesting that the Riemann Hypothesis necessarily has a determinate truth-value.) On the other hand, Maddy's contemporaries discussed in her paper seemed quite happy to speculate about the "truth" or "falsity" of CH.

Personally, not only do I see the integers as bedrock, but I'm also prepared to take any finite number of power sets before I have any problems. At least that far, I'm a diehard Platonist. I'm considerably less sure whether to be a diehard Platonist about the paradise of ridiculously big cardinals. But my intuition is happy with reals and sets of reals, so as a naive non-set-theorist I'm sticking to the belief that CH is determinate one way or the other. As one correspondent suggested, the question of the determinateness of CH is perhaps the single best way to separate the Platonists from the formalists.

And is it true or false? Well, I'd always found CH somewhat intuitively plausible. But after reading all this, it does seem that the weight of evidence tend to point the other way. On the other hand, that's only a second-order approximation based on limited knowledge - more subtle and sophisticated arguments (third-order approximations) might begin to push things the other way. Still, if I had to lay money on it (God, of course, knows the right answer and could settle the bet), I'd feel safer with the money on ~CH.

I've enclosed (with permission) a brief but enlightening message from Bill Allen on Freiling's Axiom of Symmetry. This is a good one to run your intuitions by.

Many thanks to Bill Allen, James Cummings, David Feldman, Torkel Franzen, Calvin Ostrum, Keith Ramsay, and Peter Suber. I'd be very interested to hear more about this subject.

--Dave Chalmers.

To: chalmers@bronze.ucs.indiana.edu
Subject: Re: Status of the Continuum Hypothesis
Organization: UCLA Mathematics Department
I have a colleague, Chris Freiling, here at UCLA, who, a few years ago proved that a certain plausible assertion is equivalent to the negation of continuum hypothesis (CH) over ZFC. The idea is something like this:

Let A be the set of functions mapping Real Numbers into countable sets of Real Numbers. Given a function f in A, and some arbitrary real numbers x and y, we see that x is in f(y) with probability 0, i.e. x is not in f(y) with probability 1. Similarly, y is not in f(x) with probability 1. Let AX be the axiom which states

"for every f in A, there exist x and y such that x is not in f(y) and y is not in f(x)"

The intuitive justification for AX is that we can find the x and y by choosing them at random.

In ZFC, AX = not CH.

proof:

If CH holds, then well-order R as r_0, r_1, .... , r_x, ... with x < aleph_1. Define f(r_x) as \{r_y : y <= x\}. Then f is a function which witnesses the falsity of AX.

If CH fails, then let f be some member of A. Let Y be a subset of R of cardinality aleph_1. Then Y is a proper subset. Let X be the union of all the sets f(y) with y in Y, together with Y. Then, as X is an aleph_1 union of countable sets, together with a single aleph_1 size set Y, the cardinality of X is also aleph_1, so X is not all of R. Let a be in R \ X, so that a is not in f(y) for any y in Y. Since f(a) is countable, there has to be some b in Y such that b is not in f(a). Thus we have shown that there must exist a and b such that a is not in f(b) and b is not in f(a). So AX holds. -|

I like Freiling's proof, since it does not invoke large cardinals or intense infinitary combinatorics to make the point that CH implies counter-intuitive propositions. Freiling has also pointed out that the natural extension of AX is AXL (notation mine), where AXL is AX with the notion of countable replaced by Lebesgue Measure zero. Freiling has established some interesting Fubini-type theorems using AXL.

See "Axioms of Symmetry: Throwing Darts at the Real Line", by Freiling, Journal of Symbolic Logic, 51, pages 190-200. An extension of this work appears in "Some properties of large filters", by Freiling and Payne, in the JSL, LIII, pages 1027-1035, but Chris tells me he's not as fond of the latter paper as he is the former.

I just came across your posting about CH and found it quite interesting. A few comments:

One set-theorist correspondent said that set-theorists themselves are very loathe to talk about "truth" or "falsity" of such claims. (They're prepared to concede that 2+2=4 is true, but as soon as you move beyond the integers trouble starts. e.g. most were wary even of suggesting that the Riemann Hypothesis necessarily has a determinate truth-value.) On the other hand, Maddy's contemporaries discussed in her paper seemed quite happy to speculate about the "truth" or "falsity" of CH.

Many set theorists are loathe to talk about CH being "true" or "false", but I'm not sure how many would agree that trouble starts as soon as you move beyond the integers. I recently did a small survey (only about 10 people) at a set theory conference. I had a list of 10 statements, and for each one you had to choose among 5 choices:

- True
- False
- Either true or false but I don't know which
- Neither true nor false
- Either (either true or false but I don't know which) or (neither true nor false) but I don't know which.

The statements were:

- 2+2=4
- Fermat's last theorem
- Peano's axioms are consistent
- ZF is consistent
- Fundamental Theorem of Calculus
- Riemann Hypothesis
- AC
- CH
- There are uncountable limit cardinals
- There are measurable cardinals.

One or two people were Platonists the whole way-- restricted their responses to the first three possibilities. Many were Platonists through the Riemann Hypothesis, and then switched to "neither true nor false". I was one of the few who became uncertain once I got beyond the integers. (Remarkably, one person turned in an answer sheet with many answers filled in and crossed out, and wrote "can't decide".)
In the end, the only thing he was willing to commit himself to was that $2+2=4$ is true!

Personally, not only do I see the integers as bedrock, but I'm also prepared to take any finite number of power sets before I have any problems. At least that far, I'm a diehard Platonist. I'm considerably less sure whether to be a diehard Platonist about the paradise of ridiculously big cardinals. But my intuition is happy with reals and sets of reals, so as a naive non-set-theorist I'm sticking to the belief that CH is determinate one way or the other. As one correspondent suggested, the question of the determinateness of CH is perhaps the single best way to separate the Platonists from the formalists.

Suppose we let $X_0=$the set of natural numbers, and let $X_{n+1}=$the power set of $X_n$. Then you seem to be willing to accept all of these sets as "existing" in some determinate sense. What about their union? What about the power set of their union? If you won't accept these, aren't you drawing a pretty arbitrary line? If you do accept them, then where do you stop? As for using the determinateness of CH as a test to separate Platonists from formalists: I think it's important to recognize that Platonism isn't an all-or-nothing affair. This may be a good test for a certain level of Platonism. I fail--I don't think CH has a determinate truth value. But some people (like intuitionists) don't even think Fermat's last theorem has a determinate truth value. This might be a good test for a lower level of Platonism, and I pass this test--I can't conceive of Fermat's theorem not having a determinate truth value. (By the way, on my survey everyone said Fermat's theorem was either true or false but they didn't know which, except for the guy who only would commit himself to $2+2=4$.)

Thoughts on Emergence

David J. Chalmers

Subject: Thoughts on emergence
Date: 6 Oct 90 07:08:47 GMT

Here are some thoughts on "emergence". Nothing definitive, but an attempt to get at the psychological core (or cores) of the notion. Thanks are due to others for providing a stimulating discussion.

Emergence is a tricky concept. It's easy to slide it down a slippery slope, and turn it into something implausible and easily dismissable. But it's not easy to delineate the interesting middle ground in between. Two unsatisfactory definitions of emergence, at either end of the spectrum:

(1) Emergence as "inexplicable" and "magical". This would cover high-level properties of a system that are simply not deducible from its low-level properties, no matter how sophisticated the deduction. This view leads easily into mysticism, and there is not the slightest evidence for it (except, perhaps, in the difficult case of consciousness, but let's leave that aside for now). All material properties seem to follow from low-level physical properties. Very few sophisticated people since the 19th century have actually believed in this kind of "emergence", and it's rarely what is referred to by those who invoke the term favourably. But if you mention "emergence", someone inevitably interprets you as meaning this, causing no end of confusion.

(2) Emergence as the existence of properties of a system that are not possessed by any of its parts. This, of course, is so ubiquitous a phenomenon that it's not deeply interesting. Under this definition, file cabinets and decks of cards (not to mention XOR gates) have plenty of emergent properties - so this is surely not what we mean.

The challenge, then, is to delineate a concept of emergence that falls between the deeply implausible (1) and the overly general (2). After all, serious people do like do use the term, and they think they mean something interesting by it. It probably will help to focus on a few core examples of "emergence":

- (A) The game of Life: High-level patterns and structure emerge from simple low-level rules.
- (B) Connectionist networks: High-level "cognitive" behaviour emerges from simple interactions between dumb threshold logic units.
- (C) The operating system (Hofstadter's example): The fact that overloading occurs just around when there are 35 users on the system seems to be an emergent property of the system.
- (D) Evolution: Intelligence and many other interesting properties emerge over the course of evolution by genetic recombination, mutation and natural selection.
Note that in all these cases, the "emergent" properties are in fact deducible (perhaps with great difficulty) from the low-level properties (perhaps in conjunction with knowledge of initial conditions), so a more sophisticated concept than (1) is required. Another stab at a definition might be:

(3) Emergent = "deducible but not reducible". Biological and psychological laws and properties are frequently said not to be reducible to physical laws and properties. For many reasons, not the least being that the high-level laws/properties in question might be found associated with all kinds of different physical laws/properties as substrates. (A universe without protons and electrons might nevertheless include learning and memory.)

There are some problems with this definition, though. Firstly, it's not clear what is gained by trying to explicate emergence in terms of the almost-equally-murky concept of "reduction". Secondly, it seems to let in some not-paradigmatically-emergent phenomena, and it's not clear how some emergent phenomena like (A) or (C) would fit this definition. I think that (3) picks out a very interesting class, but it's not quite the class we're after. It's on the right track, though, I think.

The notion of reduction is intimately tied to the ease of understanding one level in terms of another. Emergent properties are usually properties that are more easily understood in their own right than in terms of properties at a lower level. This suggests an important observation: Emergence is a psychological property. It is not a metaphysical absolute. Properties are classed as "emergent" based at least in part on (1) the interestingness to a given observer of the high-level property at hand; and (2) the difficulty of an observer's deducing the high-level property from low-level properties. The properties of XOR are an obvious consequence of the properties of its parts. Emergent properties aren't. Might as well give this a number:

(4) Emergent high-level properties are interesting, non-obvious consequences of low-level properties.

This still can't be the full story, though. Every high-level physical property is a consequence of low-level properties, usually non-obviously. It feels unsatisfactory, for instance, to say that computations performed by a COBOL program are an emergent property relative to the low-level circuit operations - at least this feels much less "emergent" than a connectionist network. So something is missing. The trouble seems to lie with the complex, kludgy organization of the COBOL circuits. The low-level stuff may be simple enough, but all the complexity of the high-level behaviour is due to the complex structure that is given to the low-level mechanisms (by programming). Whereas in the case of connectionism or the game of life it feels that we have simplicity in both low-level mechanisms and their organization. So in those cases, we have much more of a "something for nothing" feel. Let's try for another number:

(5) Emergence is the phenomenon wherein complex, interesting high-level function is produced as a result of combining simple low-level mechanisms in simple ways.

I think this is much closer to a good definition of emergence. Note that COBOL programs, and many biological systems, are excluded by the requirement that not only the mechanisms but their principles of
Thoughts on emergence

combination be simple. (Of course simplicity, complexity and interestingness are psychological concepts, at least for now, though we might try to explicate them in terms of Chaitin-Kolmogorov-Solomonoff complexity if we felt like it. My intuition is that this is likely to prove a little simplistic, although Chaitin has an interesting paper that attempts to derive a notion of the "organization" of a system using similar considerations.) And note also that most things that satisfy this definition should also satisfy (4) - due to our feeling that simple principles should have simple consequences (or else complex but uninteresting consequences, like random noise). Any complex, interesting consequence is likely to be non-obvious.

This does indeed fit in with the feeling that emergence is a "something for nothing" phenomenon - though in a more subtle and satisfactory way than set forth in (1), for instance. It's a phenomenon whereby "something stupid buys you something smart". And most of our examples fit. The game of Life and connectionist networks are obvious: interesting high-level behaviour as a consequence of simple dynamic rules for low-level cell dynamics. In evolution, the genetic mechanisms are very simple, but the results are very complex. (Note that there is a small difference, in that in the latter case the emergence is diachronic, i.e. over time, whereas in the first two cases the emergence is synchronic, i.e. not over time but over levels present at a given time.)

We're still not completely there - it's not clear how (C), the operating system example, fits into this paradigm of emergence. But throwing in a smidgen of teleology should get us the rest of the way. I.e., we have to notice that everything here has to be relativized to design. So we design the game of Life according to certain simple principles, but complex, interesting properties leap out and surprise us. Similarly for the connectionist network - we only design it at a low level (though in this case we hope that complex high-level properties will emerge). Whereas in the COBOL case - and in the case of much traditional AI - you only get out what you put in (N.B. I'm not necessarily knocking this: at least here, I'm trying to explicate emergence, not to defend it). And now the operating system example fits in well. The design principles of the system in this case are quite complex - unlike the other cases that fit (5) above - but still the figure "35" is not a part of that design at all. So:

(6) Emergence is the phenomenon wherein a system is designed according to certain principles, but interesting properties arise that are not included in the goals of the designer.

Notice the appearance of the word "goal" - this is important, any design is goal-relative. So the notion now is quite teleological. I notice that Russ Abbott makes a similar point in a recent posting. Notice, however, that as we've conceded that emergence is a psychological property, we're able to construe teleology in a psychological, non-absolute way. So for our purposes here, we only need the appearance of teleology. This is nice, because it allows us to include system where strictly speaking, "design" doesn't apply at all. In evolution, for instance, there is no "designer", but it is easy to treat evolutionary processes as processes of design. On more than one level.

We can view evolution as teleological at the level of the gene - as in Dawkins' theory, for instance. Then the appearance of complex, interesting high-level properties such as intelligence is quite emergent. We also can reconstrue evolution as teleological at the level of the organism (this is perhaps a more
Thoughts on emergence

straightforward Darwinian view of things). On this construal, the most salient adaptive phenomena like intelligence are no longer emergent, but the goal of the design process. However, this view does open up the possibility of other kinds of emergent phenomena: firstly, non-selected-for byproducts of the evolutionary process (such as Gould and Lewontin's "Spandrels"); secondly and more intriguingly, it allows an explanation for why "consciousness" (or "subjectivity" or "qualia" or whatever) seems emergent. Raw consciousness doesn't not seem to have been selected for, as it doesn't play any direct functional role (though it does have functional counterparts; this is a subtle issue, but remember we're talking about the way things seem, not the way they are); but it somehow emerges as a byproduct of selection for adaptive process such as intelligence.

It's probably foolish to search for a definitive construal of "emergence": like most psychological concepts, it probably is best construed as a "family resemblance" - each of the "definitions" outlined above might play some role. Personally, I'm happiest with a combination of (5) and (6) - with (5) being the "core" variety of emergence, and (6) being a more general variety of which (5) is a special case.

In article <1990Oct7.012523.3828@watdragon.waterloo.edu> cpshelley@violet.uwaterloo.ca (cameron shelley) writes:

While intelligence might not be considered emergent at the "Darwinian" level synchronically, it must still be so diachronically. Unlike a 'designer', natural selection can only passively enforce changes and so must wait until the random process of mutation gives it the proper opportunity. Therefore, at the time when a significant enough increase in intelligence occurs, it must be emergent. So intelligence should still be considered emergent in the diachronic sense you mentioned earlier (and I cut out :).

It depends on how you construe the teleology of the evolutionary process. Of course there's no real teleology there, but psychologically we can construe it an at least three different ways. My original post suggested two of these ways, your response suggests a third.

First way: Teleology at the level of the gene. Goal: get genes to replicate. At this level, intelligence is emergent.

Second way: Teleology at the level of the organism. Goal: get organisms to survive and replicate. This is your suggestion. If the only teleology we impute to the evolutionary process is that of a "natural selector" - i.e. produce systems that survive and replicate - then specific functions like intelligence are indeed emergent.

http://www.u.arizona.edu/~chalmers/notes/emergence.html (4 of 5) [4/7/2002 1:53:20 PM]
Third way: Teleology at the level of the organism. Goal: get organisms to be like X (for some X, e.g. X = strong, fast, intelligent...). Here, we are construing the teleology of the evolutionary process not as that of the natural selector, but as that of the "blind watchmaker". On this view, intelligence is the goal of the evolutionary process, and so cannot be regarded as emergent.

The teleology here not being metaphysical but psychological, all these ways of construing it are quite valid. My original post only mentioned the first and third possibilities. The second possibility is also a very reasonable construal, and serves the useful purpose of showing how intelligence can be regarded as emergent without having to descend to the level of the "selfish gene". Sorry for omitting this possibility in my original post.
B Chandrasekaran writes:

It appears that there are three realms: the realm of matter, the realm of representations, and the realm of qualia/intentions/consciousness, not just two: matter and consciousness.

I like this distinction, although I think there might more naturally be four realms to distinguish.

- **Physical realm**: atoms, quantum physics, gravitation, electromagnetism, ...
- **Functional realm**: feedback loops, networks, Turing machines,..
- **Representational realm**: knowledge, belief, desire,..
- **Consciousness realm**: consciousness, qualia, pains, sensations, ...

On the relations between the various realms:

The functional realm is uncontroversially reducible to the physical realm.

Modern cognitive science holds that the representational realm is reducible to the functional realm, and I agree, although some, e.g. Searle, disagree, holding that it is only reducible to the physical realm, and no doubt you could find some who don't accept even that (e.g. people who hold that representation is dependent on consciousness, and that consciousness isn't reducible to the physical).

Consciousness is where things get tricky. Some people think that consciousness is reducible to representation (e.g. Dennett, Harman, and possibly many cognitive scientists, though cognitive scientists don't talk much about consciousness). Many more think that consciousness is reducible to function (Lewis, Armstrong, McDermott, most functionalists, etc), but not necessarily to representation. Still others (notably Searle) thinks that consciousness is reducible to the physical, but not to the other realms. Incidentally Searle also differs from most others in holding that representation is itself dependent on consciousness.

Penrose may in some strange sense hold that consciousness is reducible to function, but believes that the right function can only be realized through quantum effects (but he's so vague that one can't know). A Cartesian dualist like Eccles doesn't think that consciousness is reducible to physics, but might just possibly think that it's reducible to function that happens to be realized by ghostly spirits.
Then there are people like me who can't see how consciousness could be reduced to physics (and consequently, to function or representation either), though it would be nice if somehow it could be.

Finally there are people who don't think that consciousness really exists as a phenomenon worth talking about (perhaps Minsky, and Dennett on some days), so there's no point reducing it to anything. Personally I think that apart from the strong anti-reductionist position, this is the only position that's at all tenable, although it does seem to be prima facie implausible.

In my paper on connectionism in AI Magazine a few years ago, I argued that part of the excitement surrounding connectionism in its early stages was the claim of skipping the second realm, i.e., it was more directly physical and not representational. Most connectionists quickly abandoned this notion, since they came to see that it was every bit as representational as the symbolic systems, only different. Edelman seems to think he is offering a purely physicalist account, without any representational intervention, but I think there is representation there nevertheless.

I think that the enlightened connectionist position has always been that the cognitive realm (which is more or less the representational realm) is reducible to the functional realm - you don't find many connectionists talking directly in terms of physics. It's just that they want to reduce it to functional mechanisms quite different from those used by traditional AI and cognitive science.

To be strictly accurate I should probably introduce the cognitive realm as a fifth realm - i.e. the realm concerned with the explanation of behaviour - and not beg any questions about the identification of this with the representational realm. Some cognitive scientists want to skip the representational realm altogether, and go straight from the cognitive to the functional (e.g. Brooks, Freeman, the Churchlands on some days, and possibly some of the connectionists you mention). Most cognitive scientists, by contrast, take it for granted that cognitive explanation will be representational explanation; or more accurately, jointly representational and functional explanation. A few people (Fodor, Pylyshyn, ...) might hold that one can perform the reduction to the representational realm fully before a reduction to the functional realm, but even these people will rely on nonrepresentational functional explanations for some cognitive phenomena, e.g. perception. But I'd better stop now. The space of realms is getting cluttered.
CAN MACHINES THINK?

Maybe so, as Deep Blue's chess prowess suggests. and that sparks a fresh debate about the nature of mind. Is it just neurons?

ROBERT WRIGHT

When Garry Kasparov faced off against an IBM computer in last month's celebrated chess match, he wasn't just after more fame and money. By his own account, the world chess champion was playing for you, me, the whole human species. He was trying, as he put it shortly before the match, to "help defend our dignity."

Nice of him to offer. But if human dignity has much to do with chess mastery, then most of us are so abject that not even Kasparov can save us. If we must vest the honor of our species in some quintessentially human feat and then defy a machine to perform it, shouldn't it be something the average human can do? Play a mediocre game of Trivial Pursuit, say? (Or lose to Kasparov in chess?)

Apparently not. As Kasparov suspected, his duel with Deep Blue indeed became an icon in musings on the meaning and dignity of human life. While the world monitored his narrow escape from a historic defeat--and at the same time marked the 50th birthday of the first real computer, ENIAC--he seemed to personify some kind of identity crisis that computers have induced in our species.

Maybe such a crisis is in order. It isn't just that as these machines get more powerful they do more jobs once done only by people, from financial analysis to secretarial work to world-class chess playing. It's that, in the process, they seem to underscore the generally dispiriting drift of scientific inquiry. First Copernicus said we're not the center of the universe. Then Darwin said we're just protozoans with a long list of add-ons--mere "survival machines," as modern Darwinians put it. And machines don't have souls, right? Certainly Deep Blue hasn't mentioned having one. The better these seemingly soulless machines get at doing things people do, the more plausible it seems that we could be soulless machines too.

But however logical this downbeat argument may sound, it doesn't appear to be prevailing among scholars who ponder such issues for a living. That isn't to say philosophers are suddenly resurrecting the
idea of a distinct, immaterial soul that governs the body for a lifetime and then drifts off to its reward. They're philosophers, not theologians. When talking about some conceivably nonphysical property of human beings, they talk not about "souls" but about "consciousness" and "mind." The point is simply that as the information age advances and computers get brainier, philosophers are taking the ethereal existence of mind, of consciousness, more seriously, not less. And one result is to leave the theologically inclined more room for spiritual speculation.

"The mystery grows more acute," says philosopher David Chalmers, whose book The Conscious Mind will be published next month by Oxford University Press. "The more we think about computers, the more we realize how strange consciousness is."

Though chess has lately been the best-publicized measure of a machine's humanity, it is not the standard gauge. That was invented by the great British computer scientist Alan Turing in a 1950 essay in the journal Mind. Turing set out to address the question "Can machines think?" and proposed what is now called the Turing test. Suppose an interrogator is communicating by keyboard with a series of entities that are concealed from view. Some entities are people, some are computers, and the interrogator has to guess which is which. To the extent that a computer fools interrogators, it can be said to think.

At least that's the way the meaning of the Turing test is usually put. In truth, midway through his famous essay, Turing wrote, "The original question, 'Can machines think?,' I believe to be too meaningless to deserve discussion." His test wasn't supposed to answer this murky question but to replace it. Still, he did add, "I believe that at the end of the century the use of words and general educated opinion will have altered so much that one will be able to speak of machines thinking without expecting to be contradicted."

Guess again. With the century's end in sight, no machine has consistently passed the Turing test. And on those few occasions when interrogators have been fooled by computers, the transcripts reveal a less-than-penetrating interrogation. (Hence one problem with the Turing test: Is it measuring the thinking power of the machines or of the humans?)

The lesson here--now dogma among researchers in artificial intelligence, or AI--is that the hardest thing for computers is the "simple" stuff. Sure they can play great chess, a game of mechanical rules and finite options. But making small talk--or, indeed, playing Trivial Pursuit--is another matter. So too with recognizing a face or recognizing a joke. As Marvin Minsky of the Massachusetts Institute of Technology likes to say, the biggest challenge is giving machines common sense. To pass the Turing test, you need some of that.

Besides, judging by the hubbub over the Kasparov match, even if computers could pass the test, debate would still rage over whether they think. No one doubted Deep Blue's chess skills, but many doubted whether it is a thinking machine. It uses "brute force"--zillions of trivial calculations, rather than a few strokes of strategic Big Think. ("You don't invite forklifts to weight-lifting competitions," an organizer of exclusively human chess tournaments said about the idea of man-vs.-machine matches.) On the other
hand, there are chess programs that work somewhat like humans. They size up the state of play and reason strategically from there. And though they aren't good enough to beat Kasparov, they're good enough to leave the average Homo sapiens writhing in humiliation.

Further, much of the progress made lately on the difficult "simple" problems--like recognizing faces--has come via parallel computers, which mirror the diffuse data-processing architecture of the brain. Though progress in AI hasn't matched the high hopes of its founders, the field is making computers more like us, not just in what they do but in how they do it--more like us on the inside.

So machines can think? Not so fast. Many people would still say no. When they talk about what's inside a human being, they mean way inside--not just the neuronal data flow corresponding to our thoughts and feelings but the thoughts and feelings themselves. You know: the exhilaration of insight or the dull anxiety of doubt. When Kasparov lost Game 1, he was gloomy. Could Deep Blue ever feel deeply blue? Does a face-recognition program have the experience of recognizing a face? Can computers--even computers whose data flow precisely mimics human data flow--actually have subjective experience? This is the question of consciousness or mind. The lights are on, but is anyone home?

For years AI researchers have tossed around the question of whether computers might be sentient. But since they often did so in casual late-night conversations, and sometimes in an altered state of consciousness, their speculations weren't hailed as major contributions to Western thought. However, as computers keep evolving, more philosophers are taking the issue of computer consciousness seriously. And some of them--such as Chalmers, a professor of philosophy at the University of California at Santa Cruz--are using it to argue that consciousness is a deeper puzzle than many philosophers have realized.

Chalmers' forthcoming book is already making a stir. His argument has been labeled "a major misdirector of attention, an illusion generator," by the well-known philosopher Daniel Dennett of Tufts University. Dennett believes consciousness is no longer a mystery. Sure there are details to work out, but the puzzle has been reduced to "a set of manageable problems."

The roots of the debate between Chalmers and Dennett--the debate over how mysterious mind is or isn't--lie in the work of Dennett's mentor at Oxford University, Gilbert Ryle. In 1949 Ryle published a landmark book called The Concept of Mind. It resoundingly dismissed the idea of a human soul--a "ghost in the machine," as Ryle derisively put it--as a hangover from prescientific thought. Ryle's juiciest target was the sort of soul imagined back in the 17th century by Rene Descartes: an immaterial, somewhat autonomous soul that steers the body through life. But the book subdued enthusiasm for even less supernatural versions of a soul: mind, consciousness, subjective experience.

Some adherents of the "materialist" line that Ryle helped spread insisted that these things don't even exist. Others said they exist but consist simply of the brain. And by this they didn't just mean that consciousness is produced by the brain the way steam is produced by a steam engine. They meant that the mind is the brain--the machine itself, period.
Some laypeople (like me, for example) have trouble seeing the difference between these two views--between saying consciousness doesn't exist and saying it is nothing more than the brain. In any event, both versions of strict materialism put a damper on cosmic speculation. As strict materialism became more mainstream, many philosophers talked as if the mind-body problem was no great problem. Consciousness became almost passe.

Ryle's book was published three years after ENIAC's birth, and at first glance his ideas would seem to draw strength from the computer age. That, at any rate, is the line Dennett takes in defending his teacher's school of thought. Dennett notes that AI is progressing, creating smart machines that process data somewhat the way human beings do. As this trend continues, he believes, it will become clearer that we're all machines, that Ryle's strict materialism was basically on target, that the mind-body problem is in principle solved. The title of Dennett's 1991 book says it all: Consciousness Explained.

Dennett's book got rave reviews and has sold well, 100,000 copies to date. But among philosophers the reaction was mixed. The can-do attitude that was common in the decades after Ryle wrote--the belief that consciousness is readily "explained"--has waned. "Most people in the field now take the problem far more seriously," says Rutgers University philosopher Colin McGinn, author of The Problem of Consciousness. By acting as if consciousness is no great mystery, says McGinn, "Dennett's fighting a rearguard action."

McGinn and Chalmers are among the philosophers who have been called the New Mysterians because they think consciousness is, well, mysterious. McGinn goes so far as to say it will always remain so. For human beings to try to grasp how subjective experience arises from matter, he says, "is like slugs trying to do Freudian psychoanalysis. They just don't have the conceptual equipment."

Actually there have long been a few mysterians insisting that the glory of human experience defies scientific dissection. But the current debate is different. The New Mysterians are fundamentally scientific in outlook. They don't begin by doubting the audacious premises of AI. O.K., they say, maybe it is possible--in principle, at least--to build an electronic machine that can do everything a human brain can do. They just think people like Dennett misunderstand the import of such a prospect: rather than bury old puzzles about consciousness, it resurrects them in clearer form than ever.

Consider, says Chalmers, the robot named Cog, being developed at M.I.T.'s artificial-intelligence lab with input from Dennett (see following story). Cog will someday have "skin"--a synthetic membrane sensitive to contact. Upon touching an object, the skin will send a data packet to the "brain." The brain may then instruct the robot to recoil from the object, depending on whether the object could damage the robot. When human beings recoil from things, they too are under the influence of data packets. If you touch something that's dangerously hot, the appropriate electrical impulses go from hand to brain, which then sends impulses instructing the hand to recoil. In that sense, Cog is a good model of human data processing, just the kind of machine that Dennett believes helps "explain" consciousness.

But wait a second. Human beings have, in addition to the physical data flow representing the heat, one
other thing: a feeling of heat and pain, subjective experience, consciousness. Why do they? According to Chalmers, studying Cog doesn't answer that question but deepens it. For the moral of Cog's story seems to be that you don't, in principle, need pain to function like a human being. After all, the reflexive withdrawal of Cog's hand is entirely explicable in terms of physical data flow, electrons coercing Cog into recoiling. There's no apparent role for subjective experience. So why do human beings have it?

Of course, it's always possible that Cog does have a kind of consciousness--a consideration that neither Dennett nor Chalmers rules out. But even then the mystery would persist, for you could still account for all the behavior by talking about physical processes, without ever mentioning feelings. And so too with humans. This, says Chalmers, is the mystery of the "extraness" of consciousness. And it is crystallized, not resolved, by advances in artificial intelligence. Because however human machines become--however deftly they someday pass the Turing test, however precisely their data flow mirrors the brain's data flow--everything they do will be explicable in strictly physical terms. And that will suggest with ever greater force that human consciousness is itself somehow "extra."

Chalmers remarks, "It seems God could have created the world physically exactly like this one, atom for atom, but with no consciousness at all. And it would have worked just as well. But our universe isn't like that. Our universe has consciousness." For some reason, God chose "to do more work" in order "to put consciousness in."

When Chalmers says "God," he doesn't mean--you know--God. He's speaking as a philosopher, using the term as a proxy for whoever, whatever (if anyone, anything) is responsible for the nature of the universe. Still, though he isn't personally inclined to religious speculation, he can see how people who grasp the extraness of consciousness might carry it in that direction.

After all, consciousness--the existence of pleasure and pain, love and grief--is a fairly central source of life's meaning. For it to have been thrown into the fabric of the universe as a freebie would suggest to some people that the thrower wanted to impart significance.

It's always possible that consciousness isn't extra, that it actually does something in the physical world, like influence behavior. Indeed, as a common-sense intuition, this strikes many people as obvious. But as a philosophical doctrine it is radical, for it would seem to carry us back toward Descartes, toward the idea that "soul stuff" helps govern the physical world. And within both philosophy and science, Descartes is dead or, at best, on life support. And the New Mysterians, a pretty hard-nosed group, have no interest in reviving him.

The extraness problem is what Chalmers calls one of the "hard" questions of consciousness. What Dennett does, Chalmers says, is skip the "hard" questions and focus on the "easy" questions--and then title his book Consciousness Explained. There is one other "hard" question that Chalmers emphasizes. It--and Dennett's alleged tendency to avoid such questions--is illustrated by something called pandemonium, an AI model that Dennett favors.
According to the model, our brain subconsciously generates competing theories about the world, and only the "winning" theory becomes part of consciousness. Is that a nearby fly or a distant airplane on the edge of your vision? Is that a baby crying or a cat meowing? By the time we become aware of such images and sounds, these debates have usually been resolved via a winner-take-all struggle. The winning theory--the one that best matches the data--has wrested control of our neurons and thus of our perceptual field.

As a scientific model, pandemonium has virtues. First, it works; you can run the model successfully on a computer. Second, it works best on massively parallel computers, whose structure resembles the brain's structure. So it's a plausible theory of data flow in the human brain, and of the criteria by which the brain admits some data, but not other data, to consciousness.

Still, says Chalmers, once we know which kinds of data become part of consciousness, and how they earned that privilege, the question remains, "How do data become part of consciousness?" Suppose that the physical information representing the "baby crying" hypothesis has carried the day and vanquished the information representing the rival "cat meowing" hypothesis. How exactly--by what physical or metaphysical alchemy--is the physical information transformed into the subjective experience of hearing a baby cry? As McGinn puts the question, "How does the brain 'turn the water into wine?'"

McGinn doesn't mean that subjective experience is literally a miracle. He considers himself a materialist, if in a "thin" sense. He presumes there is some physical explanation for subjective experience, even though he doubts that the human brain--or mind, or whatever--can ever grasp it. Nevertheless, McGinn doesn't laugh at people who take the water-into-wine metaphor more literally. "I think in a way it's legitimate to take the mystery of consciousness and convert it into a theological system. I don't do that myself, but I think in a sense it's more rational than strict materialism, because it respects the data." That is, it respects the lack of data, the yawning and perhaps eternal gap in scientific understanding.

These two "hard" questions about consciousness--the extraness question and the water-into-wine question--don't depend on artificial intelligence. They could occur (and have occurred) to people who simply take the mind-as-machine idea seriously and ponder its implications. But the actual construction of a robot like Cog, or of a pandemonium machine, makes the hard questions more vivid. Materialist dismissals of the mind-body problem may seem forceful on paper, but, says McGinn, "you start to see the limits of a concept once it gets realized." With AI, the tenets of strict materialism are being realized--and found, by some at least, incapable of explaining certain parts of human experience. Namely, the experience part.

Dennett has answers to these critiques. As for the extraness problem, the question of what function consciousness serves: if you're a strict materialist and believe "the mind is the brain," then consciousness must have a function. After all, the brain has a function, and consciousness is the brain. Similarly, turning the water into wine seems a less acute problem if the wine is water.

To people who don't share Dennett's philosophical intuitions, these arguments may seem unintelligible. (It's one thing to say feelings are generated by the brain, which Chalmers and McGinn believe, but what
does it even mean to say feelings are the brain?) Still, that doesn't mean Dennett is wrong. Some people share his intuitions and find the thinking of his critics opaque. Consciousness is one of those questions so deep that frequently people with different views don't just fail to convince one another, they fail even to communicate. The unintelligibility is often mutual.

Chalmers isn't a hard-core mysterian like McGinn. He thinks a solution to the consciousness puzzle is possible. But he thinks it will require recognizing that consciousness is something "over and above the physical" and then building a theory some might call metaphysical. This word has long been out of vogue in philosophy, and even Chalmers uses it only under duress, since it makes people think of crystals and Shirley MacLaine. He prefers "psychophysical."

In The Conscious Mind, Chalmers speculatively sets out a psychophysical theory. Maybe, he says, consciousness is a "nonphysical" property of the universe vaguely comparable to physical properties like mass or space or time. And maybe, by some law of the universe, consciousness accompanies certain configurations of information, such as brains. Maybe information, though composed of ordinary matter, is a special incarnation of matter and has two sides--the physical and the experiential. (Insert Twilight Zone music here.)

In this view, Cog may indeed have consciousness. So might a pandemonium machine. So might a thermostat. Chalmers thinks it quite possible that AI research may someday generate--may now be generating--new spheres of consciousness unsensed by the rest of us. Strange as it may seem, the prospect that we are creating a new species of sentient life is now being taken seriously in philosophy.

Though Turing generally shied away from such metaphysical questions, his 1950 paper did touch briefly on this issue. Some people, he noted, might complain that to create true thinking machines would be to create souls, and thus exercise powers reserved for God. Turing disagreed. "In attempting to construct such machines we should not be irreverently usurping his power of creating souls, any more than we are in the procreation of children," Turing wrote. "Rather we are, in either case, instruments of his will providing mansions for the souls that he creates."
Arizona Conference Grapples With Mysteries of Human Consciousness

By SANDRA BLAKESLEE

UCSON, Ariz. -- Like the proverbial blind men trying to identify by sense of touch a large, thick-hided animal with a trunk at one end and a tail at the other, some of the world's top scientists, philosophers and far-out thinkers gathered here last week to contribute their different perspectives on the elephant of consciousness.

A good time was had by all, even when the fur -- or maybe it was elephant hide -- began to fly.

Can machines be conscious? The question elicited a spirited debate between those who said, Of course, it's just a matter of time and clever engineering, and others who replied: Never! It's bad enough that you think consciousness can arise from gray lumps of tissue. It is inconceivable that sentience could ever emerge from wholly insentient matter.

Then there were less contentious questions. Does free will exist? Can consciousness exist without emotions? Are animals conscious? What happens to your conscious mind when you fall into a deep sleep?

And the most debated question of all: is consciousness something very special and unique or is it just the natural byproduct of a complex brain, emerging like wind from intricate weather patterns?

The conference, "Toward a Science of Consciousness," was sponsored by the University of Arizona with support from the Fetzer Institute and the
Institute of Noetic Sciences, two organizations dedicated to exploring the metaphysical foundations of Western science. A similar but smaller conference was held two years ago in Tucson.

"We were deliberately eclectic in choosing speakers," said Dr. Stuart Hameroff, an anesthesiologist at the Arizona Health Sciences Center who was a principal organizer of the event. Experts in various disciplines can always talk among themselves, he said, "but there needs to be an arena where everyone can mix their ideas about consciousness together."

Thus the conference drew neuroscientists, philosophers, mathematicians, computer scientists, physicists, dream researchers, pharmacologists, doctors, ethnologists, psychologists, parapsychologists, scholars of religion and a variety of prophets who claim to have solved the mystery of consciousness.

The meeting was unusual from the start. Dr. Jaron Lanier, a computer scientist from Columbia University who is a pioneer in virtual reality, opened the plenary session on Monday by playing a brief piano recital. His blond dreadlocks flew apace with the music. The audience was delighted.

The goal of the meeting was simple, Hameroff said. What is the nature of consciousness? Can we hope to understand it scientifically?

It is remarkable that such a diverse gathering could discuss the question of consciousness in a coherent manner. But this kind of cross pollination of ideas, where everything goes, is exactly what is needed, said Dr. Christof Koch, a neuroscientist at the California Institute of Technology who helped organize the event. One hundred years ago, people could not understand how life could arise out of mere chemicals, he said. But when DNA was explained, theories of vitalism -- that a magical force was needed to explain life -- disappeared.

The study of consciousness is like the study of physics before Newton, said Dr. Piet Hut, a theoretical physicist at the Institute for Advanced Studies in Princeton, N.J. In fact, he said, if people had organized a conference about physics in the Middle Ages, they would have dismissed Copernicus and Galileo as crackpots. "We shouldn't make that mistake today," Hut said.

But before progress can be made on the question, some definitions are in order. Consciousness has many guises.

In Tucson, the tone of discourse was set by a young philosopher from the
University of California at Santa Cruz, Dr. David Chalmers. He is widely credited for posing the so-called hard problem of consciousness.

To explain this concept, Chalmers first described the so-called easy problems of consciousness, the sorts of questions being tackled in neuroscience laboratories around the world: How does sensory information get integrated in the brain? How do we see and reach out for an object? How are we able to verbalize our internal states and report what we are doing or feeling?

"These problems are not trivial," Chalmers said. "They may take 100 years or more to solve, but progress is being made."

The hard problem is this: What is the nature of subjective experience? Why do we have vividly felt experiences of the world? Why is there someone home inside our heads?

Thus far, nothing in physics or chemistry or biology can explain these subjective feelings, Chalmers said. "What really happens when you see the deep red of a sunset or hear the haunting sound of a distant oboe, feel the agony of intense pain, the sparkle of happiness or meditative quality of a moment lost in thought?" he asked. "It is these phenomena, often called qualia, that pose the deep mystery of consciousness."

In Tucson, people mounted four responses to the hard problem: it doesn't exist, it will be answered soon enough by conventional science, there must be something else in the universe that we do not yet understand, and hey guys, forget it, we can never understand consciousness.

Dr. Daniel Dennett, a philosopher at Tufts University, is a forceful proponent of the idea that consciousness is no big deal. "It's like fame," Dennett said. "It doesn't exist except in the eye of the beholder." When does fame happen, he asked? Is it when 10 people know your name? A hundred people? A thousand?

Scientists have shown that information coming into the brain is broken down into separate processing streams, Dennett said. But no one has yet found any "place" where all the information comes together, presenting a whole picture of what is being felt or seen or experienced. The temptation, he said, is to believe that the information is transduced by consciousness. But it is entirely possible that the brain's networks can assume all the roles of an inner boss. Mental contents become conscious by winning a competition against other
mental contents, Dennett said. No more is needed. Consciousness is an epiphenomenon.

A second group of scientists agreed with Dennett but took a softer line. When all the "easy" problems are solved, the hard problem will disappear -- but consciousness certainly exists. "It's silly to deny it," said Dr. Pat Churchland, a philosopher at the University of California at San Diego.

Awareness and subjectivity are network effects involving many millions of nerve cells in the cortex and thalamus, Dr. Churchland said. And while the exact nature of the phenomenon cannot yet be explained, the call for a "new physics" or some mysterious forces in nature are not needed.

Dr. Rodolfo Llinas, a neuroscientist at New York University, agreed, suggesting that timing effects inside the brain produce conscious experience.

Those who believe machines can someday be conscious tended to fall into this camp. The trick will be to make computers that are sufficiently complex, said Dr. Danny Hillis, vice president of research and development at Walt Disney Imagineering in Glendale, Calif. Then, like human brains, they should give rise to the emergent properties of consciousness.

Others tried to answer a few of the easy questions. Dr. Allan Hobson, a sleep expert at Harvard Medical School, described a neurobiological theory of dreaming. It does not explain where consciousness "goes" when people are asleep, he said, but finds that different chemical states in the brain seem to produce different sorts of consciousness.

The next major group of consciousness seekers might be called modern dualists. Agreeing with the hard problem, they feel that something else is needed to explain people's subjective experiences. And they have lots of ideas about what this might be.

According to Chalmers, scientists need to come up with new fundamental laws of nature. Physicists postulate that certain properties -- gravity, space-time, electromagnetism -- are basic to any understanding of the universe, he said.

"My approach is to think of conscious experience itself as a fundamental property of the universe," he said. Thus the world has two kinds of information, one physical, one experiential. The challenge is to make theoretical connections between physical processes and conscious
experience, Chalmers said.

Another form of dualism involves the mysteries of quantum mechanics. Dr. Roger Penrose from the University of Oxford in England argued that consciousness is the link between the quantum world, in which a single object can exist in two places at the same time, and the so-called classical world of familiar objects where this cannot happen.

Moreover, with Hameroff, he has proposed a theory that the switch from quantum to classical states occurs inside certain proteins call microtubules. The brain's microtubules, they argue, are ideally situated to perform this transformation, producing "occasions of experience" that with the flow of time give rise to stream of consciousness thought.

The notion came under vigorous attack. "Pixie dust in the synapses is about as explanatorily powerful as quantum mechanics in the microtubules," Churchland said. Their logic is, consciousness is deeply mysterious, quantum mechanics is deeply mysterious, ergo the two are the same mystery, she said.

Penrose's ideas are popular, Churchland said, because many people have dualist hankerings. They want to believe in a soul, life after death and the specialness of humans and their inner thoughts. They have a negative gut reaction to the idea that neurons -- cells that can be probed under a microscope -- are the source of the "me-ness of me," she said.

Finally, there are those who argued that people can never understand consciousness. The mystery is too deep. Dr. Colin McGinn, a philosopher from Rutgers University, said that for humans to grasp how subjective experience arises from matter "is like slugs trying to do Freudian psychoanalysis -- they just don't have the conceptual equipment."

But this did not deter many from trying. During the week, presentations were made on animal consciousness (featuring apes, dolphins and gray parrots), free will and the spiritual nature of consciousness.

Dr. Robert Forman, a professor of religion at Hunter College in New York, said mystical experience had something to tell people about consciousness. "To understand genes," he said, "we look at bacteria like E. coli. To study memory, we analyze the memory of a sea slug. But to probe consciousness, we need to examine the experience of mystics, who experience their own consciousness in its simplest form."
Millions of people regard these types of experiences, feeling a oneness with the universe, as the highest experience that the conscious brain has to offer, Forman said.
How to Make a Soul

By Andrew Brown

Among the professionals, philosophical argument is a martial art. Nervous spectators pull their beer bottles out of the way in case a backhand logic chop should sweep them off the table. This is personal.

The young man defending himself in the Empire Bar is dressed like a jobbing rock star: t-shirt, tight jeans around skinny legs, great curly masses of brown hair reaching down his back. But he moves like a fighter; every point launched against him is blocked, deftly, with his outspread palms.

His opponent is older, still wiry, with black hair and moustache. The more the young man blocks, the harder the older man's arms throw new points. Soon he is arguing from his shoulders, like a boxer. Finally, he seizes a beer bottle and thrusts it in front of his opponent. "Look," he shouts. "There's only one thing I want to know. Do you think this beer bottle has consciousness?"

There's a pause. "Well, it might have," says David Chalmers. A ripple of appreciative relaxation runs round the audience. The bout is over. One of the spectators takes the bottle from Bruce Mangan's hand and carefully tears a strip from the label. He waves it in front of Chalmers. "So what happens now?" he asks. "Where has the consciousness gone in the paper? Has the label got its own little consciousness?"

It's a game. It is also extremely serious. The crowd around Chalmers and Mangan at the Empire Bar is part of a congregation of neuroscientists, philosophers, psychologists, quantum physicists and AI gurus that has come in pilgrimage to Tucson for a conference called "Towards a Science of Consciousness." There are almost a thousand people attending, and each participant worth talking to has at least half a dozen good theories, mostly incompatible. What holds all the theories and disciplines together is simple. These people think that the nature of consciousness is the most exciting intellectual frontier in the world today. It is here that science seems to be closing in on the essence of what makes us human.

Yet there is a paradox at the heart of this work. The more the researchers learn, the further the true subject recedes. The more is learned about how the brain works, the less this knowledge can be tied up with how it feels to have a brain - to feel oneself living and thinking. Science has always discussed the world from the outside. Can it ever encompass
how the world feels from the inside?

There is no doubt that the process of learning from the outside is getting better and better. You can use a brain scanner to look inside someone's head while he learns a poem or recites one back. You can see which parts of the brain are working, and how hard. But even if these scanners could track each signal in each of the brain's billions of cells, they would still not explain why that activity should feel the way it does. People may, someday, be able to find which pattern of neurons firing makes up a thought. But what does that tell you about consciousness, about the feeling of the thought?

Chalmers calls the discovery of the patterns in the brain that correspond to thinking the easy problem. By calling it easy, he does not mean to deny that it is also fiendishly difficult. It would mark the culmination of centuries of work in neurology, in biochemistry, in experimental psychology. Answer that easy problem and you have the mechanics of memory, learning, sensation laid out before you.

But easy is a relative term. To Chalmers, such questions are easy because people have some idea of how, in principle, they might be answered. This contrasts with the question of why consciousness arises from a physical process. That "why" is what Chalmers calls the hard problem. As he outlines its hardness, he speaks in a light, hurried voice. His words come in quick flurries, like snow.

Watching Chalmers talk, you realise you can see less and less; you're stuck deeper and deeper in a world of improbable contradictions. "When it comes to the hard problem, my feeling is that you need something that goes beyond physical theory, because everything in physical theory is compatible with the absence of consciousness; my feeling is that you have to take consciousness as axiomatic, like time and space. "The problem comes with constructing a theory that will link them all together. You want to get down to something that's deep and fundamental - a set of laws that's simple enough you can write them on the front of a t-shirt." The scientific study of consciousness, Chalmers says, "is like physics before Isaac Newton came along. No one knows what is really happening."

A new way of looking at the world, expressible in some practical, useful axioms. A call for a new Newton. No wonder that the brilliant and ambitious flocked to the Tucson conference, the second of its ilk and the foremost gathering of its type in the world, to try their mettle.

**All you Zombies**

Go back a few decades and you will be hard put to find any inkling of a science of consciousness. Behaviourists treated animals and humans as black boxes; neurologists
were still puzzled by the synapse. Even the study of perception was academically suspect. But fashions change, and new tools become available, and those two things shape all science. When Francis Crick, one of the discoverers of the structure of DNA, announced in the '80s that he was going to spend the rest of his life studying consciousness, he was responding to, and amplifying, a growing sense that consciousness would be the next big thing.

The idea that some animals are conscious is now almost as common among the scientists who long rejected it as it always has been with everyone else. "Most people have no difficulty in seeing consciousness in cats or dogs, though once you get down to flies it's more difficult." says Chalmers. "But there may be some very simple form of consciousness, experience, without much in the way of thought or activity - something about consciousness that is pre-intellectual." Then, as an afterthought: "Some of our machines may have that now."

With this remark he leaps across one of the great chasms that divide the field. Nothing has done more to sharpen the issues involved in consciousness research than the promise, or the spectre, of artificial intelligence (AI). As Chalmers, who studied for two years under AI guru Douglas Hofstadter, puts it, "The deep question is why any physical system, whether machine or animal, is associated with consciousness. But brains did it, so why shouldn't machines, too?" In other words, when the hard question is solved, artificial intelligence in its truest form is thrown in as an added bonus. The problem of making a computer that knows itself to be capable of thought, one with an inner life, joins the ranks of the easy questions.

Some people think it already belongs there. Dan Dennett is a large, long-legged man, with a great rounded skull like an ostrich egg, and a beard like God (in whom he does not believe). Wherever he stepped in the corridors or anterooms of the Tucson conference he became the immediate focus of a ragged, admiring ellipse of students and disputants upon whom he beamed with sharp benevolence. He is the inventor of one of the classical thought experiments of AI: the replacement of a grey porridgy brain - yours, for the sake of argument - with a shiny new one made of something utterly different.

Cell by cell, bit by bit, your neurons would be turned to silicon. But each piece of silicon would have exactly the same connections and behaviour as the cell it replaced. The neighbouring cells would get exactly the same responses as they would if the delicate electric and chemical feelers of their dendrites were still brushing against other cells, rather than just being plugged into the wiring. Would you notice? Would you care? And if you did, why?

No one has yet found anything magic about the way the neurons in the brain signal to one another. It is immensely complicated, but it's only chemicals and electricity. It can be
measured and mimicked. In the outer suburbs of the brain it already has been. There is a treatment for deafness which replaces a defective nerve with circuitry. Treatments for blindness that would replace the eye with a television camera are already thinkable. Why not replace a whole brain, and thus show that silicon can support consciousness as well as carbon does?

This sort of reasoning by equivalence has a long pedigree in AI. If the discipline has a founding principle, it is that of the Turing test: the idea that a computer which could converse as convincingly as a human could be said to have artificially captured the human intellect. By taking a similar line of thought rather further, Dennett concludes that the hard problem, as defined by Chalmers, is no more than a mirage. When all the "easy" problems about how the brain processes information have been solved, we will discover that the hard problem has simply disappeared.

Indeed, one of the things that makes the hard problem so difficult at the moment is that lots of people can't see that it is a problem at all. People like Dennett - believers in "Strong AI", also known, for obvious reasons, as zombies - are sure that consciousness will turn out to be no more than the sum of meaningless mathematical manipulations of information.

Dennett defends these views with enormous clarity, force and charm. Nonetheless, he seems to be drawing back in recent years from the particularly strong position with which he made his name. Though he still says that, in principle, any chunk of silicon (or anything else) that can perform the same functions as a brain would by definition be conscious, he now admits that some of these functions seem to be much more specialised now than they did even ten years ago. The more we know about the human brain, the less it seems likely that we can ever reproduce anything like it artificially. Among those who still believe it can be done, the methods which were fashionable when Dennett first started work are long forgotten. Danny Hillis, for example, the founder of Thinking Machines, one of the first successful parallel processing companies, and now vice-president of R&D for Disney, believes that the only way to get a machine complicated enough to have a possibility of consciousness is to breed it:

"Imagine something like the Internet, multiplied times 100, and imagine all the machines on it exchanging programs, and imagine using those programs to design a system which would run not on one machine but on the whole network - then I think you have the image of something that might be complicated enough to be conscious," Hillis told the conference. "Once you do that, it becomes easier to accept the idea of something like a conscious machine. I think people who have a strong intuition that machines can't be conscious have that feeling not because they overestimate the wonders of consciousness but because they underestimate the powers of machinery. A lot of arguments against machines thinking are made from exaggeration and distortion."
Hillis's foremost target is Sir Roger Penrose, a brilliant Oxford mathematician who is partly responsible for the conference's being in Tucson. Penrose believes that consciousness is fundamentally not like the operations of a computer, and cannot be recreated by means of those operations. Rather, he believes it has to be tied to a new set of natural laws, laws that combine the apparent randomness of the quantum world with Einstein's general theory of relativity. And laws that would explain the fundamental sympathy for mathematical form that Penrose, among other things a brilliant geometer, sees in the human mind.

After putting this set of ideas into a demanding, beautifully written and, say the strong AI types, deeply wrong-headed book - The Emperor's New Mind - Penrose came into contact with another non-traditional consciousness researcher, Stuart Hameroff. Hameroff's fascination with consciousness comes from his professional need to extinguish it; he is an anaesthesiologist at the University of Arizona's hospital. And he's fascinated by the fact that consciousness, whatever it may be, can be removed and restored with a subtle mix of simple gasses.

Hameroff came up with the idea that microtubules, tiny pipes that stiffen the insides of cells, were crucial to the whole story. Penrose got interested and the two began to collaborate. The first Tucson conference, two years ago, was one of the fruits of that collaboration.

The proteins that form the walls of the microtubules can flip between two different shapes. They can also exist, for an instant or two, in a state of quantum superposition, like Schroedinger's cat; it is the flickering through that third state that Penrose and Hameroff now believe constitutes conscious events. Their theory is resonant, especially when Hameroff explains that psychedelic drugs promote superposition in the microtubules, or when he adds that the consciousness event is a blister in space-time, and so must be quickly reduced to normal physics. "If not reduced, a blister in space-time would shear off into multiple universes - and we hate it when that happens." If ambition were all, the Penrose-Hameroff theory and its implication that consciousness is built into the very fabric of nature would score highly. However, most people reckon its chances of success are small enough to slip between a couple of electron shells. And even if the microtubules function as they are supposed to in this theory, the difficulty pointed out by Patricia Churchland, a philosopher, remains: that there is no clear account of how these quantum events should cause consciousness. The hard problem remains untouched.

Cogito Ergo Something

You don't have to believe Penrose and Hameroff to disagree with the strong AI view that a machine could be conscious. When Hillis put the question to his audience, the majority professed itself agnostic: the 60% expressing a view was pretty evenly split between pros
and antis. But it has to be said that the antis had all the best tunes. Literally so, in Jaron Lanier's case. He opened the proceedings with a self-composed piano piece that started off strange and brilliant, and as it went on became progressively less strange. This formed a counterpoint to his reasoning, which was unflaggingly brilliant but grew stranger and stranger as he argued that talk of machine consciousness veers between the futile and the really dangerous.

As well as being a musician, Lanier is a code god: he invented the term "virtual reality", and then built the gadgetry to make it real. He has a towering physical presence, being well over six feet tall and about four feet round the waist, with a great shock of maize-coloured dreadlocks reaching almost to his waist and a beard that gives his face a perfectly triangular jaw like an Egyptian painting's. His eyes are a bright, pale blue.

He's a genius, of course, and knows it in the same sort of way he knows he's tall. Talking to him, I felt as if I was talking to the spirit of the prairies: a restless, inexhaustible wind running on forever. America, he says, loves frontiers, and always peoples them with abstractions, like freedom, or computing. But it is all a mistake. The abstractions do not exist; the frontiers are only a trick of perspective.

First he disposes of the Turing test. Only a fucked-up gay Englishman being tortured with hormone injections could possibly have supposed that consciousness was some kind of social exam you had to pass, he says. There are two logically possible ways to for a machine to pass the Turing test. Either it gets smarter, or we get dumber. He is in no doubt that the likelier reason would be that we have got stupider and adapted our reasoning to the machine's expectations.

Then he demolishes the idea of computation. It is an arbitrary process, he says. It is not built into the structure of the universe, but only into the way we understand it. Anything can be measured in numbers, and any set of numbers can constitute a program for some thinkable computer. Even a meteor shower could be read as numbers, and so be read as a program on some computer somewhere. Would we therefore say that the meteor shower was computing, or conscious?

Then he has a go at the physical reality of the universe. We were sitting outside as he said this, facing each other across a concrete table which was one of the most solid objects you could hope to find. But, he insisted, on the level of quantum electrodynamics (QED), the most precisely confirmed of all physical theories, it turns out to be an illusion.

"I hate to tell you this, but QED does not acknowledge the existence of gross objects. From the point of view of physics, there are particles in positions, but no gross objects; the particles don't constitute a table." He gestures at the stone table where we sit in the dusty evening, scents of sage-brush and diesel borne round us on a gentle wind. "Gross objects
aren't needed by physics. They're actually extraneous. Ask a neutrino."

I feel as if the prairie wind had whisked me off to Oz. "This is genuinely hard stuff," he says. "Hard to think about and hard to talk about." Then he returns to the more mundane objections to a mechanistic view of consciousness. It narrows our vision of the world. The danger of believing that consciousness is computation is not that it causes us to misunderstand machines, but that it makes us misunderstand our own nature.

Lanier places the hopes that some people have for consciousness research firmly in the American tradition of faith in some apocalyptic fix to all life's problems. Indeed, the programmatic atheism of the main conference was thrown into high relief by the simple faith of some of the attendees that technology could perform all the functions once expected of God. This irrational longing gives the field of consciousness research a lot of its excitement, yet it is only the very naive who will admit to it.

I had supper one night with a man who had made enough money in mainframes never to need to work again. He could travel the world gratifying his curiosity - and the miracle he expected from consciousness research was immortality. Humans, he felt, should be migrated onto better hardware when the old stuff wears out. This is the natural development of the classic Dennett thought experiment where you replace each part of my brain by a bit of silicon, thought by byte, until I wake up one day to find myself running on entirely different hardware, as if I, a mere human, were as clever and well designed as System 7.5.

**Love and DNA**

That was far from the strangest thing I heard, even if it was one of the more poignant. There were over 500 papers delivered at Tucson, and many of them were deliciously cranky. One Californian paper displayed in a poster session, where anyone could pin their ideas up on a notice-board, claimed that "Pioneering scientific research has demonstrated the experience of love to facilitate coherent harmonic patterns in the EKG, to improve both immune function and hormonal regulation, and enable focused attention to modify the conformation of human DNA. Love has also been shown to be causal in modulating the structure of water to provide a matrix for information storage and transformation."

If love doesn't suit you as an explanation, try evolution. Physiologists and philosophers argue about what consciousness is, but there is also a raft of questions about why it is, what function it might fulfil. Here the analytical tools come easily to hand. If the question is how did a biological phenomenon come about, the answer has to include evolution. Consciousness needs to pay its evolutionary way.
It might seem obvious that an animal that deals with the world in an intelligent, coordinated fashion has an advantage. But that does not translate into a need for consciousness. Most of the intelligent, coordinated decisions crucial for an animal's survival are made far faster than the conscious mind can process things. Jeffrey Gray of the Institute of Psychiatry in Denmark Hill, South London, serves up an example from Centre Court. In the time that it takes a tennis player at Wimbledon to become consciously aware that his opponent's serve has crossed the net towards him, he must already have struck his own return ball if he is to stay in the game. Even quite high-level trains of action, like commuting by car, or talking over breakfast with your spouse, can be performed without any conscious input. So why should consciousness be selected by evolution?

Gray's answer is that consciousness works rather like a newspaper: it does not report everything that happens, only the things that are unexpected and unpredictable. In a loop that takes about half a second to complete, he says, he believes "the contents of consciousness perform a monitoring function to check whether the actual and predicted states of the perceptual world match or not." And this continuous activity is where we live.

The other function widely ascribed to consciousness is that of a global workspace. Bernard Baars, a sturdy, bearded Californian, tanned like a hazelnut, claims that consciousness takes place in an area of the brain accessible to all the separate sub-processes of our mind, any one of which may suddenly come to dominate the public arena. The technical details, as with Gray's theory, are hugely complicated. But all these theories, along with ten or twenty others, are still attempts at the easy problems. The fact that consciousness is being approached as a field of scientific study will inevitably change the way that people think about themselves, irrespective of the hard scientific results. The science provides new metaphors. They take on a life of their own. The consequences of people thinking of themselves as soft machines may matter more, in some ways, than the question of whether or not they are soft machines. Take free will, as Colin Blakemore discussed in Tucson. Blakemore, an English perceptual physiologist whose experiments on the eyesight of newborn kittens have made him something of a cause celebre among animal-rights campaigners, argues that free will must be an illusion. What happens in the mind is conditioned by what happens in the brain; what happens in the brain is determined by physical laws. Therefore, if you know the state of the brain at any one moment, you can predict its next state, and its next, and so on. Free will is then exposed as an illusion. If only we knew enough, we could see that all our states of mind are equally conditioned by the brain's physical, law-bound realities.

This position looks like science. If it doesn't feel like the truth, then consider a fact revealed by related psychological research: the brain is great at self deception. We are constantly aware of what is going on in our heads, and much of what we are aware of is false. The process of turning the blooming, buzzing confusion of the world into a coherent story involves a tremendous amount of suppression, distortion and illusion. For instance, there is a well-known experiment in which the subject is wired up to a machine that
monitors the brain, given a button to push and told to push it whenever he feels like it - and
to say whenever he feels the urge to push the button. That's all. It would seem an
untrammelled exercise of free will. Yet the experimenters, watching, know when the
subject is going to push the button before he himself is aware that he is about to, or wants
to; there is a particular burst of electrical activity in his brain half a second before the
subject himself realises that he wants to press the button.

Because of this and similar effects, Blakemore proposes that the distinction between
voluntary and involuntary acts is illusory - no more than "folk psychology", to use the
jargon sneer. This is a view with potentially enormous consequences. David Hodgson, an
Australian judge who has taken a keen interest in the problems of consciousness research,
points out that in his world, the distinction between voluntary and involuntary acts is
essential.

"I think this raises a really hard question for people who want to do away with folk
psychology of voluntary action, belief and intention, and replace it with the concepts of
neuroscience, which have a reputable place in the scientific world of cause and effect,"
Hodgson told the conference. "What do they see as replacing the consent of the woman as
the crucial factor in determining whether an act of sexual intercourse is lawful or non-
lawful? And if they can't give a non-evasive answer to that question, then I think they
should reconsider their programme."

Perhaps the answer could be supplied by the Secret Policeman's Brain Scanner. In the best
traditions of philosophy and computer science, this is a device the efficiency of which is
unimpaired by the fact that it hasn't actually been built; I invented it half way through the
conference. But it is already a very useful tool for examining consciousness researchers. It
consists of a small, portable headset full of clever little scanning widgets, and a screen that
the experimenter can study. It gives a complete readout of the state of the brain at any one
moment, just like a hardware debugger can in silicon. In short, on a personal level, it
answers all Chalmer's easy questions. To some, like Dennett and, it turns out, Blakemore,
the scanner thus answers everything, providing the policeman with better knowledge of the
subject than the subject himself has access to. David Chalmers sees it as less clear cut,
showing "the broad outline of what's going on and the likely behavioural dispositions."

Neuropsychologists, though, turned out to be less sure that the secret policeman's brain
scanner would be useful. There are two main reasons for the scepticism. The first is that
the functional unit of the brain seems not to be the neuron but, instead, networks of
neurons, and that these networks are constantly shifting coalitions, with no more stability
or definition than a cloud of fireflies. What is more, each neuron can be a member of
several different firefly clouds at once, playing different roles in each. Quite precise
regions of the brain can be mapped down as essential to certain functions - usually after a
small localised stroke has stopped the functioning. But memories and ideas appear to be
distributed all over the cortex, linked only by associations that are different in each
individual brain.

Douglas Watt, a neuropsychologist from Quincy, Massachusetts, says that the whole project of the secret policeman's scanner is doomed because our brains are just too complex, too individual. There would be no useful way to interpret the data. Each brain is unique; each has its own genes, its own history, its own consciousness. Even the simplest networks, such as the one in our speech area that recognises a single syllable, may be located a couple of million neurons away in your brain from where it is in mine. Also, the exact location of this syllable switch - not only which neurons are involved but also which other neurons they talk to - will shift over time, particularly if I learn other languages and distinguish more carefully between phonemes. This means that, to be able to use the secret policeman's scanner at a given time, you might have to have been running it throughout the scannee's life. The meaning of a snapshot image would have to be derived from its history; consciousness can only be understood as a narrative.

One does not need a human brain to establish this; the classic experiment uses rats. They were taught to recognise a particular smell, and a wonderfully subtle arrangement of electrodes detected the exact area of the olfactory bulb in their brains which twinkled into life when they did so. So far so good for the secret policeman's scanner; we know that when these particular neurons go off, the rat is conscious of a particular smell. But the next stage lifted the experiment into the realms of genius.

The brain-mapped rats were trained to associate this smell with some other stimulus - a flashing light, or a buzzer, or another of the usual forms of entertainment laid on for laboratory rats. After that training, the rats were once more exposed to the same smell, without the additional stimulus - and this time an entirely different group of neurons fired off. Even to a rat, it seems, there is no such thing as a pure sensation. Everything is stored, and experienced, in relation to other sensations and to emotions. The story of consciousness is one of feelings.

"A recent project at Yale found there was nearly no such thing as an emotionally neutral word," says Watt. "Orienting information supplied by low-level emotion is essential for working memory, and working memory is essential for consciousness. We have two cultural icons, Data and Spock, who are clearly sentient beings, and show better purpose than most of us, and yet claim to have no emotion. I think this is just impossible and these characters are just contradictions in terms."

**One-handed clapping**

If consciousness is built on feeling, then feelings about feelings may prove particularly fruitful in its study. One way to get access to them, as to so many things, is to look at what
happens when things are disrupted; in the brain, this usually means a stroke. Small strokes can explode in the brain like smart bombs, taking out one function, but no more than that. A blood vessel bursting here will rob you of the power of speech; another in a slightly different place will leave you able to speak and hear, but not to understand, language; another will produce "blindsight", a condition in which the patient can actually see things but does not know that he can, and so considers himself blind.

Vilayanur Ramachandran, of the University of California, San Diego, told the Tucson conference about a particularly odd class of stroke effects. His patients are women who have not only been paralysed down one side by a stroke, but have also been robbed by the calamity of the knowledge that this has happened to them.

If someone "normally" paralysed is asked to pick up a tray of drinks, he will use his one good hand to pick it up from the middle. If one of Dr Ramachandran's patients is asked to do so, she will grasp one side of the tray as if her left hand was grasping the other, and lift confidently. "Oh, how clumsy I am" she will exclaim when she spills the tray's contents everywhere. His patients simply cannot see that one of their hands is not taking part in the process. They are lucid in all other respects: they are able to tell him when and where they had a stroke, but simply unable to admit even to themselves that this stroke has paralysed them.

He describes one patient who was convinced that her left hand, which could not move at all, was touching his nose. "I couldn't resist the temptation ... I said, 'Mrs B: can you clap?' "She said, 'Of course I can clap.' "I said, 'Clap!' "She went" (he moves his right hand in a lurching motion through the air to the point where it would have met the left hand). "This has profound philosophical implications," he continues, as laughter ripples round the conference hall, "because it answers the age-old Zen master's riddle - 'what is the sound of one hand clapping?' You need a damaged brain to answer this question." Dr Ramachandran follows his strange findings into unpopular waters. For decades now, nothing could have been more unfashionable in serious academic psychology than Freud. Yet what Ramachandran sees reminds him inescapably of Freudian theories of denial, repression and other defence mechanisms. He believes that the pattern of denial his stroke patients exhibit points to the mind's continuous struggle to produce a coherent picture of the worlds, and to prefer coherence to accuracy - a very Freudian notion.

In Ramachandran's view, the struggle is between the brain's hemispheres. When isolated facts are reported which might upset the mind's currently held view of the world, the reaction of the left hemisphere is to ignore them. Most of the time, this will be the correct response; sensory systems are not perfect. But the right hemisphere carries out the occasional reality check, just to be sure, and if it thinks something's awry, it gets together with the left hemisphere and, quite literally, changes the mind. In stroke patients who cannot recognise their condition this mechanism stops working. The right hemisphere messages never get through and then, he says, "There is no limit to the delusions that the
left hemisphere will engage in."

The condition is not permanent. Though it will reassert itself, it can be dissipated for a few moments by squirting ice-cold water into the ear on the unparalysed side. The effect is easy to miss, because if you squirt cold water into the wrong ear, as Dr Ramachandran did the first time he tried it, you are left with a patient who is confused, and angry that anyone should have squirited cold water without warning or reason into her ear, but still unaware that she is paralysed. But if the water is squirited into the ear of the damaged hemisphere the patient experiences a period of confusion and then about ten minutes when she knows perfectly well that she has been paralysed - cannot imagine not knowing this, in fact. Six hours later, she will have forgotten the whole episode, and once more be convinced that everything is working properly.

Making a Soul

I know how they feel. The Tucson conference was a series of strange perceptions and iced water in the ear, of epiphanies that slide away, never quite recorded.

On that night in the Empire Bar, after Bruce Mangan and David Chalmers had finished their sparring, Patrick Wilken, one of the spectators, turned to me. He is executive editor of Psyche, the most severe of the three journals of consciousness research to have appeared in the last five years. He also moderates the Psyche-D mailing list, one of the few places on the Internet where real work gets done in public. "You realise what all this is about," he said. "We're trying to invent a new soul."

Over the days that statement grew on me. Instead of deep sleep, I could only dream. Instead of dreaming, I would wake up. As I lay in my hotel room in the thin desert dawn, I couldn't see the sky over the mountains, blue and purple like the flank of a rainbow trout. I could only see little pack trains of cholinergic and aminergic neurons trudging up and down my brain, from its roots to its thoughts. One morning I woke up like this but with a jingle in my head, too: "There's a fire that calls me miracle; that will not cause me chemical" - the phrase repeated over and over, up and down a scale like the trudging neurons. I was eavesdropping on my brain trying to make sense of itself. Whoever I was. This exalted, jangling state went on until I began my journey home. Outside Dallas, a razor-cut horizon bled fresh dawn into a new hotel room. And after a night of sleep I woke to find that Patrick Wilken's new soul finally made sense. It was not, as I had thought, the soul of a machine we were trying to make; it was our own souls we were inventing here. I fell back into a sleep rich with dreams.

Andrew Brown (abrown@lazy.demon.co.uk) is a brain in a vat. He believes himself to be
the religious affairs correspondent for The Independent.

Unraveling the Riddle of Identity

Exotic devices that allow the brain to be caught in the act of thinking let researchers explore science's last frontier--the source of human consciousness.

By ROBERT LEE HOTZ, Times Science Writer

I have something in mind--a thought so evanescent that it comes and goes in milliseconds.

To capture it in the act, UCLA neuroscientist Mark S. Cohen has trained on my brain a 22-ton experimental imaging device, twice as powerful as--and 30,000 times faster than--any conventional medical imager. This nuclear magnetic resonance (NMR) imager generates a magnetic field so forceful that, as it pulses and flexes around my head, the room shakes with a 100-decibel pile-driver roar.

Every 50 milliseconds, it captures an image of the physical spark of my imagination at work--and something more.

Only part of my conscious mind attends to the mental exercise that Cohen is recording. The rest is abuzz--worried whether I can perform the task properly, curious about how well my mind will photograph, and wondering most of all about the motives of these scientists who are so intent on the neurobiology of my thoughts.

This irrepressible mental chorus constitutes the background noise in the NMR image Cohen takes of my brain. It is also the core of the most perplexing problem in science: What is consciousness?

The human brain, and the self-awareness that arises from it, is a mystery wrapped in an enigma, swaddled in a tough, protective membrane and sealed inside the skull, unknowable until now except by the most indirect means.

Until recently, only a surgeon ever saw an exposed, living brain. A neuroscientist could learn more about its intangible mental
functions by reading poetry or arguing philosophy than by examining the dead organ on an autopsy table.

Today, scientists have at hand an array of exotic devices that can peer through the skull to catch the living brain at work. Researchers at UCLA and other centers are using them to explore one of the last uncharted territories: the structure and cognitive functions of the human brain.

Emboldened by their ability to capture the image of something as intangible as imagination, a growing number of scientists are trying to study the one thing that many believe cannot be labeled, scrutinized or even defined—human consciousness.

The effort to understand human consciousness is an inquiry older than science itself. It is at the heart of a riddle of identity that has preoccupied philosophers, mystics and theologians for as long as there have been words to frame the query: Who--or what--am I?

Many neuroscientists hope that by studying the neurons of the brain, its genes, sensory perceptions, memory and language systems, they may be able to collect enough information about the way it works to finally discover the organizing principles underpinning all subjective experience.

Consequently, researchers for the first time feel confident enough to frame serious questions about the physical foundations of the human spirit.

How do the physical processes of the brain give rise to subjective experience?

Somehow, the fragile synapses and cells of the human nervous system can perceive the world around them, learn from their perceptions, reinforce memories with the force of emotion, plan ahead, decide and act on incomplete information, as well as sleep, dream, wake and pay attention.

The brain captures its moods in melodies. It invents stock markets, founds religions and orbits telescopes. It is introspective enough to develop psychoanalysis.

"There is something very mysterious about consciousness," said Christoff Koch, a theoretical neurobiologist at Caltech. "Why can objective physical systems have subjective states? It is baffling.

"It gets at the central idea of the soul."

For the human brain, the scientific investigation of consciousness is the beginning of an unusual journey of self-discovery.

"We are trying to understand who we are by studying the organ that allows you to understand who you are," said Antonio Damasio, an expert at the University of Iowa on the brain, cognition and
behavior.

"Consciousness," said David Chalmers, a cognitive scientist and philosopher at UC Santa Cruz, "is the last frontier of science."

Chemistry and Electricity

Unraveling the nature of consciousness, however, is a problem too daunting for any one scientist to address in its entirety.

Instead, researchers are teasing apart isolated neural processes, such as how the brain perceives color or how neural cells focus attention, in the hope that they can gather evidence of how a conscious mind is assembled from different brain processes.

On scores of university campuses, scientists trace the ebb and flow of chemicals that trigger brain functions, the blood flows that nourish them and the electrical patterns they generate. They are trying to catch the mind in the act of being.

* As they pull together new insights into how the brain functions, a growing number of neuroscientists believe that the mental processes underlying consciousness arise from an intricate madrigal of two languages--chemistry and electricity--communicated through networks of millions of neurons, all orchestrated precisely in time.

"We are the activity of the neuronal machine," said Rudolfo Llinas, an expert at New York University on the brain and cognition.

For the first time, researchers are identifying the connections between the brain's physical anatomy and the mechanisms of perception, learning and other, higher cognitive functions.

Investigators are beginning to understand how experiences can lodge permanently among millions of scattered neurons--to be revived in milliseconds by the smell of a baking pastry, a familiar melody or a photograph.

Memory is more complicated than anyone had imagined.

Researchers such as Larry Squire at UC San Diego have discovered that the brain harbors many independent systems of memory, while Erin Schumann at Caltech and her colleagues are revising ideas of how knowledge is retained in the chemistry of nerve cells.

Scientists have determined that the brain handles memories of events and emotions differently than memories of ingrained habits and tasks.

Short-term memories are fundamentally different from long-term memories and may be forged in entirely different ways. False memories appear to be handled differently in the brain than memories based on true events, brain scans suggest.

Memory's unexpectedly intricate arrangements mirror those of
other neural systems involved in the operations of a conscious mind.

Until recently, most scientists believed that language was handled by the left side of the brain. But the mechanisms of language are much more decentralized than previously thought. And the way the growing brain handles language is much more flexible than previously believed, research by Elizabeth Bates at UC San Diego suggests.

Names of animals and names of tools are handled by largely separate brain regions, other scientists discovered. Knowledge of the concepts they describe is stored in another discrete system.

The words, syntax and concepts of a person's native tongue are stored so separately from any language learned later in life that a stroke can knock out the ability to speak one but not the other.

By highlighting nuances of brain functions, sophisticated biomedical sensors offer glimpses of tantalizing relationships between physical brain structures and conscious mental activity:

* Subtle differences in brain anatomy appear to affect the ways men and women process information, even when thinking about the same things, hearing the same words or solving similar problems.

* The most efficient brains appear also to be the smartest, with the brains of those with the highest IQs using the least energy. Learning and practice appear to improve the brain's efficiency.

* Small structural abnormalities appear to develop in the brains of people with Alzheimer's disease or Huntington's chorea long before any noticeable behavioral symptoms can be diagnosed.

* Minor alterations in neural circuits for vision and hearing may be responsible for dyslexia, while brain abnormalities in regions involved in inhibiting mental activity could be the cause of attention deficit hyperactivity disorder, which affects about 5% of school-age children.

But the search for clues to consciousness leads down stranger alleys.

From nature's own experiments--the victims of disease and brain injury--neurologists are obtaining glimpses into the workings of the conscious mind by seeing how defects twist its usual attributes.

* What is one to make of an otherwise normal man--a victim of a rare mental disorder called Charles Bonnet syndrome--who occasionally sees leprechauns, the amputee who thinks he is holding a cup in the hand he no longer has, or the engineer who
sees Technicolor cartoon characters cavorting in a blind spot in her visual field.

Stranger still are victims of a mental disorder called associative agnosia, who easily can draw any object but cannot recognize what it is, or those with "blindsight," whose sense of sight functions normally but who cannot make themselves consciously aware of what their eyes see.

Why should brain damage leave one woman unable to name animals, but able to name any other object?

From these and dozens of other hints, researchers today are identifying the puzzle pieces of the brain, yet they are far from understanding how they fit together into the cohesive whole of the human mind.

"Why does all this processing give you an inner life?" asked UC Santa Cruz's Chalmers. "Why is it that these processes should give rise to the consciousness in the first place?"

Our Uniquely Human Self-Consciousness

Some researchers argue that consciousness in some form may extend beyond humans to other species.

Each human mind may be unique, but all its higher cognitive functions take place in a brain closely resembling those of more primitive primates such as apes and chimpanzees, say experts in neural evolution.

The human brain appears to have no unique cells, chemicals, neural circuits or major anatomical structures, experts said. All the known differences are a matter of degree.

Other species can plan ahead based on experience, combining sensory stimuli, attention and short-term memory. Nor is the human mind unique in its ability to form concepts, some researchers contend. Even pigeons appear to be able to sort objects into categories and recognize abstract relationships.

What seems to distinguish human consciousness is its subjective self-awareness--the feeling of being "me."

And that is where most scientists throw up their hands in frustration, because human self-awareness is itself the best, and perhaps only, evidence of its existence: I know I have a mind because I have a mind that is aware of itself.

"How do you explain this quantum leap in control over the mind in humans, with basically the same machinery you have in monkeys?" asked neurobiologist Martin C. Sereno at UC San Diego. "People just have more control over what is going on in their heads--for better or worse."

*
There is no shortage of new theories from scientists and philosophers trying to account for the novelty of human consciousness.

Some contend that consciousness is the byproduct of a Darwinian tooth-and-claw competition between mental states trying to dominate behavior.

On the other hand, Oxford University mathematician Roger Penrose proposed that consciousness must be a property of abstruse particle physics operating inside brain cells. Free will, he contends, must arise from the random character of quantum mechanics--a rolling of the subatomic dice.

Some experts in artificial intelligence conclude that consciousness is nothing more than sophisticated computer-like information processing. Special mental switching areas integrate all the brain's perceptions into a sense of self, they suggest.

Indeed, if the raw meat of the human brain can develop consciousness, they speculate, why can't the silicon of integrated computer circuits?

Neuroscientists like Sereno and philosophers like Daniel Dennett at Tufts University believe that language is one essential prerequisite for the development of higher consciousness. How, after all, can a brain be self-aware if it cannot talk to itself?

Damasio thinks they have it backward. In his view, language developed well after the onset of awareness. The brain harbored a sense of self long before it had a word to name it, he said.

"If you look at a chimpanzee, I have no doubt it has a sense of self, just not as rich as yours or mine," he said. "What we have is enriched by a spectacular memory of our past and by a memory of the plans of our future, combined with the fact that we automatically translate whatever we think into language.

"That is truly, uniquely human."

However intoxicating the theoretical possibilities, Nobel laureate Francis Crick at the Salk Institute in La Jolla insists on keeping his ideas about consciousness tied as closely as possible to what can be measured in a laboratory.

"There was too much talk and not enough experiments, from my point of view," he said. "You really want new experimental data and to not get into too many highfalutin arguments about the nature of consciousness."

* 

In Crick's view, the sweeping question of human consciousness is too large to study. Instead he has teased off a more manageable piece of the problem.
With his collaborator Christoff Koch, Crick is looking for the neural mechanisms underlying visual awareness.

They are considering the role played by special neural cells in the higher visual cortex. Some cells respond to straight lines while other cells react to color, movement or even faces. To assemble a coherent image, rich with all the sensory impressions, memories, knowledge and emotions it conjures, these separate visual cells must somehow link up to all the other neurons that relate to what the eyes are seeing.

At the highest levels of this process, Koch and Crick believe, some cells must respond to the unified perception assembled from so many other active brain cells. It is those special cells, they speculate, that make someone "conscious" of what the brain has perceived.

"People think consciousness must arise from the incredible complexity of millions of interconnected neurons," Koch said. "We don't think it is pushing the envelope to say there are specific neurons that give rise to consciousness."

Theater of the Mind
The scanner has finished imaging my brain.

My head, still enveloped in an imaging cradle, slides out of the massive machine like a spent artillery shell.

The experiment was deceptively simple.

I had been asked to tap the fingers of my right hand together slowly, then quickly, then more slowly again. Then I was asked to imagine doing the same tasks.

The machine recorded my brain functions by tracking minute variations in the scanner's magnetic field caused by alterations in neural blood flow.

It takes Cohen, who helped design the scanner, hours on a high-speed computer to transform those thousands of individual measurements into a picture of the brain that a human eye can comprehend.

Projected on a color monitor, the scans yield rows of wrinkled raisin-shaped images of my brain. Daubs of bright color highlight the regions that became active when I physically moved my fingers and those regions that became active when I imagined the same action.

Both tasks--real and imagined--lighted up the same areas of the brain responsible for movement.

At some fundamental level, thinking about an action and performing it appear to be almost the same.

"To me that is a fascinating response," said Cohen. It runs
"counter to everything I was expecting."

The images his machine creates appear to draw a direct connection between the inner life of the mind and the physical mechanisms of the brain.

"In a sense, this kind of functional imager . . . allows me to study covert mental activity--in essence, thought," he said.

Other recent imaging studies of brain function reinforce the relationship between conscious mental states and the physical structures of the brain:

* When mental patients hallucinate and hear imaginary voices, those portions of their brain responsible for hearing respond as if the voices were real.

* When people are asked to picture a map of the United States in their mind, their brains respond as if they were looking at an actual map, activating that part of the cortex responsible for vision.

* When people are asked to picture an object and then rotate it mentally, their brains act as if the object were turning in front of them.

One surprising thing about these images of perception is that they do not show where or how the mind's eye is focused in the brain.

Subjectively, perceptions always appear seamlessly, presented in the mind as an integrated whole. But these scans showed no sign of an active anatomical area where sensory stimuli were coordinated and collated.

So how is consciousness organized in the physical structures of the brain?

To Cohen, the images suggest that consciousness is itself the act of attention.

As the brain evolved, it must have developed a way to focus itself selectively; otherwise, the constant burble of brain activity and sensory perceptions would overwhelm it. In this theory, consciousness may arise from the brain's need to concentrate, momentarily highlighting some neural activities at the expense of others.

Consciousness therefore may not be continuous, Llinas of New York University suggested.

It may flicker on and off as needed, like a spotlight flashing in the darkened theater of the mind.

An Elusive Quarry

Some scientists contend that consciousness emerges from the union of all the brain's physical properties, the way a rainbow arises from the interplay of light, suspended water droplets and air.
If that is the case, they argue, scientists will never find the human mind no matter how hard they scrutinize the brain's physical structure, any more than someone will find a rainbow in any one of its scattered parts.

Indeed, Chalmers believes scientists will discover eventually that human consciousness is an irreducible quality of the universe, like space, mass or time.

"Instead of trying to explain consciousness purely in terms of its physical processes, you should take it as a fundamental entity in its own right," he said.

"We would like a unified theory of consciousness in the same way that physicists are searching for a unified theory of matter," he said.

Some worry that by reducing human consciousness to its biological components, scientists will tarnish the worth of the human spirit or undercut ideas of personal responsibility and free will. But other researchers believe that a more detailed understanding of the brain will only enhance individual self-respect by affirming the uniqueness of each human mind.

"You will understand," said Nobel laureate Gerald Edelman at the Neurosciences Institute in La Jolla, "why your individuality is important."

In some ways, the search for the roots of human consciousness stands much of traditional scholarly inquiry on its head.

Scientists who, by temperament and training, devote their lives to the collection of objective facts about the universe around them are forced to grapple with the imponderables of the world within.

Researchers who are trained to exclude the human element from experiments discover that the human element is the experiment.

Philosophers, more accustomed to purely metaphysical speculation, are now expected to buttress their ideas with hard data.

All of them feel caught up in a uniquely human endeavor that--for better or worse--promises to alter forever humanity's sense of itself.

**

THE BRAIN: A WORK IN PROGRESS

A growing number of scientists are trying to study the one thing that many believe cannot be labeled, scrutinized or defined--human consciousness.

THE SEARCH FOR UNDERSTANDING

'There is something very mysterious about consciousness. Why
can objective physical systems have subjective states? It is baffling. It gets at the central idea of the soul.'

--Christoff Koch, a theoretical neurobiologist at Caltech.

THE CHALLENGE

'We are trying to understand who we are by studying the organ that allows you to understand who you are.'

--Antonio Damasio, an expert at the University of Iowa on the brain, cognition and behavior

GLOSSARY

Cortex:
Where most high-level functions associated with the mind are implemented. Some of its regions are highly specialized. For example, the occipital lobes located near the rear of the brain are associated with the visual system. The motor cortex helps coordinate all voluntary muscle movements.

Cerebral hemispheres:
Symmetrical halves of the brain. There are two occipital lobes, two parietal lobes and two frontal lobes. The two hemisphere are in continual communication with each other. Each acts as an independent parallel processor with complementary functions.

Left cerebral hemisphere:
Appears most closely associated with a conscious self. The left hemisphere, which usually manages the right side of the body, controls language and general cognitive functions. It dominates in deciding what response to make.

Right cerebral hemisphere:
Controls the left half of the body. In most people it manages nonverbal processes, such as attention, pattern recognition, line orientation and the detection of complex auditory tones.

Frontal lobes:
Located behind the forehead. They are most closely linked with making decisions and judgments.

Limbic system:
A number of interconnected brain structures linked to hormones, drives, temperature control, emotion, and, in one part, to memory formation. Neurons affecting heart rate and respiration appear concentrated in the hypothalamus and direct most of the physiological changes that accompany strong emotion.

Hippocampus:
Plays a crucial role in processing various forms of information as part of long-term memory. Damage to the hippocampus will produce global retrograde amnesia, or the inability to lay down new stores of information.
* * *

About This Series

Who are we? Where did we come from? While many scientists search for clues to these ultimate questions by probing the far reaches of the universe, others think the answers lie inside our own heads. Their probes are uncovering galaxies of neural cells, each twinkling with the brain's life forces. As it orchestrates human behavior, this symphony of electrochemical communication may indeed constitute our very essence.

Sunday: The explosion of knowledge in the field of brain development, where researchers are finding that those first few years of life are far more critical than anyone had guessed.

Monday: New technology is uncovering the brain's prominent role in emotions.

Tuesday: How brain researchers are overturning traditional ideas about mental illness.

Today: Human consciousness.

Special Internet Site

Beginning today, a special section of The Times' World Wide Webb will be devoted to information about the human brain. The full text, photos and graphics from this four-part series will be available, plus a wide range of additional information and graphics prepared especially for the Internet. Point your Web browser to: http://www.latimes.com/thebrain

Consciousness Studies: From Stream to Flood

By JAMES GORMAN

NEW YORK -- At a small restaurant on West 70th Street in Manhattan, Dr. Piet Hut, an astrophysicist at the Institute for Advanced Studies in Princeton, N.J., has pushed aside his French toast to draw a quick sketch of objective and subjective reality. His drawing, on a yellow pad, shows a stick figure, a chair, the stick figure's experience of the chair, the stick figure's experience of itself and the stick figure's understanding of its experience of the chair and itself.

This is not an unusual moment in the current state of the scientific study of consciousness. Everybody from neuroscientists to philosophers to physicists is in the game. And the arena of investigation ranges from high-tech brain imaging centers to breakfast brainstorms, from monkey experiments to thought experiments.

The debate is still open as to whether the problem of consciousness -- how felt experience is connected to the physical brain -- is purely philosophical, an illusory difficulty that will be swept away by progress in neuroscience, or one that requires a revamping of all of science, starting with physics, which is what Hut is suggesting.
Whatever the approach, the stream of consciousness studies, rising for more than a decade, seems to be reaching flood stage. Dr. Daniel Dennett, a philosopher and director of the Center for Cognitive Studies at Tufts University, was asked by The Quarterly Review of Biology to review some recent books on the subject. He counted 34 in the last six years, "not including the awful ones, or those by journalists" (or those by Dennett himself), and decided there were just too many. He put the project off.

Two scientific journals on consciousness have been started in recent years. A 1995 Massachusetts Institute of Technology Press book, a 1,447-page compilation of articles titled "The Cognitive Neurosciences," is in its fourth printing and has sold 9,000 copies. The book weighs eight pounds and costs $95. This spring and summer there are major conferences on consciousness in Montreal and California. "The scientific race for consciousness is on," writes Bernard Baars, a psychologist at the Wright Institute in Berkeley, Calif., in one of those new books, "The Theater of Consciousness" (Oxford University Press). If it is a race, it is an unconventional one in which neither the starting line nor the finish have been agreed on. The arguments are not only over answers to questions, they are over what the questions should be, and what the terms of the discussion mean. Neuroscientists, psychologists and philosophers, along with the odd physicists and anesthesiologist all have opinions and a stake in finding out what exactly goes on in that elusive, internal space where a person thinks, feels and wonders about everything from what kind of pizza to order for dinner to what exactly it means to "wonder."

The result is a field, or rather an effort to create a field, which is "boiling" with activity, says Dennett, the author of several books on consciousness, including the recent "Kinds of Minds" (Basic Books) and one of the main figures in debates about the mind. The intensity of current interest is "almost ridiculous," he said. And the disagreements are so large that the pursuers of consciousness sometimes dismiss each other with a wave of the hand.

David Chalmers, a philosopher at the University of California at Santa Cruz, and author of another new book, "The Conscious Mind: In Search of a Fundamental Theory" (Oxford University Press), says the situation reminds him of "physics 500 years before Newton" at a point when the intellectual vocabulary was not available to talk about things like gravity. Of course, even on that point there is disagreement. Baars says the situation is now like that right at the time of Newton, when gravity was beginning to be isolated and understood.

The players do agree that they disagree. Dr. John Searle, a philosopher at the
University of California at Berkeley, who panned Chalmers's new book recently in The New York Review of Books, a traditional jousting ground for academics, said that in the attempt to study how the physical brain and conscious mind are related, "there's no unifying principle," adding, "We're just thrashing around in the dark."

Dr. Michael Gazzaniga, a neuroscientist who started Dartmouth College's Program in Cognitive Neuroscience, said the most outrageous ideas were now reasonably discussed (he mentioned some offered by physicists), and suggested, "The reason they can get away with it is that nobody has a clue."

And among those physicists who have decided to join the fray, both Dr. Roger Penrose at Oxford and Hut say that all of science needs to be shaken up. Of course, they differ slightly in how it should be shaken up, but they both agree that modern science, as constituted, is not prepared to grapple with the conscious mind.

There are two levels of problems being solved in the pursuit of consciousness. On one level, where there is much less sound and fury, the wiring of the brain is being studied, the activity of the brain is being glimpsed in new kinds of imaging techniques and experiments are being done on animals to separate conscious from unconscious activity in the brain.

Scans of the brain, for instance, enable scientists to watch people talk to themselves, silently. Both the center for control of vocal activity and the center for analyzing speech are active while the subject says, silently, something like: "Why am I getting my brain scanned? I could be getting my hair done. What if they don't see anything happening?"

No one doubts that over the next 10 or 20 years, a much clearer picture will emerge of what happens in the brain when people, and presumably animals, have conscious experiences. But that still leaves the old, big questions that have troubled philosophers and undergraduates since there have been philosophers and undergraduates, questions like: When you talk to yourself, who talks and who listens?

And on this level, whether there is a difference between mental experience and brain activity, for instance, disagreements are dismayingly large, and on occasion blunt beyond the normal bounds of scientific discourse. In an interview, Searle said that Dennett and Chalmers were both making the "same dumb mistake" in assuming that the terms of this question were valid.
(They come up with different answers; Chalmers finds a distinction and Dennett does not.) And although his physics is respected and his books attract popular attention, almost everyone else who has a stake in consciousness dismisses Penrose out of hand. Steven Pinker at MIT, who has a much anticipated book coming out this fall from W.W. Norton, "How the Mind Works," says, "Penrose is not even in the ball park."

Penrose, on the other hand, can dismiss most of what passes for activity in neuroscience as hopeless. His contention is that something other than the computer model must be used. And he says, "The trouble with John Searle is, I don't think, although I've talked to him quite a bit, I never felt that he really grasped what a noncomputational system is. I don't think he's really got that on board yet."

Sometimes it seems like a free-for-all. Dennett said in an interview, chuckling, that "one of the really refreshing discoveries of the last few years was the advent of physics getting into the act," because it proved that "there's a discipline that is even more ignorant about the brain and even more arrogant than philosophy."

Among the several positions held about consciousness and the self, Dennett and many others believe consciousness is simply what the brain does, a process, like life or growth, not a great philosophical problem. Gazzaniga believes that it is indeed something the brain does, but he offers a location for the self, an "interpreter module" in the left cerebral cortex. Some philosophers say the whole notion that activity in the brain can account for subjective experience is naïve and unacceptable.

The headier discussions are worrisome to some more traditional neuroscientists. Dr. Francis Crick, who won the Nobel Prize for his discovery with Dr. James Watson of the structure of DNA, has attracted many neuroscientists to the field with his forays into the subject of the mind. But he said at a recent talk that he wished journalists would stop writing about consciousness.

Dr. Christof Koch, a neuroscientist at the California Institute of Technology, said the interest in consciousness "might be too much of a good thing." He and others say that there is essentially no progress on the more difficult philosophical problems of self-awareness, and that the concentration should be in hard experimental studies on subjects like visual perception.

"We're going to be called to the table in 5 or 10 years," said Koch, and the
current fascination with the mind could well fade, as it has in the past, and research support with it. Chalmers said, "If the results aren't delivered in a few years someone might say, well, there was this consciousness craze in the 1990's and look what came of it."

If all goes well, said Chalmers, himself a philosopher, scientific interest in consciousness will continue to increase, and the problem will move further and further away from philosophy as it gets closer to being solved.

Chalmers remarked, "I'd hate for it to go the other way."

Online papers on consciousness, part 1: Philosophy of consciousness

Compiled by David Chalmers

Part 1 of Online papers on consciousness

- Part 1: Philosophy of consciousness
- Part 2: Other philosophy of mind
- Part 3: Science of Consciousness

TABLE OF CONTENTS [368 papers]

- The concept of consciousness [26 papers]
- The explanatory gap [33]
- Materialism and dualism [29]
- The knowledge argument [16]
- Materialism and modality [29]
- Metaphysics of consciousness [33]
- Panpsychism [11]
- Zombies [18]
- Qualia, color, etc. [39]
- The contents of consciousness [20]
- Representationalism [17]
- Consciousness as higher-order thought [23]
- Introspection, self-knowledge, and self-consciousness [28]
- The unity of consciousness [11]
- The function of consciousness [18]
- Philosophy of consciousness (misc.) [23]

The Concept of Consciousness

- Michael Antony, Outline of a general methodology for consciousness research
- Michael Antony, Is "consciousness" ambiguous?
- Ned Block, On a confusion about a function of consciousness
- David Chalmers, Availability: The cognitive basis of experience?
- Austen Clark, Phenomenal consciousness so-called
- Ronnie de Sousa, Twelve varieties of subjectivity
- Eric Gillett, Searle and the "deep unconscious" (and Dan Lloyd's commentary)
- Alvin Goldman, Consciousness, folk psychology, and cognitive science
The Explanatory Gap

- Marcus Arvan, Out with qualia and in with consciousness: Why the hard problem is a myth
- Giorgio Ascoli, Is it already time to give up on a science of consciousness?
- Ned Block, The harder problem of consciousness
- Ned Block and Robert Stalnaker, Conceptual analysis and the explanatory gap
- Peter Carruthers, Consciousness: Explaining the phenomena
- David Chalmers, Facing up to the problem of consciousness
- David Chalmers, Moving forward on the problem of consciousness
- David Chalmers, The puzzle of conscious experience
- David Chalmers and Frank Jackson, Conceptual analysis and reductive explanation
- Patricia Churchland, The hornswoggle problem (and Chalmers' reply)
- Austen Clark, How to respond to philosophers on raw feels
- Austen Clark, I am Joe's explanatory gap
- Tom Clark, Function and phenomenology: Closing the explanatory gap
- David de Leon, The limits of thought and the mind-body problem
- Daniel Dennett, Facing backwards on the problem of consciousness (and Chalmers' reply)
- James Garvey, What does McGinn think we cannot know?
- Brie Gertler, The explanatory gap is not an illusion
- Brie Gertler, Explanatory reduction, conceptual analysis, and conceivability arguments about the mind
Materialism and Dualism

- Torin Alter, Nagel on imagination and physicalism
- John Beloff, What are minds for?
- John Beloff, The mind-brain problem
- Glenn Braddock, Against Chalmers' epiphenomenalism
- Selmer Bringsjord, Searle on the brink
- David Chalmers, Consciousness and its place in nature
- Andrew Chrucky, Critique of Wilfrid Sellars' materialism
- Rene Descartes, Meditations on First Philosophy
- John Hubbard, Parsimony and the mind
- Peter J. King, Dualism: An empirical test
- E.J. Lowe, Self, agency, and mental causation
- Peter Lloyd, Is the mind physical? Dissecting conscious brain tissue
- Marvin Minsky, Minds are simply what brains do
- Marvin Minsky, Matter, minds, and models
- Barbara Montero, The body problem
- Barbara Montero, Post-physicalism
- Hans Moravec, Dualism through reductionism
- David Papineau, Thinking about Consciousness
- David Papineau, The rise of physicalism
- Thomas Polger, Escaping the epiphenomenal trap
- Karl Popper, Language and the body-mind problem: A restatement of interactionism
- Karl Popper, A note on the body-mind problem
- Howard Robinson, Materialism in the philosophy of mind
The Knowledge Argument

- Torin Alter, *The knowledge argument*
- Torin Alter, *Know-how, ability, and the ability hypothesis*
- Laurence BonJour, *What is it like to be human (instead of a bat)?*
- Alex Byrne, *Something about Mary*
- Max Deutsch, *Subjective physical facts*
- Brie Gertler, *A defense of the knowledge argument*
- Frank Jackson, *Epiphenomenal qualia*
- William Lycan, *Perspectival representation and the knowledge argument*
- Thomas Nagel, *What is it like to be a bat?*
- David Rosenthal, *Reductionism and knowledge*
- Fredrik Stjernberg, *Not so epiphenomenal qualia*
- Nigel Thomas, *Mary doesn't know science: On misconceiving a science of consciousness*
- Michael Tye, *Knowing what it is like: The ability hypothesis and the knowledge argument*
- Adam Vinueza, *The knowledge argument (and another)*
- Sven Walter, *Terry, Terry, quite contrary*

Materialism and Modality

- Murat Aydede & Guven Guzeldere, *Consciousness, conceivability arguments, and perspectivalism*
- Katalin Balog, *Conceivability arguments, or revenge of the zombies*
- Alex Byrne, *Cosmic hermeneutics*
- David Chalmers, *Insentience, indexicality, and intensions (review of Perry)*
- David Chalmers, *Materialism and the metaphysics of modality*
- David Chalmers, *Mind and modality*
- David Chalmers, *The nature of epistemic space*
- David Chalmers, *Does conceivability entail possibility?*
- Adam Elga, *A conceivability argument*
- Ivan Havel, *Living in conceivable worlds*
- Christopher Hill, *Chalmers on the apriority of modal knowledge*
Mark Johnston, It necessarily ain't so
Navin Kartik, In the hands of zombies
Brian Loar, Phenomenal states
Farid Masrour, Are zombies positively conceivable?
Farid Masrour, Taking Kripke seriously
Wallace Matson, Logical possibility, laws of nature, and mind in the history of philosophy
Thomas Nagel, Conceiving the impossible and the mind-body problem
Matthew Phillips, Why positive and negative conceivability can't save the conceivability-possibility link
Paul Raymore, A materialist response to David Chalmers' The Conscious Mind
Robert Stalnaker, On considering a possible world as actual
Ralph Wedgwood, The price of nonreductive physicalism
Stephen White, Why the property dualism argument won't go away
Crispin Wright, The conceivability of naturalism
Stephen Yablo, Concepts and consciousness
Stephen Yablo, Coulda, woulda, shoulda
Stephen Yablo, Modal rationalism and logical empiricism: Some similarities
Stephen Yablo, Textbook Kripkeanism and the open texture of language
Stephen Yablo, Grokking pain

Metaphysics of Consciousness

Sophie Allen, A space oddity: McGinn on consciousness and space
John Bolender, Factual phenomenalism: A supervenience theory
C.D. Broad, Mind and Its Place in Nature
Dan Bruiger, The rise and fall of reality
David Chalmers, Consciousness and cognition
Fergus Duniho, The mind/body problem and its solution
Ed Feser, Hayek's solution to the mind-body problem
Richard Gale, William James on the misery and glory of consciousness
Rom Harre, Nagel's challenge and the mind-body problem
Dan Hutto, An ideal solution to the problem of consciousness
Ted Honderich, Consciousness, neural functionalism, and real subjectivity
Ted Honderich, Functionalism, identity theories, the union theory
Piet Hut & Bas van Fraassen, Elements of reality: A dialogue
William James, A world of pure experience
Mark Johnston, The Manifest, Chapter 1 (also Chapter 5, Chapter 7)
Peter Lloyd, Berkelian ontology as a fundamental approach to consciousness
- Michael Lockwood, *The grain problem*
- Ron McClamrock, *Irreducibility and subjectivity*
- Colin McGinn, *Consciousness and space*
- Paul Meehl & Wilfrid Sellars, *The concept of emergence*
- Anil Mitra, *Problems in the science and philosophy of mind and consciousness*
- David Newman, *Chaos, emergence, and the mind-body problem*

VISION IN A COMPLETE ACHROMAT: A PERSONAL ACCOUNT

By: Knut Nordby

INTRODUCTION

Being myself a vision scientist who is also a complete achromat, I have, upon demand from friends and collaborators, taken on the task of trying to convey some of my visual experiences and to explain how I cope with my visual handicap. I rely on recollections, both my own and those of my family, and try to separate information that can be documented or is supported by other sources from the mere anecdotal. I also draw on information from interviews with other achromats, but only to supplement or comment on my personal experiences.

My recollections may have become distorted over time, they may not be precise and may also be biased - and they may not, in all cases, apply to other achromats. It is my hope, though, that my account will give both vision scientists and the general reader a glimpse, not only into the manifestations of achromatopsia and rod-vision - topics usually not covered by the learned papers - but also into the practical problems and obstacles encountered by a completely colour-blind person.

A SHORT BIOGRAPHY

Infancy.

I was born on November the 11th, 1942, in Oslo, Norway, as the first child of Kjell Nordby (28.11. 1914 - 30.3.1987) and Mary Camilla Nordby, nee Bredesen, (born 21.12.1914). The pregnancy was normal and the birth went well. My birth-weight was 3845 g and my length 510 mm. There is some early written and photographic documentation showing that, on the whole, I was a healthy baby who seems to have developed normally and, except for a stenosis of the pylorus which was quickly cured, I gave my parents little cause for alarm during the first six months of my life.

Both my parents were born with normal vision and, indeed, excellent colour-vision. I tested both with the Ishihara and the Msterberg pseudo-isochromatic plate tests, and I also tested my father with the Farnsworth 100 Hue test. They both performed normally. I have one sister (born 8.10.1943) and one brother (born 5.10.1945) who are both, like myself, typical, complete achromats, confirmed by the anomaloscope.

There is no evidence of consanguinity between my parents, although the possibility cannot entirely be ruled out. My paternal and my maternal grandmother both came from the same small coastal town in
southern Norway, but nothing is known with certainty about any relationship between the families. If there is any relationship, it must be at least four generations removed (see Fig. 1).

The prevailing view, then and now, is that typical, total achromatopsia with reduced visual acuity is a recessive, autosomal (i.e. not linked to the pair of X-Y- or sex-chromosomes) inherited condition. The statistical probability, according to Mendelian laws of inheritance, of all three siblings inheriting and displaying a recessive trait from parents who do not exhibit the phenotype is exceedingly small. On the average, and assuming that only one gene is responsible, only one child out of four from heterozygous parents will be homozygous for and display a recessively inherited trait.

No documented case of achromatopsia is known to have existed in either branch of my family. There are, however, rumours of an aunt of my materna grandmother who, reportedly, had "very weak eyes" and "rarely ventured out-of-doors in full daylight. Despite the suggestive symptoms, such ,nedcotal evidence cannot be accepted to infer a bona fide case of achromatopsia, since no ophthalmological report is known (it is most improbable that any medical assessment of her eyes was ever performed), and her symptoms can be attributed to several other causes (e.g. retinitis pigmentosa from diabetes).

According to my parents, I could control my eyes and direct my gaze even at the age of three weeks. Photographs taken of me only a few weeks after birth show me with fully open eyes and not a trace of squinting, or partial closing of the eyes, in bright light (see Fig. 2). Nothing unusual was recorded at the time about my visual behaviour (i.e. light aversion or "photophobia') or eye-movements (i.e. nystagmus).

Due to enemy actions in Norway, my parents fled with me to Sweden in May 1943, when I was only 6 months old. One to two months later my parents began noticing that I had developed some strange symptoms. My eyes had started to quiver from side to side (i.e. horizontal, pendular nystagmus) and my eye-movements were irregulnr. I had begun to blink continuously and partially close my eyes, or squint (looking through the narrow slits between the eyelids), in bright light, and I habitually avo"ided bright light, something I had not done before. Earlier, according to my mother, I had sometimes even looked straight into the sun with no signs of distress, and she often had to turn me around, being worried that I would damage my eyes. This special behaviour has also been reported to me spontaneously by the mothers of several other achromats. One mother, in fact, believed that this habit of gazing into the sun had harmed her son's eyes and was the actual cause of his achromatopsia and low visual acuity.

After seeing several general practitioners and some ophthalmologists, who could offer no explanation for the symptoms, my parents finally consulted a prestigious professor in ophthalmology (no-one in the family can now recall his name). Hereditary achromatopsia totalis [i.e. total colour-blindnessl with concomitant horizontal pendular nystagmus, light aversion, and reduced visual acuity was diagnosed. He also found that I was hypermetropic with a slight astigmatism. At an age of only nine months I thus received my very first pair of spectacles. As far as can now be established these first lenses had a strength of about +3 diopters and had a 1 diopter vertical cylinder.

My parents were told that I was severely visually handicapped, that I was totally colour-blind and that my
visual acuity was so low that I would never be able to read and write. They were also told that I would have to attend institutions for the blind and learn to read Braille, and, at best, could be trained for one of the traditional vocations for the blind (e.g. piano tuner, Telephone switch-board operator, etc.). As it happens, the authority was disproved in some of his predictions by the course of events, but I am getting ahead of myself.

After hostilities ended my parents decided to stay in Sweden. Because of my father's work we moved many times; living in Stockholm, in Gothenburg, in the small town Treboda and again in Stockholm; until the summer of 1954, when his work took us to Caracas, Venezuela. There we stayed four years, until the summer of 1958, after which we returned to Norway and settled in Oslo.

**Early childhood.**

My first clear memories seem all to be connected with nights and evenings, or they occur indoors in subdued lighting. As far back as I can remember, I have always avoided bright light and direct sunlight as much as possible. Photographs taken of me, and my siblings, during our childhood normally show us with nearly shut eyes, usually looking away from the sun, except when photographers demanded that we look towards the sun for the pictures (see Fig. 3). As a child I preferred playing indoors with the curtains drawn, in cellars, attics and barns or outdoors when it was overcast, in the evenings, or at night.

This, of course, was quite the opposite of what well-meaning parents and grown-ups considered to be right for children. My whole childhood was, in fact, a continuous struggle against the prevailing views about what is proper for children, i.e. being out in the sunshine as much as possible, not playing outdoors after it is dark, not drawing the curtains during the day, not playing in cellars and other dark places, and so on.

It soon became apparent to my parents that the learned ophthalmologist was correct insofar as I was completely colour-blind. My father told me that he had noticed that when sorting my coloured playing blocks in day-light I usually put the red and the black blocks together in one pile, the green and the blue ones in another pile, the yellow were usually, but not always, put in a pile by themselves, and so were the white. Indoors in artificial lighting, on the other hand, I sometimes separated the red and the black in different piles, but frequently confused the green and the blue blocks; the yellow and the white blocks, though, I still put in separate piles.

When using colouring pencils or crayons, I am told, I always confused the colours, breaking all the conventions and "rules" about what were the "correct" colours to use: I would happily colour the sky light green, yellow or pink; the grass and leaves orange or dark blue; the sun white or light blue, and so on. I was always corrected in my choice of colours by those who knew better, and, eventually, I gave up painting and colouring my drawings. Unfortunately no coloured drawings from my early childhood seem to have survived.

When I was five we were living in Gothenburg, and from then on my recollections are much clearer. At this time my circle of activity expanded beyond the limits of the house and the garden and into the near
parts of the town. I then developed a system for finding my way back, which I still use. The city-block was the basic unit in my system. I always kept myself orientated where I was on the block. When going further away the system consisted of counting the streets I had crossed, keeping count of right and left turns, counting doors or shops along a block, thus forming a mental, topological map of my path. When returning I reversed direction, retracing my path, making turns in the opposite direction, and counting backwards the streets I had crossed.

I also learned to make use of various prominent landmarks, e.g. parks, squares, churches, towers, underpasses, bridges, etc., as important checkpoints along the route. Even today, I find it much easier to orientate myself in cities with rivers, canals, tramways, overground railway lines and other conspicuous and easily identifiable "boundaries" that divide the city into smaller parts. I cannot remember ever having lost my way returning from a place I had first located myself. On the other hand, it can be more difficult when going with others to keep track of the route, especially when travelling by car.

When five, I nearly fooled my parents into believing that I could read. My parents often read stories and fairy tales to us children, and I was very much intrigued by this activity. I had a children's picture book with a few lines of narrative on each page, all of which I had learned by heart. Sitting with the book at normal reading distance, where, of course, I could not discern the individual letters I "read" the text out loud and clear, following the lines with my eyes, turning the pages at the right points. Eventually, I was found out when, by mistake, I turned two pages at a time and continued to read on before realizing my error. This desire to master the art of reading never left me.

Schoolyears.

When the time came for me to start school we lived in the small village of T"reboda, about halfway between Stockholm and Gothenburg. In Sweden it is compulsory to begin school in the year that children reach the age of seven. The nearest school for the blind and partially sighted was in Stockholm. My parents did not want to send me away to a boarding school at such a young age, and, in defiance of the professor's earlier advice, it was decided that I should try to attend an ordinary school and see if I could manage. Thus, in the autumn of 1948 I started out in the first form of the municipal, primary school in Töreboda.

At this time it became very obvious to me that my vision was different from that of other children. They could see things that I could not see; such as recognizing each other at a distance, spotting ripe berries on bushes and trees, reading cars' licence plates at a distance, etc. They could also take part in activities and sports, especially ball-games, that I could not. Hitting a ball with a bat, or catching a ball thrown towards me, was next to impossible for me, except under the most optimal light-conditions, such as in twilight; When teams were set up, I was always the last one to be taken on.

I must have been a difficult pupil, inquisitive about all that was going on, talkative, always avoiding doing things when my vision would prevent me from performing and thus give me away. I did learn the letters of the alphabet, but I did not really learn to read properly in the first and second form.
The school-books used had ordinary size print, and no-one had thought about getting me books with extra large print, if, indeed, such books existed then. Nor had anyone thought about providing me with a reading-glass. The lenses of my glasses, which by now had been increased in strength to about +6 diopters, did not have enough magnification power for me to read the small print easily.

Since I could actually not discern the individual letters even in ordinary book-print, I again resorted to my old reading hoax; bringing it to new and un-precedented heights. I had developed a very keen memory, and it was usually enough if a class-mate or someone in the household read my home-assignment aloud to me once or twice, in order for me to remember and reproduce it, and to perform a rather convincing reading behaviour in class.

An important discovery that I made during my first school-year is worth noting. As an aid for teaching the letters of the alphabet, the teacher placed large cards, each holding a printed letter, in a row over the blackboard as the letters were introduced. To differentiate between the two categories of letters they had different colours; the vowels were red, while the consonants were black. I could not see any difference between them and could not understand what the teacher meant, until early one morning late in the autumn when the room-lights had been turned on, and, unexpectedly, I saw that some of the letters, i.e. the A E I O U Y Å Ä Ö, were now suddenly a darkish grey, while the others were still solid black. This experience taught me that colours may look different under different light-sources, and that the same colour can be matched to different grey-tones in different kinds of illumination. I have since often used this phenomenon of spectral differentiation as an aid to separate colours by their different grey-tones under various light-sources.

A constantly recurring harassment throughout my childhood, and later on too, was having to name colours on scarves, ties, plaid skirts, tartans and all kinds of multi-coloured pieces of clothing, for people who found my inability to do so rather amusing and quite entertaining. As a small child I could not easily escape these situations. As a pure defence measure, I always memorized the colours of my own clothes and of other things around me, and eventually I learned some of the "rules" for "correct' use of colours and the most probable colours of various things: As an example, I learned that glass that was very dark to me usually was a dark cobalt-blue, glass that looked a bit lighter was usually bottlegreen, and so on. In this way, I could fool some people into believing that I had colour-vision and stop them from pestering me. A friend of the family, though, actually believed that my inability to name colours came from my parents not having taken the trouble to teach me the colour-names. She often tried, but in vain, to train me in naming colours, but had to admit in the end that I could not, in fact, differentiate between the different colour hues.

When I was eight, my three year younger brother was given a small bicycle. This was quite irresistible to me and I soon learned to ride it. At first I only dared to go around the block, keeping to the left-hand side of the road and only making left turns (Sweden had left-hand drive at this time), but as I gained confidence my activity area expanded. Traffic in post-war Sweden was very light, in our village we scarcely saw more than a couple of cars a day, much Transport being carried out by horse and cart, and the conditions of the roads in the area did not allow speeding: Riding the bicycle in traffic did not,
therefore, constitute too grave a danger to me, despite my visual handicap.

I often "borrowed" the bicycle, getting up early in the morning, and set out on long journeys visiting outlying farms, clay-pits, brick-works, factories, railway stations and all kinds of interesting places. When not chased away at once, I would often stay for hours. My curiosity was unbounded, and I learned many wonderful things; how bricks are made, the working of farm machinery, railway operations, etc. When visiting the local railway station the engine driver found it was safest for me (and best for his peace of mind) to take me with him in the cab of the locomotive, rather than have me nosing around the tracks - to which I did not object at all. This inquisitive self-education may have been the origins of my later interest in research.

In the summer of 1950 we moved to Stockholm and I started the third form in a large, municipal school in one of the newly built suburbs south of the city. This did not work out very well. With large classes, the teachers had little time to give me the special tuition and extra training I needed, and after only a month or two it was finally decided that I, and my sister, who had started school the previous year, should attend the state school for the blind and partially sighted at Tomteboda, just north of Stockholm (my brother was not due to start school until the following year). Because the trip each day between the home and the school took too long, my sister and I were forced to live in, seeing our family only in the weekends and during vacations.

At this school my sister and I were, in all practical matters, treated as blind. Although the staff must have known that I actually could see quite well in some situations, a régime was set up to teach me to write and read Braille. Reading with the tips of my index-fingers I did not find easy and I quickly developed the knack of reading Braille by eye, because the raised dimples of the Braille letters cast shadows on the paper, making them much easier to read by sight than by touch. For this I was punished; it was considered to be cheating, and for a week I was confined to my bed after classes, being denied to see the other pupils. And, for the next couple of months I had to wear a heavy, lined, black velvet mask covering my eyes in class when reading - to keep me from peeking. Eventually my Braille reading proficiency increased to such a level that the mask could be dispensed with.

Although I had in many ways become a leader at the school for the blind, having a definite visual advantage over the genuinely blind and the gravely partially sighted pupils, and thus gained much confidence in dealing with other children, I was quite unhappy there and strongly resented being treated as blind. So one day I ran away. Completely on my own I crossed Stockholm, from the north to the far south of the city where we lived. I reached my home by midnight, after more than ten hours of walking, retracing the exact route my father used to take us home by car on the week-ends. This caused a great scandal: Unbeknownst to me the bishop was to hold his visitation of the school on that very day, but the staff had to search for me and the police had to be called in to help them, thus ruining the whole event. This in no way improved my popularity with the staff; although, as was later somewhat reluctantly admitted, it was considered to be no mean feat, even for a child with normal vision, to find his way across the entire city of Stockholm.

Thus, after only two years at the school for the blind and visually disabled, it was decided that, as a trial, I
should again try to attend an ordinary school for the sighted. I was transferred to a newly opened municipal, primary school very close to where we lived, although it meant being moved down one form to compensate for all I had lost during my two years at the school for the blind.

I have a strong suspicion that at the school for the blind and partially sighted they actually just wanted to get rid of me, since I had always created much turbulence and was considered to be rather detrimental for morale among the more seriously handicapped pupils. My sister and my brother (who had entered the school for the blind the previous year) both continued to attend the school, though, staying for two more years until we left Sweden in 1954.

Seen in retrospect, the curriculum at the school for the blind may appear to have been extremely old-fashioned, but it should be borne in mind that at the time this school was considered to be one of the world's leading institutions for the blind and partially sighted, and it was run according to the most modern pedagogical principles. Today, 35 years later, we can only be happy that some of these principles now seem to have been abandoned.

During the summer holidays of 1952, before joining my new school, a problem troubled me very much; although I told no-one about it: While at the school for the blind I had forgotten practically all of what little I had learnt before of reading ordinary print, and I did not cherish the prospect of facing my new fourth form class not being able to read and write.

My father, being at that time sales director with a large company, kept a stock of handouts and gifts for customers, which among other things contained lighters, pocket knives, and -pocket magnifiers. One day I borrowed a magnifier and used it to look at pictures in a comic-book. I was frustrated at not remembering how to read the text in the speaking bubbles, since I could now clearly discern the individual letters with the help of the magnifier. I then remembered that my parents had been given a sample-sheet with the Braille alphabet embossed on it together with the ordinary printed alphabet. Using the sheet as a "cipher-key", I managed to "decipher" and read the text in the speaking bubbles.

This incident was truly a turning-point for me and, more than anything else, opened a whole new world to me, who had always so much wanted to be able to read. In just a few weeks' time I secretly taught myself to read properly and my reading skills very quickly improved. I became a voracious reader who devoured all I could lay my hands on, buying magazines and borrowing books in libraries on practically any imaginable topic.

In my new school I had the unforeseen fortune of having a teacher who had an understanding for my handicap and who really tried to help me overcome my problems in class. He was in many ways a very progressive teacher, ahead of his time. He did not adhere to the strict régime practiced in the schools in those days. As an example he let me move my desk up close to the blackboard so that I could actually see what was written, breaking the regular geometric order of the desks in the classroom, then so much cherished by the other teachers, and he let me move around in the classroom during lessons so that I could inspect at close quarters things that were demonstrated; something completely unthinkable with his
colleagues who put their pride in having their pupils sitting quietly at their places. And he made a habit of always telling us what he wrote on the blackboard, which was of great help to me.

Even today, when attending lectures and talks, I always try to sit close to the screen when slides are shown, and I find it easier to follow the presentation when the speaker also tells the audience what is written on the transparencies. When lecturing or giving talks myself, I always do this, showing slides with large print and not crowding too much information into each transparency. In fact, I often treat my audience as visually disabled: If I can see well from a front row seat what I am presenting I know that my audience also will see it.

Because of this outstanding teacher I soon managed to catch up with my peers, regaining much that was lost in the years at the school for the blind. It was also very good for my self-esteem to be able, at least in some fields, to perform like other children of my age, and it also encouraged my parents to try sending my siblings to an ordinary school.

As it happened this was to take place in Caracas, Venezuela. For four years my siblings and I attended a private school run there by a Scotsman. It was a very small school, and we had no great problems in learning English and otherwise adapting to his somewhat unorthodox style of teaching.

After returning to Norway in 1958 we consulted the Department of Ophthalmology at the National Hospital in Oslo. Here Dr. Egill Hansen confirmed the earlier diagnosis of complete achromatopsia with reduced visual acuity, light aversion and nystagmus in all three of us using the anomaloscope and the standard battery of tests - and we were entered into the Archive of the Blind. In Norway, like in many other countries, people with visual acuities of 6/60 (1/10) or less are legally considered as blind. This entitled us to special education and to pensions for the disabled, which we have never made use of.

Instead we started to attend grammar school (gymnasium in Norway) where we each, in turn, sat for the General Certificate of Education, Advanced Level (which is required for going to the university). At exams we were given an extra hour for finishing our papers, but little else was done by the school authorities to facilitate us attending a school for sighted pupils. By now, however, we had all become rather expert in coping with the practical problems of attending a school for the sighted. Upon getting our exams we all, in turn, went on to university.

At this time I started my musical education, taking lessons on the clarinet, the cello, and in theory of music at the Oslo Conservatory of Music. I did not have any special plans of becoming a musician, but acquired a professional education along with the Gymnasium. Reading printed music proved to be a real obstacle for me, especially prima vista, i.e. sight reading. Today I can easily make enlargements of sheet-music on an office copier, but in the early 60's this was not available to me. For soloists this may not be a great problem, since they often have to learn their parts by heart anyway, but in orchestra play it can be a great handicap.

At university I didn't do too bad. From early in my studies I was employed by the University as part-time
lecturer, which meant that I could have my own office. There I had full control of the light level, drawing the curtains during the day if necessary to shut out sunlight, and I could thus work under the conditions that suited me best. When attending lectures and seminars I made a habit of arriving early, not out of courtesy to the lecturer, but to be able to get a good seat, sitting, if possible, with my back to the windows and close to the blackboard or projection screen.

After first having a go at law, which I gave up after one year, I eventually ended up studying psychology at the Institute of Psychology at the University of Oslo. In addition I studied philosophy of science, physiology and music science. My interests soon turned to sensory psychology and perception. As I wanted to work independently, I took up auditory research, partly out of interest for audition, but also because I believed that my visual handicap would not be a big obstacle to me in this field of research.

At this institute also worked Professor Ivar Lie, Svein Magnussen, Bjorn Stabell and Ulf Stabell, all very accomplished vision scientists. They realized that, being trained in psychophysics, I would be a unique subject in research on rod vision, and they tried to persuade me to leave audition for vision. I first wanted to get my Ph.D. (Mag. art. in Norway), and after my dissertation (on auditory localization and dichotic time/intensity-trading) I switched to vision research.

I have been in research ever since; first as assistant professor (stipendiat in Norway) at the Institute of Psychology, University of Oslo, working in vision research and lecturing in perception and neuroscience, and today as senior research scientist with the Norwegian Telecommunications Administration Research Department, where I am currently doing research and development work on human factors in telecommunications, on telecommunication equipment and services for disabled people and in telemedicine.

My vision research activities soon brought me into contact with vision researchers in laboratories outside Norway, some of which I have visited many times and where I have made many good friends. Beside work in Norway with Svein Magnussen and Bjorn and Ulf Stabell, I have also visited and collaborated with Dr. Robert E Hess at the Physiological Laboratory, University of Cambridge, England, with Dr. Lindsay T. Sharpe, in Dr. Lothar Espmann\'s laboratory at the Minikum der Albert-Ludwigs Universit\'at, Freiburg, the Federal Republic of Germany, and with Dr. L. Henk van der Tweel, at the Laboratorium voor Medische Fysica, Universiteit van Amsterdam, The Netherlands - collaborations that have continued after I joined the Telecommunications Administration. The results of these experiments are dealt with in other chapters of this book (for a full list of these works see the Bibliography below).

My siblings also entered university; my sister studied Latin, English and music science, and my brother qualified as a psychologist. My sister now works at the library of the Norwegian Association for the Blind in Oslo, translating and producing books in Braille; unlike me she has not forgotten her four-year training at the school for the blind. My brother is employed as a high-ranking civil servant with the Norwegian Directorate for Labour, working mainly in organizational development.

In 1965 I met Nina Marie Loberg (born 10.7.1944), who studied psychology, and we were married the
following year. There are no known achromats in her family and there are no relations between our families. We have two sons, Cato (born 1.3.1967) and Alexander (born 19.1.1969). Both Nina and the boys have perfectly normal colour-vision as tested with the Farnsworth 100 Hue Test. My brother is also married and has four children, two sons and two daughters; all with normal colour-vision. My sister has not married and has no children.

I have never, nor have my siblings, received any qualified vocational counselling or help in planning my education and my career. What advice I have had has usually been unfounded and ill-conceived. The suggestions have included everything; from simple clerical and assembly-line work to the traditional work for the blind, usually involving simple, manual, low-paying jobs requiring little or no education, and showing complete disregard for what actual tasks the work demanded. Most so-called 44 simple'jobs, e.g. filling in forms, sorting mail, filing and retrieving files, assembling components, cleaning, tending machines etc., usually require good visual acuity and colour-vision. No one ever suggested theoretical or academic work requiring higher education. Luckily my parents had always wanted their children to have an academic educa- tion, and circumstances were highly favourable for this in Norway in the 60's and 70's.

In my research work I have had few problems related to my visual handieap. I work in areas where, to a large extent, I can plan my own work and choose my own tasks. In addition to the research activities my work also includes administrative duties, giving interviews, going to meetings and giving talks, both in Norway and abroad, and I also lecture regularly at the University of Oslo. These activities pose few practical problems for an achromat. Typing used to be quite a bother, since I had to lean over the type-writer with my magnifier to be able to read what I had written, but now I use a PC and a word-processing program for all my typing, and this is a very useful tool to me. To overcome my low visual acuity I have to get close (150-200 mm) to the screen, and I have a large (19") screen installed. With modern printers I can have my documents printed in large type-face, making them easier to read.

**ROD VISION**

Trying to explain to someone with normal, or nearly normal, colour-vision what it is like to be totally colour-blind, is probably a bit like trying to describe to a normally hearing person what it is like to be completely tone-deaf, i.e. not possessing the ability to perceive tonal pitch and music. My task, though, is probably a bit simpler than the case of the tone-deaf, since practically everyone has had experiences of achromatic (i.e. colourless, or black & white) or monochrom pictures and renderings, and certainly must have witnessed the gradual disappearance of colours when darkness sets in.

A first approximation, then, in explaining what my colour-less world is like, is to compare it to the visual experiences people with normal colour-vision have when viewing a black & white film in a cinema or when looking at good black & white photographic prints (good here meaning sharply focused, high contrast with a long grey-scale, as in crisp, high quality, glossy, technical prints).

This, however, is only part of the story because I have so far only dealt with the achromatic aspect of my
perception. To get a fuller understanding of my visual world one must, in addition to my colour-blindness, also take into account my light aversion (i.e. hyper-sensitivity to light) and my reduced visual acuity. In the following I will deal in turn with each of these aspects of typical, total achromatopsia.

Total colour-blindness

As mentioned above, I only see the world in shades that colour-normals describe as black, white and grey. My subjective spectral sensitivity is not unlike that of orthochromatic black & white film'. I experience the colour called red as a very dark grey, nearly black, even in very bright light. On a grey-scale the blue and green colours I see as mid-greys, somewhat darker greys if they are saturated, somewhat lighter greys when unsaturated, like pastel colours. Yellow is usually a rather light grey to me, but is usually not confused with white. Brown usually appears as a dark grey and so does a very saturated orange. When asking other total achromats to do such matches I get practically the same judgements from them. In the literature I have also found several descriptions of the colour-determinations made by other typical, total achromats, which all very closely match my own judgements (see e.g. Bjerrum, 1904; Larsen, 1918).

Although I have acquired a thorough theoretical knowledge of the physics of colours and the physiology of the colour receptor mechanisms, nothing of this can help me to understand the true nature of colours. From the history of art I have also learned about the meanings often attributed to colours and how colours have been used at different times, but this too does not give me an understanding of the essential character or quality of colours.

Coloured and B & W pictures are usually indistinguishable to me. But sometimes I can, often quite easily, tell coloured and noncoloured pictures apart. Coloured pictures may look less crisp, or slightly less in focus, and often have less contrast than comparable monochrom pictures. Under some conditions I am able to tell a polychrom picture from a monochrom one by noting the different surface textures of the coloured inks used to print the picture. I do this by tilting it so that the light reflects differently in the different inks: Coloured inks ’t vary various hues show up as duller or glossier patches. I am sometimes able to see the numbers on the Ishihara and ™sterberg pseudo-isochromatic plate tests by this technique. Given the time I might be able to fool an unwary tester. A few other achromats have also shown me this trick, not because they wanted to deceive me, but because they thought that they had a vestige of colour-vision. However, if I cover the test- plate with a glossy, transparent foil they are unable to do this trick: Varnishing or covering pictures with high-gloss films destroys the effect.

I have never experienced anything "dirty", "impure", 44 stained' or "washed out" about colours, as reported by the artist Jonathan I. who completely lost his colour-vision after a cerebral concussion (Sacks & Wasserman, 1987). When, occasionally, bolour-pictures do look less crisp to me than B & W pictures, it is usually because of bad printing, lower contrast or faded inks.

Once when Bjorn and Ulf Stabell were measuring my spectral equal-brightness function (using their Wright colorimeter) I felt that I could detect slight differences between colour hues by distance cues,
which could be due to chromatic aberration in the optics. I informed the Stabell brothers about my suspicion and an ad hoc experiment was quickly set up to test my conjecture. I was to try any ploy that I could think of to guess the hue of the test field, and they were to counter my ploy, making mock changes or unexpected changes of hue. When the day was over I had not been able to guess any colour hue beyond the pure chance level.

When I know the colour of an object I may often refer to its colour name when describing it or referring to it to other people. Since colour names have meanings for most people, communication is made easier. This, in turn, leads to other people using colour names when addressing me, even those who know of my colour-blindness. Sometimes this can be of help to me, when e.g. they refer to a red book among other light-coloured books, but referring to a red book among black and dark-coloured books is of little help to me.

Colours do not help me to distinguish objects from their backgrounds. Since the grey-tone that I can match to a particular colour changes with changing illumination, objects that are partly in bright light and partly in shadow, such as flowers in the mOTTled sunlight coming through the branches of a tree, can be very hard to see. The same applies to objects under glass, behind windows or under water, since shiny surfaces give off reflections and glare which makes it very difficult to see what is behind them. It is usually impossible for me to recognize people in cars or see if they are waving at me, sometimes even at close quarters, because of the destructive reflections from the windows. NMcere the colour-normal can use the continuity of the colour-hues of an object to perceive the figure through disturbing reflections, I see the reflections and the objects behind them translated into different shades of grey, and only when the contrast between the object and its background is very high, or the movements are very distinct, can I see what is behind a strongly reflecting surface as an object. Wearing polarizing clip-on sun-glasses improves things to some extent, and I use them much, although I am sometime's distracted by seeing the mOTTled stress-patterns in glass that are normally invisible.

When I was about 14 I discovered, quite by accident, the use of coloured filters for analyzing and identifying different colour hues. We had a large salad bowl made of transparent, red-coloured plastic. One day, holding the bowl before my eyes, I noticed that the pattern of the table-cloth turned nearly white when seen through the bowl. By moving the bowl to and fro, I could make the red-coloured pattern change from light to dark. I was intrigued by my discovery and tried out several other transparent filters of various colours, thinking that I would be able to solve the problem of my colour-blindness by using a few differently coloured pieces of plastic to analyze and thus be able to name any colour. From a purely practical point of view I contemplated the great advantage of being able to determine for myself the name of a colour without having to ask other people. I even envisaged a solution of narrow strips of filters mounted at the upper edge behind the lenses of my glasses, thus dispensing with a set of hand-held filters, and making their use more discreet.

Nothing came out of these ideas of mine as I did not have the resources at my disposal for ear"rying them through. I have since learned that such filters for analyzing colours are actually made for "normal' (i.e. anomalous trichromat and dichromat) colour-blind electronic engineers to aid them in reading the colour-coded rings denoting the values of resistors. I have tried, but never succeeded in, obtaining a set of such
filters, although the spectral transmission bands of these filters would probably not suit the spectral sensitivity of my rods very well.

Traffic-lights can sometimes pose a problem to me. I have long since learned that red is the top light, amber is the middle light and green is at the bottom. At night, in the evening or in the day if the traffic-lights are in a shadow, I have no problem in detecting which aspect is shown: By noting its position I can be a law-abiding cyclist or pedestrian. In full sun-light, on the other hand, determining which aspect is shown can be quite impossible; if the traffic-lights are back-lit I am dazzled by the sun and cannot see the weak lights; if the sun is behind me, the reflections in the lenses of the light signals can be so strong that it is impossible to determine which one is showing. In such situations I have to watch the traffic, following the other pedestrians when they cross the street. This can lead to dangerous situations when encountering unsuspect’ed cars if I follow someone crossing a street against a red light, believing that the crossing is safe.

I often visit art galleries and I am very interested in the visual arts. Looking at paintings I can appreciate form, composition and technique, although of course, I cannot appreciate the coloristic aspects. Monochrome prints and graphic art I can normally enjoy in the same way as colour-normal people and the same goes for sculpture and architecture. When lecturing on vision and perception I frequently show transparencies with works of art to demonstrate my points.

When painting house or redecorating I must always make sure that I use the correct colours by carefully reading the labels on the paint tins. My wife normally selects the colours for the house. If the contrast between the new and old colour in terms of grey-tones is not too small, I have no problem painting the house. If I repaint with the same colour, I sometimes have a problem telling the freshly painted areas from the unpainted ones, especially after a break, when the fresh paint is not so "wet" anymore. If I repaint with a different colour that is very close to the old one in terms of grey-contrast, I have difficulties in seeing if the new coat covers the old colour properly. Sometimes the only way to resolve this problem is either to paint very systematically, or to look obliquely at the wall for the shiny "wet" freshly painted parts.

When buying clothes on my own I will only take advice from a sales-person in whom I have the highest confidence, otherwise I usually ask for "safe" or neutral colours; white shirts, grey trousers, black socks and shoes: I would e.g. never select a tie on my own. For the important colour-choices I have to rely completely on my wife or on close friends who I trust and who know my taste and preferences. To avoid embarrassment I often have to mark my socks in some way so that I will not mix up differently coloured pairs, it can be impossible for me to tell light blue, beige and light grey, or dark blue and black socks apart.

Picking berries has always been a big problem for me. I usually have to grope around among the leaves with my fingers, feeling for the berries by their shape, except in the shade or in the evenings when light levels are low. Then I can usually see the berries; the red ones as small "black" spheres among the "grey" leaves. The only berries I can easily see in bright sun-light are the white 'snow-ball" berries of the Guelder-rose bush.
Indoors most flowers are easy for me to discern, out-of-doors, though, I usually only recognize the white and the yellow ones: The oxeye-daisies, not to speak of the dandelions in my lawn, are most conspicuous to me; red roses on bushes I see best in the twilight when I can separate the "black' flowers from the icgrey" leaves.

Colours are frequently used to code or to highlight information. For me this usually makes matters worse because good colour contrast very often does not transform into good grey-contrast. Sometimes the contrast is so low that the information is next to lost. Black print on red price labels, yellow print on a light blue background, dark green on a bright red background are all extremely difficult for me to read. A teaching aid that has always failed with me is the use of colours in e.g. arithmetic; adding the red and the green objects, subtracting the blue ones from the yellow ones. Colourful Venn diagrams for teaching basic set theory only makes the task more difficult for me.

**Hypersensitivity to light**

As far as can be determined, the retinae of my eyes do not contain any cone-receptors at all, only rod-receptors; or cones are present but in such reduced numbers that they do not in any measurable amount contribute to the visual process (see Sharpe and Nordby, THE PHOTO-RECEPTORS IN THE ACHROMAT, chapter X). Since the rods are much more sensitive to light but also saturate at lower light intensities than the cones, my visual system is well adapted for vision only under low-lighting conditions. In fact, my vision will not function at all in bright light (e.g. out-of-doors in full day-light), if I do not adopt specialized visual strategies and behaviour.

I am easily dazzled and, in effect, blinded if I expose my eyes to bright light. If I open my eyes fully for more than one or two seconds under such conditions (about 1000 scotopic trolands and up), the scene I am gazing at is quickly washed out, turned into a bright haze and all structured vision is lost. It can be very distressing for me, and sometimes even painful, to perform demanding visual tasks in very bright light.

This hypersensitivity to light, or light aversion, is usually referred to as photophobia, but has nothing to do with the irrational psychodynamic "phobias". In fact, I really like being out in the warm sun, provided I dont have to perform exacting visual tasks. I do not like to read or write in the sun; digging the garden or mowing the lawn, on the other hand, is no problem for me even in bright sun-light.

My main problem, then, is to restrict the intensity of the light entering my eyes. This, as I will show, can be achieved in several ways and I tend to use them all, alone or in combination, according to what the situation demands. In common with nearly all the other achromats I have interviewen, I have developed special visual strategies for restricting the amount of light entering my eyes.

The most obvious strategy is, of course, simply to avoid direct strong light. Staying indoors or in the shade is one way of achieving this if there is no special reason for being in intense sunshine (such as on a
bright beach in the summer or in bright sun-lit snow in the winter). Indoors, whenever possible, I try to place myself with my back towards bright windows and strong light sources and avoid having direct sunlight falling on my work-place.

Shading my eyes from direct, intense light with my hand or a visor may be necessary. Ordinarily I wear sun-glasses, in casu, the lenses of my glasses are photo-chromatic (i.e. tinted lenses which darken in bright light). Out-of-doors I often wear an extra clip-on polarizing filter for cutting down on bright light and for dealing with visually destructive glare and reflections from shiny surfaces. The best sun filters I have tried, though, are the special coloured glasses which are made for the retinitis pigmentosa patients. They have a spectral cut-off at 550 nm, passing only the long wavelengths and they give a very pleasing light-attenuation, but they are socially less attractive because of their red appearance.

Actually, it is not only the brightness of what I am looking at that is most bothersome, but the brightness of the total visual field; the larger the part of the field that is illuminated, the more bothered I am. Blinkers or side-shields on the spectacle frame may help in shutting out unwanted light, but they also prevent motion detection in the peripheral visual field, which is important for moving safely about, and I don't use them. If I must see small detail in bright light, e.g. read printed information or look at a map in the bright sun, I turn away from the light, putting the material in my shadow.

The most typical visual strategies, though, that I resort to consists in squinting, i.e. partially closing the eyes and looking through the narrow slits formed by the eyelids, and in frequently blinking the eyes. This habit has been reported by nearly every author and seems to be universally resorted to by typical, complete achromats (see e.g. Bjerrum, 1904; Larsen, 1918; Krill, 1977). If light levels rise and my retinal illuminance approaches 1000 scotopic trolands, my fully constricted pupils cannot further contract and I have to squint to deal with the higher intensities and to avoid saturating the rods.

At higher light intensities even this is not enough, and I also have to start blinking my eyes to shut out excessive light. My blinking is triggered when saturation sets in. The blinking frequency is slow at first, only once every four-five seconds, but the periodicity increases with increasing light intensity, to three to four blinks a second.

At lower light levels, when the blinking rate is slow, the blinks themselves are also rather brief. As light levels go up, the blinking rate also goes up, but the blinks become longer, i.e. the duty-cycle increases. At the very highest light levels where my visual system will function (e.g. new snow in bright sunlight) the blinks are so long that my eyes are, in fact, closed most of the time except for brief opening blinks once every two to three second. Whether blinking my eyes briefly at low light levels or extending the length of the blinks at high intensities, I still experience a visually stable world in which I can orientate myself and move about. It should be mentioned, though, that I am able to suppress the blinking on some occasions. In laboratory investigations I have actually sustained luminances over 500,000 photopic trolands, blinking only occasionally to keep my corneas moist.

This squinting and blinking behaviour is a strain socially. In bright light people immediately notice that
sometl-iiing is wrong with mv eves. and show this by their reactions to me. As a child I was often approached by complete strangers who wanted to know what was wrong with my eyes. Wearing dark glasses or clip-on sun filters can alleviate this social burden to some extent.

At higher light levels the peripheral visual field is much more affected than the central part of the field, which results in a partial tunnel vision. I will still detect movement in the far periphery, but have much more difficulty in identifying what is moving and reacting adequately to it. This makes me move in a rather hesitant and stiff way, sometimes bumping into people or things, and to be overcautious when moving about in agitated surroundings or in strange places. As soon I am in the shadow or indoors again I move in a more relaxed and confident manner.

It is very clear to me today that the most debilitating, handicapping and distressing consequence of my achromatopsia has been my hypersensitivity to light and the resulting light aversion, which is also reported by all other authors. This is also the unanimous verdict of all the achromats I have interviewed so far. Both the practical problems of being dazzled, the narrowing of the visual fields, resulting in restricted mobility, and the social problems of light aversion and feeling clumsy in intense light is frequently reported by my informants as being more of a hindrance to them than not being able to experience colour hues or to discern small detail.

Reduced visual acuity

In a retina where only rods function, visual acuity will be drastically reduced, since it is the densely packed foveal cones that are responsible for the high acuity of central vision in the normal retina. My visual acuity is 6/60 Snellen (i.e. 0.1 of normal acuity) which means that at a distance of 6 meters I can read those letters on the Snellen chart that people with normal acuity can read at 60 meters. This low acuity is typical for all typical, complete achromats reported in the literature and for those I have interviewed. Measured with an interferometer under optimal conditions my acuity improves to 6/50.

My visual acuity, though, may vary quite a bit depending on the illumination. At higher luminances my acuity very quickly deteriorates, but it may improve slightly at lower light intensities, such as at dusk after the sun has set, but before it gets really dark, or indoors with the curtains drawn during the day, or in the evening with not-too-strong incandescent, tungsten illumination. My best acuity seems to coincide with the illuminance levels at which I do not have to squint or blink my eyes.

I experience a visual world where things appear to me to be well-focused, have sharp and clearly defined boundaries and are not fuzzy or cloudy: I can easily tell the difference between what people with normal vision call a well-focused and a not so well-focused photograph. When giving a talk to the Kenneth Craik laboratory in Cambridge, one of my slides came up slightly out of focus because of a thinner slide-Mount. I quickly refocused the slide myself, but Professor Fergus W. Campbell, who attended the talk, commented aloud that to his astonishment I did this as well as any projectionist. Details that are too small for the low resolution of my coarse retinal matrix disappear, blending into the background, but when they are brought closer and become large enough for me to discern, they are just as sharp and well-defined as
other objects.

I am hypermetropic, or far-sighted, and my ophthalmic correction today is +8 diopters. This is rather fortunate since my lenses thus magnify the retinal image by a factor of 0.7; it would have been worse had I been myopic, or near-sighted, thus requiring minus-lenses. With my glasses I can read small print by bringing the text close up to my eyes; about 250 mm away for 6 mm high letters, 150 mm away for 4.5 mm letters, 80 mm away for 3 mm letters.

Letters smaller than 2 mm, such as used in the telephone directories in most countries, I cannot read without additional optical magnification.

I use a small, folding, pocket magnifier for reading newspapers, magazines, books, typed documents, etc., even when the print is large enough to read with my glasses alone. My first pocket-magnifier (see above) had a +9 diopter, 50 mm o lens set in a transparent perspex frame, rivetted in one corner to a piece of leather. The lens could be folded up into the leather cover to protect it, when unfolded the leather cover served as a handle for holding the glass. Today I use a magnifier with a +16 diopter, 30 mm o, biconvex lens, which gives me the necessary magnification for reading large amounts of text without undue visual strain, and makes it possible for me to manage the very small print in Telephone directories etc. When reading I usually hold the glass in my right hand, the book in my left, and I always use my dominant left eye. Together with my spectacles, this magnifier is the most important tool I have, and I always carry it with me.

I have, of course, tried many other different loupes, reading glasses and magnifiers of various designs offered by opticians, but they are usually either too big, too heavy, too obtrusive, not pocketable, too weak or too strong for my needs. The best design is one that I can carry in my shirt breast pocket so that it is always at hand, one that is small and easy to hold, but with sufficient power for reading small print such as the print found in the Telephone directory.

I have considered other types of visual aids, such as video-systems etc., but they all seem to fail on one or several points. Usually they are too large and heavy to carry around, they are complicated in use or they are too powerful, giving a very small field of view which makes it rather hard to read continuous text. It is most important to me that I can always take the aid with me and use it wherever I go.

Reading things at a distance, such as street names, destination boards on buses and trains, time-tables in stations, flight-departure indicators in airports, signs and labels in museums, price labels in shop windows etc., is usually impossible or, at best, very difficult. To use my magnifier to make the letters legible to me I have to get close to the material, but this is not possible when signs are placed high up on walls or poles, behind windows, in glass cases or behind barriers. One special problem is reading the destination boards on approaching buses which only stop on signal. Occasionally, as a last resort, I have had to stop every approaching bus until the right one came along, invoking the drivers'wrath and being showered with abuse for my pains.
It can be difficult for me to find my way in unknown surroundings, a problem when travelling or visiting strange places. I solve this by carrying with me a small, monocular, 8 power, close-focusing telescope, which I can conceal in my hand, and which I use for reading street names, destination signs and other information that I cannot otherwise reach. I also procure information in advance by studying maps and plans, and by inquiring for detailed directions on how to find my way.

Much more serious, though, than the problem of finding my way in strange places, is my disability to identify people only from their facial features at a distance of more than a few metres. I may easily pass people I know well in the street without recognizing them, and those who do not know of my visual handicap may find me aloof or downright rude. Picking out people I know well in a crowd or in a large room, e.g. a restaurant or theater, is very difficult and socially embarrassing. I usually recognize people from their total appearance, i.e. their clothes, their way of moving, prominent or special features; but foremost, from their voices. I can manage to identify them at 10-15 metres distance, and if I know what clothes they will be wearing I may even be able to identify them at distances of 20 metres and more. Often, though, I fail to recognize people I know, with embarrassing consequences. Sometimes even people who know about my visual handicap are offended by my seemingly disinterest and neglect of them. The reason may be that I often, apparently, behave visually rather normally, leading them to believe that my disregard is intentional.

A problem that seemed more serious to me earlier than it does now is that I cannot hold a driver's licence. My brother and I cycle and we have ridden mopeds in Oslo. Driving a car, though, is not possible for us, although my brother actually took some driving lessons. He had to give up, though, after attempting to drive down some stairs in a park. Today I only cycle where I have access to reserved cycle lanes or when traffic is light.

In other fields, however, low visual acuity has not been an insurmountable obstacle. My sister has since her early teens done all kinds of needlework, producing tatting, bobbin-lace and embroideries to very high standards. To keep her hands free, she uses a clip-on, jeweller's loupe with her working-glasses. This gives her a large magnification (10 times), but a very small field of view, and it is not very suitable for reading. She needs help in selecting the colours of the threads and yarns, but once they are selected and labelled she manages on her own.

**CLOSING REMARKS**

From my account it can be seen that I often avoid showing my visual handicap and sometimes simulate having normal vision. I often experience negative attitudes if I expose my visual disability before people get to know me. The stigma of being partially sighted can be very unpleasant. If I show my handicap early to people who do not know me I will be categorized as a disabled person and will be treated in a patronizing way and often not taken seriously. If, on the other hand, I first expose my visual handicap to people after they get to know me, I get fewer reactions. With most vision scientists and ophthalmologists I feel at ease, they can even be overcautious about offending me, but some ophthalmologists have treated me in the condescending way they sometimes treat their patients.
In spite of this and all the other practical and social problems I encounter, I still feel that I live a very rich and interesting and useful life. It is my ambition that these very personal and rather private accounts given here will prove to be of some use to vision researchers and to people dealing with typical complete achromats.

ACKNOWLEDGMENTS

I wish to thank my colleague and friend Dr. Lindsay Theodore Sharpe for his critical comments on the manuscript. I also want to thank my collaborators and friends Bjorn Stabell and Ulf Stabell for many helpful suggestions.

FIGURE CAPTIONS

The pictures are not implemented, because of their bad quality (copied).

Figure 1. My family pedigree. Solid, black symbols indicate the typical, total achromats, i.e. my siblings and I, light grey symbols indicate non-achromats.

Figure 2. Photograph taken of me 1-2 weeks after birth. I showed no obvious signs of squinting or light aversion at the time.

Figure 3. Photograph of me, my sister and my brother (from left to right) in bright sun-light. We all display squinting and light aversion behaviour typical of the complete achromat.

Figure 4. Spectrum with grey-matches in sun-light (upper) and in incandescent light (lower row). The matches of the grey patches are made at the points indicated on the spectrum. The Spectrum was obtained from the Rochester Institute of Technology, the grey patches are from the KodakLyrev scale.

BIBLIOGRAPHY

The following is a list of all the investigations of my visual system that have been published.

  Spatial vision of the achromat:
  Spatial frequency and orientation specific adaptation.
  *Journal of Physiology (London)* 395, 661-678.

  Spatial and temporal limits of vision in the achromat.

  Spatial and temporal properties of human rod vision in the achromat.

  Regional variation of contrast sensitivity across the retina of the achromat: Sensitivity of human rod vision.

  Sosiale mekanismer, stemplingseffekt m.v. ved synshandikap.
  Skolepsykologi 239 1-8, (ISSN 0333-0389).
  (Social mechanisms, stigma etc. connected with visual handicaps.)

  The directional sensitivity of the photoreceptors in the human achromat.

  Dark-adaptation of the human rod system.
  Vision Research 24, 841-849.

- Rosness, R., (1981)
  Corticale konsekuenser av stavmonokromasi.
  En psykofysisk studie av orienteringsselektivitet.
  (Master's Thesis, Institute of Psychology, University of Oslo, 1981)
  ISBN 82-569-0541-7, 83 pages, 12 figures.

  Fixation, pursuit and optokinetic nystagmus in a complete achromat.
  Clinical Vision Sciences 1, 39-49.

  Rod increment and flicker thresholds in the normal and achromat.
  Perception 17 (in the press).

  The pupillary response of the achromat.
  Clinical Vision Sciences (in the press).

  Pigment regeneration, visual adaptation and spectral sensitivity in the achromat.
  Clinical Vision Sciences 3, 9-17.

  Rod monochromat sensitivity to sine wave flicker at luminances saturating the rods.

  Photopic and scotopic flicker sensitivity of a rod monochromat.

  Temporal summation in a rod monochromat.
  Vision Research 22, 491-493.

People with online papers in philosophy

Compiled by David Chalmers

This is a list of individuals who have made available online papers in philosophy and related areas. This practice is very much to be encouraged! Note that this list concentrates mostly on academic philosophers, although some scientists and others in related fields are included. If you know of people I should add to this list, please tell me.

For other sources of online papers see:

- online papers on consciousness
- web resources related to consciousness, philosophy, and such
- directory of online philosophy papers (Joe Lau)

Philosophy of mind (esp. consciousness)

- Torin Alter (qualia, free will, etc)
- Tim Bayne (consciousness, personal identity)
- Ned Block (consciousness, reduction, content, etc)
- Alex Byrne (consciousness, metaphysics, etc.)
- Peter Carruthers (consciousness, language)
- David Chalmers (philosophy of mind and language, cognitive science, metaphysics)
- Austen Clark (color, consciousness, vision)
- David Cole (consciousness, language)
- Craig DeLancey (emotion, consciousness)
- Daniel Dennett (philosophy of mind)
- Shaun Gallagher (phenomenology, self-consciousness)
- Brie Gertler (consciousness, introspection, metaphysics)
- Benj Hellie (consciousness, Nietzsche)
- Ted Honderich (consciousness, free will, ethics)
- Susan Hurley (consciousness, perception, political philosophy)
- Sean Kelly (perceptual experience, action)
- Peter Lloyd (consciousness, idealism)
- Eric Lormand (consciousness, meaning, cognitive architecture)
- William Lycan (consciousness, epistemology)
- Thomas Metzinger (consciousness)
- Gerard O'Brien (consciousness, connectionism)
- David Papineau (consciousness, epistemology, philosophy of science)
People with online papers in philosophy:

- **Tom Polger** (consciousness, evolution)
- **Gregg Rosenberg** (*A Place for Consciousness*, etc.)
- **David Rosenthal** (consciousness, intentionality, *Sellars*)
- **William Seager** (consciousness, metaphysics)
- **John Searle** (consciousness, AI; and [here](#))
- **Pär Sundström** (consciousness)
- **Nigel Thomas** (imagery, consciousness, *zombie killer*)
- **Michael Tye** (consciousness, qualia, content)

**Philosophy of mind (esp. artificial intelligence and cognitive science)**

- **William Bechtel** (foundations of connectionism & cognitive science)
- **Istvan Berkeley** (connectionism, foundations of cognitive science)
- **Mark Bickhard** (representation, computation, etc.)
- **Selmer Bringsjord** (philosophy of AI, etc.)
- **David Buller** (evolution, AI, metaphysics)
- **Ron Chrisley** (connectionism, computation, non-conceptual content)
- **Jack Copeland** (computation, AI, logic)
- **Hubert Dreyfus** (philosophy of AI and technology, Heidegger, etc)
- **Chris Eliasmith** (dynamic systems, philosophy of science)
- **Rick Grush** (foundations of cognitive science, perceptual content)
- **Larry Hauser** (consciousness, AI, *philosophy comics*, etc.)
- **Brian Keeley** (philosophy of neurobiology, artificial life)
- **J. R. Lucas** (mechanism, *Gödel* and AI, time, etc.)
- **Gregory Mulhauser** (robots, consciousness)
- **William Rapaport** (foundations of AI)
- **Eric Schwitzgebel** (theory of mind, belief, consciousness)
- **Aaron Sloman** (foundations of AI, *rock consciousness*)
- **Stephen Stich** (theory of mind, rationality, etc)
- **John Sutton** (memory)
- **Tim van Gelder** (philosophy of mind, dynamic systems)

**Philosophy of mind (miscellaneous)**

- **Colin Allen** (animal cognition, evolution, *Species of Mind*, etc.)
- **Murat Aydede** (language of thought, connectionism, content)
- **John Beloff** (mind-body problem, parapsychology)
- **Andrew Brook** (Kant, cognitive science, psychoanalysis)
- **Filip Buekens** (supervenience, observation)

Foundational Issues in the Science of Consciousness

David Chalmers

E-mail: chalmers@arizona.edu
Phone: 621-7105
Web: http://www.u.arizona.edu/~chalmers/
Office hours: Thursday 1:30-3pm (Social Sciences 226A)
Class meeting (Fall 1999): Tuesday 3:30-6pm, Social Sciences 311.

Overview

In recent years there has been an explosion of work on consciousness, within philosophy, psychology, and neuroscience. This seminar will examine the science of consciousness, addressing both empirical and philosophical issues within it.

Some empirical areas to be covered include:

- the search for the neural correlate of consciousness
- neuropsychological disorders of consciousness
- the processes involved in conscious vision
- implicit processes in memory, learning, and perception
- the relationship between consciousness and attention
- cognitive models of consciousness
- consciousness and metacognition
- animal consciousness
- phenomenological approaches to consciousness.

Some philosophical issues to be addressed include:

- What are the varieties of "consciousness"?
- Can consciousness be explained in terms of neurobiology?
- How can we gain experimental access to consciousness?
- What is an appropriate epistemology for the science of consciousness?
- What might a final theory of consciousness look like?
- What can one being know about the consciousness of another?
- Might consciousness differ radically between individuals?
Some weeks will be devoted to "empirical" topics and some weeks to "philosophical" topics, but for any given topic we will read papers by both empirical researchers and philosophers, often spending half the meeting on each. In the empirical areas, we will make an effort to address the foundational questions that lie behind the research. In the philosophical areas, we will examine how empirical work can illuminate and occasionally reshape these issues.

This course is intended as an interdisciplinary seminar. Material in both philosophy and cognitive science will be approached in such a way to be accessible to students without much background in one or the other. Any graduate student in philosophy, psychology, or other relevant areas would be welcome.

**Readings**

There is no required textbook. Recommended texts are:

- Cohen and Schooler (eds.): *Scientific Approaches to Consciousness*. Lawrence Erlbaum.

Many readings will be available on the web, and others will be made available for copying. Students will be expected to make brief seminar presentations of the readings.

**Web page**

The web page for the class is at

[http://www.u.arizona.edu/~chalmers/phil596v.html](http://www.u.arizona.edu/~chalmers/phil596v.html)

**Mailing list**

I will set up a mailing list, scicon@listserv.arizona.edu, for class discussion. Everyone will be expected to make reasonably regular contributions to this list (at least one reasonably substantial posting every two weeks), discussing issues arising from the readings, from class discussion, and from the mailing list itself. Think of this as a substitute for biweekly short papers of 1-2 pages each.

**Assessment**

Assessment will be based most heavily on a final paper, and will also be based on in-class presentations, mailing list contributions, and class participation.
Schedule

Here is a very approximate week-by-week plan for the course, with associated readings. Note that this is very likely to be revised and supplemented as things develop. Readings that are not available on the web will be made available in the department office. Full bibliographical information can be found in my online bibliographies of consciousness in philosophy and of consciousness in science.

1. What is consciousness?
   - Norton Nelkin, "What is consciousness?"
   - Edoardo Bisiach, "The (haunted) brain and consciousness".

   Week 1 discussion

2. Can consciousness be reductively explained?
   - David Chalmers, Facing up to the problem of consciousness
   - Paul Churchland, "The rediscovery of light"
   - Daniel Dennett, Facing backwards on the problem of consciousness
   - Francis Crick and Christof Koch, Why neuroscience may be able to explain consciousness
   - David Chalmers, Moving forward on the problem of consciousness

   Week 2 discussion

3. What can be known about the consciousness of another?
   - Frank Jackson, Epiphenomenal qualia
   - Paul Churchland, "Reduction, qualia, and the direct introspection of brain states"
   - Evan Thompson, "Novel colours"
   - Knut Nordby, Vision in a complete achromat: A personal account

   Week 3 discussion

4. Neural correlates of consciousness I.
   - Francis Crick and Christof Koch, "Toward a neurobiological account of consciousness"
   - Joseph Bogen, On the neurophysiology of consciousness, part I: An overview.
   - Ned Block, How to find the neural correlate of consciousness
   - David Chalmers, On the search for the neural correlate of consciousness
Week 4 discussion

5. Neural correlates of consciousness II.

- D.L. Sheinberg & Nikos Logothetis, *The role of temporal cortical areas in perceptual organization*
- Francis Crick and Christof Koch, *Consciousness and neuroscience*
- Davida Teller and E.N. Pugh Jr., Linking propositions in color vision
- David Chalmers, *What is a neural correlate of consciousness?*

Week 5 discussion

6. Blindsight

- Petra Stoerig and Alan Cowey, *Blindsight in man and monkey*
- Semir Zeki and Dominic ffytche, *The Riddoch syndrome: Insights into the neurobiology of conscious vision*
- Ned Block, *On a confusion about a function of consciousness*

Week 6 discussion

7. Conscious and unconscious perception

- David Milner and Melvyn Goodale, *The visual brain in action (precis)*
- Philip Merikle & Meredyth Daneman, *Psychological investigations of unconscious perception*
- Anthony Greenwald, New Look 3: Unconscious cognition reclaimed
- Max Velmans, *Is human information processing conscious?*

Week 7 discussion

8. Change blindness, consciousness, and attention.

- Arien Mack and Irvin Rock, *Inattentional blindness: An overview*
- Daniel Simons, Change blindness
- Jeremy Wolfe, *Inattentional amnesia*
- Valerie Hardcastle, *Consciousness and attention: A distinction with a difference*
- Alva Noe and Evan Thompson, *Beyond the grand illusion: What change blindness really teaches us about vision*

Week 8 discussion

- Bernard Baars, *In the theatre of consciousness*
- Daniel Schacter, On the relation between memory and consciousness: Dissociable interactions and conscious experience
- Daniel Dennett & Marcel Kinsbourne, *Time and the observer: The where and when of consciousness in the brain*

Week 9 discussion

10. Consciousness and metacognition.

- Thomas Nelson, Consciousness and metacognition
- Marcia Johnson and John Reeder, Consciousness as meta-processing
- David Rosenthal, *Consciousness, content, and metacognitive judgments*

Week 10 discussion

- Gordon Gallup, *Are animals self-aware? Yes*
- Daniel Povinelli, *Are animals self-aware? Maybe not*
- Thomas Nagel, *What is it like to be a bat?*
- Kathleen Akins, What is it like to be boring and myopic?

Week 11 discussion

12. The inverted spectrum.

- Stephen Palmer, *Color, consciousness, and the isomorphism constraint*
- C.L. Hardin, Color quality and color structure
- Martine Nida-Rumelin, Pseudonormal vision: An actual case of spectrum inversion?

- Eyal Reingold and Philip Merikle, Theory and measurement in the study of unconscious processes
- Jonathan Schooler, Consciousness and the limits of language
- Alvin Goldman, Can science know when you're conscious? Epistemological foundations of consciousness research
14. First-person approaches.

- David Chalmers, *First-person methods in the science of consciousness*
- Francisco Varela, *Neurophenomenology: A methodological remedy for the hard problem*
- Steven Horst, *Phenomenology and psychophysics*

15. To be determined

Web resources

Some useful resources on the web include:

- Consciousness in Science: A Bibliography
- Web resources related to consciousness, philosophy, and such
Philosophy 596B: Metaphysics

Meaning, Reason, and Possibility

David Chalmers

E-mail: chalmers@arizona.edu
Web: http://www.u.arizona.edu/~chalmers/
Office hours (Spring 2002): Wednesday 1:30-3pm (Social Sciences 226A)
Class meetings: Monday/Wednesday 3:30-5pm, Social Sciences 311.

Overview

This seminar is nominally listed as metaphysics, but it will address issues in the philosophy of language, metaphysics, epistemology, and the philosophy of mind. The seminar will explore the constitutive connections among reason, meaning, and possibility.

Frege's notion of sense tied meaning to reason. Carnap's notion of intension tied meaning to possibility. In conjunction with a Kantian view connecting reason and possibility, this yielded a golden triangle of connections among the three notions. Kripke's work broke the triangle by severing meaning and possibility from reason. One might see the central focus of this seminar as the project of once again articulating an approach to meaning and possibility on which they are constitutively tied to reason, thus restoring the golden triangle.

We will be discussing a fair amount of my own recent work on these topics, as well as work by others. Topics to be discussed include:

- Fregean theories of meaning
- two-dimensional semantics
- epistemic possibility and epistemic space
- conceptual analysis and its role in metaphysics
- narrow content and the semantics of thought
- conceivability and possibility
- the mind-body problem

Readings

There is no textbook. Many readings will be available on the web, and other will be made available for photocopying in a folder in the department office.
Web page

The web page for the class is at

http://www.u.arizona.edu/~chalmers/phil596b.html

Mailing list

I will set up a mailing list, phil596b@philosophy.arizona.edu, for class discussion. Everyone enrolled in the class is expected to make reasonably regular contributions to this list: at least one reasonably substantial posting every week (you can miss three weeks without penalty), discussing issues arising from the readings, from class discussion, and from the mailing list itself. Of course people are welcome and encouraged to post more often. These postings substitute for biweekly short papers of 1-2 pages each.

Assessment

Assessment will be based most heavily on a final paper, and will also be based on in-class presentations, mailing list contributions, and class participation.

Schedule

Here is a very approximate plan for the course, with associated readings. This is very likely to be revised as things develop.

Note that I will be out of town on quite a few meeting dates: Wed 1/23 (Cornell), Wed 2/6 (Rutgers), Wed 2/20 (ANU), Mon 2/25 (ANU), Wed 3/21 (North Carolina), Mon-Wed 4/8-10 (consciousness conference). These dates will be made up either by having double meetings on neighboring dates, or by rescheduling. I hope to have a more precise schedule of meetings soon.

Meeting 1 (Wed 1/9): Introduction

PART I: SENSE AND INTENSION

Meeting 2 (Mon 1/14): Frege on sense

- Frege, On sense and reference
- Chalmers, On sense and intension, sections 1-3

Meeting 3 (Mon 1/14): Carnap on intension
Meeting 4 (Wed 1/16): Epistemic intensions

- Carnap, *Meaning and Necessity*, pp. 1-32
- Chalmers, *The foundations of two-dimensional semantics*, section 1.1

Meeting 5 (Tue 1/22, 6:30pm): Indexicality and centering

- Perry, Frege on demonstratives
- Chalmers, *On sense and intension*, section 5

Meeting 6 (Mon 1/28): Kripke's modal argument

Meeting 7 (Wed 1/30): Two-dimensional intensions

- Chalmers, *On sense and intension*, section 6

Meeting 8 (Mon 2/4): Kripke's epistemic argument

- Kripke, *Naming and Necessity*, Lecture 2 (esp. pp. 79-97)
- Chalmers, *On sense and intension*, section 7

Meeting 9 (Mon 2/4): Variability

- Burge, Sinning against Frege
- Chalmers, *On sense and intension*, section 8

PART II: CONCEPTUAL ANALYSIS AND THE SCRUTABILITY OF TRUTH

Meeting 10 (Mon 2/11): Conceptual analysis and scrutability

- Chalmers and Jackson, *Conceptual analysis and reductive explanation*, sections 1-4
- Chalmers, *Does conceivability entail possibility*, section on "Inscrutabilities"

Meeting 11 (Wed 2/13): Block and Stalnaker against scrutability
Meeting 12 (Mon 2/18): Yablo against scrutability

- Stephen Yablo, Coulda, woulda, shoulda, especially section 20
- Chalmers, Does conceivability entail possibility, section on "modal rationalism and logical empiricism"

Meeting 13 (Mon 2/18): Hard cases

- Chalmers, Does conceivability entail possibility, second half of section on "inscrutabilities"

PART III: APRORITY AND EPISTEMIC SPACE

Meeting 14 (Wed 2/27): Apriority

- Bonjour, In Defense of Pure Reason, Chapter 1

Meeting 15 (Wed 2/27): Quine against apriority Quine, Two dogmas of empiricism

- Quine, Two dogmas of empiricism

Meeting 16 (Mon 3/4): Epistemic possibility and epistemic space

- Chalmers, The nature of epistemic space, sections 1-3

Meeting 17 (Wed 3/6): Scenarios as possible worlds

- Chalmers, The nature of epistemic space, section 4

Meeting 18 (Mon 3/18): Constructing possible worlds

- Lewis, Possible worlds
- Lewis, On the Plurality of Worlds, Chapter 3

Meeting 19 (Mon 3/18): The epistemic construction of scenarios

- Chalmers, The nature of epistemic space, section 5

PART IV: TWO-DIMENSIONAL SEMANTICS
Meeting 20 (Mon 3/25): Stalnaker's diagonal construction

- Stalnaker, Assertion
- Block and Stalnaker, *Conceptual analysis, dualism, and the explanatory gap*, section 10

Meeting 21 (Wed 3/27): The contextual and epistemic understandings

- Chalmers, *The foundations of two-dimensional semantics*, section 2-4

3. Other approaches

- Kaplan, *On the logic of demonstratives*
- Evans, *Reference and contingency*
- Davies and Humberstone, *Two notions of necessity*
- Chalmers, *The foundations of two-dimensional semantics*, section 5

PART V: MENTAL CONTENT

1. Arguments for externalism

- Putnam, *The meaning of 'meaning'*
- Burge, *Individualism and the mental*

2. Narrow content

- Loar, *Social content and psychological content*
- Stalnaker, *Narrow content*
- Horgan and Tienson, *The intentionality of phenomenology and the phenomenology of intentionality*

3. Epistemic content as narrow content

- Chalmers, *The components of content*, sections 1-6

4. Belief ascriptions

- Schiffer, *The mode-of-presentation problem*
- Chalmers, *The components of content*, section 7

PART VI: CONCEIVABILITY, POSSIBILITY, AND THE MIND-BODY PROBLEM
1. Varieties of conceivability

- Chalmers, *Does conceivability entail possibility* (through "GAPS")

2. Does conceivability entail possibility?

- Chalmers, *Does conceivability entail possibility* ("GAPS" and "THESES")
- van Cleve, Conceiving and the Cartesian argument for dualism
- Yablo, Is conceivability a guide to possibility?

3. The mind-body problem

- Chalmers, *Consciousness and its place in nature*, sections 1-5

4. Two-dimensionalism and the mind-body problem

- Kripke, *Naming and Necessity*, pp. 144-55
- Chalmers, *Consciousness and its place in nature*, section 6
- Chalmers, *Does conceivability entail possibility*, appendix

5. Materialist responses

- Hill & McLauglin, from PPR symposium
- Loar, from PPR symposium
- Yablo, *Concepts and consciousness*

6. Strong necessitaites and modal monism

- Chalmers, *Materialism and the metaphysics of modality*, section 3
- Chalmers, *Does conceivability entail possibility*, "From positive conceivability to possibility"
INDV 101: Philosophical Perspectives on the Individual

David Chalmers

E-mail: chalmers@arizona.edu
Phone: 621-7105
Web: http://www.u.arizona.edu/~chalmers/
Office hours: Thursday 1:30-3pm (Social Sciences 226A)
Class meeting (fall 1999): Monday/Wednesday 2-2:50pm, Modern Languages 350

Teaching Assistants:

- Allen Habib (anhabib@u.arizona.edu): Sections 6, 7, 13
- Ashley McDowell (ashleym@u.arizona.edu): Sections 4, 5, 10
- Seungbae Park (park@u.arizona.edu): Sections 3, 8, 11

Overview

This class is devoted to philosophical issues concerning the self and the mind. Some of the issues we will examine include:

- What is the self?
- What is the mind?
- What is the relationship between mind and body?
- Can consciousness be scientifically explained?
- How can we know about external reality?
- Do we have free will?
- Are animals conscious?
- Could computers have minds?

Texts

Further readings will be made available on this web page.

Assessment
There will be three short papers of 4-5 pages each, a midterm and a final exam, and occasional quizzes. Late papers will be penalized at a rate of one letter grade per day (except with medical documentation). No incompletes will be given, except for very good medical reasons. If you have special needs, let me know soon. Attendance at discussion section is required; if you miss more than two meetings, your grade will suffer.

**Second paper! (due Wednesday December 1)**

**First paper! (due Monday October 4)**

**Tips on doing philosophy**

Here are some very useful resources on how to write philosophy papers. Read these carefully!

- [Writing a Philosophy Paper](#) (Peter Horban)
- [Guide to the Study of Philosophy](#) (Garth Kemerling)
- [What Does He Want?](#) (Geoffrey Payzant)
- [Undergraduate Philosophical Writing](#) (Martin Young)
- [Writing a Philosophy Paper](#) (Sanford Levy)
- [Guidelines on Writing a Philosophy Paper](#) (James Pryor)

**Schedule**

Here is a very approximate week-by-week plan for the course, with associated readings. Note that this is very likely to be revised as things develop, and further readings will be added.

**TOPIC 1. INTRODUCTION** (1 week)

- DP, Chapter 1
- TMI, Introduction

**TOPIC 2: KNOWLEDGE AND SKEPTICISM** (1 week)

- DP, Section 2.1
- Descartes, Meditations I & II (DP)
- DP, Section 7.1
TOPIC 3: DUALISM (2 weeks)

- DP, Section 2.1
- Beloff, *The mind-brain problem*
- Smullyan, An Unfortunate Dualist (TMI)

TOPIC 4: BEHAVIORISM (1 week)

- DP, Section 2.2
- Miedaner, *The Soul of Martha, a beast* (TMI)
- Miedaner, *The Soul of the Mark III beast* (TMI)
- [Behaviorism](http://www.u.arizona.edu/~chalmers/indv101.html) (Internet Encyclopedia of Philosophy)

TOPIC 5: MATERIALISM (2 weeks)

- DP, Section 2.2
- Minsky, *Minds are simply what brains do*
- Dawkins, *Selfish genes and selfish memes* (TMI)
- Hofstadter, Prelude...ant fugue (TMI)

TOPIC 6: CONSCIOUSNESS (1-2 weeks)

- DP, Sections 2.4, 2.5
- Nagel, *What is it like to be a bat?* (TMI; also on the [web](http://www.u.arizona.edu/~chalmers/indv101.html))
- Frank Jackson, *Epiphenomenal qualia*
- Chalmers, The puzzle of conscious experience (DP; also on the [web](http://www.u.arizona.edu/~chalmers/indv101.html))

TOPIC 7: FREE WILL (2 weeks)

- DP, Chapter 3 (including readings)
- Smullyan, *Is God a Taoist?* (TMI)

TOPIC 8: PERSONAL IDENTITY (2 weeks)

- DP, Chapter 4 (including readings)
- Dennett, *Where am I?* (TMI)

TOPIC 9: ARTIFICIAL INTELLIGENCE (2-3 weeks)

- DP, Section 2.3
- Turing, Computing machinery and intelligence (TMI) (also on the web)
- Searle, Minds, brains, and programs (TMI) (also on the web)
- Bisson, They're made of meat

Web resources

Some useful resources on the web include:

- Online papers on consciousness
- Consciousness in Philosophy: A Bibliography
- Consciousness in Science: A Bibliography
- Web resources related to consciousness, philosophy, and such
This is a web page for my course Philosophy 80E: Paradoxes and Dilemmas. It contains links to a number of papers and other resources related to paradoxes on the web. This page is still under construction and may be developed as time goes on.

Miscellaneous

- Zeno's Coffeehouse (Ron Barnette)
- Contradictionary Web Page

Logic/Language Paradoxes

- Logic Puzzles
- Unexpected Hanging Paradox
- The Berry Paradox (Gregory Chaitin)
- The Paradox of the Question (Ned Markosian)

Sorites Paradox & Vagueness

- Dilemmas of Ambiguity and Vagueness (Leon Felkins)
- Understanding Vagueness (Leon Felkins)
- A Fuzzy Fairly Happy Face (Patrick Grim)

Grue/Raven Paradoxes

- Hempel's Ravens (Franz Kiekeben)

Teletransporters, etc

- Online papers on consciousness (see especially the self)

Time Travel

- Time Travel (Frank Kiekeben)

Prisoner's Dilemmas, etc
- **Paradoxes and Dilemmas** (Leon Felkins)
- **Social Dilemmas** (Leon Felkins) (plus examples and games)
- **The Voter's Paradox** (Leon Felkins) (see also here and here)
- **Prisoner's Dilemma** (Leon Felkins)
- **Prisoner's Dilemma** (Ethical Spectacle)
- **Prisoner's Dilemma** (Francis Heylighen)
- **Potential Solutions to the Prisoner's Dilemma** (Bjorn Brembs)
- **Interactive Prisoner's Dilemma**
- **The Tragedy of the Commons** (Garrett Hardin)

**Newcomb's Problem**

- **Newcomb's Paradox** (William Poundstone)
- **Newcomb's Paradox** (Franz Kiekeben)

Go to:

- [David Chalmers' home page](http://www.u.arizona.edu/~chalmers/class/paradox.html)
I have a couple of questions that have stuck in my mind, any and all input is welcome.

1) With regard to Denett's proposition that we "only think there is phenomenal consciousness" via many complex functions; my question, "is there "something it is like" to think that we have phenomenal consciousness? :)

2) With regard to phenomenally conscious states: It was given in the first lecture that a state "Y" is phenomenally conscious if there is something it is like to be in "Y". What followed was a list of "primary" or "foundationally" phenomenal conscious states. I may have mistaken this, but it seemed to imply to me that if a state was not "foundational" it did not belong on the list. This could have been because the list was of "primary" states, though that is not in my notes (i may have missed it). If this was meant to be a list of the kind of possible phenomenal states and not only of foundational or primary phenomenal states, it seems monumentally incomplete given that conscious experience is often multimodal. It would also seem to be the case that one could mix these primary states and come up with phenomenal experience that as a whole cannot be predicted accurately by the sum of its parts (a sort of systemic interaction of experience) as was proposed to be the case with "drunkenness" or "hypnotic states". Would it then be the case that one could think of the list that was put on the board as a "periodic table of phenomenal states" out of which all other complex states are constructed?

If so, what would one propose as the formula for "what it is like" to be in any given complex state (pick one) And / or how might we go about delineating empirically what the "formula" is for any given complex state?

Just thoughts,
-Lonnie

It is a common fate of all knowledge to begin as heresy and end as orthodoxy.
Lonnie writes:

>2) With regard to phenomenally conscious states: It was given in the first
>lecture that a state "Y" is phenomenally conscious if there is something
>it is like to be in "Y". What followed was a list of "primary" or
>"foundationally" phenomenal conscious states. I may have mistaken this,
>but it seemed to imply to me that if a state was not "foundational" it did
>not belong on the list. This could have been because the list was of
>"primary" states, though that is not in my notes (I may have missed it).
>It was meant to be a list of the kind of possible phenomenal states
>and not only of foundational or primary phenomenal states, it seems
>monumentally incomplete given that conscious experience is often
>multimodal. It would also seem to be the case that one could mix these
>primary states and come up with phenomenal experience that is accurate
>interaction of experience) as was proposed to be the case with
>"drunkenness" or "hypnotic states". Would it then be the case that one
>could think of the list that was put on the board as a "periodic table of
>phenomenal states" out of which all other complex states are constructed?

Well, the list wasn't intended to be taken too seriously, but there's
a sense in which it was trying to get at the "basic" sorts of
conscious states. As you say, there are any number of multimodal
states, but those get awfully complex. And one could argue that these
are decomposable to compositions of their various "modal" parts. If
they can't be so decomposed, then there may be something basic in
these states too (as we said e.g. for the category of "background
states"), and the only "periodic table" we would get would be an
indefinitely extendable one.
If it turns out that many or most such cases can be decomposed, though, then just perhaps it could turn out that we could have just a small number of classes of basic conscious states. In a way this might be a little bit like a periodic table. One big disanalogy, though, would be that within each class, there would be a huge number of "elements" (e.g. different sorts of sensory experiences) which may not be easily catalogable, and may not even be finite.

If so, what would one propose as the formula for "what it is like" to be in any given complex state (pick one)? And / or how might we go about delineating empirically what the "formula" is for any given complex state?

Good question. I suppose the simple answer to try would be to say that being in a composition of X and Y is like simultaneously being in X and being in Y. Of course, if decomposability fails, then your multimodal states won't really be compositions after all and this formula won't work. But I suspect that if decomposability fails, then there won't be any good formula, precisely because in that case the "whole" won't be a function of the "parts".

The question of how we go about determining whether a given complex state (e.g. hypnosis, drunkenness) is wholly decomposable into more specific elements is awfully tricky. I haven't thought about it a great deal and don't have any immediate ideas about it. It seems that phenomenology has to provide the primary database here. In some cases it seems clear phenomenologically that it would be possible to have states A and B without state C, so state C can't be reducible to A and B. (E.g., take C = the experience of humor and A and B = sensory experiences.) But in other cases it may be less clear. I think patient and reflective attention to phenomenology can go a long way here, but maybe there are "fringe" properties that are hard to resolve phenomenologically. It's not immediately obvious how empirical investigation can settle the matter, but maybe there are ways to bring it to bear. Any suggestions here are very welcome!

I have a couple of comments in response to Lonnie and Dave's chat about decomposability of complex conscious states, which went something like this:

> If so, what would one propose as the formula for "what it is like" to be in any given complex state (pick one) And / or how might we go about delineating empirically what the "formula" is for any given complex state? (Lonnie)

Good question. I suppose the simple answer to try would be to say that being in a composition of X and Y is like simultaneously being in X and being in Y. Of course, if decomposability fails, then your multimodal states won't really be compositions after all and this formula won't work. But I suspect that if decomposability fails, then there won't be any good formula, precisely because in that case the "whole" won't be a function of the "parts".

... It seems that phenomenology has to provide the primary database here. In some cases it seems clear phenomenologically that it would be possible to have states A and B without state C, so state C can't be reducible to A and B. (E.g., take C = the experience of humor and A and B = sensory experiences.) But in other cases it may be less clear. I think patient and reflective attention to phenomenology can go a long way here, but maybe there are "fringe" properties that are hard to resolve phenomenologically. It's not immediately obvious how empirical investigation can settle the matter, but maybe there are ways to bring it to bear. Any suggestions here are very welcome! (Dave)

My comments:

First, in our lab, we ask subjects to report on their experience of emotion (elicited by visual images) using an instrument called the Self-Assessment Manikin (Likert-like scales developed by Lang and colleagues at the University of Florida) that taps the dimensions of valence and arousal in emotional experience. (See attached document for a copy of the scales and instructions for their use). This procedure is based on the assumption that valence and arousal are two basic dimensions on which all emotional experiences vary. The support for this assumption comes from factor analysis work on emotional language, where valence and arousal turn out to be the two factors that best account for subjects' classifications of emotion words.

There are a number of advantages to this type of decomposition. It allows us to find reliable correlations between distinct features of phenomenal states and distinct components of emotional physiology. It allows us to compare groups of subjects on these distinct measures and determine whether...
the two dimensions dissociate. For example, normal subjects will usually report higher arousal to images they have rated as highly negative or highly positive, while reporting lower arousal to neutral pictures. Some patients with frontal brain injuries give valence (positive or negative) ratings similar to normal subjects, but report diminished and undifferentiated arousal across image types. This suggests that the two components are separable.

The problem with the scales (and the dimensions in general) is that it is not at all clear (though I tend to vacillate on this issue) that they represent more than linguistic classifications subjects are able to make. Moreover, the scales are presented as linear scales with specific endpoints. Negative and positive are presented on the same dimension with neutral as a midpoint, ruling out the possibility of experiences being a little negative and a little positive. The advantages of simplicity for data collection can lead to serious limitations in our understanding of the fundamental dimensions (or elements) of conscious experience. That said, it does seem possible for us to abstract dimensions from our emotional experience, just as we can extract visual dimensions from our experience of objects (color, shape, etc.). Most subjects have no problem making the ratings, and report that they were able to rate their experiences on both dimensions.

For a science of phenomenal experience to develop, one needs to begin by assuming some sorts of dimensions, in order to make progress. The problem comes in making assumptions about what is basic. Reservations that we have had about what counts as basic in emotional experience have led us to consider the use of open-ended emotion narratives as data. This demands that we develop a coding scheme that can render these narratives scientifically interpretable. In the development of this scheme, we begin by making some general assumptions about the elements that constitute emotional experiences (based on a lot of background theory) without committing ourselves to any particular map of the phenomenal space. We remain open to the question of what is basic and what is complex, hoping that the data will reveal this. In implementing this type of measurement in our lab, we will also be using the SAM scales, to determine whether there are any reliable mappings between the classifications our data reveal and the SAM dimensions.

My guess is that we may be able to identify certain emotion prototypes, and that these may turn out to vary along certain basic dimensions. Perhaps these will look something like the SAM dimensions, but I expect they will be a bit more complex. I do not think we will be able to identify primitive or basic qualia into which emotional experiences can be reduced. I am always surprised at the desire to implement some form of atomic reductionism at the phenomenal level, and wonder whether it doesn't result from our entrenchment in a predominantly reductive-materialist Western scientific mindset.

Some miscellaneous comments on things that have come up:

(1) Logan raises the interesting possibility that as well as the role that intrinsic properties play in grounding extrinsic properties (on a panprotopsychist view), there may also be the possibility of further "direct interactions" between intrinsic properties which would then be empirically testable. I guess my question here is what the principled difference is between this and standard "extrinsic" interactions. After all, when one particle affects another in standard ways, a panprotopsychist can construe this as the intrinsic properties of one directly having effects on the intrinsic properties of the other. Of course physics doesn't "see" the intrinsic part and characterizes only the extrinsic structure. But the same would go for Logan's new "direct" interactions, it seems to me. Even in parapsychology, one could characterize the causal structure extrinsically. All these would have an extrinsic structure that an objective science could characterize, and all would basic intrinsic properties that are really doing the causing and being affected. On either case, the extrinsic structure is just a way of getting at the basic causal relations among the intrinsic properties. So I'm not sure that I see the difference in kind here.

(2) Lis raises lots of interesting issues re her study of dimensions of emotional experience. The distinction between identifying dimensions of experience and reducing experience to basic components is important. It may well be that we can do the former but not the latter. For certain experiences, we can do both: e.g. for color, it's arguable that the experience is reducible to the components of hue, brightness, and saturation. But maybe it will turn out that for emotional experience, we will find at best a limited number of parameters that don't come close to exhausting the phenomenal character of the experience. I guess it's partly an empirical question whether the sort of reductive analysis that works for color will work elsewhere, but there's no obvious reason to believe that it should.

Philosophically, one might put the issue here in terms of supervenience. Just say one has identified a number of parameters of experience, and are wondering whether an experience is reducible to those parameters. I guess this comes down to whether the character of the experience supervenes on those parameters. I.e., would it be possible in principle (even logically possible) to have two different

---

http://www.u.arizona.edu/~chalmers/class/596v/week1.txt (6 of 7) [4/7/2002 1:54:18 PM]
experiences with the same values of those parameters but different overall character? With color, one might well argue that it is logically impossible to have two experiences with the same hue, saturation, and brightness, but a different color quality. (Though maybe there are issues about further parameters such as shimmer, etc.) But with emotion, for any set of parameters we have identified at least so far, the parameters don't seem to determine the quality of the experience in the same way. Maybe that just means we have to come up with better parameters, but again, it's not obvious that any full set of such parameters should exist.

I note that when I put forward the (very tentative and speculative) suggestion about five or six basic sorts of phenomenal states, I wasn't really suggesting anything quite this reductive. Here, the basic categories were as broad as perceptual experiences, emotional experiences, cognitive experiences, etc, and the claim was in effect that the overall character of a subject's experiences is fully determined by the character of these components. This is consistent with the view that within each category, there may be a huge variety of states that are not reducible to any more basic building blocks (as e.g. Lis suggests re emotion).

In effect we have two questions: (i) whether a subject's overall state of experience is determined by the character of their experiences in the five or six categories, and (ii) whether the character of an experiences within those five or six categories is determined by some set of more basic parameters. Both of these seem to be interesting open questions, and the answer isn't obvious (at least to me) one way or another.

(3) Re Lonnie's and Joel's discussion of the baseball player: Actually there is recent empirical work that bears on this. The research of Milner and Goodale, which we'll be discussing, suggests that there are two pathways in the visual system, one for making cognitive and conscious identifications, and one for controlling online motor action. In certain cases (e.g. due to brain damage), representations in these two pathways can come apart, and one finds subjects who can perform fine-grained motor actions on objects even when they apparently don't have conscious knowledge of those objects. (E.g., a subject who can "post" a letter through a horizontal or vertical slot even though she doesn't consciously know whether it is horizontal or vertical.) It even turns out that one can find such subtle versions of such dissociations in ordinary subjects under certain conditions, and in these cases one finds that how a subject acts with respect to (say) the position of an object may be out of line with their conscious judgments.

It's not out of the question that Joel's observations re the phenomenology of baseball could be partly grounded in this framework. It could turn out that representations in the "cognitive" system are less fine-grained than representations in the "motor" system. Milner and Goodale believe that the contents of visual consciousness are determined by the cognitive system, not the motor system. If that's the case, then one would expect that one would be able to performed fine-grained motor tasks (e.g. catching a baseball) that rely on visual information that is not present in consciousness at all).

--Dave.
This question is directed at David, but may be replied by anyone in the class who has something to say. I noticed that when David presented his non-reductive strategy to investigating consciousness, he drew a single one-way arrow pointing from physical processes to consciousness. David, were you trying to imply that the causal-functional relationship between physical and qualitative processes is only one way (from physical to consciousness)? What reasons do we have to think that it couldn't go both ways (kind of like J. Sarfatti's idea of backaction between mental and physical)? I ask this because if we want to introduce consciousness as an explanatory primitive, and if we further wish to characterize it as playing a causal-functional role in the universe, then it may be that our current account of non-conscious physical processes is incomplete in that the intrinsic nature to material particles may be playing a role in the dynamics of physical systems that are currently characterized in terms of extrinsic relationships. Such a possibility could produce empirically testable consequences.

Such a possibility would be consistent with both pan-experiential and interactionist viewpoints in that the ontology could be construed in the sense of the former - consciousness (or at least qualitative experience) is an intrinsic property to material processes - yet the dynamics could be understood in the sense of the latter in that there could be a functional, interactive relationship between the intrinsic and extrinsic parameters of physical reality. Physical reality would still be causally closed, but only if one takes both its inner and outer aspects into account.

Just a thought.

Best,

Logan Trujillo

Actually, I didn't mean to rule out that the relation could be

two-way. In my alphabetical taxonomy, the one-way relationship is a
type-E dualism (epiphenomenalism), and the two-way relationship is a
type-D dualism (D for Descartes, i.e. Cartesian dualism, or
interactionism).

The reason many people are suspicious of the type-D view is that it
seems to introduce gaps in physical causation; i.e., it suggests that
the physical world is not "causally closed". And many people think
that the evidence from physics is that physics is causally closed, and
that there is no room for "spooky causation". Of course some people
deny that, and suggest that in particular quantum mechanics may leave
room for interaction between physical and mental.

Many are suspicious of the type-E view for a different reason, namely
that it suggests that consciousness has no effect on the physical
world. And seems very counterintuitive to hold that a pain doesn't
cause our pain reaction, that the visual experience of the sunset
doesn't cause me to keep looking at it, that my consciousness plays no
causal role in my writing books about consciousness, etc. But then
one might respond that the epiphenomenalist can explain the
counterintuitiveness at least to some extent, by noting that there are
strong regularities between experiences and consequent physical
events, so that we tend to infer a causal connection even when it is
not there.

Of course all that is controversial. My own view is that if arguments
against materialism are accepted, then the conclusion ought to be a
disjunction of (i.e. a choice between) interactionism, epiphenomenalism, and panprotopsychism (i.e. the type-D, type-E, and type-F views I mentioned). The choice between those depends on a lot of subtle matters and is by no means obvious, and may to some extent depend on where a science of consciousness ends up going.

I ask this because if we want to introduce consciousness as an explanatory primitive, and if we further wish to characterize it as playing a causal-functional role in the universe, then it may be that our current account of non-conscious physical processes is incomplete in that the intrinsic nature to material particles may be playing a role in the dynamics of physical systems that are currently characterized in terms of extrinsic relationships. Such a possibility could produce empirically testable consequences.

Such a possibility would be consistent with both pan-experiential and interactionist viewpoints in that the ontology could be construed in the sense of the former - consciousness (or at least qualitative experience) is an intrinsic property to material processes - yet the dynamics could be understood in the sense of the latter in that there could be a functional, interactive relationship between the intrinsic and extrinsic parameters of physical reality. Physical reality would still be causally closed, but only if one takes both its inner and outer aspects into account.

Hmm, your talk of the "intrinsic aspects of material reality" suggests the panprotopsychist view to me. Of course on that view, the intrinsic aspects have causal effects (they are the ultimate causes of all physical action!), but on this view, the physical world will still be causally closed, so it isn't a type-D view. I'm not sure just how you mean the view to have empirical consequences, though. On my reading of such a view, the intrinsic aspects play a causal role in all physical interactions (they are the ultimate things doing the causing), so it's not as if there will be a new and special set of interactions that they do the causing in. So it's not clear that the view makes empirical predictions (at least about third-person matters such as the motion of particles) that are distinct from those made by ordinary physical theory.

If, on the other hand, you want to introduce phenomenal properties as a new set of properties at the bottom level without having them underlie all causal interactions, then it seems that you'll be regarding them as a further property like mass, etc, right at the bottom. Then it's true that you could have new laws and new interactions governing them. But now you'll be up against the problem that there is no apparent evidence for them in physics, and that the view will thus require revolutionizing our well-supported physical theories to incorporate consciousness. Maybe this could happen, but it's going out on a big limb. Basically, on this view, we'll say that there's a certain physical parameter C (to be discovered) such that C has consciousness as its intrinsic nature. Maybe it would be easier to say that some existing physical parameter (mass or spin, say) has consciousness as its intrinsic nature, and that it interacts with all the others. Then, it seems to me, you might get the benefits of the view without the costs.

Feel free to clarify...

[Logan]

I think that we should clarify what we mean by "physical". On a
panprotopsychist account, the intrinsic aspects to material particles would still be "physical". However they have a distinction from physical properties that are characterized extrinsically (mass, charge, etc).

It is this distinction that proponents of this view seek to utilize in an account for the "difference in kind" of experiential properties from the extrinsic properties we know. Another terminology that could be used is "material/immaterial" in place of "extrinsic/intrinsic". "Material" properties may be conceived as those arising due to extrinsic relationships, "immaterial" properties are those due to intrinsic.

Now on a panprotopsychist viewpoint the intrinsic properties certainly may be construed as carrying the causal weight of the extrinsic interactions (see below). However physics for the most part maps out extrinsic properties (an argument against this may be made in the case of spin; spin is considered an "intrinsic" property because it does not depend explicitly on spatiotemporal parameters. However it does have extrinsic effects and thus may be characterized in terms of this relational ability). The intrinsic nature to reality may account for this causally, but the possibility remains that certain physical processes exist that are purely "immaterial", i.e. interact via direct relationships among intrinsic properties. These may have influences extrinsically in the sense that these interactions produce changes in the intrinsic state space of a system in a manner that carries over into the portion of the intrinsic causal network underlying extrinsic properties. Although panprotopsychist, this view is also interactionist in the sense of a material/immaterial categorization to the ONE physical reality that is causally closed on a global (intrinsic/extrinsic) scale (this would be a conjunction of type D and F).

I guess it comes down to the question, can the possible set of intrinsic property relations and interactions outrun the possible set of extrinsic property relations and interactions? I see no reason why this couldn't be the case, and recent arguments based in physics approaches to understanding consciousness, as well as the data from parapsychology seem to suggest that this might be the case (although this is very controversial). An analogy from mathematics might help to illustrate: by definition, all real numbers are complex numbers, but not all complex numbers are real numbers. I would argue in analogy that the intrinsic stands to the complex numbers as the extrinsic stands to the reals. To be extrinsic is to have an accompanying intrinsic component; but being intrinsic does not imply that one has an accompanying component in any direct sense.

[David]

I'm not sure just how
> you mean the view to have empirical consequences, though.
On my

> ordinary physical theory.

The consequences may be as everyday as a solution to phenomenal binding, to the existence of a freewill, to the more controversial "anomalies of consciousness" data mentioned above. These are all phenomena that seem to defy extrinsic relational explanations.
If, on the other hand, you want to introduce phenomenal properties as a new set of properties at the bottom level without having them underlie all causal interactions, then it seems that you'll be regarding them as a further property like mass, etc, right at the bottom. Then it's true that you could have new laws and new interactions governing them. But now you'll be up against the problem that there is no apparent evidence for them in physics, and that the view will thus require revolutionizing our well-supported physical theories to incorporate consciousness. Maybe this could happen, but it's going on a big limb. Basically, on this view, we'll say that there's a certain physical parameter C (to be discovered) such that C has consciousness as its intrinsic nature. Maybe it would be easier to say that some existing physical parameter (mass or spin, say) has consciousness as its intrinsic nature, and that it interacts with all the others. Then, it seems to me, you might get the benefits of the view without the costs.

[Logan]
This almost sounds like my viewpoint except that I suspect that phenomenal consciousness does underlie all extrinsic interactions. It is just that phenomenal properties may interact in a manner over and above the purely extrinsic interactions. Again I don't think there is any good reason to deny this, especially in the face of the fact that physics, when first conceived, split off primary qualities from secondary qualities a priori, with the former deemed proper subject of study. The whole edifice of physics is rooted in this distinction. Thus when trying to slip secondary (phenomenal) properties "under the carpet", so to speak, what a priori justification do we have to maintain that the relationships within and between intrinsics/extrinsic properties must match up in a one-to-one manner?

> Feel free to clarify...
>
> --Dave.
>
> Thanks for the opportunity!

Logan
All-

This post deals primarily with Daves "Facing Up to the Problem of Consciousness," so I suppose it is directed somewhat at him (its terribly useful to have the author of the paper so readily available.) However, I think that the issue that follows may lend itself to lots of group input, at least for those interested. The point Im going to try to make is at least largely an empirical one, but I am pretty certain that my own knowledge of this subject only scratches the surface of the available evidence. So anyone who can think of other experimental results or examples that either confirm or disconfirm my point would be welcome to add their evidence to the pile.

What I want to write about here is Daves Principle of Structural Coherence, which is intended as the backbone of his scientific theory of consciousness. But before I do, I should say that I think this part of his paper (and book) is tremendously important. This is because it defends him against one of the stronger arguments against dualism, namely the argument that dualism amounts to just giving up on explaining consciousness. Many materialists refuse to even consider dualism because most dualists claim that consciousness must forever remain a mystery. (See Dennetts Consciousness Explained, p. 37 for an example of this.) However, if something like Daves Principle of Structural Coherence could be confirmed, this might take the sting out of dualism by opening phenomenal consciousness to scientific investigation.

The problem is that several psychological facts seem to disconfirm the Principle of Structural Coherence as outlined in section seven of "Facing Up to the Problem of Consciousness." The basic idea here is that the structure of "consciousness" (phenomenal consciousness) and the structure of "awareness" (direct availability for global control) mirror each other. The following are examples where the two seem (at least to me) to diverge:

Awareness without Consciousness - In the Nelkin paper, "What is Consciousness," he defends several examples of what he takes to be intentionality without introspection, which I take to be awfully similar to awareness without consciousness. If a persons brain can be shown to be carrying on complex and integrated intentional behavior while they themselves report no consciousness of these facts, it seems that there is information in their brain that is available for global control but not conscious.

Unified Consciousness vs. Dis-unified Awareness - In the Bisiach paper, "The (Haunted) Brain and Consciousness," he starts the section on "The modularity of consciousness" with the claim that "Data from investigation of brain-damaged subjects show dramatically how C2 is far from being a unitary process(and how vain it would be to try to map Clonto C2)." If awareness is generally dis-unified, with the brain processes responsible for various tasks working largely independently, at different speeds, and so on, this does not seem to correspond to our phenomenological consciousness of the goings on in our mind.
Detailed Awareness vs. Approximate Consciousness - This example is just based on personal observation, though I wouldn't be surprised to find that more careful experiments have been done. Many tasks seem to require more detailed awareness than we are conscious of when we perform them. For example, if you ask a baseball player to guess the angle and initial velocity of the fly ball coming off the bat, even the most mathematically and scientifically astute baseball player will only be able to roughly estimate these quantities. The same player, however, will successfully position himself or herself to catch the ball. It seems that the player needs to be aware of data with a significantly smaller margin of error than he or she would report being conscious of.

There are lots of responses that Dave can make to these sorts of observations. Indeed, as I am sure that other people have raised similar questions, I fully expect that he has ready responses for most of them. I realize that I've been fairly vague about giving specific examples of the sorts of phenomena I think conflict with the Structural Coherence Principle, but I wanted to get the main points across. Perhaps if Dave doesn't have a way of dismissing the lot in one fell swoop, we'll get into talking about specific cases. If anyone has examples of phenomena that seem to fit the bill, let me know.

Thanks,

Joel

PS - I really do know how to use apostrophes. MS Word and PINE don't seem to get along in this respect.
perform them. For example, if you ask a baseball player to guess the angle and initial velocity of the fly ball coming off the bat, even the most mathematically and scientifically astute baseball player will only be able to roughly estimate these quantities. The same player, however, will successfully position himself or herself to catch the ball. It seems that the player needs to be aware of data with a significantly smaller margin of error than he or she would report being conscious of.

I think I would say that in these cases the player isn't aware of the information, either. As you note yourself, the information isn't available for verbal report. In effect it is playing a local control role in the regulation of certain sorts of specific and practiced behavior, but it isn't available in the sort of general and global manner required for awareness. So again, if awareness is delineated appropriately, there's no dissociation.

It seems to me that the information that is being referred to here is of a cognitive domain (mathematically astute athlete) would be dealing in arbitrary units with which to quantify his (or her) experience. The player would not experience the ball in terms of degrees, as a "degree" is not a naturally occurring concept to most of us, we give estimates of these sorts of measures in order to communicate, but when you are catching a fly ball, you are accessing a "natural" schema of prior experience. "What this particular fly ball is like" is very apparent to the player, and if you could be shown his (or her) mind, from the inside they could direct you to which set of memories merged to tell them how to behave. I realize that this came off sounding rather self assured, but really the above is only a string of hypotheses generated by my own experience. And therefore are entirely open to alternative interpretation...Anyone?

Lonnie,

Actually, misleading remarks about mathematics to the side, I was thinking of the baseball player's visual representation. When I catch a fly ball, it seems to me as though the information contained in my phenomenal visual field is less precise than that needed to catch the ball. I'm not sure about this either. For one thing, I haven't caught many fly balls lately, so maybe I'm remembering it wrong. Or maybe I've just discovered the reason that I'm only a mediocre outfielder.

Thanks for the reply,

Joel

---

Some miscellaneous comments on things that have come up:

(1) Logan raises the interesting possibility that as well as the role that intrinsic properties play in grounding extrinsic properties (on a panprotopsychist view), there may also be the possibility of further "direct interactions" between intrinsic properties which would then be empirically testable. I guess my question here is what the principled difference is between this and standard "extrinsic" interactions. After all, when one particle affects another in standard ways, a panprotopsychist can construe this as the intrinsic properties of one directly having effects on the intrinsic properties of the other.

Of course physics doesn't "see" the intrinsic part and characterizes...
only the extrinsic structure. But the same would go for Logan's new "direct" interactions, it seems to me. Even in parapsychology, one could characterize the causal structure extrinsically. All these would have an extrinsic structure that an objective science could characterize, and all would basic intrinsic properties that are really doing the causing and being affected. On either case, the extrinsic structure is just a way of getting at the basic causal relations among the intrinsic properties. So I'm not sure that I see the difference in kind here.

(2) Lis raises lots of interesting issues re her study of dimensions of emotional experience. The distinction between identifying dimensions of experience and reducing experience to basic components is important. It may well be that we can do the former but not the latter. For certain experiences, we can do both: e.g. for color, it's arguable that the experience is reducible to the components of hue, brightness, and saturation. But maybe it will turn out that for emotional experience, we will find at best a limited number of parameters that don't come close to exhausting the phenomenal character of the experience. I guess it's partly an empirical question whether the sort of reductive analysis that works for color will work elsewhere, but there's no obvious reason to believe that it should.

Philosophically, one might put the issue here in terms of supervenience. Just say one has identified a number of parameters of experience, and are wondering whether an experience is reducible to those parameters. I guess this comes down to whether the character of the experience supervenes on those parameters. I.e., would it be possible in principle (even logically possible) to have two different experiences with the same values of those parameters but different overall character? With color, one might well argue that it is logically impossible to have two experiences with the same hue, saturation, and brightness, but a different color quality. (Though maybe there are issues about further parameters such as shimmer, etc.) But with emotion, for any set of parameters we have identified at least so far, the parameters don't seem to determine the quality of the experience in the same way. Maybe that just means we have to come up with better parameters, but again, it's not obvious that any full set of such parameters should exist.

I note that when I put forward the (very tentative and speculative) suggestion about five or six basic sorts of phenomenal states, I wasn't really suggesting anything quite this reductive. Here, the basic categories were as broad as perceptual experiences, emotional experiences, cognitive experiences, etc, and the claim was in effect that the overall character of a subject's experiences is fully determined by the character of these components. This is consistent with the view that within each category, there may be a huge variety of states that are not reducible to any more basic building blocks (as e.g. Lis suggests re emotion).

In effect we have two questions: (i) whether a subject's overall state of experience is determined by the character of their experiences in the five or six categories, and (ii) whether the character of an experiences within those five or six categories is determined by some set of more basic parameters. Both of these seem to be interesting open questions, and the answer isn't obvious (at least to me) one way or another.

(3) Re Lonnie's and Joel's discussion of the baseball player: Actually
there is recent empirical work that bears on this. The research of Milner and Goodale, which we'll be discussing, suggests that there are two pathways in the visual system, one for making cognitive and conscious identifications, and one for controlling online motor action. In certain cases (e.g. due to brain damage), representations in these two pathways can come apart, and one finds subjects who can perform fine-grained motor actions on objects even when they apparently don't have conscious knowledge of those objects. (E.g., a subject who can "post" a letter through a horizontal or vertical slot even though she doesn't consciously know whether it is horizontal or vertical.) It even turns out that one can find such subtle versions of such dissociations in ordinary subjects under certain conditions, and in these cases one finds that how a subject acts with respect to (say) the position of an object may be out of line with their conscious judgments.

It's not out of the question that Joel's observations re the phenomenology of baseball could be partly grounded in this framework. It could turn out that representations in the "cognitive" system are less fine-grained than representations in the "motor" system. Milner and Goodale believe that the contents of visual consciousness are determined by the cognitive system, not the motor system. If that's the case, then one would expect that one would be able to performed fine-grained motor tasks (e.g. catching a baseball) that rely on visual information that is not present in consciousness at all).

http://www.u.arizona.edu/~chalmers/class/596v/week2.txt
empirically testable. I guess my question here is what the principled
difference is between this and standard "extrinsic" interactions.
After all, when one particle affects another in standard ways, a
panprotopsychist can construe this as the intrinsic properties of one
directly having effects on the intrinsic properties of the other.
Of course physics doesn't "see" the intrinsic part and characterizes
only the extrinsic structure. But the same would go for Logan's new
"direct" interactions, it seems to me. Even in parapsychology, one
could characterize the causal structure extrinsically. All these
would have an extrinsic structure that an objective science could
characterize, and all would basic intrinsic properties that are really
doing the causing and being affected. On either case, the extrinsic
structure is just a way of getting at the basic causal relations among
the intrinsic properties. So I'm not sure that I see the difference
in kind here.

[Logan]
At the time I made the comment that Dave discusses above I had a
misunderstanding of what philosophers meant by the term "intrinsic". Now
that I have this term clarified in my mind, I believe that I can explain,
in a more satisfactory way, what I was trying to get across by the notion
of "direct interactions". Dave is absolutely correct in his statement that
"the extrinsic structure is just a way of getting at the basic causal
relations among the intrinsic properties". Essentially what I am trying to
suggest is that proper characterization of the intrinsic properties (with
regards to accounting for phenomenal consciousness) may lead to new extrinsic
functional relationships among physical primitives that are not predicted
by current scientific theory. Such new functional possibilities would
presumably arise during the integration of said intrinsic properties with
current theory. This possibility can be seen by considering Thompson's
discussion of color spaces.
Thompson asks on what basis may we consider Fred to be seeing a
new hue as opposed to the possibility that what he is experiencing is not
a new hue or color quale, but some other novel form of visual qualia. If I
understood his argument correctly, he concluded that we may consider
Fred's novel qualitative experience to be that of color if (through
relevant psychophysical experimentation) we may determine that the nature
of the functional relationships between the new "hue" and the originals
are the same as those found in our 3-dimensional color space. Thus Fred's
color space is just a 4-dimensional space containing our color space, with
the same functional rules of the latter. It is on this basis that we may
say that we can have some idea of what Fred's novel experiences are like,
since we may use our knowledge of those functional relationships to
extrapolate to Fred's experience (although as was discussed in class, we
still wouldn't know very much). However if it was determined that
Fred's extra quale did not engage in the same functional relationships
with the original elements of our color space, then we can no longer say that
what Fred is experiencing is color; it must be some other form of visual
quaia (by the way, could it be this type of distinction that Nagel was getting
at in his discussion of the qualitative experiences of bats?).

Now in either case the new qualitative feature that Fred is able
to perceive may still be considered to be intrinsic in the sense that Dave
uses the term in regards to qualia. And in the case that the presence of
the new feature merely expands the dimension of the color space without changing
the functional/relational rules between the intrinsic elements of the
space, we may say that the intrinsic nature of the new "hue" is of
essentially the same nature of the primitive elements that make up our
color space (i.e. it is a color quale). However in the case that the
presence of the new qualitative feature within the space results in a change
amongst the functional relationships of the space, then it would seem that the
new feature would have an intrinsic nature substantially different from the elements constituting our color space; it would be such a difference that presumably would be the cause of the change in functionality of the space.

I guess the point that I was trying to make with my last listserve posting was that it may be that the proper characterization of the intrinsic properties (proper in the sense that the characterizations are forced upon us to adequately account for phenomenal consciousness) may lead to functional relationships not predicted by current scientific theory (physical/neuroscientific/psychologic) once such intrinsic properties are integrated into current theory. The existence of such functional relationships may lead to consequences that are empirically testable. Hence the notion of "direct interactions" between intrinsics is really meant to describe possible extrinsic interactions outside the scope of interactions currently postulated by conventional theory.

I just wanted to make a comment about an alternate form of Type -A Materialism that I find to be a bit more plausible than the general form the you gloss in Moving Forward on the Problem of Consciousness. In the analogies from Dennett and the Churchlands, the alternate property to be explained seems to be (at least plausibly thought of as) a natural kind. Life, light, and heat, if they are properties to be explained, all seem to be natural kinds. However in one of Dennett's other examples, that of cuteness, the properties admissibility as capturing a natural kind might be brought into question.

Although you have objected to the general schema of using analogies with other properties to undermine the project of identifying consciousness, if you will bear with me, I think that one further analogy may be used to highlight a different objection. This is an analogy with the property (or
at least those things that fall under the description) "In this room". As with those things that fall under the description "What it is like", we have a convenient way to pick out these entities. But having a catch phrase to pick out objects shouldn't lead us to automatically take the grouping as representing a natural kind.

So, let us say that the objects falling under the description "In this room" do not in fact make up a natural kind. We will then absolve our best theories of the world from explaining what it is that gives an object its "In this room"ness; in particular we will not demand that our theories give us a unified explanation of "In this room"ness. Even so, we will want our theories to explain many facts about the individual objects in this room: How my computer works, why my desk weighs as much as it does, etc... One of these individual facts may be: how my desk got into the room. To explain this we do not need to explain the property of "In the room"ness, but rather need to give the history of the desk to trace its path into my house; we want to show how the property of being a desk, and the non-(full fledged)-property of "In the room" came to accidentally occur in the same object.

Ok, so on to "What it is like". Let us say, for the moment that things falling under this description also do not make up a natural kind. If so then, in the same way, our theories do not need to give a unified explanation of "What it is like"ness. Still, of course, we will want to explain many facts about our experiences (those events that fall under the "What it is like"ness) and these are what I take cognitive science to be after. In addition we may want to explain how a particular neural state came to be associated with an experience; in this case we will give the history of the neural state, and how it came, accidentally, to fall under the description "What it is like".**

[[**Also, as an interesting sidenote, if we are actually after a history for each type of experience, we run into further problems. For, as I think Richard Lewontin has argued quite forcefully, there are limitations on the historical explanations available for mental processes. We simply lack the record to make definite judgements about the (long term) history of our mental abilities.]]

An argument based upon this sort of analogy seems to me to fit your Type-A Materialism, but without being eliminativist. Rather than eliminating experiences as things to be explained, this approach simply sets limits on the kinds of explanations we should expect for our experiences.

I don't know if anyone advocates exactly this view, but it seems like a plausible middle road to me.

Sarah
I want to point to an epistemological problem that underlies Chalmers' schema for a science of consciousness now (rather than the third-to-last week when we are scheduled to discuss epistemological issues) since the worry, if serious, seems to undermine the very foundation of the project.

Blind Mary

In class, in the context of altered Mary scenarios, Allen mentioned "blind Mary". It was in passing, and he didn't follow through with the concept, but I want to take the idea and use it to bring out the problem I'm concerned with. Now, it seems to me that a blind Mary scenario (blind, mind you, not just color-blind) would be problematic for the following reason: brain science is reliant on perception (i.e., the perception of the brain scientist(s)). Now it might be argued that any given brain scientist could learn all there is to know regarding the brain even if she were blind (still, I'd imagine there would be problems when she tried to conceptualize the spatio-temporal layout of even the most simple neural networks), but this is not my real worry. My real worry concerns not individual scientists but the nature of the brain sciences themselves. And it seems relatively obvious to me that such sciences rely heavily on perception (observation) for their data. Consider, say, neurophysiology--PET scans, single-cell investigation, brain imaging, exploratory surgery, etc.--without perception there is no data.

The Problem with Perception or What It's Like to be a Human

The problem put short is this: what it's like to be a human might not be what it's like...full stop. In other words, the structure of our experience might not match up as nicely as we might like with the structure of the world. Take Nagel's bat. There is this rich phenomenology--a phenomenological "world" if you will--a this bat has access to. Now, presumably, it is different (perhaps VERY different) from our own phenomenology (the paper hinges on this point). What it's like for a bat to experience the world is very different from what it's like for a human to experience the world. The world for a human is a world of objects. The human body looks a certain way, feels a certain way, When we observe it, and do so rigorously, adhering to a scientific method, we get things like anatomy and physiology. When we observe the brain at a neuronal level, we get neurophysiology. Now, given that we think a bat's rich phenomenology is different from our own, a bat's neurophysiology (if
it had one) would, presumably, look different. That is, depending how different it is to be a bat rather than a human, that's how different it's scientific picture would be from our own (if you don't like the bat analogy substitute your favorite species, earth-bound or no). But this sounds ridiculous. First, other species do not have science (at least no known one's, we think). Second, we seem to think that, as humans, we are the state of the art of species-making. We are as good as it has gotten so far. That is, we seem to think we stand in some epistemically privileged position with respect to other species. Thus, our science, even if other species' had a science, would be the best. What the world seems like to humans is closer to what the world is actually like than for any other species. The last claim needs some arguing, but it might turn out to be true. Yet even if it is true, it does not get us what we want (or think we already have). That is, we might be the closest of anyone trying to the real story, yet, what it's like to be a human may still not be what it is like.

Kant and the Critique of Chalmers' Proposal for a Science of Consciousness

The neumenal and the phenomenal. Kant thought that no matter how hard we tried, we were stuck in the phenomenal world. All we could ever get was the world as it appeared to humans. The world as it really was, was closed to us. Now, using Kant's distinction as a springboard, I want to make a criticism of Chalmers' proposal for a science of consciousness. Chalmers says that a science of consciousness will consist in something like the following: micro physical facts (facts got by the brain sciences, spec., neurophysiology), linked by bridging laws (perhaps psychophysical) to macro facts (facts about one's own (or human) phenomenology. That is, a science of consciousness will consist in facts about brain processes, or states, linked by laws to facts about human experience. The third person (data from brain observation) adequately linked to the first person (data from experience). The problem is that when it comes time to do the science, i.e., to glean the microphysical facts, we observe the brain. We form theories based on observation. But when we observe the brain we observe it as humans. It is part of what it is like to be a human to have that certain brain-appearance. So the microphysical facts are indexicals--they are facts-for-humans, as it were. In Kantian terms, we get phenomenal facts. So, our science of consciousness ends up linking certain phenomenal facts (i.e., 3rd person ones) with certain OTHER phenomenal facts (i.e., 1st person ones). This isn't what we want. What we want are NEUMENAL facts linked with phenomenal facts. Herein lies explanation. "But I thought Kant said we could never get neumenal facts." is what your thinking. True, but other philosophers after him, those taking the neumena/phenomena distinction seriously, didn't necessarily agree. I don't think we're stuck, and that therefore there can be no science of consciousness as Chalmers' construes it... so more needs to be said about why I think this. However, not today. See my next post (it will still be a pertinent worry as we are now discussing whether or not we can find the neural correlates of consciousness).
Dave,

Sorry to bother you again, but I can't get this sent to the listserv. I copied the address from your homepage; not sure what the problem is. Feel free to post to listserv if possible. Thanks

Matt

Jackson's distinction between the physical facts about sensing and the sensory experience itself is similar in some important ways to Russell's distinction between knowledge by description and knowledge by acquaintance. (In turn, Russell and other philosophers probably owe a debt to Aristotle for suggesting this distinction in _Posterior Analytics_, but I'm happy to let the scholars handle that issue.) I'm not sure if Russell's analysis will comfort the qualia freaks or the reductionists, but it will be worth a look.

First some background is in order (Cf _The Problems of Philosophy_, chapt. 4,5). Russell is out to give an exhaustive taxonomy of knowledge, and his first cut is between knowledge of facts and knowledge of things. This distinction expresses the difference between knowledge that p and familiarity with x. The acquaintance/description distinction is a refinement of the familiarity-with-x concept. I won't attempt to improve on Russell's clarity regarding this distinction:

"In the preceding chapter we saw that there are two sorts of knowledge: knowledge of things, and knowledge of truths. In this chapter we shall be concerned exclusively with knowledge of things, of which in turn we shall have to distinguish two kinds. Knowledge of things, when it is of the kind we call knowledge by _acquaintance_, is essentially simpler than any knowledge of truths, and is logically independent of knowledge of truths, though it would be rash to assume that human beings ever, in fact, have acquaintance with things without at the same time knowing some truth about them. Knowledge of things by _description_, on the contrary, always
involves . . . some knowledge of truths as its source and ground" (p. 46).

It may be helpful to think of Mary as lacking acquaintance with a certain quale (say, redness), despite having maximal descriptive knowledge of it. Russell's characterization of acquaintance as logically independent of description matches up with this intuition: one may possess all the descriptions of x and yet not be able to infer what the experience of x is like.

It seems that both Russell and Jackson are making an implicit appeal to the operation of distinct faculties. There are inference modules, whose input can only be facts and whose output can only provide furhter, extrinsic facts about x's (how they relate to y's, what they do under condition c, etc.), and there are sensory modules, whose input is experience of x and whose output, strictly speaking, is non-propositional, intrinsic information about x's which nonetheless can give rise to propositions to be fed into the inference module.

A faculty of description and a faculty of acquaintance, if you will.

I apologize for not drawing a moral from these bits; it's only a clarifying illustration. I might as well admit my allegiance, however. I think there are good arguments and intuitions in favor of the Russell/Jackson view about qualia. The arguments (that I know) are epistemological and have to do with the need to anchor propositional knowledge in non-propositional experience; the intuitions are those of first-person phenomenology that Dave alludes to in _The Conscious Mind_.

Ok, we have been talking a lot about Jackson yesterday, but we didn't really touch the issue of epiphenomenalism. And there are couple this I want to know about it.

First, I pretty much understand the statement that qualia are epiphenomenal. I suppose my intentional zombie twin riding her car would stop on the red color the very same way I would. And maybe that is what we do - we stop because we process the information about the light and then the thing is somehow accompanied by an experience. So there is a slight intuition about it. But epiphenomenalism (E) seems to come in two forms - (E) of mental states and (E) of qualia. Now I do not know much about the first one, but I trust Fodor in his Making minds matter more that is is compatible with physicalism to say the mental events produces causes on the physical.

What I am more interested into is how (E) of qualia is possible. There are two ways to proceed - qualia are inefficacious on the physical and qualia and inefficacious on the mental. It seems like Jackson is switching between the two views. Can qualia be absolutely inefficacious, that is can they have no influence on mental? Well, if that is the case, then they would not be stored in the memory, they would be just passing by. But then the knowledge argument does not work, because they would be NEW at every single moment. In fact, how would one even talk about knowledge, if there is no connection between a quale and the mental event (knowing of x)?

But if they are not epiphenominal toward other mental states, they might as well have role in a causal chain toward a physical. If I take for granted that my experiencing of a red light does not cause me to stop (via zombie example), then it still might have a role of comparison this particular red mental image with those previously stored and therefore possibly influence my next zombie-like stop at the redlight. To put it in a different way, my qualia might not influence my physical behavior at the moment they are experienced, but leave their guiding trace for later unconscious processing.

So I am quite unsure where exactly (E) comes into the picture.

Juraj
On Matt's comments re qualia and knowledge: I think it is right that the difference between knowledge of qualia and knowledge of the external world is closely related to Russell's distinction between knowledge by acquaintance and knowledge by description. Certainly Russell believed that the only true cases of knowledge by acquaintance are cases of direct knowledge of phenomenal states, and he believed that knowledge of the external world was knowledge by description. A lot of contemporary philosophers have disagreed with him about this (e.g. holding that we have perceptual knowledge by acquaintance with external objects), but my own view is that there is something right about his view.

It's certainly true that a "qualia freak" has to pay special attention to the first-person epistemology of qualia, which may well end up being different in interesting ways from the epistemology of the external world. For example, there may be something special to say about the justification of our beliefs about qualia. My own view is that justification of our beliefs in qualia stems at least in part from our acquaintance with the qualia themselves, in a way that doesn't apply to knowledge of external knowledge. Unlike Russell, I'm not sure that I'd call acquaintance a form of knowledge, though; I'd prefer to reserve the latter term for knowledge of truths. Of course like Russell I think that we also have knowledge of truths about qualia that is in some ways grounded in acquaintance.

I talk about this a bit in Chapter 5 of my book, and Tim Bayne has an interesting paper taking issue with some aspects of the view coming out in Philosophy and Phenomenological Research. I've been working on a more developed view in the vicinity of this in a paper called "The Content and Epistemology of Phenomenal Belief", which is online in outline form at

http://ling.ucsc.edu/~chalmers/papers/belief.html

I'll probably also give a colloquium in the philosophy dept on this topic in the spring.

I don't think Jackson needs to assume these somewhat controversial views about acquaintance in order for his argument to go through. He needn't make any such theoretical claims about acquaintance, modules, etc, in order to make it plausible that Mary gains new knowledge. Nevertheless, one might well argue that the special character of knowledge of qualia that his thought-experiment exploits stems from the special underlying epistemology.

--Dave.
Juraj raises the issue of epiphenomenalism. I'd prefer not to
distinguish qualia from mental states, as qualia are examples of
mental states; maybe it's clearer here to distinguish qualia from
intentional states such as beliefs. The question Juraj raises is then
whether, according to the epiphenomenalist, qualia have causal effects
on beliefs. There seem to be at least two possibilities, depending on
the status of beliefs:

(1) Qualia cause beliefs, but beliefs don't cause behavior.

(2) Beliefs cause behavior, but qualia don't cause beliefs.

(One might also hold that there is no causal connection between either
pair, but I'll set that position aside.)

As far as I recall, Jackson isn't explicit about the causal status of
beliefs in his paper, but it's clear from elsewhere that he thinks
beliefs are not epiphenomenal and that he is a materialist about
beliefs. That seems to commit him to option (2). Some other
epiphenomenalists might hold e.g. that beliefs themselves are
essentially tied to the phenomenal and so are non-physical, and so
would embrace option (1). Both of these are somewhat
counterintuitive, especially when it comes to beliefs about qualia. I
talk about this issue a fair bit in my book (Chapter 5 again), as I
think it's the most serious problem for the epiphenomenalist.

Position (2) seems to raise questions about how we could ever know
about qualia, and about how we could ever remember qualia, as Juraj
said. In the book I try to defend position (2), or at least to argue
that it isn't fatally flawed, partly by arguing that our knowledge of
qualia is grounded in our acquaintance with them rather than through
any causal connection between qualia and beliefs. In effect the
suggestion is that the causal theory of knowledge is inappropriate for
knowledge of qualia, for reasons partly to do with those discussed
above. One can say something similar about memories. On this view,
one would still have the beliefs about the qualia, and the memories;
it's just that they wouldn't be directly caused by the qualia.

Of course the view is still somewhat counterintuitive in the way it
separates our qualia and our beliefs. I now hold a slightly different
view (in the paper mentioned in my reply to Matt; it's also in the
book but less emphasized there) on which beliefs about qualia are
partly *constituted* by qualia. In effect a quale is a component of a
belief about that quale. If that's the case, the relation between
qualia and beliefs about qualia is tighter than a mere causal
connection; it's a constitutive connection (in effect one is "part" of
the other). I think there is strong, independently motivated reasons
for believing this in any case. And it gets around the problem about
the disconnection between the belief and the quale.

Of course it will turn out that now, on the epiphenomenalist view,
beliefs (or at least beliefs about qualia) will be at least partly
nonphysical too, because of the part that is grounded in qualia. Note
that one needn't say that they are entirely nonphysical or
epiphenomenal. It may be that beliefs are partly constituted by
physical/functional states and partly by phenomenal states; if so,
their phenomenal part won't have an effect on behavior, but the other
part will. I guess something similar *could* apply as a way of making
sense of another view Juraj mentions, on which qualia causally affect
beliefs which later causally affect behavior. If the aspect of the
belief that a quale affects is not the same aspect that causes
behavior, then maybe these two things could be reconciled even for an
epiphenomenalist.

There are still some awkwardnesses about this position, and all in all
I have some preference for the panprotopsychist view over the
epiphenomenalist view partly because of the awkwardnesses, but I do
think that epiphenomenalism can at least avoid any fatal flaws here.

--Dave.

I think that this was an interesting remark that Matt made regarding the
knowledge argument and its relationship to Russell's distinction between
knowledge by acquaintance and kn. by description:

> It seems that both Russell and Jackson are making an implicit
> appeal to the
operation of distinct faculties. There are inference modules, whose input can only be facts and whose output can only provide further, extrinsic facts about x's (how they relate to y's, what they do under condition c, etc.), and there are sensory modules, whose input is experience of x and whose output, strictly speaking, is non-propositional, intrinsic information about x's which nonetheless can give rise to propositions to be fed into the inference module. A faculty of description and a faculty of acquaintance, if you will.

I don't agree that Jackson needs to make such an appeal (though it is certainly not incompatible with his argument and it has an independent plausibility). What I find interesting about the suggestion, though, is that it really points toward one of the stronger materialist defenses against the knowledge argument. Jackson's argument requires that there can be no inference (logically or semantically speaking) from the physical facts to the phenomenal facts. But I think that the Mary thought experiment *by itself* really only demonstrates something weaker--that one cannot make an inference from the physical facts to the phenomenal facts in what one might call a "psychological sense" of inference. And the above psychological story explains why: our representations of sensory states are in a different "format" or a different module (or psychologically encapsulated in some other way) than our so-called descriptive representations of theoretical knowledge.

This is essentially one of Churchland's points in the article we read. But by itself I don't think it fully succeeds against the knowledge argument, since one is still struck by the strong intuition that Mary does in fact learn a new *fact* rather than just acquire a new representation of an old fact. But once again, the above psychological story suggests a materialist solution--one of "explaining away" the apparent distinctness of the two types of facts. It's basically the same point about inferences mentioned above, except now we're not concerned with Mary's psychology but rather with our own psychology (when we are considering the thought experiment). I try to imagine being Mary in the black-and-white room, and so I activate a set of my own descriptive, theoretical representations. This doesn't put me in a state in which my sensory representations of redness are activated (since, according to the present hypothesis, these two types of representations reside in different modules or the like). I then imagine being Mary and seeing a ripe tomatoe--and this *does* activate the relevant sensory representations. This explains why it *seems* to us that Mary learns something new. It would seem that way even if Mary *didn't* learn something new. So the seeming as such can't be taken as evidence for either hypothesis. (This strategy is similar to one given by Christopher Hill in the paper that Dave mentioned before).

We're left now with the question of whether or not we have good reason for thinking that our sensory concept of red is co-referential with some descriptive term in the language of neuroscience (or other science). The above materialist response to the knowledge argument doesn't answer *that* question, but it does suggest that it *could* be for all the knowledge argument shows.

Brad
In what follows I present some of David Lewis' objections (in "What Experience Teaches") concerning Jackson's Knowledge argument. I also include a brief explanation of the ability hypothesis, as he presents it, along with some of my own comments. (Since I was not sure how many people have read Lewis' paper I included more summary. This made my e-mail longer. I apologize for the length.)

Lewis denies what he calls "The Hypothesis of Phenomenal Information" (HPI) on the grounds that it commits us to a much more "peculiar" view of the world (his words, not mine) than does materialism. But first, let me be clear about what the Hypothesis is; it is familiar to all of us, maybe just not under this name. It is the claim that besides physical information there is an irreducibly different kind of information to be had: *phenomenal information*. So, it is possible for there to be two cases that do not differ physically but do, however, differ, phenomenally. According to Lewis, the characterization of information according to the HPI, is in terms of excluding possibilities. That is, when we get physical information we narrow down the possibilities, sometimes even to one, but there is a range of phenomenal possibilities which we leave open. He uses an analogy of a location of a point on an x-y plane. We may be able to pinpoint the x coordinate exactly, but no amount of x-coordinate info. is going to help us figure out where the y-coordinate lies. "Any amount of x-information leaves open all the y-possibilities." (pg. 583) When we finally do make our y-measurement we acquire a new kind of information, which allows us to eliminate possibilities which were previously open. Similarly, when Mary finally sees red, she is able to eliminate possibilities that were previously left open to her.

Now, invoking the HPI (as a reason why no amount of physical information suffices to teach us what a new experience is like) allows Jackson to construct the knowledge argument. Lewis cannot formulate a version of Materialism (even a very limited version in terms of a small class of possible worlds) which holds given the HPI. He show us that the two are incompatible. As mentioned above, Lewis opts to reject the HPI. He rejects is for two reasons: 1) It is more
"peculiar", 'and therefore less tempting than it may at first seem.' (pg. 586-587) 2) we are not *forced* to accept it. B/c an alternative hypothesis (the ability hypothesis) allows us to explain how experience can best teach us what it is like. That is, we can hold (a) that experience, and nothing else (at least in the actual world) can teach us "what it is like", while still (b) rejecting the HPI and (c) accepting Materialism.

1: Why the HPI is so "peculiar":

First, b/c it is actually opposed to more than just Materialism, according to Lewis. He shows this with the following argument:

"Let parapsychology be the science of all the non-physical things, properties, causal processes, laws of nature, and so forth that may be required to explain the things we do. Let us suppose that we learn ever so much parapsychology. It will make no difference. Black-and-white mary may study all the parapsychology as well as all the psychophysics of color vision, but she still won't know what it is like...our intuitive starting point wasn't just that *physics* lessons could not help the inexperienced to know what it is like. It was that *lessons* couldn't help. If there is such a thing as phenomenal information it isn't just independent of physical information. It's independent of *every sort of information that could be served up in lessons for the inexperienced*. For it is supposed to eliminate possibilities that any amount of lessons leave open. Therefore phenomenal information is not just parapsychological information, if such there be. It's something very much stronger."

(I think there is quite a lot to say about this argument, but I want to comment on the ability hypothesis and, since this is already getting long I will save commentary on this for someone else or for some other time.)

2) The second reason why HPI is so "peculiar" is that, according to Lewis, the possible alternatives, in the case of something the likes of which we have never experienced (like the alternatives concerning what it would be like to be a bat), is completely unthinkable. Lewis admits that a range of unthinkable alternatives is not impossible; but it is, he says, "peculiar" and is "enough to suggest that we may somehow have gone astray. (I think that the Thompson paper actually suggests something counter to this. It may be possible to get an idea of what some completely foreign experience may be like (e.g. we can plot a novel color by changing the geometry of our color space), and hence generate some range of possibilities. So, the HPI may not be so peculiar, in this respect, after all.)"

3) The third peculiarity is how "isolated" phenomenal information is from all other kinds of info. (I take Lewis here to mean by "isolated", seemingly not making any difference in the physical world.) Mary's behavior would presumably change when she saw green for the first time. to quote Lewis "...her jaw drops and she says "At last! So this is what it's like to see colors!" But, if the HPI is right, she could not be doing any of this as a result of seeing colors for the first time. In order for Mary to do or say anything different her particles must move differently. But how can acquiring phenomenal information make a difference as to the motion of her particles? Lewis makes this point in a somewhat dramatic fashion. "If something non-physical sometimes makes a difference to the motions of physical particles, then physics as we know it is wrong. Not just silent, not just incomplete--wrong." (pg. 590).
The Ability Hypothesis— (Since we discussed this in class, I will say only what is relevant to the comments I make.) So, Lewis sees better reason for rejecting the HPI than materialism. He then (following Nemirow) wants to replace talk of learning a new fact with learning a new ability. Learning what it is like to see a new color is then, like learning to wiggle your ears or eat with chopsticks. No amount of information will suffice for you to acquire the ability. Information might help, but until you do it, you will not know what it is like. Once you know what it is like you have the ability to recall memories of wiggling your ears, imagine wiggling your ears, etc. So, the ability hypothesis can be formulated as follows "knowing what an experience is like just *is* the possession of these abilities to remember, imagine, and recognize". Lewis' point is that, what enables one to do all this new stuff is not the possession of a new kind of "information"; for Lewis, there are no "phenomenal facts". It is simply *knowing how* to do something.

Commentary:

I think that it would be interesting to look at empirical research that is being done concerning recognition of colors, tastes, etc. in children. I say this b/c when I consider my experience of red or the taste of broccoli, it does not seem to me that I am engaging in the performance of some kind of skill. Red, the experience of it, seems to me to be a given in my subjective experience in the world. But, if it is an acquired ability, then I would have had to develop it, like I developed my ability to use chopsticks. I definitely don't remember developing the ability to see red, but I very well may have when I was very young. I don't know, that is why I think it would be interesting to look at such studies (I am sure there are some out there.). For, if the Ability Hypothesis is right, shouldn't we be able to see this ability develop in children? That is, they would get better at "recognizing" colors; not "naming colors" b/c that could very well concern language acquisition and not sensory experience. Of course, a defender of the ability hypothesis could then say that not all abilities are acquired. Some are natural abilities. This seems plausible to me.

So, the materialist has a response to the question of whether this ability is acquired. But, there remains something unsatisfying about the ability hypothesis. That is, I might be able to see red (and other people cannot) but, explaining *how* I do it still does not seem to me to get around the fact that *I am seeing it*. They still seem to be two different phenomena; the seeing and the ability to see seem distinct to me.

As I have tried to comment above, I also do not think that Lewis has succeeded in making the HPI sound incredibly peculiar. Thompson's paper helps make sense of how we may be able to develop a range of possibilities.

I hope that some find Lewis' arguments interesting. Again, I apologize about the length.

To all,

I know I'm jumping into the fray a little late, and you might all be heartily sick of hearing about Jackson's knowledge argument, but here are some (few) thoughts about it and the postings concerning it so far.

Just to quickly recap Jackson's initial argument, I think it might be schematised like so:

Premis 1. If materialism is true, then in principle, all mental facts are reducible to physical facts.

Premis 2. If this is the case, then Mary can't learn anything new when she (finally) sees a red tomato, since ex hypothesi Mary already knew all there was to know about the physical facts that might underlay such an experience, i.e. a whole bunch of scientific facts about the workings of the brain.

Premis 3. But Mary certainly seems to learn something new when she sees the tomato. She has a new experience, and all her prior knowledge about the neurology that might underpin such an event is not sufficient to give her this new knowledge without the experience.

Conclusion 1. Not all mental facts are exhausted by physical facts

Conclusion 2. Materialism is false

As Churchland points out, the argument is subject to attack at the second premis, and the charge is one of equivocation. Specifically, two senses of the word 'learn' (or alternatley, the word 'know' if the argument is phrased in those terms) are employed. As Matt
pointed out in his Sept. 8 posting, these two senses might be understood by using Russell's distinction between 'knowledge that' and 'knowledge of' or knowledge of truths and knowledge of things. Matt opines that these terms might correspond to different faculties of the mind: a descriptive faculty and a faculty of acquaintance, respectfully. This would help explain why Mary learns something new, because she receives input to her faculty of acquaintance upon viewing the red tomato, where previously she only had information concerning red in her descriptive faculty.

Dave's reply to Matt (also on Sept 8th) seems to endorse this reading, although Dave is quick to point out that Jackson need not tie himself down to this story of things mental for his argument to go through. All he needs, says Dave, is for Premis three to sound plausible, that is for it to seem to us that Mary does learn something new upon seeing the tomato, regardless of the possible mental ontology underlying it.

But, as Brad points out in his Sept 10th posting, this distinction in types of knowledge can be used against Jackson, especially if something like Matt's 'faculties of the mind' story is adopted. As he (Brad) says "our respresentaions of sensory states are in a different 'format' or a different module (or psychologically encapsulated in some other way) than our so-called descriptive representations of theoretical knowledge." Brad goes on to say that in fact Mary doesn't learn anything new, but that she is simply put into a state where her sensory representaions of red are activated when she sees the tomato. And, since until she sees the tomato, all she has are the representaions of red to be found in her descriptive faculty, and since those two faculties are insulated from one another, it seems as if she does learn something new. But this intuition (that she does learn something new) is explained by the fact that we can put ourselves into representational states by an effort of the will, whereas it seems that Mary cannot, consequently it seems to us that these latter representations are new or extra information, when in fact they are but different representations of the same information, stored in different formats in the different modules of our mind. (this last bit is just my feeble attempt at a recounting of Brad's argument, and may well be completely incorrect. I would welcome comments and corrections if this is the case, from Brad or anyone)

Here I part ways with Brad, and I think that a materialist might better reply to Jackson that it is because of the equivocation on knowledge or learning in his argument that it seems that Mary 'knows' or 'learns' something new. My argument would go like this: Mary has a neural event(s) that she had never had before upon seeing the red tomato, and insofar as that neural event had causal repercussions on the rest of her brain (i.e. leaving traces in memory, or altering or adding to those parts of the brain that are responsible for what we have here been calling the descriptive faculty) then, if this is what we mean by learning something, Mary has definitely learned something. But this is as it should be, since Mary's brain underwent changes that it had never undergone before. This is at least a necessary condition for learning something new, on a materialists analysis of that term, so it is not surprising that Mary has learned something new when it occurs. The problem is that, in premise two, we are told that Mary already 'knows' everything there is to know about the physical facts that underlay colour-vision, and this is disingenuous. By 'knows' here do we mean that Mary has had the neural events that correlate with every pertinent bit of information about colour-vision? or do we just mean that Mary has studied and memorised (and believes) all the propositions that correspond to facts about the neural correlate(s) of colour-vision. If the latter, then a different sense of knowledge is being employed than the one in the above explanation of how Mary comes to learn something new, since it artificially limits the range of neural events
that are to count as learning to those involved with reading and understanding sentences.

If the former sense is in use, then what reasons do we have for excluding those neural events that underwrite normal colour-vision as pertinent? How can we say truly of Mary that she has all the knowledge about colour-vision there is to have if her brain has never undergone these paradigm transformations? I don't think we can. It is only if we invoke the restricted sense of knowledge, that of sentence appreciation, that this exclusion makes sense, but then of course Jackson's argument has no sting, since all it seems to be saying is that Mary didn't have a certain type of neural event before she saw the tomato, and she did after she saw the tomato, and that the differences in her brain between the two stages qualifies her as having learned something after having seen it.

In other words (if anybody is still with me) I don't think materialists need to deny that Mary learns anything new, they can simply say that in the broad, materialistic sense of knowledge, Mary does learn something new, since her brain acts in ways it never did before, but in this sense of learning, new physical facts are appealed to, namely the events in the brain that underwrite colour-vision, and if we deny 'knowledge' of these, meaning of course that we deny her the actual neural events, and not just sentences describing the neural events, then we can't say that she knows everything that there is to know about colour-vision.

Pheeeew. Sory that took so long, and I also apologise for the inelegant writing, but the material forces some very laboured constructions. Also I'm a terrible writer. Please help me on this or any other score with your comments.

Thanx to all
Allen

"Time flies like an arrow. Fruit flies like a banana."

Groucho Marx
I have some concerns regarding reduction, particularly as it is laid out by Churchland in "Reduction, Qualia, and the Direct Introspection of Brain States." In this article, Churchland seems to be arguing for a weaker type of reduction, one in which not even indirect deducibility is a requirement. On the D-N model of reduction we see that thermodynamics is reducible: molecule dynamics plus dynamic/thermodynamic bridge laws entail thermodynamics. Churchland weakens this view by arguing that there does not necessarily have to be a smooth reduction. My first question is- how is this view of reduction so different from an epiphenomenal view that brain facts plus psychophysical bridge laws entail phenomenal facts?

In class, Dave argued that the epiphenomenalist view is not really a reduction* of experience to brain states. This is because psychophysical laws are not necessary but contingent. Dave further argued that for a strong sense of reduction you need the micro facts to entail the macro facts without an irreducible appeal to laws. This is a view in which P (micro facts) necessarily implies Q (macro facts). Or in other words, in all possible worlds which P holds, Q holds.

But what are the micro facts? They are a combination of microphysical entities and microphysical laws. If you take away the laws, the reduction can not hold. (We can imagine a world where the microphysical entities are the same but the microphysical laws have changed. This world would be very different from our own.) My second question is this: if we throw psychophysical laws into the pot, then couldn't we say that the micro facts (which include various bridge laws, particularly psychophysical bridge laws) necessarily entail the macro facts (including consciousness). So it would be impossible to conceive of a world that had the same micro facts/laws as ours that did not also have the same macro facts, (again, including consciousness.)

I guess my concern can be traced back to Dave's contention that psychophysical laws are not necessary but contingent. It seems to me that most physical laws are not necessary across all possible worlds. The view that brain facts plus psychophysical bridge laws entail phenomenal facts does not seem that different from other scientific reductions, especially given Churchland's weaker requirements for reduction. If someone could please elucidate on the difference between scientific reduction in the realm of physics, for example, and Dave's non-reductive view of consciousness I would appreciate it.

Cheers,
Rachael
Hi, here are some very brief comments on people's postings:

(1) Re Sarah's comments: The idea that consciousness might not be a natural kind is interesting. Personally I think it is, if anything is; but I'm not sure whether any of these issues really turn on the matter. Even when a property is a very unnatural kind (e.g. "in my desk"), maybe we won't be able to give a unified explanation of its instances, but that won't stop one from giving a fine explanation of any single instance of the property. Here we're not concerned so much with historical explanation (which can be tricky) as reductive explanation -- just giving an account of the micro facts which will necessitate and explain the fact that e.g. a particular pen is in my desk. And that doesn't seem too hard in principle. But for consciousness, even explaining a single instance seems tricky. So I'm not sure the issues are entirely analogous.

(2) Re Allen's comments: I think what really matters is not sentence-knowledge but what we might call factual knowledge, i.e. knowledge of the way the world is. Even if knowing what red is like isn't sentence knowledge, it seems to be factual knowledge. I take it that Allen's central response is to deny that Mary has complete physical knowledge before seeing red, because she hasn't experienced red yet. If that is to apply to factual knowledge (which is what's relevant here), then I suppose it implies that knowing all the truths of physics doesn't give one complete factual knowledge. In a certain sense that might be enough for Jackson already -- if there are facts that go beyond physical facts, he might say he's home. Perhaps he might concede the point that to know those facts, one has to go into a certain neural state. That would imply there is a close connection between the neural state and the new fact; maybe one could even construe it as a fact about the state (e.g. what it's like to be in that state). But there's nothing here that suggests or implies that it's a *physical* fact about that state, and Jackson would presumably argue that the situation dictates the opposite. So I think the materialist may need to appeal to something more than the mere fact that being in the neural state is required for knowledge here.

(3) Re Rachael's comments: On the entailment model of reductive explanation, the claim will be that the micro facts entail the macro facts. The micro facts here may include the micro laws, but they may not include any special bridge laws. E.g. for chemistry to be reductively explained in terms of physics, on this view, is for the chemical facts to be entailed by the physical facts (including physical laws). But in the case of consciousness, the anti-reductionist's claim is that the physical facts and physical laws don't entail the existence or character of consciousness. If we throw the bridge laws into the base, then we might get an entailment, but that's just what we're not allowed to do where reductive explanation is concerned.

The relevant difference here is that ordinary scientific reductions will have an entailment from micro facts and laws without bridge laws, whereas on the nonreductive view of consciousness, one needs to
include bridge laws to get an entailment. The very different status of micro laws and bridge laws is what makes the difference here.

(4) Re Simon's and Joel M.'s comments: Some good points, to which I don't have much to add here. I think Crick and Koch managed to get a bit confused in the logic of their reasoning about essential features of consciousness, in just the way that Simon nicely points out. Re the psychophysical principles that I give, these are certainly very far from complete, and they certainly don't give sufficient conditions for consciousness. A final theory of consciousness will need principles that are much more detailed and specific.

--Dave.

All-

Allen's solution to Jackson's knowledge argument is similar to one that I've been mulling over for several days now. Actually, it is probably the very same argument. I dont think I can greatly improve on Allen's statement of it, so I'll just re-post it before talking about an anticipated objection.

>My argument would go like this: Mary has a neural
>event(s) that she had never had before upon seeing the red tomato, and
>insofar as that neural event had causal repercussions on the rest of her
>brain (i.e. leaving traces in memory, or altering or adding to those
>parts
>of the brain that are responsible for what we have here been calling the
>descriptive faculty) then, if this is what we mean by learning something,
>Mary has definitely learned something. But this is as it should be, since
>Mary's brain underwent changes that it had never undergone before. This
>is
>at least a necessary condition for learning something new, on a
>materialists analysis of that term, so it is not surprising that Mary has
>learned something new when it occurs. The problem is that, in premise
two,
>we are told that Mary already 'knows' everything there is to know about
>the physical facts that underlay colour-vision, and this is disingenuous.
>By 'knows' here do we mean that Mary has had the neural events that
>correlate with every pertinent bit of information about colour-vision? or
>do we just mean that Mary has studied and memorised (and believes) all
>the
>propositions that correspond to facts about the neural correlate(s) of
>colour-vision. If the latter, then a different sense of knowledge is being
>employed than the one in the above explanation of how Mary comes to learn
>something new, since it artificially limits the range of neural events
>that are to count as learning to those involved with reading and
>understanding sentences.
>      If the former sense is in use, then what reasons do we have for
>excluding those neural events that underwrite normal colour-vision as
>pertinent? How can we say truly of Mary that she has all the knowledge
>about colour-vision there is to have if her brain has never undergone
>these paradigm transformations? I don't think we can. It is only if we
>invoke the restricted sense of knowledge, that of sentence appreciation,
>that this exclusion makes sense, but then of course Jackson's argument
>has
>no sting, since all it seems to be saying is that Mary didn't have a
>certain type of neural event before she saw the tomato, and she did after
>she saw the tomato, and that the differences in her brain between the two
>stages qualifies her as having learned something after having seen it.
>      In other words (if anybody is still with me) I don't think
>materialists need to deny that Mary learns anything new,

Just to ensure that we are indeed thinking the same thing, the idea is
that learning (coming to know) on the materialist account (and on some
dualist accounts too really) just comes down to having a brain state that
somehow represents the fact known. If we suppose that materialism is
true, Mary's experience when she first sees a ripe tomato also comes down
to having a particular sort of brain state. So the materialist can claim
that though Mary does indeed learn something when she has her first
experience of red, he can also claim that she learns a materialistic fact,
i.e. what happens when that brain state occurs in her brain.

The objection to this argument that I see looming, and that (I think) Dave
alluded to when we were discussing Churchland, is that Allen and I have
missed the point - namely that Mary can gain this knowledge ONLY through
experiencing it. She can know everything else about color vision through
other means, so the experience fact (what it is like) cannot be reduced to
these other facts. It seems, the objector might say, that if the
experience fact were just one more physical fact, Mary ought to be able to
deduce it from the rest of the physical facts she knows. After all, Mary
even knows everything there is to know about the very particular brain
state that produces red sensations, but she cannot know what it is like to
have that brain state in her brain without experiencing it. I suppose
Allen and I can still claim that the experience fact is still a physical
fact of some sort, but it is apparently a weird sort of non-reductive
physical fact, which is about as bad as a non-reductive non-physical fact
from a reductivists point of view. At least with non-physical facts there
would be an explanation of why the reduction fails.

I think the way around this objection is to show that, while there is a
difference between the way Mary knows "what it is like to experience red," and
the way that she knows about other physical facts (like which brain
state causes subjects to experience red), this difference is not a
fundamental difference between two different ways of knowing (a la Matts
reference to Russell). The claim is that all learning just comes down to finding ways of appropriately modifying ones brain, and that all functionally equivalent means of achieving this end count as learning the same thing.

Consider the various ways that Mary can learn about "what it is like to experience red."

1) Mary looks at a ripe tomato (or other red object). Light bounces off the tomato, interacts with her retinae, causing neurons to fire, and a particular brain state arises. So long as Mary remembers the salient features of this experience, she knows what it is like to experience redness.

2) While still in her black and white room, Mary uses her extensive knowledge of brain physiology and the other sciences to directly stimulate her brain in such a way that it enters the state that she knows should cause her to have an experience of redness.

3) While still in her black and white room, Mary uses her extensive knowledge of brain physiology and the other sciences to develop monitoring devices with which she can observe the various processes going on in her brain (like an EEG only much much better). Using the real-time information provided by these devices as biofeedback, she trains herself to manipulate her brain into any state she desires. (I think I read somewhere that some people can manipulate a computer mouse pointer by learning to manipulate certain brain waves. The ability I'm attributing to Mary is like that, but much more complex. Mary, of course, has a complete knowledge of her own brain, so she can achieve a higher level of control.) Once she has mastered the control of her brain, (and no longer needs the crutch of the monitoring devices) she decides she wants to experience redness, so she manipulates herself into the appropriate state and learns about this experience.

The point is not that Mary experiences red in 1) but learns about red in 3), but rather that she both learns and experiences in all the cases. The implementation of learning varies greatly, but in each case she comes to know the same fact. 1) is the way most of us learn about redness. In 2) Mary learns about redness without ever seeing a red object. In 3) she learns about red without any external manipulation. All she needs are lots of facts about her brain and practice with controlling it. Once she has really mastered these techniques, when color-deprived Mary thinks, "What is red like?" the answer is just a thought away. But 1), 2), and 3) all produce the same knowledge.

These imagined cases are obviously pretty far-fetched, but then so is Jacksons claim that Mary knows "all the physical facts." But I can make the same point about learning with a more down to earth example.

When we learn basic mathematics, like multiplication say, we use different techniques as we go. When I first learned multiplication we were given worksheets with grids on them. For 4x5 there would be a 4 by 5 grid, and we were supposed to count the 20 squares formed by the grid to get the answer. I thought this was cool, so I used it for quite a while. However, as the numbers got bigger the grids got clumsier and I grudgingly learned to multiply multi-digit numbers on paper, then in my head. Though they differed in implementation, all of these exercises counted as learning the product of two numbers.

There's probably much more that could be said about this. But not tonight. Let me know what you think.
PS - I see that Dave has already replied to Allen by the time I've written and posted this. (Do you never sleep?) I only looked at that post briefly, but I think my comments are relevant to Dave's reply. However, since I do sleep, I will let these comments stand as is for now.

Joel Press asks us to "consider the various ways that Mary can learn about 'what it is like to experience red.'" But all three of the ways he mentions involve actually experiencing red. It is not clear to me that this is necessary. Suppose Mary knows enough about what her reactions would be to seeing red that she could actually recognize red. This could be fairly automatic given Mary's advanced state of knowledge. Further suppose that she COULD induce the experience of red in herself. Again, this could be fairly automatic since she knows a lot about how the brain works and presumably understands the mental gymnastics involved in biofeedback kind of activities better than anyone currently does. Here is the question, if Mary can recognize red experiences and can induce red experiences in herself in what sense is she missing "facts" about what red is like?

My argument would go like this: Mary has a neural event(s) that she had never had before upon seeing the red tomato, and insofar as that neural event had causal repercussions on the rest of her brain (i.e. leaving traces in memory, or altering or adding to those parts of the brain that are responsible for what we have here been calling the descriptive faculty) then, if this is what we mean by learning something, Mary has definitely learned something. But this is as it should be, since Mary's brain underwent changes that it had never undergone before. This is at least a necessary condition for learning something new, on a materialist analysis of that term, so it is not surprising that Mary has learned something new when it occurs. The problem is that, in premise two, we are told that Mary already 'knows' everything there is to know about the physical facts that underlay colour-vision, and this is disingenuous. By 'knows' here do we mean that Mary has had the neural events that correlate with every pertinent bit of information about colour-vision? or do we just mean that Mary has studied and memorised (and believes) all the propositions that correspond to facts about the neural correlate(s) of colour-vision. If the latter, then a different sense of knowledge is being employed than the one in the above explanation of how Mary comes to learn something new, since it artificially limits the range of neural events that are to count as learning to those involved with reading and understanding sentences.

If the former sense is in use, then what reasons do we have for excluding those neural events that underwrite normal colour-vision as pertinent? How can we say truly of Mary that she has all the knowledge about colour-vision there is to have if her brain has never undergone these paradigm transformations? I don't think we can. It is only if we invoke the restricted sense of knowledge, that of sentence appreciation, that this exclusion makes sense, but then of course Jackson's argument has no sting, since all it seems to be saying is that Mary didn't have a certain type of neural event before she saw the tomato, and she did after she saw the tomato, and that the differences in her brain between the two stages qualifies her as having learned something after having seen it.

In other words (if anybody is still with me) I don't think materialists need to deny that Mary learns anything new, just to ensure that we are indeed thinking the same thing, the idea is that learning (coming to know) on the materialist account (and on some dualist accounts too really) just comes down to having a brain state that somehow represents the fact known. If we suppose that materialism is true, Mary's experience when she first sees a ripe tomato also comes down to having a particular sort of brain state. So the materialist can claim that though Mary does indeed learn something when she has her first experience of red, he can also claim that she learns a materialistic fact, i.e. what happens when that brain state occurs in her brain.

The objection to this argument that I see looming, and that (I think) Dave alluded to when we were discussing Churchland, is that Allen and I have missed the point - namely that Mary can gain this knowledge ONLY through experiencing it. PS - I see that Dave has already replied to Allen by the time I've written and posted this. (Do you never sleep?) I only looked at that post briefly, but I think my comments are relevant to Dave's reply. However, since I do sleep, I will let these comments stand as is for now.
seeing red that she could actually recognize red. This could be fairly automatic given Mary's advanced state of knowledge. Further suppose that she COULD induce the experience of red in herself. Again, this could be fairly automatic since she knows a lot about how the brain works and presumably understands the mental gymnastics involved in biofeedback kind of activities better than anyone currently does. Here is the question, if Mary can recognize red experiences and can induce red experiences in herself in what sense is she missing "facts" about what red is like?

Both of these additional ways of learning about red seem plausible to me if we assume Jackson's stipulation that Mary knows everything about brains, science and so on. We could add these to the list I started as numbers 4) and 5). However, the reason that all my examples contained an experiencing of red is that those who share Jackson's intuitions probably won't accept Joel L.'s cases as real possibilities. My cases were designed to show that experiencing red and other ways of coming to know about red blend into each other, leaving Jackson no reasonable place to draw the line between the two. Joel L.'s cases nicely extend the spectrum of cases.

Thanks for the input.

Quick comments on messages from Joel and Joel (inc.):

(1) Re Joel P: I think Jackson might say the same thing I said to Allen. In a certain sense it might be a "materialistic fact" in that it's a fact about what it's like to be in a given brain state, but on the face of it this still involves different properties of the state in question, properties distinct from the physical properties she knows about already. It may be true that to know the fact in question one has to be in the brain state, but it's not clear that that suffices to make the fact a physical fact. Compare: I may have to be in a certain physical state to know that Paris is in France, but that doesn't mean the Paris fact is a fact about my brain state.

(2) Re Joel L.: Joel suggests that on the basis of her physical knowledge, Mary could learn to indirectly recognize red experiences (by noticing her reactions) and could learn to induce the experiences
in herself. The question then, in what sense is she missing "facts" about what red is like? This is complex, but on the face of it there are lots of cases where a capacity for indirectly recognizing X and constructing X's leaves us mostly ignorant about Xs. Just say we know that fire always cause smoke, and that matches always cause fire, and that's all we know about fire (we've never even seen it). Then we might be in a position where we could recognize the presence of fire (by observing smoke) and where we could bring about the presence of fire (by lighting matches), while knowing hardly anything about the character of fire. We'd just know about one or two associated causal relations. So indirect recognition and construction seem to be fairly weak criteria for knowledge.

Dave,

I don't think I was clear enough about how this example is supposed to work. I think you can automatically and instantaneously recognize something you have never seen before. That was definitely the experience I had when I heard that bat in my bedroom. On a fairly regular basis I recognize things that I have never seen before without doing any "conscious" (nonautomatic) reasoning. I bet when you were first introduced to your girlfriend's parents (assuming such an even has occurred), you recognized her father/mother/brother/dog without having to think "Hmmm, this person is male and about 25 yrs older than her, while this other person it about her age so this must be the father..." It is just automatic when you have enough background information. There are lots of things that people recognize instantly without having seen them. Similarly for imagining things.
Now it seems to me quite plausible that Mary can recognize red automatically. That is, it is not clear to me that it would be necessary for Mary to do any conscious reasoning to see red. Further it is pretty clear that you and I go through unconscious reasoning in recognizing color so any distinction is going to have to lie with the conscious reasoning.

In essence I think that it is quite plausible to think that Mary is just like you and me except that she is not having a red experience and she has no memories of having had such an experience. I don't see how either of those is going to buy you an absence of knowledge.

I also don't like your fire example. It seems to me that in the fire example I know almost nothing about fire, while Mary knows everything (or nearly everything) about red. Similarly, the average person knows much more about fire than that it produces smoke, while the average person knows almost nothing about red except that it causes red sensations. It seems to me that a better analogy might be to compare someone who has only seen flames (say he has seen candles burn), but otherwise knows nothing about fire, to someone who has read extensively about fires but has never actually seen a flame. Who will more quickly identify a forest fire?

Joel

Regarding all of the previous... A somewhat annoying trait that I have is that I like to know what I am referring to before I refer to it, therefore, I was wondering, Would someone (anyone) mind defining exactly what is meant by "knowledge", specifically that which mary does or does not have. It seems to me that a person can mean various things when they use the word knowledge.

If it is being used in the "knowledge about the things in the world" sense, I would like a definition (operational, of course) of the word "things" in this sense. It seems to me that an experience is a "thing". Unless you are talking about "things composed of known forms of matter". So, how is "Knowledge" meant?

Dear all,

Given that at this stage we are going on to talk about the neural correlates of consciousness, it may be useful to make clear a relatively simple distinction - that between necessary and sufficient causes. The reason why I think that this is important is that, whilst reading the Crick and Koch article, it occurred to me that they seem to have made the mistake of conflating the two.

Specifically, I would refer you to their 1998 article (in this weeks reading), where they are talking about those aspects of the discussion about consciousness that they have deliberately decided to leave out. In (2), they say:

"It is plausible that some species of animals ... possess some of the essential features of consciousness, but not necessarily all. For this reason, appropriate experiments on such animals may be relevant to finding the mechanisms underlying consciousness. It follows that a language system (of the type found in humans) is not essential for consciousness -- that is, one can have the key features of consciousness without language."

This passage seems rather confused. It seems that they are suggesting that since some animals both have some essential features of consciousness and do not have language, then language is not essential for consciousness. What, however, do they mean by "essential"? If they mean that higher mammals have some of the cognitive mechanisms that are necessary* for consciousness, then their conclusion does not follow - there is no reason to suppose that language is not necessary for consciousness as we understand it. Whilst those animals might possess some of the necessary features of consciousness, it is at least uncertain whether those features are *sufficient* for them to be considered conscious. If on the other hand they are saying that these animals have cognitive features that are sufficient for consciousness, then why do they say that these animals only possess some, but not all, of the "essential"
features of consciousness? It would seem that by definition that these animals would have all the cognitive faculties that are required for consciousness.

The importance of this distinction may perhaps be made clearer by applying it to a familiar example - Dave's psychophysical principles. If these three principles are merely necessary for connecting processing and experience, then we need to ask the further question of whether they are also sufficient. If the answer is no, then we need to search for further principles that are necessary and which, in combination with the other three, will be sufficient principles.

I hope this has helped

Simon.

---

Hi all, we were discussing (in class and in break) the frontal lobe, prefrontal cortex, etc. There's a nice simple diagram at

http://www.waiting.com/frontallobe.html

It seems that the frontal lobe consists of prefrontal cortex, premotor cortex, and motor cortex (plus the frontal eye fields which are distinct on some accounts). The prefrontal cortex is the front part of the lobe (all the way to the very front), as a couple of us thought. The premotor and motor areas are behind that.

You can get from that page to another simple picture of areas of the brain, if that's helpful.

There is some info (and diagrams) on the differences between non-human primate vs. human brains at

You can get to lots of other pictures of the brain by going to
http://www.u.arizona.edu/~chalmers/class/596v/week4.txt

Finally, it turns out the Sheinberg and Logothetis reading for next week is on the web. I've put in a link to it from the main web page for the seminar.

Okay, I haven't been saving people's mail and I can't remember exactly what Sarah wrote, but Dave's reply resonated with something I didn't like in his paper from this week's readings. Thus I will reply even if this is off the thread.

In the readings for this week both Chalmers and Block seem to assume that it is possible to find a neural correlate of consciousness. This struck me as odd. It seems to me that we are about as likely to find a neural correlate of consciousness as we are to find a silicon correlate of word processing. Lets face it, everything in your computer is involved in word processing, and everything that is involved in word processing is also involved in functions which are not word processing. It seems to me that consciousness is likely to be something like this. In particular, I don't see any reason to think that consciousness is a natural kind from the point of view of neuroscience or cognitive psychology.

So, Question: Is it necessary for consciousness to be a natural kind from the point of view of neuroscience (cognitive psychology) for their to be a neural (cognitive) correlate of consciousness?

Whether or not it is necessary, it is pretty clear that people who are in the business or looking for correlates of consciousness are looking for natural kinds from their own scientific point of view. Look at the list which begins Dave's paper for this week. People just are not proposing correlates which involve complex conditions and interactions between brain/cognitive states.

The point here is that whether or not we think of consciousness as a
natural kind (from the point of view of "science") has a big influence on how we carry out the enterprise of creating a science of consciousness.

Joel

Dave,

I thought I'd post directly to you since I seem to take a radically
different angle than you and the others on the topics we've covered so
far. The assigned readings just seem to miss the mark, in my opinion, so
I'm using some outside sources to inform my posting.

Here I'm using the article by Depraz in The View From Within, and Varela's
Neurophenomenology paper from the penultimate week's reading list.
Perhaps, after reading the post, you could point me to more like this (if
there is any).

The problem I have with current NCC research projects is a
methodological/epistemological one. The criticism is inspired by the Husserlian notion of reductions. A recent trend in first-person approaches insists that it is only within a Husserlian methodological framework that we will be able to get rigorous enough about first-person conscious experiential data such that a Chalmersian science of consciousness project will be possible. That is, the claim is that it is only by practicing Husserlian reductions (the epoche and eidetic) that researchers will be able to rigorously gather relevant 1st person data such that such data can successfully be bridged with 3rd person neuroscientific data (among other 3r person data). The problem is this. Such reductions aim, by definition, at uncovering the essential (irreducible) structure of conscious experience (see Varela p.4 of web print-out). That is, the thought is that what we get when we casually look at the world is only one possible "presentation" (or representation), one we have in virtue of a habitual way of looking at the world. If we bracket this habitual mode, allowing room for other possible presentations, we go from contingent "facts" to essential facts (i.e., we go from facts that are contingent in virtue of being derived from a single perspective to those that are universal in virtue of being derived from a multitude of perspectives--see Depraz p.101).

Now, Varela writes:

We are similarly assuming that human experience follows fundamental structural principals which...enforces the nature of what is given to us as contents of experience (p.8)

and

It is one of the most impressive discoveries of the phenomenological movement to have quickly realized that an investigation of the structure of human experience inevitably induces a shift towards considering several levels of my consciousness as inextricably linked to those of others and to the phenomenal world in an emphatic mesh. Consequently, the usual opposition of first-person vs. third-person accounts is misleading. It makes us forget that so-called third-person, objective accounts are done by a community of concrete people who are embodied in their social and natural worlds as much as first-person accounts... (p.9).

In other words, the relevant phenomenological reductions aim at irreducible structures of not only the act of consciousness but of the objects of consciousness as well. Depraz uses the example of the experience of red (p.101). After performing the reductions one is left with the essential structure of an experience of red--presumably, one that is much richer than the one had previous to the reduction. In other words, one gets essential (or the essence of) red (as an object of consciousness), and this is DIFFERENT (and epistemically privileged) from contingent red (red as an object of consciousness before the reductions are performed).

The result seems to be that, after one performs these phenomenological reductions, one is left with a more robust and fuller phenomenal world. The world looks different, feels different. And--here's the meat of it-- if a neuroscientist performs these reductions, the BRAIN will look and feel different, perhaps quite different. The essential structure of an experience of the brain might be altogether different from the one we have from habitual observation. For example, the way neurons look and seem to behave before the reductions might radically differ from the way they look and seem to behave after--if what we get after can even be called a neuron any longer (i.e., things might look VERY different!).
With a more robust phenomenal world we would presumably get a more robust neuroscience (since most of neuroscientific data is predicated on observation). After some progress on the first-person side of the project, it would seem necessary that, with this honed observational tool, we revamp the third-person side. Only then could we be said to be on our way to a RIGOROUS science of consciousness (after all, this was Husserl's goal).

Of course, this is only a criticism of someone interested in a science of consciousness who takes Husserlian phenomenology seriously as a means of gathering first-person data (specifically, someone like Varela). If one doesn't take Husserl seriously, one doesn't have to take the criticism seriously. As someone who does take Husserl seriously, it seems that, given the above, it is from the first-person perspective that a science of consciousness must begin. The task of gathering third-person data follows only after significant work has been done on the first-person side. Work done in the third-person beforehand, is, if Husserl is right, haphazard. It may be science, but not, as Husserl says, rigorous science.

All,
The assigned readings just seem to miss the mark, in my opinion, so
I'm using some outside sources to inform my posting.

Here I'm using the article by Depraz in The View From Within, and Varela's
Neurophenomenology paper from the penultimate week's reading list.

The problem I have with current NCC research projects is a
methodological/epistemological one. The criticism is inspired by the
Husserlian notion of reductions. A recent trend in first-person
approaches insists that it is only within a Husserlian methodological
framework that we will be able to get rigorous enough about first-person
conscious experiential data such that a Chalmersian science of
consciousness project will be possible. That is, the claim is that it
is only by practicing Husserlian reductions (the epoche and eidetic)
that researchers will be able to rigorously gather relevant 1st person
neuroscientific data (among other 3r person data). The problem is this.
Such reductions aim, by definition, at uncovering
the essential (irreducible) structure of conscious experience (see
Varela p.4 of web print-out). That is, the thought is that what we get
when we casually look at the world is only one possible "presentation" (or
representation), one we have in virtue of a habitual way of looking at the
world. If we bracket this habitual mode, allowing room for
other possible presentations, we go from contingent "facts" to essential
facts (i.e., we go from facts that are contingent in virtue of being
derived from a single perspective to those that are universal in virtue of
being derived from a multitude of perspectives--see Depraz p.101).

Now, Varela writes:

We are similarly assuming that human experience follows
fundamental structural principals which...enforces the nature of
what is given to us as contents of experience (p.8)

and

It is one of the most impressive discoveries of the
phenomenological movement to have quickly realized that an
investigation of the structure of human experience inevitably
induces a shift towards considering several levels of my
consciousness as inextricably linked to those of others and to the
phenomenal world in an emphatic mesh. Consequently, the usual
opposition of first-person vs. third-person accounts is
misleading. It makes us forget that so-called third-person,
objective accounts are done by a community of concrete people who
are embodied in their social and natural worlds as much as
first-person accounts... (p.9).

In other words, the relevant phenomenological reductions aim at
irreducible structures of not only the act of consciousness but of the
objects of consciousness as well. Depraz uses the example of the
experience of red (p.101). After performing the reductions one is left
with the essential structure of an experience of red--presumably, one that
is much richer than the one had previous to the reduction. In other
words, one gets essential (or the essence of) red (as an object of
consciousness), and this is DIFFERENT (and epistemically privelleged) from
contingent red (red as an object of consciousness before the reductions
are performed).

The result seems to be that, after one performs these
phenomenological reductions, one is left with a more robust and fuller
phenomenal world. The world looks different, feels different. And--here's
the meat of it-- if a neuroscientist performs these reductions, the BRAIN will look and feel different, perhaps quite different. The essential structure of an experience of the brain might be altogether different from the one we have from habitual observation. For example, the way neurons look and seem to behave before the reductions might radically differ from the way they look and seem to behave after--if what we get after can even be called a neuron any longer (i.e., things might look VERY different!). With a more robust phenomenal world we would presumably get a more robust neurosciences (since most of neuroscientific data is predicated on observation). After some progress on the first-person side of the project, it would seem necessary that, with this honed observational tool, we revamp the third-person side. Only then could we be said to be on our way to a RIGOROUS science of consciousness (after all, this was Husserl's goal).

Of course, this is only a criticism of someone interested in a science of consciousness who takes Husserlian phenomenology seriously as a means of gathering first-person data (specifically, someone like Varela). If one doesn't take Husserl seriously, one doesn't have to take the criticism seriously. As someone who does take Husserl seriously, it seems that, given the above, it is from the first-person perspective that a science of consciousness must begin. The task of gathering third-person data follows only after significant work has been done on the first-person side. Work done in the third-person beforehand, is, if Husserl is right, haphazard. It may be science, but not, as Husserl says, rigorous science.
Chalmers wrote:

> ADAM: Adam worries that the whole NCC approach is premature, since we need to get a good phenomenological method off the ground first. Not just to gather the first-person data, but also to gather the third-person data from neuroscience, etc. My worry here is that the same presumably goes for third-person data in any science at all, e.g. physics, chemistry, biology. But if Newton had waited for phenomenology to be properly developed, we would have been waiting a long time! My own view is that a developed phenomenology is vital for gathering first-person data, and may end up helping us gather third-person data, but that at least the third-person part of the story ought to be able to get off the ground without it. It's not clear why the NCC search is any worse off here than any other area of neuroscience, or of science in general.
>
> --Dave.

Exactly. Husserl's methodology was intended as an epistemological overhaul of the sciences--i.e., ALL sciences. What he was looking for was a rigorous method, a reliable means to put it another way, of gathering data for an epistemically privileged science. A contemporary analytic analog might by the theory-ladenness of perception/observation doctrine--which, in short, claims that conceptual learning influences the mode and content of perception. If perception is theory-laden, proponents of the doctrine say, we may pose an epistemological criticism of traditional science--wherein the data that is to be explained is gathered via observation. This is a real worry in the philosophy of science. That is, it has well-respected advocates and the debate is far being putatively settled. If Husserl (and theory-ladenness advocates) are right, we MUST proceed with the first-person project first. Had we recognized this earlier and directed our focus appropriately, perhaps Newtonian physics would have looked quite different and maybe even gotten things right!

Okay, maybe I am too hung up with my own traditional psychological way of thinking but I really don't understand this first person data business and I am hoping that someone can explain it to me. It seems to me that if we understand the third person perspective in a reasonably thorough manner we can predict any possible finding from the use of first person data. That is because our beliefs about what we are experiencing are accessible from a third person viewpoint. It is hard to see what good first person evidence is going to do us if we don't believe it, but if we believe it it is accessible as third person evidence.

Return-Path: <acboch@U.Arizona.EDU>
Joel (and all listening in),

I'm having some trouble understanding your post, especially the stuff about belief in the last two sentences.

You start with:

It seems to me that if we understand the third-person perspective in a reasonably thorough manner we can predict any possible finding from the use of first-person data.

You seem to be saying that once we have an adequately robust neuroscience, we can correlate brain states (or processes) with our first-person data, and so be able to, from then on, predict first-person experience just from looking at the third-person data.

But then you say that this is the case because, "...our beliefs about what we are experiencing are accessible from a third-person viewpoint".

First, I don't understand the role beliefs are (or ought to be) playing here. Second, you seem to be saying that after we correlate third-person and first-person data, by looking at the former we can predict the latter, and that this is BECAUSE first-person experience is accessible from third-person data. But this doesn't seem to be saying anything substantial.

Finally, you write:

It is hard to see what good first-person evidence is going to do us if we don't believe it, but if we believe it it is accessible as third-person evidence.

Here, again, I'm not sure I understand what role beliefs are playing (or, perhaps I think you mean one thing by beliefs but you really mean something else). Also, I'm unsure in what way you are using 'third-person data' and 'first-person data'. At first, I thought you just meant to point to observations in neuroscience when you uses 'third-person data'. But then you seemed to mean observation of verbal reports when you
used the phrase later. But verbal reports can also be considered indicators of first-person experience.

I hope that you will take the time to clarify these points. Perhaps just mentally noting them and re-phrasing your point would be enough. I am excited about this dialogue and eagerly await your reply.

Adam

Let me see if I can be clearer.

Step one. I do not see any way of having first person data which the person
whose first person data it is does not believe. This is not supposed to be
any claim about NCCs or something which we might discover. This seems to me
like a conceptual truth. If I had some experience, but I did not believe
that I had it don't see how I could use it as data. Furthermore, if I
believe I have a certain experience I will count it as data. Someone might
convince me that I am incorrect in thinking that I had this experience, but
then I will throw out the data just as I no longer believe I had the
experience. Thus it seems to me that the information available from first
person data is the same information available from beliefs about
experience. I don't think this is an a posteriori discovery. I think this
is conceptually necessary: Data is data only insofar as you believe it.

Step two. Beliefs are accessible via third person methods. Unlike qualia,
we have third person methods for getting at beliefs. We have every reason
to think that we will have a very good understanding of beliefs based on
cognitive psychology and neuroscience. Anticipating an objection, it may be
that we cannot completely individuate beliefs without qualia. If you and I
have inverted qualia, one might argue that there is some part of our color
beliefs that is different. However, whatever there might be to beliefs that
is not accessible to third person analysis, it is not structural. Whatever
theory you develop with your inverted qualia will be structurally identical
to one based on my qualia or one simply based on the third person data.
Notice that any data which you could potentially communicate (even through
demonstration) is third person data. Thus it is not clear how useful any residual first person properties of beliefs are going to be in any science of consciousness.

Step three. From these it follows all the information available from first person methodologies is also available through third person methodologies (modulo qualia inversion type issues).

Adam
Hi all, I'm back from Memphis. Here are some thoughts on recent discussion topics. First, the issue of reducing first-person data to third-person data.

I think there is definitely something important in what Joel says. Given that first-person data are only usable if they give rise to beliefs, and given that beliefs always show up in behavioral dispositions such as reportability, then it may seem that first-person data insofar as they are usable can be found in third-person data. A few comments that might be made in response:

(i) Even if the content of first-person data had analogs in third-person data (as is suggested e.g. by my principle of structural coherence), this wouldn't mean that the data themselves are eliminable or reducible. It would just mean that we have a natural mapping between the two. Of course this mapping is used all the time by experimenters who use reportability etc as their epistemic route to consciousness. Note that the reports and beliefs themselves aren't so much what the experimenters care about (as they would be if they were studying third-person data); rather, they are mostly interested in them as a guide to first-person phenomenal experience.

(ii) It could be that there are first-person data that don't give rise to beliefs, or that can't be articulated in reports. If so, they may be usable in our science, but that doesn't mean their reality as data must be denied.

(iii) There may be aspects of the first-person data that can only be understood from a first-person point of view. The obvious example is Joel's inverted spectrum case. For someone who has experienced color, the distinction between red and blue first-person data is obvious, but it doesn't really show up in the third-person data. Does that mean we can't have a science of it? Well, if we can assume that our scientists have the concepts of red and blue experience, then we can, as long as our science includes interpreted first-person concepts such as these. Whereas from the third-person case, we'd have to give up right away. Of course, this method isn't useful for those without the concepts, such as Mary in her room. Still, it can take us some distance (and e.g. suggests that Robinson Crusoe might be able to come up with a rich first-person science that third-person data wouldn't approach).

There are also more general versions of this problem (not just for...
intrinsic" inverted spectrum cases), e.g. in understanding the very concept of consciousness and first-person data. Someone without consciousness couldn't even start on this part of the science, for all their grasp of the third-person data, since they wouldn't know what we're talking about re first-person data. But a conscious scientist has no problems at all. So one shouldn't underestimate the role of first-person concept possession in individuating the subject matter of our science here. And it may be the possession of those concepts that makes third-person data indirectly usable in just the way Joel suggests. Without it, one couldn't use third-person data as a guide to first-person data. One would be stuck with zombie science.

At 11:42 PM -0700 10/4/99, David Chalmers wrote:
> One would be stuck with zombie science.

Exactly my point. A zombie (being exactly the same as a normal person physically) could be just as good a visual scientist as anyone else. (i) A zombie would ask to see the stimuli just like anyone else. It is not like he is just faking it when he asks. He wants to see the data that everyone else sees. And he does. Seeing the stimuli causes him to have beliefs about the strategies used by the subjects in the experiment and the information provided by the stimuli just like anyone else. (ii) It seems to me that any "first person data" that can be used when collected from a non-zombie, can also be collected from a zombie. But in what sense is it "first person" then? (iii) The zombie distinguishes red and blue. The zombie can argue about the inverted spectrum problem.

What is it about our science of vision that we could not discover if we were zombies?

Joel

Without it, one couldn't use third-person data as a guide to first-person data. One would be stuck with zombie science.

--Dave.
I don't think it matters if you substitute consciousness scientist, science of consciousness etc (or anything else for that matter). But since it is a science of consciousness not vision that is at issue, I should have used "consciousness" not "vision."

Joel,
I guess the source of my confusion was the following. I was trying to interpret your point regarding beliefs about first-person data vis-a-vis my point regarding Husserlian reductions.

That was a mistake since it seems to be a separate point.

But now I would like to address the point by invoking some of the notions I brought out for discussion before.

You wanted to say that all this business about first-person experience was superfluous, since any relevant first-person data (i.e., the ones a subject has beliefs about) can be had by third-person investigation, viz., observation of subject reports.

But, there are still problems (Dave mentioned a few. I'll mention some more, maybe overlapping a bit with his stuff.).

There might be much we are missing if we limit first-person data to those that we can glean from subject reports.

(1) There may be important experiential data that subjects are not forming beliefs about.

I talked before about possible "presentations" of objects of consciousness. These are other 'points of view' to put it simply, other perspectives with respect to objects of consciousness and modes of being conscious. If Husserl is right, in virtue of relying solely on our habitual perspectives we miss out on the other possibilities. That is, we are conscious of less than is possible and so limit our domain of inquiry. If our domain of conscious experience is restricted, so is our domain of belief with respect to what we are conscious of.

(2) There are some experiences that just cannot adequately be reported.

Take as an example, G.Y., a subject used in the blindsight experiments we've discussed. The experimenters made a point to convey statements made by G.Y. to the effect that he could not accurately explain to the experimenters the content of his "blindsight" experiences. He would say things like "the closest I could come to describing it", which points to his inability to EXACTLY describe it. Other subjects in blindsight experiments express similar difficulties. The notion seems to be that 'if you haven't experienced it for yourself, you can't know what I'm talking about'.

Luckily, a phenomenologically-based research project eliminates these problems.

Regarding (1), those other possible perspectives of objects (or modes) of consciousness are opened up via employment of the reductions. One's domain of conscious experience expands thereby expanding ones domain of belief with respect to conscious experience.

But the point about belief and reportability is moot since...

Regarding (2), in a phenomenologically-based research program, each individual experimenter is herself her own subject. Each individual investigator performs his own reductions. When a given phenomenon is experienced by all, a common language to describe it is set up, and intersubjectivity is reached.

Using blindsight experimentation as an example, we can see the limitations
pointed to above. The subjects, by the very nature of their maladies, are limited with respect to their domain of P-consciousness. Also, they have trouble describing to their investigators just what they ARE P-conscious of.

Perhaps, using a different methodological paradigm, namely a Husserlian phenomenological one, we might be able to experience the 'blindsight' phenomenon for ourselves. That is, the phenomenon would be one amongst a variety of different modes of being conscious. Each investigator could perform the necessary reductions such that she came to have the relevant experience. Perhaps then, other, closely related modes could be experienced, and the data compared with that of other investigators (who themselves had had the same experiences), to arrive at some objective (i.e., intersubjective) explanation of the matter (of course this might need to include the relevant 'neural' data, but, as I have said before, this itself must be done only after the relevant reductions have been performed (viz., those having to do with physical objects, motion, tie, etc., i.e., the one's pertinent to doing brain science)).

Perhaps notions of A and P consciousness would become more clearly individuated (or perhaps they would bleed into each other).

Regardless of the outcome, the point is that the methodological tools provided by phenomenology provide a solution to problems that arise upon employment of more traditional methodological tools, namely, those of experimental psychology.

Cheers,

Adam
In his talk of September 10, Dave accorded a prominent place to the search for the NCC in an overall science of consciousness. He viewed it as playing an important role in leading to the discovery of bridging principles linking the physical and phenomenal facts. My comments here address why I think this expectation is premature, and why approaches like those of Logothetis and Crick & Koch, while clever and interesting, are unlikely to give us much new information about consciousness. (I make no claims regarding the originality of these ideas, as they are greatly influenced by comments made by others in class. Writing them out has merely helped to focus my thinking on these issues.)

Whenever we have found specific brain correlates for particular psychological functions, we seem to feel that we have better understood those functions. In fact, often all that we have understood is why damage to those brain areas leads to deficits of this or that sort. In the current climate where high-tech brain mapping is so fervently pursued, this feeling of making explanatory progress is reinforced by numerous social factors that drive research. I remain skeptical that any substantial explanatory progress is actually made in this field, beyond the continued confirmation and refinement of our existing hypotheses about brain localization. The following (recently

---

Hi Dave,

I'm out of town and don't have access to my own e-mail accounts, so I can't post to the list. Would you please submit it for me?

Thanks,

Lis
encountered) quote on the relevance of neural correlates to the shaping of developmental theory expresses part of my worry as regards how this kind of evidence can inform a theory of consciousness:

"Suppose we have a psychological theory that says that function A leads ontogenetically into function B. Being able to suggest brain correlates for A and B has great merits, but it does not by itself advance developmental theory. This can only be done if there is information about those brain correlates that can be used to inform the developmental theory, such as the relationship between physiological substrates of A and B. ... [P]hysiology on its own has never been a prerequisite to developmental theory, since sometimes the psychological and neurological facts match on levels and sometimes they do not." (Segalowitz, 1994):
circuits independent of content-related processing that are, perhaps, firing all the time, i.e., those circuits that show no deviation from their baseline when we are conscious of a stimulus. That's the activity that usually gets subtracted out of any brain imaging or mapping study - the activity that is constant across all trials. Content-related firings (such as those in IT) might just feed into whatever background circuits are maintaining this overall conscious state, accounting for their differential localization as a function of stimulation or attention. But this is not surprising, once one already knows that the brain compartmentalizes its content in various ways. We had a good idea about this already, from numerous lesion and experimental studies that continue to be confirmed and refined by brain mapping techniques.

What neural activity or circuitry determines whether and how a particular content gets into consciousness seems to me a far more interesting question that what neural areas are active when that particular content is represented. The more piecemeal approaches of the binocular rivalry type are likely to leave us with a huge and unwieldy catalogue of NCCs in multiple modalities and at multiple levels of processing. My guess is that they will tell us little NEW about consciousness. In my opinion, our search for the neural correlates of consciousness should focus on questions of access. They should be guided by our current best understanding of the function of consciousness, and of why certain contents are made available to consciousness at any given time. Finally, until we have a more fine-grained mapping of the phenomenal realm, our questions about what phenomenal content states map onto what neural states would seem premature.

I'd like to know whether I'm thinking of NCCs in the right way. It appears that an NCC is a sequence of neural firings. Then, characterizing any NCC requires the identification of a set of neurons and the order in which they fire. If this is on the right track, then a horde of issues descends upon me.

1. First, a small point: Dave wrote in his last email that the argument for the sufficiency of an NCC N might be damaged if the brain is. There could be, he suggests, activity in N without the conscious state that
correlates ever arising. He might mean that there is activity in the set of neurons that partially make up an NCC. But there's no reason to expect that firing alone should give rise to the conscious experience N gives rise to, because N only becomes sufficient for the conscious experience when N is fully instantiated, the neurons in the relevant set fire in the precisely ordered way. The strengths of the argument for sufficiency are not harmed in the case Dave suggests.

2. Second, let there be a lesion. Now, I might imagine that the set of neurons relevant to a particular NCC N might be unscathed by this nasty lesion and the consciousness-bestowing, magical, exact sequence of firings in this set, call the set \{N\}, takes place, but the conscious experience the mind was wont to have does not arise. Intuitively, we might say that lesions leave us woozy; it's difficult having the same experience after undergoing them. What this situation suggests to me is that there might be important relational properties adhering the neurons of \{N\}. How the neurons are related to one another and to other parts of the brain—how off(or off-off) Cartesian broadway they are—might give clues to why they and not another set of neurons are used to instantiate N. Presumably we couldn't string together the elements of \{N\}(in a string that might cross itself), watch them firecrack in sequence, and expect the conscious experience to arise. The geometry of the set is relevant. Indeed, this idea might suggest an explanation how the damaged brain finds another set of neurons, \{M\}, in which to allow a certain conscious experience to take place, one that N used to correlate. The relational properties of the neurons in \{M\} might be required to be isomorphic to those of the elements of \{N\}, for M and N to be able to give rise to the same conscious experience.

3. Last, I think Lis is right, if I understand her correctly. Apparently, talk of neural correlates just means the brain mapping project is getting closer to the neural level of description and not necessarily that we are any closer to an explanation of consciousness. Maybe sets of neurons that might serve as NCC-platforms might be isolated and identified. Maybe isomorphic functions between neural sets might be described, to explain the flexibility of NCCs. Perhaps rules will be found that govern the interaction of neurons participating in an NCC, rules that might be strongly correlated to certain types of conscious experience. Won't the hard question remain?

A last, interesting paragraph of Lis's is on the extension of experience and its neural correlate through time. It calls to my mind arguments about the nature of time. We think ourselves to be instantaneously conscious, but clearly we wouldn't say that the neurons firing in an NCC at a particular instant give rise to that instant's experience.

Nick

ps Sorry for all the wanton speculation. I hope the analogues weren't too loose. I am grateful to any who would explain me my folly.
As I was thinking about the problem David rises concerning the issues of lesion and their relation to discrimination of the NCC, it now looks to me that if his reasoning is correct (and I believe it is), the distinction between "good" and "bad" lesions is nmore than necessary. Why? Well, because it not only applies to the search for NCC, but to any neurological correlate of any disorder. Take any dissociation studies, such as prosopagnosia.

In order to study it, neuroscientists have determind a possible "prosopagnosia correlate", that is a part of bring, which, if dmaaged, patients are unable to recognize familiar faces. But what if the reasoning is mistaken and the thing they have identified is only somehow part of a causal chain, which leads to face recognition. That is, the "real" correlate is more downstream, but this particular place is so important, that it in fact bears all the important sings of the real correlate. Does it make sense?

Well, if it does, then we have to face consequences. One of them would be, that the proposals Dave's talk about as correct ways to determine correlates (unusual percepts and direct brain stimulation) might not also be so helpful. How do you, for example, want to test "correlate" of faces recognition with UNUSUAL stimulus? What is an unusual face. If the correlate functions only in usual conditions, then such cases might not work.

We would still be safe as far as the brain stimulation works, but concerning the overall technical difficulties, the sceptic might conclude that the time we determine the real correlate is infinitely far away...

Great weekend to everyone!

Hello All:

I have a couple of comments to make concerning the discussion of NCCs. First, Lis Nielsen recently made a post that I believe is relevant to the arguments Brad and I made on Tuesday concerning the difficulty in localizing a NCC. Here is an excerpt from her posting:

> The approaches of both Logothetis and Crick and Koch make further assumptions about the NCC that are not necessarily justified. First, they assume that phenomenal consciousness and neural firings will correlate on temporal dimensions. But, as Amanda pointed out, they have established no guidelines for what degree of correlation is acceptable. One might be tempted to conclude that binocular rivalry studies confirm the temporal correlation hypothesis, but in fact all they show is that there is a place in the processing stream where there is a (rough) temporal correlation between phenomenal consciousness and visual information processing.

> It could be that the neural correlate of consciousness resides in the circuits independent of content-related processing that are, perhaps, firing all the time, i.e., those circuits that show no deviation from their baseline when we are conscious of a stimulus. That's the activity that usually gets subtracted out of any brain imaging or mapping study - the activity that is constant across all trials. Content-related firings (such as those in IT) might just feed into whatever background circuits are maintaining this overall conscious state, accounting for their differential localization as a function of stimulation or attention. But this is not surprising, once one already knows that the brain compartmentalizes its content in various ways.

We had a good idea about this already, from numerous lesion and experimental studies that continue to be confirmed and refined by brain mapping techniques.

Lis' comment seems to accord with the metaphor I put forward about IT being the sculptor that acts upon the clay (lower visual cortical areas, i.e. V1-5 et al) to produce a conscious visual percept. What reason do we have to think that visual qualia are restricted to only one area of the visual pathway and not another? The example of blindsight may seem to suggest that certain portions of the visual stream have qualia producing aspects in that damage to these areas leads to a loss of phenomenology on the part of the blindsight patient. However there are two things to consider: (1) if we remove processing at lower levels (as in blindsight) there is no lower level visual information for higher level areas to act upon to create a visual percept (i.e. no clay). Thus both lower and higher visual areas are needed for the creation of a conscious percept. Given this, does it make sense to say that one area is a NCC and the other is not?; (2) as we will see in the case of blindsight, damage to lower visual areas does not preclude the possibility that visual information can still reach conscious awareness. It is just that the phenomenological manifestation of this information within the blindsighted individual is extremely impoverished. Depending upon the extent of the damage, the phenomenology may range from absolutely nothing to vague (almost indescribable) sensations. In the case of the latter, could it be that the vague sensations are produced from higher order visual areas that receive the information via roundabout loops that bypass the lower visual areas? Since this information is not coming through the visual stream...
It is concluded from the empirical work of Logothetis on vision in monkeys that "V1 is unlikely to be or involve an NCC, for example, due to the failure of V1 cells to correlate with the contents of consciousness." I don't follow the reasoning here. What is being lost is the issue of networks in the brain, and that these networks, through interaction, may bring about the consciousness phenomenon. And, how exactly can the inferior temporal (IT) cortex be the NCC, and not V1, when the IT receives projections, either directly or indirectly, from V1? With all the rush toward localization, do we risk losing ground in the search for NCC by missing the bigger picture? A person can lose a part of their brain that is thought to be important in some function through lesions, but not lose that function completely. There are often multiple pathways, and losing part of the circuit does not guarantee that there are not other ways the circuit can be completed. Of course, it is always possible that there is more than one NCC, and that a lesion in one does not disrupt the other. Or perhaps there is remapping of a function elsewhere in the brain. How would that change a NCC?
As for whether the NCC state is required to be necessity/sufficient for the conscious state... If an NCC state is only required to be sufficient for the corresponding state, but not necessary, are we any further in understanding how the NCC leads to consciousness or an experience of conscious state? If it is only sufficient, and not necessary, than how do we know its truly improtant for the conscious state?

All -

When Dave endorses minimal sufficiency as the proper criterion for identifying the NCC, he notes that on this criterion it will be possible that there will be more than one NCC. He seems untroubled by this, and in one sense I share that attitude. Not only should we not be surprised if there is no "Cartesian Theater" where all the representations involved in phenomenal consciousness occur together, but we should not be surprised if there are redundant NCCs. Given the prevalence of redundant systems throughout the body (kidneys, lungs, etc.) it seems to make good evolutionary sense, other things being equal, to have multiple systems for consciousness.

In fact, I think there is strong evidence that this is the case which can be found in studies of split brain patients. Im sure that the psychologists among us know much more about these experiments than I do, and perhaps some of the philosophers too, but just in case some dont, heres a brief (and somewhat idealized) synopsis:

When the bundle of nerve fibers (corpus callosum) that connect the right and left cerebral hemispheres is severed, the patients suffer a dissociation phenomenon. Because each hemisphere receives input from and has control over (primarily) the opposite side of the body, it is possible to create situations in which one hemisphere knows something that the other doesnt. For example, if the experimenter were to show the word
"handbag" to one of these patients in such a way that the "hand" part would only be perceived by the left hemisphere and the "bag" part only by the right hemisphere, and if the patient were then asked to point at the object named (from a more or less random collection of objects provided), the right hand (controlled by the left hemisphere) would point to, say, a mannequin hand, and the left hand would point to, say, a paper bag. The patient would not point out the purse. Many would say that this is evidence that in the split brain patient there are two independent streams of conscious states.

Though the split brain cases are fascinating in themselves, what they suggest about normal cases is more relevant to my point here. Since cutting the corpus callosum has no effect on the structure of the rest of the brain, it seems reasonable to conclude that the structures responsible for consciousness must be duplicated in each hemisphere even in normal patients. Since each of these structures can function on its own in the split brain cases, each would seem to be an NCC. In normal patients, the corpus callosum seems to have an information sharing function, so that the two NCCs end up with the same content. (For the sake of simplicity, assume that there is a single Cartesian-Theater-style NCC in each hemisphere).

Dave doesn't seem to be worried about this, but I think that perhaps he should. The worry I have is that the existence of multiple NCCs may raise a set of questions to which he cannot provide an answer. For example, if every normal person has a right NCC and a left NCC, how could we decide which of the following views is true.

1) A normal person's phenomenal consciousness is produced by both NCCs running in parallel.

2) A normal person's phenomenal consciousness is produced by his left NCC. The right NCC performs all the same operations as the left NCC but does so without producing any phenomenal properties.

3) 2) but with right and left reversed.

4) A normal person has two independent sets of phenomenal consciousness (two minds), one produced by each NCC. Since the two run in parallel, the phenomenal contents of each mind is identical, but they are nevertheless separate minds.

The problem would only get worse if we found that there were other redundancies within the hemispheres, or if the Cartesian Theater model turned out to be inaccurate in such a way that redundant versions of all sorts of representations of conscious contents were scattered about in the brain.

The reason that I think Dave will have a hard time defending one of the options above is that he has no causal explanation of phenomenal properties, merely a correlation. If we had a theory of consciousness that told us that the NCC causes consciousness by emitting "phenomenal particles" which we could detect with a "phenomometer," we might be able to verify that, say, 2) was the correct option because normal subjects only emit "phenomenal particles" from their left hemispheres. But, of course, this is precisely what Dave doesn't think we will ever be able to do. I suppose he could appeal to criteria of simplicity, appeal to the best explanation, and so on, but it is not clear to me that any one of these possible claims is any simpler, or a better explanation, etc. Of course, maybe a theory of consciousness that narrows things down to one of the above alternatives is the best we can do given our epistemological situation, but if so, I think a critic could justifiably claim that our
"explanation" of consciousness is much too weak. After all, if we cannot even tell how many minds (streams of consciousness, conscious states) a person has, how much do we really know about the phenomena we claim to have explained?

Joel

Dear all,

Many of the recent mails have tended to be rather scathing of either the use of correlation in the search for NCC, or the use (or interpretation) of lesion studies. I thought that it might be interesting to try and defend both of these - perhaps it will help us to focus more clearly on their problems.

(1) Correlation

The criticisms of correlation seem to be centred on the idea that we are failing to advance our knowledge of *consciousness* when we correlate neuronal firing with specific conscious experience. Nicholas seems to suggest that all we are doing is improving our 'maps', and not answering the real questions. In a similar vein, Lis is worried that the *real* work of consciousness might be taking place in an area where firing is unrelated to content, and hence would fail to sow up in these mapping studies. I will try to answer each charge in turn.

With respect to Nicholas' concern, it may well be that all we are doing when we study neuronal firing is improving our 'maps' of the brain. However, it does not seem to me that this is a problem. Presumably any theory of consciousness will need to account for the correlations between specific content and firing patterns - a part of what such studies are doing is defining the things that a brain-based theory of consciousness needs to address. Thus whilst these studies do not in themselves give us a theory, they are essential in that they define part of the problem.
Turning now to Lis' point, it is certainly possible that the real is such that its firing is not specifically related to content. Instead, areas of the brain whose firing is content-related feed into this (continually?)-firing area, which then produces consciousness. Whilst this view is possible, however, it seems to me to be implausible. If the real NCC does not change its firing rate or pattern when confronted with differing stimuli, then how do we have differing content in consciousness? It seems reasonable to assume that if there is a central NCC, then it must use something like differential firing rates to engender different conscious experiences. If this is so, then presumably such changes should appear of the scans (if not, then this must be due to the limits of the equipment, and not the theory behind their use). In other words, there will be some sort of correlation between the firing and the experience.

(2) Lesion Studies.

One of the problems with the use of lesion studies that was discussed both here and in class, was the concern that whilst a particular lesion might result in the loss of a certain type of consciousness, there is no reason to assume that the area in which the lesion is situated is the NCC for that particular type of consciousness. It may be that the region is merely a part of a chain which leads to the particular NCC. Likewise, there might be multiple pathways to an NCC, such that the loss of one does not result in the loss of that particular consciousness. In response to these concerns, I would like to say that this is not a reason not to use lesion studies, but merely a reason to be careful of how such studies are interpreted. Thus if we had one lesion study which suggested that region A was involved in visual consciousness, then we should not necessarily assume that visual consciousness takes place in A, but rather the much weaker claim that A is involved in visual consciousness. If there were to be multiple studies of related lesion studies, all of which seemed to result in a loss of visual consciousness, then perhaps we could 'map out' the visual pathway (of course, if the brain turns out to be very plastic, then this would be more difficult). In a similar way, it might be possible to identify redundant pathways. Thus these studies will help us to identify what parts of the brain are necessary and/or sufficient for consciousness.

I hope that I have managed to put together a passable defence of the above concepts. I think that they are likely to be very important to the study of consciousness, and should not be dismissed lightly.

Simon.
Hey all,

I have three thoughts on the NCC that have been bothering me since our class talk. The first is this, why are we limiting our discussion solely to considerations of necessity and sufficiency? If we are willing to admit that there may be more than one NCC for even a very specific conscious state (what Dave would call a content state), and if we are willing (pace Dave) to admit the possibility that an NCC could be instantiated, even concomitantly with the requisite background state C, without the conscious state arising? (I should note here that Dave argues for this not from his thesis that any physical state can be separated from any conscious state because consciousness is not reducible to physicality, but rather from the hypothetical situation of 'downstream lesions', lesions that cut off an NCC from other, later processing that might result in a loss of consciousness, even though the NCC was intact and in state N, Sarah has something to say against this possibility, but even if her argument is correct, Dave could always rely on his earlier claim of separability.) Anyway, the point I want to make is that if we take these two possibilities seriously, from a practical standpoint we might never arrive at the 100% correlation that necessity, sufficiency or even minimal sufficiency demands. Mightn't we be better off (epistemically) if we were to take a reliabilist stance, and judge putative NCCs by their correlation percentages, positive and negative, with conscious states? So, for example, NCC1 might have a 85% positive correlation with Conscious State 1 (CS1), meaning that 85% of the time that NCC1 is in state N, CS1 occurs, and a 90% negative correlation, meaning that 90% of the time that NCC1 is not in state N, CS1 does not occur. Of course, these ratios can come apart because of the possibilities of multiple realisability and full physical instantiation without phenomenal (conscious) instantiation. Then we could compare different candidate NCCs by seeing how their numbers stack up, and we could figure out what sort of shortcomings an NCC might have given its different performances on the two scales, e.g. an NCC with a high positive but low negative correlation might be one of a number of individually sufficient NCCs for that CS. Also, we could use these scores to settle questions about where to draw the boundaries of an NCC, by referring to the changes in the numbers that occur when we include (or exclude) certain substructures of an NCC. For these reasons, I think it might behoove us to focus on this probabilistic correlation as the defining one of NCCs, and not the all-or-nothing one we have been using so far.

My second worry is over Dave's suggestion that artificial brain stimulation might be used to exclude non-core elements of an NCC, in the following way: If we can artificially stimulate a neural network 'downstream' from a putative NCC, and we get the same CS as we did when the NCC was supplying the inputs, then we have a case for eliminating the earlier NCC, since it no longer seems necessary for the CS. What worries me here is that it seem that what we are doing when we 'artificially stimulate' the downstream system is taking on the functional role of the earlier system. But if this is the case, why is it impossible to take on the functional role of part of an NCC? And if it is possible, how will we differentiate between 'merely' background or enabling states and actual
(parts of) NCC states? It seems to me that unless there is some a priori reason that a machine cannot assume the functional role of part of an NCC, then we have to come up with a way to tell them apart, otherwise we risk arbitrarily excluding neuronal groups that are possibly part of an NCC.

Which brings me to my third point. One might argue that one way to tell a background or non-core neural state from an NCC one is via temporal indexing, using the onset of consciousness as a benchmark. So, we might say, anything that occurs prior to the onset of consciousness is a possible background system, but not part of an NCC, and anything that occurs afterward is at least possibly part of one. But this is insufficient in two ways: Firstly, even if it were a viable method of parsing, it would only answer questions about upstream neural candidates, and second, it doesn’t even seem a viable method, to me, because it tacitly assumes a symmetry between conscious temporality and physical temporality. If we are going to use the onset of consciousness as our temporal benchmark, and exclude neural candidates for NCChood on the basis of their preceeding this benchmark, then we have to assume that the onset of consciousness is co-temporaneous with the NCC processing that is responsible for it, and this is not necessarily the case. It might be that the onset of consciousness lags behind NCC processing, and as a result the subject enters the CS after the crucial NCC processing has occurred. We can imagine further that some other processing, downstream of the NCC, occurs co-temporaneously with the onset of consciousness. In such a scenario (which seems completely possible to me) if we were to employ the benchmarking method outlined above, we might well associate the CS with the later, non-NCC processing, because the actual NCC processing occurs before the onset of consciousness, and is therefore 'upstream'. As to why consciousness might lag behind the NCC processing that underlies it, who knows, but the relationship between the physical and the phenomenal is certainly mysterious enough for this to be possible.

(I apologise to Dave for the lateness and to everybody for the long-windedness and pedantry)

Al.
I wanted to dwell a bit on the worries about lesions in "What is the Neural Correlate of Consciousness?" and from last class. It seems that lesion studies should be scrutinized with care both because they can lead us to exclude some of the NCC from our NCC, and because they can lead us to include some non-NCC in our NCC. (They seem to make the NCC both too wide and too narrow.)

In the first case, we have the worries about plasticity of the brain. If, after a lesion, the brain is capable of rerouting its processing in such a way that the NCC actually changes location, then the information from the study of such lesions might give us a sufficient NCC, but not the NORMAL sufficient NCC. Relying only on lesion studies might cause us to reject as the NCC an area of the brain that we normally use as the NCC, but which in marginal cases we can work around.

In the second case, we have the putative NCC in a petri dish, or other less extreme versions of this problem. In these cases it seems that the putative NCC would not be conscious. However we don't want to hold this against the NCC we have isolated, since there are certain background conditions we want to hold fixed in our search for the NCC. These background conditions might include getting appropriate (not processed) sensory data, or, if there is an on switch for consciousness, having that switch on. Requiring the NCC to operate despite all lesions (down to amputation) seems to ignore the fact that we are looking for the MINIMAL sufficient NCC.

Now the impetus for each of the worries above seem to be directed at lesions that occur upstream of (or in) the NCC. Sensory input should occur far upstream of the NCC, and, whatever an "on switch" might turn out to be it should be activated either before or at the time of consciousness. Likewise, it seems that lesions before or in the NCC are the ones we could use plasticity to get around.

These concerns have brought us to the the question of where to draw the upstream line on the NCC, or how far back we need to go. There is another related question of how far forward we should draw the downstream line of the NCC.

In particular I was bothered by this claim in "What is the Neural Correlate of Consciousness?"

>Less radically, one can imagine placing lesions immediately downstream from a candidate NCC N, so that N's effects on the rest of the brain are significantly reduced. In such a case, it is probable that N can be active without the usual behavioral effects associated with consciousness, and *quite plausibly without consciousness itself*.

I am willing to admit that the downstream limit of the NCC need not be as far down as behavior; we certainly don't want to say that someone who is paralyzed cannot have a full NCC simply because they cannot report it. But it seems to me that a lesion downstream of the NCC should not interfere with consciousness itself.

In the petri dish case we discount certain background conditions because while we can't have consciousness without them, they also don't seem relevant to conscious experience. Sensory input and brain "on"ness are plausible examples. But what could the background conditions here be? These would be conditions that occur after consciousness, but also enable it. I cannot think of any plausible examples of this sort of background condition. If an event downstream from our NCC is needed for consciousness, rather than discount this event, we should update our NCC to include the substrate of that later event. (Note that the background conditions...)
conditions needed here aren't those (epistemological ones) that make the
consciousness of others available to us, but rather those (ontological
ones) that allow conscious experience.)

If you all can think of any examples of a downstream background condition
that should be discounted, please let me know.

Given that the necessity and sufficiency issue has lead the discussion to
speculate about possible versions of "conditions C" which would be the
"normal conditions under which we would expect a NCC to operate". The
question has become "what are normal conditions?" As Dave mentioned in
class one could start as far away from the brain as the type of stimulus
that one is exposed to and only allow "environmentally valid" stimuli.
This has coherence under the "natural functioning" band of thought, but it
won't really allow us to play with the conscious/subliminal distinction
that would need to be experimentally allowed in order to have any data
whatssoever to procede with.

While I believe that we should leave the brain and perceptual
systems in as pristine a state as possible so that we can observe the
system's "normal functioning", I would question what is referred to as
"environmentally valid" regarding the allowed for stimuli set. While
binocular rivalry may be a supremely unlikely situation to find oneself
in, we have in no way said that the stimuli needed to be "evolutionarily
valid" as the only monkeys finding themselves needing to discern binocular
rivalrous stimuli are in a lab with electrodes in their brains, hence not a
"naturally occurring" condition. However, if we take Environmentally
valid, and make it into "natural reception system". thus cutting the world
off, for the time being at the level of the organism, we have a reasonably
wide array of possible manipulations that we are able to subject the
system to and that we may monitor its activity in response to.

For these "natural modes of signal reception" we have (as should be
obvious) our five senses. The most easily controlled of the phenomenal
consciousness set. The case being that psychophysics has given us a
pretty good idea of general thresholds for the various senses with regard
to their respective stimuli; we should be able to monitor the difference
between JND (Just noticeable difference) below and above the threshold for conscious experience. The difference in activity of the system between these two inputs should give us a reasonable approximation of the brain subsystems involved in "phenomenal experience" of a selected modality. Given that the actual energy difference in the light input for the two stimulus strengths can be known, a subtraction from the output values (in units expressed by activity) could be used to determine the generative potential of conscious experience, and the localization of this activity can be carried out via PET imaging, or fMRI (as long as you aren't using audition as your mode of exploration). And while these imaging techniques certainly have their drawbacks in terms of fine versus rough grained localization, we are given the added benefit of not having to disturb the system or "sacrifice" it post experiment to make sure that we were measuring the right (fine grained) place.

While this methodology will surely only give us a rough picture of a NCC it will also be an accurate one in the "natural state of the system", which may be of some extra value, given that we would not have to deal directly with the plasticity problem.

Just some thoughts,

subtract visual distinctions which are just below one just noticeable distance (JND) from those that are just above it. While this seems plausible in principle there are a couple things to keep in mind. First, notions like "JND" and "threshold" are really statistical. They are defined as the point where an observer can get some percentage of trials correct (usually 75%). Thus, just below a JND, the subject will usually be getting 70% correct and just above they will be getting 80%. The whole system is graded, and the parts necessary for consciousness are not likely to be much different.

Second, you are likely to get bigger differences as you move downstream independent of the location of any NCC. This is because all that downstream stuff that is hanging out thinking "Is that something? Where is it? Oh, I think that was it? Maybe not...," is going to act differently when it actually is getting information from when it is just hanging out.

Third, it is not clear that objective and subjective thresholds are the same or should be measured the same way (you are likely to get a lot of flack on this no matter how you do it).

In short, while this is an appealing idea, I don't think it could actually be made to work.

Joel

> think that was it? Maybe not...." is going to act differently when it
> actually is getting information from when it is just hanging out.

Wonderful, these are the differences that we will be looking for. What we
want to subtract is the "just hanging out" from the "getting information",
the larger the differences, the happier we should be. One would expect
that the largest difference should be able to be found in the actual NCC
itself, as it "got new information" and is no longer "just hanging out".

> Third, it is not clear that objective and subjective thresholds are the
> same or should be measured the same way (you are likely to get a lot of
> flack on this no matter how you do it).

This can be done in some way similar to the first reply I made (see
above) on individual thresholds. And when you are trying to do something
in a novel way, you will always catch flack, the object should be to get
the most valid form of information that you can for each subject that you
test. and While I realize that this sounds easier than it would be in
actuality, this is not so big a problem that the whole process could not
be made to work, imho.

I don't know how much it is worth belaboring this point but...

The problem is that you can't pick out the trials on which subjects saw the stimulus from the trials on which they did not. When you are performing such a task you feel like you are guessing on every trial, and the computer is often telling you you are wrong on those few trials you feel somewhat confident about. The correct trials are contaminated by ones where you were just guessing. The wrong trials are contaminated by ones where you thought you saw something but answered the other way because the last three times you responded that you saw it when you were not completely sure you got it wrong. It is not the case that you either see these stimuli or you don't. There is a gray area. When you have stimuli near threshold you are in that gray area.

> One would expect

I would not expect it to turn out that way. Some might say that that almost guarantees that it would turn out that way:-) However, it seems to me that any plausible NCC is going to be in some gray area, reflecting how well the observer can actually see the stimulus. Areas farther downstream, however are going to be acting differently because they are not providing a graded output. Downstream areas will act in qualitatively different ways depending on how much information they have (eg., little information = frustration, thoughts of breaking computer; midlevel = interest, pride when you get it right, anger when you get it wrong; higher level = boredom, can do in sleep, thoughts of lunch). In all probability the NCC does not think "Did I see something?" It just represents the available information. Stuff farther downstream thinks about this information and thinks and acts in entirely different ways depending on the amount of information available.

It is not the case that you either see these stimuli or you don't.

> There is a gray area. When you have stimuli near threshold you are in that gray area.

There should, then be a place on either side of that gray area, one of which is above, and one of which is below or within that gray area.

> One would expect that the largest difference should be able to be found in the actual NCC itself, as it "got new information" and is no longer "just hanging out".

> I would not expect it to turn out that way. Some might say that that almost guarantees that it would turn out that way:-) However, it seems to me that any plausible NCC is going to be in some gray area, reflecting how well the observer can actually see the stimulus.

Which is why the Above condition would have to be "above" and the other would have to be within the grey or below it.

> Areas farther downstream, however are going to be acting differently because they are not providing a graded output. Downstream areas will act in qualitatively different ways depending on how much information they have (eg., little information = frustration, thoughts of breaking computer; midlevel = interest, pride when you get it right, anger when you get it wrong; higher level = boredom, can do in sleep, thoughts of lunch).

This could undoubtedly be made at least a little bit interesting, the vast majority of cognitive research is really boring for the subject, but people participate and effects are found. If there is sufficient difference between trials that can be seen with high accuracy (~100% +/- 3%) vs. slightly below threshold (~chance) the task would not necessarily be that difficult or frustrating, (though boredom will definitely be a factor, but hopefully thoughts of lunch would be randomly distributed across your sample:-) and the imaging should still tell us the differences in the reactivity of the brain. Though we would likely get a picture of the processing going on afterward, this is arguably part of the reaction of the NCC.

> In all probability the NCC does not think "Did I
see something?" It just represents the available information. Stuff farther
downstream thinks about this information and thinks and acts in entirely
different ways depending on the amount of information available.

Maybe we are drawing the line in different places for an NCC, I have no
desire to cut off the "higher order processes" of consciousness, only to
separate out the difference between conscious percept and *not*.

It seems to me (tell me where I am wrong) that you are proposing running an experiment with two conditions. In condition A the subject can see the stimuli. In condition B the subject cannot see the stimuli. We then do a subtraction to see where "seeing" is occurring. If I have reconstructed your proposal correctly I see two problems with it. One is that you cannot make condition A and condition B comparable on the low level visual stuff (and still keep your clean distinction between being able to see the stimuli and not being able to see the stimuli). As a result, low level things will light up in your subtraction. Similarly, you cannot keep condition A and condition B comparable with respect to high level stuff. Doing a task when you can see the stimuli from doing it when you cannot see the stimuli in more ways than simply being able to see the stimuli. These conditions also differ in cognitive and emotional respects which are likely to cascade throughout the system. So the problem is, before running the experiment, I don't have any strong intuition telling me that the neural correlate of seeing these stimuli is going to light up more strongly than, say, the neural correlate of attending to the banging of the magnet, or the neural correlate of fidgeting. Thus I don't see how you can tell after running the experiment whether you have found the neural correlate of seeing vs a myriad of other possibilities.

Hi all, good to see the spate of interesting NCC postings. Here are a few brief comments:

Overall comment: we have to distinguish the three questions: (i) what is it to be an NCC, (ii) is there likely to be an NCC, and (iii) what will an NCC tell us about consciousness?

In my own paper, I was mostly trying to give a plausible answer to (i) based on the way the notion is used in the field. I also said a few words about (ii), suggesting that it wasn't unreasonable to expect that there may turn out to be NCCs so defined. I said very little about (iii).

As I said in the paper, I think it is strategically useful for people in the field to define NCC in terms of correlation alone, without any
additional claims such as, the NCC is the basis of consciousness, the NCC generates consciousness, the NCC explains consciousness, the NCC is the key to a theory of consciousness. That way, the search for NCCs is a common, relatively "objective" project that almost everyone can participate in without too much ideological baggage. Of course at the end of the day, that does leave open the question of what, if anything, the NCC will tell us about consciousness.

LIS: I take it that Lis is mostly concerned with (iii). The worry is that physiology alone doesn't tell us much; it will only tell us something in the context of a theory. I think there's a lot to be said for that; on the other hand, it is quite possible that isolating an NCC will itself help in the development of a theory. To take Li's example of binocularly rivalry, learning that IT is an NCC doesn't tell us anything much interesting about binocularly rivalry per se. But once we know this, we can look at how and when IT is activated, and how it related to other brain areas, and perhaps reach some very interesting conclusions about the place of conscious vision in binocular rivalry.

I do agree with a lot of what Lis says about Crick & Koch and Logothetis's approach being based on assumptions (re temporality, re connections to prefrontal cortex) that may not be justified. The trouble is that everyone needs to make some assumptions to get these things off the ground. Some assumptions are more reasonable than others; when they seem weak, one had better hope that the assumption itself will ultimately be testable. Of course I think that at the end of the day there are some pre-experimental background assumptions that everyone needs to rely on, but these had better be pretty straightforward. (E.g., the connection between report and consciousness.)

Lis points that consciousness might somehow be grounded in neural areas independent of content, and that content just "feeds into" consciousness, is interesting. I guess there still has to be a distinction between those contents that make it into consciousness and those that don't; it's not as if merely representing a content anywhere in the brain gets it into consciousness. So one will still have a relevant distinct between content-related neural systems here. Then the further question is whether the content has to "go somewhere" (e.g. to Lis's base system) to make it into consciousness. If that's the case, then content representation in the base system will be relevant after all. If that's not the case, then (as Simon points out) it's hard to see just why some contents make it into consciousness and not others.

NICK: Nick says that a potential NCC N may not be sufficient on its own for consciousness, since one needs the right kind of activity in N. I think that's right, and strictly speaking an NCC should be characterized also in terms of the sort of activity. But the sort of general point I was making will still hold -- one can imagine that exactly that sort of activity could be happening inside N in a petri dish, and one presumably wouldn't get consciousness. So even this activity in N isn't sufficient for consciousness, except against the background of conditions C. The relations to other brain areas that Nick talks about might in effect be part of conditions C (normal functioning brain).

JURAJ: Juraj makes the excellent point that the sort of questions I raise (re lesions etc.) about NCCs also come up for neural correlates of other sorts of mental states and conditions, such as prosopagnosia.
(and presumably learning, memory, language, etc, etc, etc). In fact they arguably come up throughout biology, engineering, etc, when we are concerned with finding the "area for X", the "mechanism of X", and so on. I don't know if there is much literature on the general problem, but there ought to be. And maybe some conditions, such as prosopagnosia, will raise special problems (for the reasons Juraj suggests), so one will only be able to identify correlates in a coarse-grained way. Maybe the thing to say would be that in these cases, there is just no fact of the matter about what the "real correlate" is -- there's just a complex causal chain.

LOGAN: Logan raises the interesting possibility that early visual areas may produce "low-level" qualia while later areas produce "high-level qualia". A normal visual experience has elements of each and so has correlates in both places. Cases such as intermediate blindsight may have the info in the later areas but not the early areas, yielding high-level qualia without the low-level qualia, which would be understandably strange!

I guess, if the high-level qualia are "cognitive qualia", we have interpretation (3) (I think) of intermediate blindsight from today, i.e. conscious visual judgment but no sensory phenomenology. On the other hand, if the high-level qualia are more like high-level sensory phenomenology, something like the grouping of the pixels, or the "seeing" of the light patterns as a dalmatian, then we'd have something closer to (i) or (ii). Understandably, this could be very strange.

PETER: Peter asks, how can IT and not V1 be the NCC, but IT gets input from V1? I guess the answer is that the NCC could come at an intermediate stage (because e.g. it takes processing for info to become conscious), in which case, it's only to be expected that it will get input from areas that aren't themselves part of the NCC.

Of course there may well be multiple NCCs, as Peter says. I think this actually answers Peter's other question, of why we only require sufficiency and not necessity of an NCC. If there are multiple NCCs, any one won't be necessary. But sufficiency alone will mean that it's "important" for consciousness in some sense -- activate this system, and we get consciousness! Of course, one still has to understand how and why the NCC correlates with consciousness, but sufficiency might be taken as a sign that we're at least looking in the right ballpark.

JOEL P.: Joel suggests that split brain studies give reasons to believe in multiple NCCs. These people might be interpreted as having two streams of consciousness, and two NCCs. Normal people like us presumably have both neural systems, so why don't we have two consciousnesses two? I guess one could get the beginnings of an answer by saying that the difference in normal functioning between ourselves and split brain cases is such that there's no reason to believe that the NCC for one will also be the NCC for the other -- it's just the sort of case where we don't want to draw conclusions about our own NCC from lesion studies!

Personally I'm not at all sure that split brain cases involve two streams of consciousness. But let's say they do, and that they have two corresponding NCC's. My own guess would be that nevertheless, we don't have two corresponding NCCs, but rather one corresponding NCC that goes across both hemispheres. Most of the time, the info in the two hemispheres is in synch, so we get a coherent consciousness; if the info were to come radically apart, we might have a weird consciousness, but still within a single consciousness. Basically,
the reason would be that streams of consciousness might go with something like loci of integration and integrability. In the split brain cases, the info in the two NCCs is not integrable with each other, so we get two streams. In our case, info is integrable (e.g. across the corpus callosum), so we get one stream.

SIMON: Simon makes interesting points both re what Lis says about content (as above) and about lesions. The weaker interpretation of lesion studies will basically be that if lesioning area N affects visual consciousness, then area N will be involved in the causal chain underlying visual consciousness. That seems like a reasonable conclusion. Though of course for all we've said it could be a fairly distant and indirect part of the causal chain, in the way that the heart is!

SARAH: Sarah worries about how downstream lesions could change the location of the NCC. I admit my remarks here were a bit brief and cryptic. But here's one way things might work. Let's say that the NCC will be the locus of direct availability for global control, as I suggest, or the mechanism of the global workspace, as Baars suggests. Then it may be that if one lesions downstream from the NCC, this system will no longer be the locus of direct availability for global control (it won't play the control role any more), and it won't be the global workspace (as it won't transmit the info any more). Maybe other areas will take over and fill the void instead, they'll send forward the info that controls behavior, etc. If so, the original system will no longer be the NCC, and other systems will become the NCC.

Something like this will happen if we think that what makes the NCC an NCC is in part its functional role, or at least its downstream functional role (whatever that role is). Downstream lesions may kill off that role, and so may kill off the fact that the system is an NCC. Of course, if one doesn't think that downstream functional role is relevant to making the NCC an NCC, this won't follow.

ALLEN: Allen suggests, as does Logan, that maybe weak (less than 100%) correlation might be enough to qualify a system as an NCC. My main worry here is that this way, too many brain systems might qualify as NCCs. E.g., the retina state, V1 state, etc, might all fairly reliably correlate with consciousness, and come apart only in special circumstances (e.g. binocular rivalry). It seems that in such cases we want to say there's something special NCC-wise about the system that still correlates as opposed to dissociating. So I think maybe there's a case for requiring full correlation. If a system sometimes dissociates from consciousness, then we should be looking either elsewhere or to a broader system for an NCC.

Allen also raises the very interesting point that artificial brain stimulation might make another system M take on the functional role definitive of the NCC, where system N had played it before. In this case, we'll dissociate N from consciousness, suggesting that N isn't really the NCC; but maybe we want to say is that in this case we've actually moved the NCC from N to M, because of the stimulation. Maybe this is another reason for being suspicious of artificial brain stimulation as a criterion, just as we are suspicious of lesions. At least, for being suspicious of too much stimulation. If it's just a little stimulation, making M active in a normal way when it hadn't been a moment ago, it's hard to see how this could make M play a functional role that it couldn't normally play. What would be required for Allen's scenario is stimulation that makes M active in an
abnormal way, thus making it play an abnormal functional role. Maybe we should have some sort of restriction to stimulation of "normal" patterns of activity, if that makes any sense.

Allen also raises the worry that if consciousness lags behind NCC activity, the temporal matching methodology may go wrong. That's a good point, and in synch with what Lis says about the temporal methodology being based on assumptions. One question is whether the assumption could itself be tested, e.g. by finding correlations based wholly on non-temporal aspects, and then seeing how the temporal aspects line up. If they don't, then we'll have to be careful! In advance of doing that, presumably any conclusions based only on temporal matching will have to be fairly tentative.

LONNIE AND JOEL L.: Lonnie suggests that one route to finding the NCC might involve imaging the brain across closely related conditions of conscious and unconscious perception, separated by a JND or some such. Joel points out that around the "threshold" one is really almost arbitrarily guessing that one saw it or not, so it may not correspond to a deep conscious/unconscious distinction.

One potential way to avoid this problem is to give up on the JND idea, and to image relevantly similar episodes of clearly conscious vs. clearly unconscious perception. E.g., that is what Weiskrantz, Zeki, and others have done with blindsight patients such as G.Y. Image him in "blind" seeing, image him in standard seeing, and see what brain areas are different. The result is that a lot of different brain areas show up as different, as Joel predicted. Presumably one reason is that a difference in consciousness will also be associated with a lot of differences "downstream" from consciousness, e.g. in language, planning, thinking, etc, and related areas. Zeki does claim to find some fairly consistent relevance of V5, though.

ADAM: Adam worries that the whole NCC approach is premature, since we need to get a good phenomenological method off the ground first. Not just to gather the first-person data, but also to gather the third-person data from neuroscience, etc. My worry here is that the same presumably goes for third-person data in any science at all, e.g. physics, chemistry, biology. But if Newton had waited for phenomenology to be properly developed, we would have been waiting a long time! My own view is that a developed phenomenology is vital for gathering first-person data, and may end up helping us gather third-person data, but that at least the third-person part of the story ought to be able to get off the ground without it. It's not clear why the NCC search is any worse off here than any other area of neuroscience, or of science in general.

--Dave.
Just one more thing on NCCs...

In "What is the Neural Correlate of Consciousness?" Chalmers discusses what sorts of conscious states would be relevant to determining the neural correlate of consciousness. He explores three classes of states that we should consider: that of being conscious (or unconscious), background states of consciousness (including sleep, hypnosis, dreaming, etc.) and contents of consciousness. It is the latter, contents of consciousness, that Chalmers argues may be the most interesting states of consciousness. It is these that I am concerned with in this post.

It seems to me that, with the right methodology and experimentation, we may come to discover neural correlates of vision, for example. Certainly the work of Logothetis and others points to something positive in that direction. Suppose then, that we were to discover a correlate between particular 'horizontal' neurons and first-person 'horizontal' experience. Though I agree that this would be a significant step in developing a Chalmersian science of consciousness, I would be reluctant to identify such a finding as the 'neural correlate of consciousness.' This is because it is inadequate to the data of our phenomenal experience which rarely, if ever, consists of the single experience of a horizontal line. Our phenomenal experience is rich and diverse and it somehow comes together in our unified subjective experience. It seems to me that a neural correlate of consciousness then, must at least point to what unifies our phenomenal experience. If it does not, then it seems that what we are looking at is merely the 'neural correlate of vision' or the 'neural correlate of audition.'

Note that I am not advocating any sort of a priori claims about a Cartesian theater. It may well be that the unity of consciousness cannot be attributed to any particular set of neurons or brain processes. But it seems that what we should be looking for in our search for the neural correlate of consciousness is something that, though not offering a reductive explanation, can account for, or point to, that thing which correlates with our *unified* phenomenal, conscious experience.

What do others think on this matter?

Best,
Rachael
Block says that a blindsight patient is both phenomenal- and access-unconscious. This runs contrary to what some theorists think. The striking fact about blindsight is supposed to be that it is a case of access without phenomenal experience. The patient makes an inference about x without experiencing x. I wonder if Block isn't setting the bar too high when he characterizes what might pass for blindsight as superblindsight.

Block's distinctions, to review, are among blindsight, superblindsight and super-duperblindsight. The blindsighter has no P-consciousness of x and does not use information about x spontaneously to make inferences, guide action, etc. The superblindsighter has no P-consciousness of x but can be trained/will herself to use information about x spontaneously to make inferences, guide action, etc. The super-duperblindsighter has no P-consciousness of x, but all her relevant cognitive systems function as if she had non-degraded P-consciousness of x.

A lot seems to be riding on Block's invocation of spontaneity. So what if the typical blindsighter does not *spontaneously* form judgments about objects that impinge on her sensory organs, as long as the relevant judgments can be elicited? Block seems to contradict himself when he characterizes the blindsighter as having low-grade access. Does she have access or not? If access comes in degrees (which seems perfectly plausible), it should not matter that the blindsighter's access is of a low-grade. To repair this inconsistency (that the blindsighter has no access and low-grade access), Block really ought to say that the blindsighter doesn't have A-consciousness capable of yielding spontaneous reports.

There is the possibility that non-spontaneous access turns into low-grade access because the forced choice/training focuses the subject's attention on a phenomenal item that is too low-grade to attract attention. To understand such a scenario, we can extrapolate from the vague phenomenal items of our phenomenal periphery (although it is unclear what these peripheries are like for the non-visual dimensions of the phenomenal field) that barely attract...
attention to even vaguer items that don't attract attention at all. What are they like when we attend to them?  Hmm, probably a poor example, since attention focusing would tend, under normal conditions, to resolve the vague phenomenal item into a more cleanly bounded one. But what I have in mind is something that resolves into a slightly less vague phenomenal item. Maybe one could think of attending to a visual percept in one's far periphery without turning one's head or moving one's eyes.

None of this solves any problems for Block, of course, since it would still tie P-consciousness to A-consciousness.

Matt Herbert  "Nim eat Nim eat.  
Drink eat me Nim.  
Me gum me gum.  
You me banana me banana you."

--Nim the signing chimp
The functional status of P consciousness by suggesting that P consciousness is fundamentally necessary for access (in terms of consciousness) to the information carried throughout various processes in the brain; hence P consciousness would not be epiphenomenal. I don't think the case of blindsight goes against this notion; evidence from the Riddoch syndrome suggests that the processing that is spared from the effects of lesioning still has a qualitative component, however impoverished and seemingly different in nature from the qualia that arises from V1 activity. Patients with intermediate blindsight claim some kinds of experiences (however strange and distorted) associated with their cognitive/perceptual appraisal of the various visual situations they are presented with experimentally. Thus it may be that this associated qualia is part of the mechanism by which the patients gain conscious access to their remaining cognitive/perceptual representations.

In the case of full blindsight this view runs into a little more difficulty in that the patients report no explicit qualia in conjunction with their guesses as towards the nature of the visual stimuli that they are presented with. However it may be that such qualia are merged into the individual's "background" qualitative state that is present due to the processing occurring in the rest of the the brain. Such a background is presumably awash with all kinds of qualia that may not be explicitly distinguishable from one another. Thus the patient would not be able to explicitly differentiate them from the other qualia present in the background state, and hence would report an absence of any qualia associated with the identification task they are presented with. Therefore even in the case of full blindsight, it is still coherent to say that P consciousness plays a functional role in regards to access.

Such a viewpoint would also have something to say about the search for a NCC in that P consciousness would be present throughout all brain processes, and thus there could not be a NCC in any localized sense. Such a view would also be consistent with panprotopsychism in that qualia could be present in all matter/energy and would play a fundamental role in material/energetic processes (as evidenced by their role in the brain).

Logan T.
I am still quite puzzled about the connection of access consciousness (AC) and phenomenal consciousness (PC). Ok, Block claims that they are fairly tied together, there are hardly any existent cases of AC without PC and there is a slight possibility of PC without AC. Let us take into account Dave's reply where he says that the exchange of the notion "poised" for the notion "available" in the definition of AC, might lead to an even stronger connection between those two. (So AC is going to be defined as "availability for (global) rational control of behavior). So far so good.

But how is the strong relation realized in the case Dave was mentioning at the end of class? I forgot the name of the guy he mentioned, but the case involved two people, one blindsight and one with a very bad vision (let's say strongly shortsighted). Now it might be the case that these two people supposedly have the same access, but they would strongly differ in phenomenality. (I am intentionally not speaking about neither AC nor PC, because supposedly there is not such a thing in blindsight.)

Well, I somehow question this conclusion. First because we are comparing a case of access to a case of AC and then show they have a different phenomenality. Well, surely they have, after all they are two different things! So if this case was supposed to show that there is a real distinction between access and phenomenality, it in fact didn't reveal anything.

Second, my prediction would be that if we would be somehow capable of measuring access (it surely is easier than measuring phenomenality), we would always end up with the same phenomenality (at least as "measured" from the first person perspective). So on one hand Dave might be right about the intrinsic relation between those two, but on the other hand if somebody is not buying the "phenomenal stuff", this strict correlation really boost Dennett in saying the second thing is an absolutely redundant.

I agree with Logan that in the case of partial blindsight we can still find a role for P-consciousness. That is, there is still some phenomenal experience, however degraded and vague, which provides the individual with some information for making a judgement. So, these cases would be compatible with the view that it is through P-consciousness that A-conscious information is instantiated or made available.

I also agree that it is the cases of full blindsight that create a real problem. I think what Logan says here is interesting:

> In the case of full blindsight this view runs into a little more difficulty in that the patients report no explicit qualia in conjunction with their guesses as towards the nature of the visual stimuli that they are presented with. However it may be that such qualia are merged into the individual's "background" qualitative state that is present due to the processing occurring in the rest of the brain. Such a background is presumably awash with all kinds of qualia that may not be explicitly distinguishable from one another. Thus the patient would not be able to explicitly differentiate them from the other qualia present in the background state, and hence would report an absence of any qualia associated with the identification task they are presented with. Therefore even in the case of full blindsight, it is still coherent to say that P consciousness plays a functional role in regards to access.

What I think is interesting here is the notion of qualia as an element of one's background state. These qualia that are merged in the background state could be taken to be like the, for lack of a better phrase, "strange qualia" mentioned in the session last Tuesday. That is, qualia that are so wierd that the brain would not know what to do with them and, hence, not process the info. as anything. (This would result in the subject not reporting any experience). I did not buy that suggestion, for various reasons, and I dont think others did either.

So, I think we want to distinguish the background state and associated qualia that Logan talks about from "strange qualia". But, this is where I become confused. How do we distinguish the background state and associated qualia that Logan talks about from Block's examples of P-consciousness w/out A-consciousness (like the refrigerator example)? That is, Logan's description of the background state and the relevant qualia that are merged in it sounds to me like a case where one has P-cons. without A-consciousness.

The goal is to find a role for P-consciousness as the means through which A-consciousness is instantiated (as I understand it this means how the information becomes available for rational control,etc...). So, in the case of full blindsight (since this is a case of A-unconsciousness) we want to say that one is not A-conscious b/c one is not P-cons., something like that. However, we still need to explain how there is low-grade access. Logan explains this by making reference to the "background state". That is, there is still a background state that influences the behavior of the individual and gives her low-grade access.

I guess my worry is that we need to make sure that we are talking about a background state different from P-Conscious "background" states where one is A-unconscious (like my background state, including the buzz of the refrigerator, which I dont notice as I type this posting). This is because, 1), we dont want to separate P-consciousness from A-consciousness too much; and, 2), Block's examples
of P-consciousness w/out A-consciousness are very controversial (its not clear what is going on in those examples).

I don't have anything against Logan's suggestion in principle (I think it sounds interesting). I just think that in trying to keep A-consciousness and P-consciousness tied together we should be careful that we don't actually push them farther apart.

Re A and P consciousness, and blindsight:

It's very important to remember that access consciousness and mere access are not the same thing. There are zillions of different sorts of access. Access consciousness is the very specific sort where information that one has access to is made available for verbal report, rational inference, and spontaneous voluntary control of behavior, and so on. Most instances of access won't be instances of access consciousness.

In particular, the access that a blindsight patient has won't necessarily be access consciousness. The point of talk of "low-grade access" is for just this reason. High-grade access is the specific sort of access above that corresponds to A-consciousness. Low-grade
access is mere access that may have some impact on brain or behavior, but that doesn't play the role specified in the definition of A-consciousness.

Matt suggests that Block's invocation of spontaneity in the definition of A-consciousness leads to inconsistency, since one can have access without spontaneity. I think this would only lead to inconsistency if it were held that all instances of access should be instances of A-consciousness. As it is, Block can define A-consciousness how he likes, so he is welcome to include spontaneity in his definition if he wants.

Juraj asks about Siewert's case discussed in class of (i) Belinda with blindsight on one visual hemifield and (ii) Connie with low-grade phenomenal vision in that hemifield. These two people might have quite similar functional capacities. One difference is that the blindsight patient might not make spontaneous judgments. Siewert in his discussion stipulates that they do make these judgments; the cost is that the case may now be impossible in nature, but he says it is quite conceptually possible. Apart from this, the obvious difference is that Belinda will report conscious vision and Connie won't; Siewert is willing to keep this difference, so this isn't a zombie case.

If we stipulate spontaneous judgments and voluntary control, etc, then it seems that both Belinda and Connie have visual A-consciousness, but only Belinda has visual P-consciousness (this is part of Siewert's point about the irreducibility of P-consciousness). Of course Belinda is somewhat hypothetical, so this may not be a counterexample to the link between A and P in the actual world. If we go with actual counterparts of Connie, we may have to lose spontaneous judgments etc, and thereby lose visual A-consciousness. Either way, measurements of A-con will differ slightly from measurements of P-con here, since Connie will have verbal reports of consciousness and Belinda won't. So we don't evidently end up collapsing the notions into one, even on measurement grounds.

Re a functional role for P-consciousness: I agree with Logan and Joel M. that all the empirical results are compatible with the hypothesis that the role of P-consciousness is to enable A-consciousness. Though I do think there are other problems here, concerning the sufficiency of neural mechanisms and the apparent redundancy of P-consciousness in this role.

I like Joel's idea that "strange qualia" that we can't deal with are potentially cases of P-con without A-con. No rational control etc, just phenomenality. Of course it is not clear that there are really such cases. Neglect is one interesting possibility, though one could argue that there is limited A-con in such a case, and the phenomenal aspect of neglect is never clear. But anyway, it does seem that these strange qualia might have the effect of separating P and A.

So if Logan wants to keep the two associated, it might be better to make the "background state" that he appeals to in blindsight either not a matter of qualia, or a matter of a special sort of qualia that don't play the usual access role. (E.g., maybe nonstrange qualia play the access role, and strange qualia play the enabling role?) I suspect that we don't need to say qualia do everything here -- we know that lots of what happens in the brain (e.g. low-grade access everywhere) is not obviously qualia-associated, so maybe one could leave the role of qualia for the high-grade stuff. Though of course there are still the general epiphenomenalistic problems mentioned above.

All,

At the end of our last session, we only briefly touched on Velmans' (rather bizarre) claim that phenomenal consciousness plays a causal role in the production of behavior on a first person description, but not on a third person description. Even so, we probably gave it as much consideration as it really deserves. The consensus of the class at least seemed to be that "causal relativism" doesn't make sense. I certainly agree, but I think that Velmans' point is a bit more sophisticated than our brief discussion of it let on.

The relevant paragraph reads as follows:

"Of course, the question of whether it is actually a given brain state or a given experience that determines a particular behaviour remains - and, on this point, I suggest, no choice is necessary. These are events viewed from different perspectives. Events viewed from an external observer's perspective (via exteroceptors) appear different from the same events experienced by the subject (via interoceptors) because the methods of observation are different. However, each perspective is legitimate."

The emphasis here seems to be on regarding introspection as a type of perception. If introspection is similar to the other modes of perception, then it seems reasonable to say that we should not give any more or less weight to this particular mode of perception. If the data (about the very same event) collected from different sensory modalities conflicts, we may find ourselves with two very different models of the world based on those different sets of data.

So he seems to be thinking that the difference between first and third person accounts of the causal role of consciousness (or lack thereof) is like a situation in which two of our other senses conflict. For example, consider the case of a person confronted with a cup sitting on a transparent glass tabletop. If the tabletop is invisible to our subject
suppose it's really clean, no light glinting off it, etc.), the cup might look like it is levitating in thin air. However, if the subject is allowed to touch the tabletop, he will believe that the cup is resting on it.

Now, if there were no way to cross-check the data gathered by these two different senses, we might be forced to accept both descriptions as equally valid, even though they were inconsistent. However, it generally seems to be the case that we can cross-check. Our table-observing subject can probably move to a different observational angle, shine a bright light on the table, or whatever. Or, if cross-checking is impossible, we can at least explain why one sense modality fails to detect some fact (or appears to detect an inconsistent one.) Even if our tabletop were made out of some sort of exotically invisible material (maybe a Star Trek type force field or something) we ought to be able to use data gathered from our other senses and/or other visual data to explain why our eyes can't detect it.

Velmans seems to think that this will not be possible with consciousness. Both the first and third person perspectives are, he says, incomplete. Neither is adequate to explain the other. Though I disagree with this position, it does not seem entirely unreasonable to me. Since none of our means of perception, including introspection, can, by itself, give us a complete description of the world, we should perhaps not expect the various descriptions they provide to always be consistent. Perhaps first and third person descriptions are accurately describing different aspects of the same thing, but both fail to include the data that would link them.

Even so, I am not about to grant Velmans his conclusion, because he is too quick to dismiss the possibility that an improved first or third person account will be able to account for the alternate set of perceptions. Even if there is good evidence that the two accounts are incompatible (and this does not seem clear either) I think most of us would be extremely reluctant to give up on the attempt at a unified explanation. Our third person description of the brain and its functioning is obviously incomplete, and as many of the issues we have been discussing lately show, introspection may not provide as detailed a description as we might have thought. (For example, if a blindsight patient cannot tell whether his own behavior was accompanied by no qualia, very faint qualia, "weird" qualia, or neglected qualia, I for one start to wonder how complete our introspective accounts of our mental lives really are.) Surely Velmans is premature in his declaration that no future improvement of one of these descriptions could ever explain the seemingly inconsistent perceptions of the other.

I think Joel is right to suggest that Velman's proposal concerning the complementarity of first and third-person perspectives regarding their causal status deserves a second-glance. I gave it a second-glance after reading Joel's post, and am now prepared to defend it completely! In fact, Velman's view speaks directly to the issue we've discussed off-and-on regarding the possible causal role of P-consciousness (perhaps as a "gateway" to access--Lis mentions this idea again in her post, and Block seemed to be attracted to it).

The big problem with the idea that P-consciousness serves as the means of an event or state's becoming A-conscious is that the metaphysics is difficult to make sense of. My zombie twin has all the same A-conscious states but no P-conscious states. This suggests that P-consciousness isn't doing any real causal work. Another way to the same point is simply to note that the availability of a state for global control (etc.) could be understood entirely from the third-person point of view even if the observer did not know which states were P-conscious or not. Even if P-conscious states are identical to neural states, if those states are what "give rise" to A-consciousness it is not in virtue of their being P-conscious.

The above point is entirely compatible with what Velman's suggestion. The third-person point of view leaves out phenomenal consciousness, and doesn't need to posit P-consciousness as a variable which plays a role in human information processing. But consciousness certainly *seems* to play a causal role in our behavior. Velman saves us from epiphenomenalism by arguing that the two perspectives are compatible. I would read his view (at least in the passages Joel cites) as a type of identity theorist, where perhaps we are directly acquainted with the intrinsic nature of neural states from the first-person perspective. But Dave suggested in class that Velman's was some type of idealist, so perhaps Velman's has developed these views in a different direction.

----------------------
Brad J Thompson
bradt@U.Arizona.EDU
I would just like to make a few points in response to Joel and Brad. As
Joel pointed out, we seemed to have decided in class that Velmans was
committed to some sort of causal relativism, and hence we pretty much
ignored what he had to say. Both Joel and Brad, however, seem to contend
that Velmans has something worthwhile to say. As Brad says:

> human information processing. But consciousness certainly *seems* to
> play a causal role in our behavior. Velman saves us from epiphenomenalism
> by arguing that the two perspectives are compatible. I would read his
> view (at least in the passages Joel cites) as a type of identity theorist,
> where perhaps we are directly acquainted with the intrinsic nature of
> neural states from the first-person perspective. But Dave suggested in

Whilst I agree that this particular passage may be read as suggesting that
Velmans is some sort of identity theorist, this is incompatible with what
he says elsewhere. In 9.2 he says:

"It should be apparent that the dissociation of awareness from cerebral
functioning poses problems for reductionist theories of consciousness. It
is inconsistent with the functionalist view that consciousness simply is
(ontologically identical to) a mode of functioning of the brain. Nor is it
consistent with physicalism ... The exclusion of consciousness from
cerebral functioning is equally inconsistent with emergent interactionism
... and with the interactionist forms of dualism"

It is difficult to say exactly what sort of theory he advocates, but it
does not seem to be an identity theory. Velmans goes on to say that the
psychological evidence seems "to support epiphenomenalism", but that "from
a first person perspective ... epiphenomenalism appears false". From this
he concludes that these two perspectives are "complementary, [but]
mutually irreducible". Needless to say, this conclusion is inadequate. It
seems to me that the reasonable conclusion to draw from the evidence is
not that epiphenomenalism is both true and false, depending on the
viewpoint adopted, but that one of these viewpoints must be mistaken.
Velmans does seem to be arguing for some sort of relativism, and this view
cannot be sustained by the evidence that he puts forward. We should either
be arguing that the information processing models that he adopts are
incomplete, in so far as they do not account for our first person accounts
of the causal efficacy of consciousness, or we should argue that our
first person accounts are mistaken.
Thus I think that the conclusions that Velmans draws are disputable at best, and just plain wrong at worst. We should not accept that epiphenomenalism is both true and false, depending on your point of view, unless there is absolutely no other conclusion that we can draw. In the case above, I think that there are many other more plausible conclusions that can be drawn, and hence we should reject Velmans' conclusions.

Simon.

On the issue of fleeting awareness in unconscious perception: If you are exposed to something briefly, or while in a "less-conscious" state such as sleep or under anesthesia, what does this say about the experience? For example, healthy normal sleepers have, on average, 4-5 dreams per night. Many people do not recall this many, as you need to have a brief awakening at the end of the REM sequence in order to have any free recall of the dream. So, if you have a dream, but don't remember it, did you have a phenomenal experience? I would say yes, although it is not remembered. If an experience is not remembered, or falls away immediately (from memory), the experience could still be access-consciousness (such as in priming). Just because you don't remember a particular dream during the night does not mean that this experience will not have an affect on you the following day (through some kind of priming or perhaps a deja vu experience). This seems to relate to the experiments where the 3 x 3 grid of letters are flashed, and the subject can report on any of the lines, but not all of them. This suggests that the person is phenomenally aware of all of the stimuli (for some time afterward), but only access conscious of one line.
Re the limitations of the unconscious: As Dave pointed out, there seems to be a tension between Greenwald's claims that "attentionless unconscious cognition is generally quite limited in the sophistication of analyses it can perform," and Velmans' claims to the effect that much complex cognition can occur outside of consciousness.

As I said in class, I don't think that the two claims made here are incompatible. Greenwald and Velmans are both concerned with how information comes to play a function in complex cognition and under what conditions this is possible. Both argue that attention is key to these functions, and that manipulations that disrupt attention leave behind only very low level influences of the presented information on subsequent processing. The critical issue concerns whether such information can become access-conscious, to use Block's term (either in the sense of poised for direct, voluntary control of action, etc., or in the sense of cerebral celebrity, which I take to mean currently being in such control). From Greenwald's review, it seems that information must be P-conscious in order to be available for complex cognition. Velmans argues that it is focal attention rather than P-consciousness that enables access.

The various manipulations in unconscious perception studies degrade P-consciousness sufficiently to limit the access of the information to global processing. In the absence of high-grade P-consciousness, the information that gets into the system can only play a passive role, via processes like the spreading of activation in semantic networks or the priming of motor, affective or other responses. The passivity of these processes lies in their purely data-driven nature; spreading of activation
or priming cannot lead to interpretation or evaluation of the information at the conscious level nor, perhaps, does it allow its active integration as premises in 'unconscious reasoning', i.e., unconscious processes like addition that are set in motion by conscious presentation of inputs. However, if a context for interpretation or response is provided (say one is looking for an answer to a difficult problem or one is required to give a word stem completion in an experimental task) then the information can have effects on these outputs. These effects appear in multiple ways - as sudden insights or intuitions, as response biases or shortened response latencies, without the subject having explicit awareness of how these effects came about. The processing of information that is presented under conditions where subjects cannot report consciousness of the information has this kind of passive characteristic.

The passive, data-driven processing set in motion by unconsciously perceived information stands in contrast to the active, theory-driven processing of information that is consciously perceived. For example, what we consciously perceive sets up expectations for what we might see next; it enables us to organize complex behaviors in response to the information. That many aspects of these subsequent cognitive functions will proceed unconsciously seems to be Velmans' main point in the first half of his article. This sophistication of the unconscious under normal stimulus conditions is widely accepted, though Velmans wants to make the further point that it is not due to P-consciousness that this kind of information processing takes place, rather that focal attention (A-consciousness) is all that is required. I don't think Greenwald would challenge Velmans' claims about the sophistication of the unconscious under normal conditions. He might, however, take issue with the claim that focal attention alone has the function of making information widely available. Focal attention is present in unconscious perception experiments, it simply doesn't have the right kinds of inputs to operate on. Greenwald wants to emphasize is that high-level unconscious information processing doesn't get going all on its own, even if focal attention is engaged. Sophisticated unconscious processing requires that information be the object of attention, and that it be so long enough to set up an enduring conscious representation of that information.

One of the implications of the unconscious perception experiments is that we are not vulnerable to unlimited, complex, subliminal manipulations that bias our behavior. In order for information to actively play a role in ongoing behavior and cognition, it needs to be P-conscious first, much along the lines of Block's current claim that P-consciousness is the means by which information becomes A-conscious. The effects of "unconsciously perceived" stimuli discovered so far do not meet the criteria for A-consciousness, which seems to line up well with this analysis.

Now, given Block's reasonable suggestion on Friday that there is fleeting P-consciousness in the unconscious perception cases (without A- or R-consciousness), we would want to say that while P-consciousness might be necessary for A-consciousness, it is not sufficient for A-consciousness. Other conditions are required, involving contextual and temporal factors that may vary from situation to situation to set up the kind of representational stability suggested above. It would seem that our notion of P-consciousness will require some revision.

Our discourse of last week and of this has as one of its foci the distinction between conscious and unconscious perception. Conscious perception has its distinguishing characteristics 1)a phenomenology that extends through time--it's not instantaneous--2)accessibility, in terms of availability for verbal report, and instantiation in memory. Unconscious perception is a trickier thing. It appears from the Mack and Rock experiments that visual percepts, at least those relatively near to point of visual attention, are encoded in some detail, although they are never made available for verbal report and never make it into memory. In fact, between the two, availability for verbal report and memory, memory is clearly the more fundamental. I don't think it makes much sense to talk about instantaneous conscious perception and I think it is memory that allows perceptions that might have been collected at discrete moments to extend through time. But I'm not sure that I could go as far as saying conscious perception is only unconscious perception plus memory of the percepts; actually, I'm sure I can't: necessary is some sort of organization and ordering of the memories.

One way to think about unconscious perception might be to call it a variety of priming. When we are asked a question or by some other means instigate a search for something in our perceptual field, items that are already unconsciously encoded pop out or grab our attention. In a way it seems the brain is continually overprocessing, preparing information that mostly gets dumped, never makes it into consciousness, the stream of occurrent thought, or into memory. Encoded information about the visual field might be readied in case it needs being attended to, but since the higher-level powers that deem the information of lower priority or irrelevant to the tasks at hand, never call the info over the threshold into consciousness.
So what decides which primed pathways will be trodden by victorious electrical impulses into the Cartesian circus? Well, the individual has some explicit control over what searches it establishes, and once the search is on, an answer receptacle is prepared in memory. There might also be other searches that are continually and quietly going on. Searches for particular learned or instinctual icons might be such latent and implicit procedures that run constantly. Or if these searches don't run constantly, they run especially smoothly, for how else is a complex icon like one's own name recognized with rapidity far exceeding that for other percepts?

nick
In seminar yesterday we discussed three different views of the nature of consciousness and attention and considered them as possible interpretations of the change blindness studies. As these views are relevant to my comment, I will go over them here briefly:

1) The 'grand illusion' view: Our visual consciousness is course-grained with limited internal representation. On this view, there is no consciousness outside attention. This is the view that we identified with Dennett and Mack and Rock.

2) The reconstructionist theory of vision: There is no grand illusion. In fact, we have fine grained visual consciousness that gives rise to detailed internal representation. We do have consciousness without attention. To account for the change blindness studies, some explanation may be offered. For example, perhaps we do not have memory without attention. This view is associated with Wolfe and Hardcastle.

3) The enactive approach: On this view, we do have fine grained visual consciousness though we only have a limited internal representation. There is consciousness outside of attention. But we must be clear, the fine-grained detail of our visual consciousness is a result of external availability and is not a matter of internal representation. Thus, the contents of consciousness need only be *available* in the world. this externalist view is the one espoused by Noe, Pessoa, and Thompson.

I would like to suggest a fourth option. On this view, there is consciousness outside of attention, but that visual consciousness is course-grained, while the consciousness within attention is fine-grained. Thus, we have detailed internal representation of what we are paying attention to and limited internal representation of what we are not. Let me illustrate. We have all had the experience of driving without paying attention or of staring off into space. If attention where required for consciousness, it seems that we would not be phenomenally aware *in any sense* of the outside world. But this does not seem to me to be the case when I reflect on my own experience. In these cases, I would want to say...
that I was limitedly visually conscious (of course I could not describe the detail of my visual environment) even though my attention is directed elsewhere. If for example, the whole world were to disappear in one of these 'reflective' moments I would be more inclined to say that I was conscious of the world around me and the change directed my attention to it then that I was not conscious of the world until it's 'disappearance'.

I think this view make sense of the cocktail party phenomenon and others like it as it seems that some conscious processing must be going on for your name to jump out at you. We are limitedly phenomenally conscious of what is going on around us at the cocktail party, though we are not paying attention. Hearing our name spoken is something we are already conscious of but now pay attention to.

This view may sound a lot like the third view proposed by Noe, Pessoa, and Thompson. But this view is not meant to be an externalist view. It does not merely require that the contents of consciousness be available in the outside world (a very tricky notion as Dave pointed out in class.) The contents of consciousness are those that we have internal representations of; those that we are paying more attention to will be more detailed, those that we are not paying attention to will be significantly less detailed. Maybe we will only be vaguely aware of color, shape, size outside of our attention. Minimally, we will be aware of the existence of this course grained visual experience. This is compatible with the change blindness studies because I am not suggesting that we will be aware of particular changes in our unattended environment. Only that we are aware, in a general and vague sense, of our unattended environment. Perhaps it is this awareness that gives rise to the illusion of a complete detailed visual consciousness.

Sorry for the length of my post. Any thoughts on this view?

Best,
-Rachael
results from Robert Kentridge, presented at Tucson III, showing that blindsight subject's performance is improved when they attend to the relevant areas of the visual field. So we have a sort of attention to the object without phenomenal consciousness of the object? Or perhaps, it's safer to say that it's just attention to the spatial location where the object is present. That way, the contents of attention and the contents of consciousness will still line up.

(2) Nick suggests that it doesn't make much sense to talk about instantaneous conscious perception, and that memory may be required for consciousness. That's an interesting claim. If one accepted this claim, then one might argue that the change blindness studies show that we aren't conscious of the relevant detail in our visual field; and it might suggest that attention mechanisms operate on largely unconscious (not just unattended) stimuli. But why accept that claim? I'd be interested to see reasons for it.

(3) Rachael suggests a view on which we have fine-grained consciousness within attention, and coarse-grained consciousness outside attention. That seems reasonable and phenomenologically apt to me -- it seems reasonable that the "attentional spotlight" makes things more vivid and detailed. One relevant question, I guess, is just how coarse-grained the consciousness outside attention is. For example, in the change blindness cases, will there be a change (unnoticed, of course) in the coarse-grained consciousness outside attention, or will it stay the same? If the latter, then we are not so far from the Dennett and Mack/Rock views. If the former, we are closer to the Wolfe/Hardcastle view, with the qualification that consciousness outside attention is not as fine-grained as we might think.

(4) If anyone is interested to check out the web demos from Wednesday, they are online (along with a few articles) at:

http://nivea.psycho.univ-paris5.fr/

For something different but very interesting in the ballpark of "experimental phenomenology", check out:

> consciousness. That's an interesting claim. If one accepted this
> claim, then one might argue that the change blindness studies show
> that we aren't conscious of the relevant detail in our visual field;
> and it might suggest that attention mechanisms operate on largely
> unconscious (not just unattended) stimuli. But why accept that claim?
> I'd be interested to see reasons for it.

The closest thing that I can think of to a reason for this (though I was
not the person who proposed it) is in line with the Physicist Fred Allan
Wolf's assertion that we are never conscious of anything as it occurs,
there is at least, the time taken for the light to reach the eye, the
neural signals to become processed, etc. On that view, we are always time
behind the world. But this does not speak to whether or not memory is
necessary for consciousness since we would not have to have memory of what
the world experienced as we would be a constant (t) behind actual
occurrence and would not need to access our memory (that was never formed)
from that time frame.

However, for the change blindness business, memory may be the
determining factor of whether or not change is noticed, unless you are
looking at the thing that is changing when it changes, since then you have
to compare your memory to the current picture in order to detect a change.

> (3) Rachael suggests a view on which we have fine-grained

This view makes more sense to me than any of the others presented so
far. As far as the degree of coarse grainedness of the consciousness
outside of attentional focus, I would bring up two variables that could be
looked to as possible answer providing lines of thought (or research).
The first would be the individual person's "attentional sharpness" that i,
the degree of detail that they are capable of percieving visually.
Someone with horrid eyesight is going to be likely to have less attention
invested in that mode to begin with, and when they do, they will probab lly
be using a pen light as opposed to a mag-lite so to speak.
Another variable that I would look to is the degree of patterning present
in the stimuli outside the focus of attention. Since the findings
regarding the relevance of a stimulus indicate that pattern detection exists outside of attention, one could say that this coarse grained consciousness is constantly undergoing change of content. Unless Dave is referring to something else by "change in consciousness."

Just thoughts.

Last class had made me a little puzzled. Prior to it I have always had a strong feeling about the correlation between consciousness and attention. Because so little is known about P-consciousness, I guess I will be more or less talking about AC now.

First of all, the clear difference between attention and AC seems to be that one is actual and the other dispositional. Well, exactly this difference is a little mystery to me. What does it mean to talk about being dispositional here? I guess I am only conscious of the events which do actually make it to my attention. There is no awareness whatsoever about any disposition. Consciousness seems to possess no dispositional qualities. It is just what is being realized.

One might object that certain inconclusive reports made by conscious
subjets imply dispositional character of AC. Statements such as "I have seen something on the screen..." in my understanding show no such a character. They simply refer to what was actually realized, to what the attention was paid. That the attention wasn't sufficient for a detailed account of an event implies very little about the event "being potentially accessible".

I apologize for being probably too messy here. If I have to put it in a different wording, it would be something like this - my first person experience (not restected to phenomenality) seems to recognize no dispositional account of consciousness, but supposedly vast majority of my AC events is just that - dispositional mental events.

I wonder about this, because the third person description of attention seems to perfectly fit the first person perspective - I perceive something as being attended anytime any third person observer perceives me attending to something. There is no talk about disposition/realization. But it seems like this in the case of AC does not really work

Hello all:

In a recent posting Rachel proposed a fourth alternative to the three viewpoints discussed in last Tuesday's class concerning the relationship between consciousness and attention. Here is a quote from her posting:

> I would like to suggest a fourth option. On this view, there is
> consciousness outside of attention, but that visual consciousness is
> course-grained, while the consciousness within attention is fine-grained.
> Thus, we have detailed internal representation of what we are paying
> attention to and limited internal representation of what we are not. Let
> me illustrate. We have all had the experience of driving without paying
> attention or of staring off into space. If attention where required for
> consciousness, it seems that we would not be phenomenally aware *in any*
> sense* of the outside world. But this does not seem to me to be the case
> when I reflect on my own experience. In these cases, I would want to say
> that I was limitedly visually conscious (of course I could not describe
> the detail of my visual environment) even though my attention is directed
> elsewhere. If for example, the whole world were to disappear in one of
> these 'reflective' moments I would be more inclined to say that I was
> conscious of the world around me and the change directed my attention to it
> then that I was not conscious of the world until it's 'disappearance'.

I like this proposal for two reasons. First, it allows attention and
consciousness to be disassociated from one another. Up until our last
class meeting, I never thought about the possibility that these two
aspects could be decoupled. However in light of the class discussion I now
find this notion to be very intriguing. It brings up the possibility that
consciousness may be divided into two categories: attentionally focused and
non-attentionally focused. Attentionally focused consciousness would be the
consciousness of contents that are within the attentional spotlight of one's
visual field. It is within this spotlight that detailed visual
information would be perceived and made globally accessible to the rest of the
processing in the brain. Non-attentionally focused consciousness would be the
consciousness of contents outside the attentional spotlight. Here there
would be a considerable lack of detailed visual information, yet the
information would still be globally available. Such a distinction may
also tie in to discussion of conscious vs. unconscious processing in that
it may be that certain processes that are usually considered unconscious
may in fact be conscious but do not occur within the spotlight of attentional
focus.

The second reason why I like Rachel's proposal is that it still
allows that internal representations of visual stimuli are being produced by the
visual system. The central idea of the enactive view - that no internal
representations are necessary for consciousness- I find difficult to
swallow. If a percept is conscious in virtue of the fact that it is
externally available, how does this account for imagination and internal
visual imagery? One could close their eyes and recreate in the mind's eye
the experience of a perceptual stimulus. Such a percept would no longer be
externally available, yet still will be robustly conscious.
The fact that such contentful imagery is conscious seems to be a
counterargument to the idea that no internal representation is necessary for
conscious contents. If in the case of imagination the brain is not creating an
internal representation, then just what is going on? I suppose that one
could argue that the case in which one views a stimulus with eyes open is
different from the case in which one imagines the stimulus; perhaps the
various correlations in brain activity that accompany visual perception are
just registrations or acknowledgements of the presence and nature of visual
stimuli and not representations per se. However there is much empirical
evidence that seems to indicate that the same systems that are
involved in visual perception are also involved in visual imagery. To
suggest that these systems are representing in one case and not
representing in the other flies in the face of providing a parsimonious
explanation. However Rachel's idea is parsimonious in that internal
representation would be occurring in both cases, where the detail of
representation is a function of the attention allocated to the features of
the stimulus.

Logan T.
All,

I had some residual questions/worries from the discussion of attention and consciousness last week, so here goes.

Hardcastle evades the problem of change blindness across saccades by suggesting that incoming visual data displaces the old data from iconic memory so quickly that the subject simply cannot remember them to report them. What looked like a gap in consciousness turns out to be a failure of memory. I'm wondering what this view, if correct, entails for the phenomenal present. If sensory experiences are so fleeting as to be pushed out of iconic memory in as little as 250msec, it would seem that all our so-called perceptual reports are actually mnemonic reports. (A question for those in the know: Is iconic memory the same mechanism as the "buffer" for a given modality? It appears by all descriptions that it is, but I cannot track down a definitive answer.) Implications for a theory of consciousness are potentially significant. If our visual experience is so transient, and it is always the fate of our visual data to be stored in iconic memory, perhaps consciousness will be nothing more than the ephemeral contents of iconic memory. This doesn't sound very likely to me, but it is a possible result of Hardcastle's line of thought.

Hardcastle's alternative explanation of Right Parietal Extinction and Balint's syndrome patients' symptoms suggest that she herself would not favor a conception of consciousness on which its contents are so highly processed as to make it into iconic memory. The consensus explanation of the Extinction patients' symptoms is that the apparent visual defect is due to attentional deficits. Hardcastle suggests, however, that even the apparent attentional deficits are not enough to show that there are no objects of perceptual experience. There might be something being experienced that is not sufficiently processed (integrated, conceptualized) to be reported. I don't have Hardcastle's text available at the moment, but I believe she suggests that bare consciousness provides the inchoate elements of experienced objects (unintegrated features), but attentional processes provide the objects themselves. I'm not sure this is a plausible defense. If there is a proto-experience that underlies full-blown
experience, it seems to be not quite what is meant by "the contents of consciousness." To speak only of my own phenomenology, I do not experience unintegrated features, but integrated objects. I believe as firmly as Hardcastle that there are data present in my phenomenal field that are, in a sense, prior to the neatly-bounded objects of my experience, but I *infer* their presence; I do not experience it. In short, I think it's fair to say that something like James' blooming buzzing confusion underlies one's phenomenal experience, but such proto-experience is *less* properly called experience than its more processed relatives.

Matt asked:
Is iconic memory the same mechanism as the "buffer" for a given modality? It appears by all descriptions that it is, but I cannot track down a definitive answer.

Iconic memory is the memory of the stimulus that persists in the sensory system for a very brief time after stimulus presentation. Visual afterimages are an example of iconic memory. In the auditory modality, one speaks of echoic memory. These 'memories' require no rehearsal in order to hang around. On the other hand, buffer storage refers to information in working memory that is rehearsed and available for ongoing processing. The phonological loop (in which you repeat the phone number you want to remember) or the visuo-spatial scratch pad (in which you store the memory of some visual image in order to access it again) are examples of types of buffers related to different modalities in Baddeley's working memory system. I don't have the Hardcastle paper with me to see if she uses the term buffer to refer to iconic memory, but the distinctions above are those that I am familiar with from Cognitive Psychology.

Quick notes about attention and consciousness:

(1) Logan suggests that phenomena of imagination and imagery provide evidence against the "enactive" claim that internal representation is not required for consciousness. In reply, an enactivist could say: internal representation is *compatible* with consciousness, and may even be required for some *kinds* of consciousness (perhaps for imagery, imagination, attention, etc). The claim is just that it isn't necessary -- so there are some conscious states that can be present without internal representation. When the claim is viewed this way, these phenomena may no longer be evidence against it.

(2) Juraj asks about the difference between A-consciousness and attention. He notes that A-consciousness is dispositional but consciousness doesn't seem dispositional. One response is to say that P-consciousness certainly isn't dispositional, and maybe Juraj is just importing intuitions about P-consciousness here. A second would be to say that A-consciousness is *defined* in terms of accessibility, so it is dispositional by definition. A third response would be to say maybe Juraj is implicitly understanding A-consciousness to be defined
differently, so that access rather than just accessibility is required. That would be OK, but it would be a terminological point; A-consciousness is itself a term of art and we can define it how we like. I like to stress the definition in terms of accessibility, since this correlates best with P-consciousness. But if one is less concerned with this correlation, there is certainly some valid notion of consciousness -- call it A'-consciousness -- that requires not just accessibility but access. And it may well be that A'-consciousness is strongly connected to attention.

(3) Matt draws some interesting consequences from Hardcastle's point that phenomenal iconic memory is really short and that this can distort the accuracy of phenomenal reports. He says this might suggest that phenomenal perceptual reports are really mnemonic reports; he also suggests that maybe then consciousness is no more than iconic memory. These are interesting claims but I'm not quite sure why they follow.

Re the first claim, presumably there roughly two sorts of reports (of visual experiences, say): those made while the experience is still present and those made after the experience is absent. Presumably we'd say the latter are in some sense mnemonic and the former are in some sense perceptual. It's not clear to me how the shortness of memory will itself make reports in the first class mnemonic; on the face of it, this point would have more impact on those in the second class (those we already take to be mnemonic). If the experience is still present, the shortness of memory will presumably be fairly irrelevant, and the reports of the experience will be broadly perceptual. Of course there is processing time involved, which one might argue will introduce a mnemonic element, but it's not clear how the shortness of memory will make a difference to this point.

Re the second claim, maybe one could argue that our reports of consciousness are really reflecting our iconic memory (somewhat as in the last point above). But presumably Hardcastle would use this to suggest that the reports don't fully reflect consciousness itself, as there is a difference between consciousness and memories thereof. It's not clear to me how one gets from this observation to the claim that all there is to consciousness is iconic memory. But maybe Matt can elaborate on the reasoning here.

Re Matt's point about pre-integrated experience: it's true that in familiar cases, where there is integration of experience, we count the integrated objects as part of experience, not the pre-integrated stuff. But that's compatible with saying that in fringe or fleeting cases where the experience never gets integrated at all, the pre-integrated stuff is still part of experience. It's as if experience can be processed and developed to various levels. The sort that we are most familiar with (from attention etc) is the integrated sort, but the other sort might also exist, even if for obvious reasons it is natural that it is not so familiar.

--Dave.
I think Rachael's suggestion sounds interesting. Ultimately, though, I think to defend this view one would have to answer some version of Dave's question. (Namely, how coarse-grained is consciousness outside attention?) This is because this view walks a fine line between the Dennett/Mack-Rock view and the Wolf/Hardcastle views.

A comment Logan made drew attention to an aspect of Rachael's suggestion that I think is interesting and potentially problematic. Logan has a favorable attitude towards this view b/c it separates consciousness and attention. So, non-attentionally focused consciousness would be very coarse grained but still globally available, in some sense. But, I think its worth asking in what sense non-attentionally focused consciousness is available. The change blindness studies seem to show that the information is not available. Subjects cannot use it to help guide action, they do not have any memory of something passing in front of their visual field, etc... So, in what sense is the information available? If we are going to call the non-attentionally focused consciousness conscious should'nt we be able to say something here?

I think this is just a version of Dave's question. (To what extent do we notice changes in the periphery of our visual field?) B/c I am really just trying to put some pressure on the idea that we can be conscious of what we are not attending to.

As Rachael points out, the cocktail party phenomena is relevant here. She comments that conscious processes must be going on if one is going to notice, through all the background noise, someone mention her name. This, along with Lonnie's idea of "attentional sharpness" (where she briefly mentions how one mode, say vision, may not be so "sharp" in some individuals), started me thinking about the relevance of other modes of perception here. We have different senses at work constantly. It seems likely to me that they influence one another (e.g. hearing affects vision, in some way), and each acts in its own way to help produce a full conscious experience. While this does not help with the question of how coarse-grained the periphery of our visual field is, it may help to explain how our experience can seem unified. That is, there is a lot more than visual input that is relevant when discussing the "smooth-ness" and completeness of conscious experience. I guess what I am wondering is whether information received through modes other than our visual mode of perception is relevant in considering the "smooth-ness" of *visual consciousness*. I am not quite sure how this might work yet. Just a thought. (This is a bit off topic, but I hope its not too unrelated.)

This question echoes Dave's concern when he asks just how coarse-grained
the consciousness outside attention is. I think my view is closer to that
of Wolfe and Hardcastle than to Dennett/Mack-Rock. On the 'grand
illusion' view there is no consciousness outside attention. I would
disagree with this. Dennett/Mack and Rock have a claim about internal representation that is similar to mine, that is, that it is limited in some way. But the difference is this: For them, internal representation is limited to what we are attending to. On my view, there is internal representation, albeit course grained (and therefore 'limited') outside of attention. So we are pointing to different things when we suggest that our internal representation is limited. This view differs from the Wolfe/Hardcastle view only in that it recognizes that consciousness outside of attention is 'fuzzy' and does not have the detail that consciousness within attention does.

Joel goes on to point out:

> A comment Logan made drew attention to an aspect of Rachael's suggestion that I think is interesting and potentially problematic. Logan has a favorable attitude towards this view b/c it separates consciousness and attention. So, non-attentionally focused consciousness would be very coarse grained but still globally available, in some sense. But, I think its worth asking in what sense non-attentionally focused consciousness is available. The change blindness studies seem to show that the information is not available. Subjects cannot use it to help guide action, they do not have any memory of something passing in front of thier visual field, etc... So, in what sense is the information available? If we are going to call the non-attentionally focused consciousness conscious should'nt we be able to say something here? I think this is just a version of Dave's question. (To what extent do we notice changes in the periphery of our visual field?) B/c I am really just trying to put some pressure on the idea that we can be conscious of what we are not attending to.

I guess I think that my view can accommodate the change blindness studies because those things that are being changed are pretty fine grained (take the lines in the road or the engine on the plane, for example). I do not think that we are aware of the engine or the lines in the road when we are not attending to them. Thus, the awareness that there is an engine is most likely not globally available. Consciousness outside attention is much more course grained than this.

Recall that in my original e-mail I suggested that consciousness outside of attention may be so course grained that the most that we can say of it is that we recognize it (our fuzzy phenomenal experience) only when it is missing. Of course, it would be nice to discover that consciousness outside attention is not quite so course grained as that; perhaps we are aware of color, shape, or particularly large or 'intrusive' aspects of our inattentional conscious field. ('intrusive' like our names at a cocktail party.)

It would be interesting to develop further change blindness studies to see if we are aware of particular course grained features of our unattended consciousness. Of course, I find the arguments that there may be limited or no memory outside of attention persuasive. Even if we were to find that there are no course grained features of consciousness that subjects recognize in change blindness studies, we would have to rule out the possibility that the subjects were conscious of but could not remember those course grained features.

I hope these points help to clarify my view.

-Rachael
A note about the connection between mental processing and brain anatomy:

Baars is quick to point out that his model of the processing involved in consciousness does not necessarily closely correspond to our best present neurological pictures. This is not a requirement for his model since it is meant to capture the level of processing, not of neuroanatomy. So he is allowing, quite judiciously, that the organization of the brain into processing systems need not follow any sort of gross brain grouping. A process can be spread out all over the brain, or isolated into a small area, and this has no effect on the processing model.

This is in sharp contrast with Schacter, who uses current theories of neuroanatomy to motivate the distinction between the CAS and the Executive system. One is in the posterior parietal cortex and the other is in the prefrontal cortex; they can't be the same thing! Of course, making such an argument requires a reason to think that processing follows gross grouping, and we haven't seen a reason to accept that yet.

I have a question and a comment about this issue.

1) Does anyone know exactly how the evidence is developing in other areas besides consciousness? Is there reason to think that simple brain processes are quite diffuse?

Is the focus on finding processes for brain areas driven by a prediction that processes will be so localized, or is it merely an artifact of the limitations of current brain mapping technology?

2) If there is reason to believe that brain processes are diffuse, that seems to be at odds with the methodology and results that we have seen in the search for the NCC, which seemed to focus on finding a particular location, and which differed primarily in the size of the NCC and the location chosen.

The methodology in those experiments focused on causing the mental process
to be tested (e.g. conscious perception), then looking to a particular brain region for any signs of neural activity. In the experiments in which a single cell was monitored, the results from that one cell were taken to indicate the activity of a general area of cells; such a generalization would require a strong thesis that neural grouping follows mental processing.

So perhaps we should look back at the results about the NCC from the beginning of the class to see what has actually been demonstrated if we do not assume that all cells in a brain area are engaged in the same sorts of processing activities.

Any thoughts on this problem?

Sarah

All,

First, a confession. During my formative years as a philosopher, I have been rather heavily exposed to both Dennett and verificationism, and there are soft spots in my heart for both of them. In general, I do not think this has lead to corresponding soft spots in my head, but full disclosure nevertheless seemed appropriate. With that in mind, a few thoughts about Dennett, verificationism, and consciousness.

Even if we agree that verificationism is flawed as a theory of meaning, the related epistemological lessons are worthwhile in themselves. I think Simon was right to point out that the issues Dennett and Kinsbourne raise only really show that certain theories of consciousness are underdetermined by the data. But isn't this a fairly serious problem in its own right? Several of the issues we've been discussing lately seem
to be in this situation. Is the color-phi phenomenon due to an Orwellian revision of memory or a Stalinesque manipulation of the perceptual data? Is inattentional blindness the result of a lack of conscious perception or near-instantaneous memory loss? Do blindsight patients have qualia, and if so, how faded and/or distorted are they? These questions all seem to be unanswerable because any actual or imaginable data appears to be fully and equally consistent with all the answers.

Now, a full-fledged verificationist would claim that this makes these questions meaningless. This seems wrong, because even if we cannot decide between them based on the available data, they certainly seem to be conceptually distinct possibilities. But my point would be that even if there is a fact of the matter here, if nothing we can ever observe will verify our acceptance of one or the other of these theories, what is the point of endorsing any theory about these phenomena at all? We can, of course, decide to take a stand on one side of these issues, and others could decide to take a stand on the opposite sides, but on what grounds should the two opposing camps argue? It seems that any evidence offered in support of one side could equally well be used by the opposition. If so, we have guaranteed the existence of a perpetual philosophical argument, which, though possibly good for individual philosophers, is bad for philosophy generally.

I'm not sure whether Dennett would agree with this analysis, but when he calls these sorts of issues, "differences that make no difference," I read this as meaning that even if there really is a difference, it wouldn't make us any smarter to believe the true theory than its alternative (we wouldn't be able to explain anything more with the theory than we could without it). Dennett seems to want to take things further by saying that such differences are not really differences at all, but either way, this seems to be bad news for a fair amount of what's been said about consciousness so far. If we really believe that there is a difference between Orwellian and Stalinesque revisions and so forth, it seems that we need to be looking at ways of teasing apart the verification conditions of the two if at all possible. The other possibility would be to admit that we are only preferring one theory to another for practical or conventional reasons, but if we really believe that there is an actual factual difference, this won't be satisfactory. Or, even less satisfactorily, we could give up, as I suggested Velmans was doing a couple of weeks ago.

I think there is probably more to be said on this subject, but the post has gotten rather long already, so I'll let it rest at this for now.

Verbosely,
Joel

I found the Baars article from last week unsatisfying, so here are a few criticisms that come to mind (in addition to those we discussed in class).

1. "...we can create access to any part of the brain using consciousness"

Baars supports this bold claim with the example of biofeedback techniques in which subjects are able to "control" the behavior of even single neurons if given feedback regarding the activity of the neuron (such as a tone). But I don't see what this has to do with consciousness (other than the fact that subjects are conscious human subjects and that they happen to be conscious of the tones, etc.). And it is certainly misleading to say that this ability shows that we have "access" to the particular brain region under "control". If he means by "access" something like consciousness or global availability, it is surely false. And it isn't clear that consciousness is playing a critical role in these cases. I would think that simple behaviorist mechanisms could be at work here. Give a rat yummy food when it is generating high levels of alpha waves, and shock it when it is not, and I'll bet that it will gain "control" too. Maybe I'm wrong about this prediction, but it is still true that Baars doesn't do a very good job of motivating the view that some special property of consciousness is at work here. Rather, the "control" at issue seems extremely indirect and unconscious.

Likewise with his example of changes in our understanding of the meaning of the word "set" depending on the conscious hearing of another word, such as "tool". The changes in the meaning of "set" is due to the activation of a semantic representation of "tool". Now maybe semantic representations don't get activated unless the word "tool" is heard consciously. But we can't conclude from this as Baars does that "consciousness is required to integrate the meaning of each word pair." Rather, you have to *hear* (consciously) a word in order for its semantic representation to be activated, and the latter has an effect on the interpretation of subsequent ambiguous words. Consciousness is playing an incidental, not an essential role here.

The above criticisms apply as well to some of Baars' other examples, such as memory for visual images.

2. "The Universality of theatre models"

Baars seemed to be trying to bolster his theatre metaphor by pointing out how often people appeal to it. That it is a horrible way to argue for a
On Sun, 24 Oct 1999, Joel K Press wrote:

position. And it should be pointed out that his citing of Plato's allegory of the cave was way off the mark as an example of a theatre model of consciousness.

3. The function of consciousness

I found the following passage weird. "Consciousness creates access to unconscious problem-solving. The famous "incubation process" in mathematics involves a conscious question, unconscious work on the problem, and a conscious emergence of the solution." Baars takes this as another example of the function of consciousness being to present in the theatre something for the (unconscious) audience to do work on. But again, as in my criticisms above (1), why think that consciousness per se is doing the work here? And why would this support the theatre metaphor anyway? Maybe the question posed must have some threshold of activation in order to trigger some further process of problem solving--but this can all be explained without positing some place (physically or merely functionally specified) where it all comes together.

One final problem. Baars says in his conclusion that consciousness "creates" access to many independent knowledge sources in the brain, most of them quite unconscious*. But in the next paragraph, he says that global access may be a necessary condition for consciousness. This would support the view that consciousness *is* a special kind of access, not that it "creates" access. It looks like Baars is confused between these two different views. I think that the rest of the paper supports the "create access" reading, since that is more in line with his view that consciousness has the function of making information available to unconscious processes.
Joel summarizes the verification and underdetermination of theory by data below. It seems to me that the problems of orwellian revision and Stalinesque manipulation of perceptual data each suggest a "possible world" which are very different worlds. It would seem based on the existence of these possible worlds that it is also likely that if these two issues are different in these worlds, they would imply further differences in the worlds. These further differences would likely be

1) either resultant of the nature of a conscious system that operates this way (Orwellian or stalinesque) also showing the same sort of processing in other modalities and time scales that is at least more consistent with one story than the other. So the question to ask here is: IF this variable is operating according to story X, what else in this world should be different and in what way?

OR 2) determined by two or more possible structures in disparate function of the instantiating system in each of these worlds. So the question here is: IF Story x is true, we should see the memory centers behave in way x, if story y is true, we should see perceptual systems behave in way y; which way do these things behave?

This view of the problem admits the impossibility of choosing between the two possible worlds based on the single story/case of the color Phi instance with the data already available, but also hypothesizes that there would be other findings that should be more consistent with one overall depiction of how consciousness operates under various conditions than the other story. So at the end of the day we are not choosing an entire story of consciousness based on this one example, but we are choosing the most consistent story of this example based on that story's fit with our overall story of consciousness.

Thus one avoids giving up, by looking for other possible supporting evidence that is more consistent with one overall story than the other but not directly applicable to the smaller scale question that one desires a direct explanation for. Does this make sense to anyone but me?

At least equally verbosely,
--Lonnie

Even if we agree that verificationism is flawed as a theory of meaning, the related epistemological lessons are worthwhile in themselves. I think Simon was right to point out that the issues Dennett and Kinsbourne raise only really show that certain theories of consciousness are underdetermined by the data. But isn't this a fairly serious problem in its own right? Several of the issues we've been discussing lately seem to be in this situation. Is the color-phi phenomenon due to an Orwellian revision of memory or a Stalinesque manipulation of the perceptual data? Is inattentional blindness the result of a lack of conscious perception or near-instantaneous memory loss? Do blindsight patients have qualia, and if so, how faded and/or distorted are they? These questions all seem to be unanswerable because any actual or imaginable data appears to be fully and equally consistent with all the answers.

Now, a full-fledged verificationist would claim that this makes these questions meaningless. This seems wrong, because even if we cannot decide between them based on the available data, they certainly seem to be conceptually distinct possibilities. But my point would be that even if there is a fact of the matter here, if nothing we can ever observe will verify our acceptance of one or the other of these theories, what is the point of endorsing any theory about these phenomena at all? We can, of course, decide to take a stand on one side of these issues, and others could decide to take a stand on the opposite sides, but on what grounds should the two opposing camps argue? It seems that any evidence offered in support of one side could equally well be used by the opposition. If

Hey all,

Last discussion left me hankering for a clarification of Dennett and Kinsbourne's argument. I'll try to give one, and use it to examine what I think are some problems with their thesis:

0. Cartesian theories of consciousness can offer two explanations of the aberrant phenomena that D&K adduce

1. Both the Orwellian and Stalinesque theories adequately explain both the first person and third person data of the various phenomena that D&K adduce (colour phi, sub cutaneous rabbit, etc).

2. But the two theories posit different (non-isomorphic) mechanisms for the phenomena.

3. No empirical test, actual or possible, could tell the difference between these two hypotheses.

4. Any two theories that posit such an untestable difference are suspect.

Conclusion: Cartesian theories of consciousness are suspect

I can see two major problems with this line. The first one is with premise three. Arguably it is the case that current science has not found a way to tell which of these two stories is the correct one, but what proof do D&K proffer for their modal claim, that no evidence could ever do this job? Precious little. They do provide an example of the way a Stalinesque theorist might defend against a piece of data that imperils their theory, but this fails as a demonstration of the plausibility of the infinite room available for such moves.

Consider, say D&K, what would happen if the subject were asked to signal the moment that they become conscious of the first flash in the colour phi experiment. Further, imagine if this signal came in advance of the appearance of the second flash. It might seem that this is a decisive piece of evidence in favour of the Orwellian theory, since, regardless of the memory trace or subsequent verbal report of the subject, we have proof that the subject was conscious of the first flash as a stationary red point, since such consciousness was reported before the advent of the second flash. Not so, say D&K, because the Stalinesque theorist might reply by saying that the subject in such a case signaled the event before she was actually conscious of it. How? Well, the conscious mind of
the subject might have 'leaked' the instruction to push the button to the 'editing room' (the locus posited by Stalinists where the editing of conscious experience gets done), and the editing room pre-consciously initiated the button push.

But, as we can plainly see, this greatly sophisticates the Stalinesque theory. It requires that the editing room be able to receive instructions from the consciousness center, that the editing room have executive control over the motor cortex, etc. Also, if the experiment is done in such a way that the subjects are instructed not to push the button unless they have a conscious experience (and the results are the same), then the Stalinist must posit that the editing room acts upon the 'leaked' command in spite of the conscious determination not to on the part of the subject. Spooky, and more than a little ad hoc. This is not to say that the Stalinist couldn't say such things, but rather to point out that only rarely does one definitive test separate two competing theories. Normally what happens is that over a series of experiments a preponderance of evidence builds up in favor of one or another hypothesis. And while there is some room for a theorist to make amendments to her theory in the face of recalcitrant data, there isn't an infinite amount, and eventually the theorist is forced to either give up the theory or to make it completely ad hoc. D&K's contention that no evidence could ever surface that would definitively decide between these two theories seems false on its face.

Also, as was discussed in class, there is a problem for the fourth premise. This is the verificationist premise, and I have attempted here to provide the least contentious version of it that I could muster. As it stands, I don't think it is too objectionable, but as a result of its weakness, it doesn't grant D&K the conceptual purchase that they might like on cartesian materialism. If we grant that these two theories couldn't ever be decided between on the basis of empirical evidence, then we might well have a reason to question them, or, more specifically, to question the theoretical entities that underly the conflict. In this case, it would be the cartesian theatre (finish line of consciousness) that D&K would have us question. But D&K's answer, i.e. throw out the idea of a cartesian theatre altogether, seems a bit hasty. If we could simply amend the theatre idea in such a way as to solve D&K's problems, but leave the theatre intact, then we wouldn't have to by their new product.

And we might well accomplish this (as we said in class) by making the temporal borders of the cartesian theatre 'fuzzy'. If we say that there is a brief span of time in the course of a percept's journey from unconsciousness to consciousness when there is no determinate fact of the matter whether that percept is conscious or not, then we can solve all of D&K's temporality problems without throwing out the cartesian baby with the bath. Also, such temporal fuzziness is of a piece with the spatial (regional?) fuzziness of consciousness evidenced by peripheral and unattended conscious percepts. If consciousness' spatial borders are blurred, why not its temporal ones, as well? Any thoughts?

(Sorry about the length)
Al
Rosenthal writes, "We can reasonably assume that many of these children's mental states are conscious. But on the HOT hypothesis those states can be conscious only if the children have HOTs about them." I'm a bit confused about what it means to have an experience of something and to _not_ have a HOT about it, or is Rosenthal just saying that the young kids actually have HOTs that are not verbally expressed. What is the difference between having a conscious experience and having a HOT about it? Can one happen independently of the other? If three year old children do not have HOTs, to what extent, then, are they conscious of thoughts, sensations/perceptions, and the like?

Additionally, Rosenthal states that, "even adult HOTs are expressing their nonconscious HOTs in words. Indeed, although almost all verbally expressed thoughts are conscious, HOTs are an important exception. ... Not being conscious does not prevent HOTs from being verbally expressed." But, once a thought is expressed, isn't it then conscious? I'm not sure what else it would be.

As to Rosenthal's point about how false HOTs might be used to explain repressed beliefs and desires, I do not follow his argument. "Erroneous HOTs may well also figure in cases of so-called self-deception; there one's HOTs would misrepresent not what one desires but what one believes." This places too much omnipotence of HOTs. Sometimes, we just aren't good guessers (as research on human statistical inferences shows), perceivers, knowers of knowledge, etc.. Humans make a lot of mistakes, rely on heuristics, etc.. Thus, its not simply an erroneous HOT.
A few notes about HOTs and consciousness, especially as treated by Rosenthal. First, Peter's concern about children's consciousness. Peter writes:

Rosenthal writes, "We can reasonable assume that many of these children's mental states are conscious. But on the HOT hypothesis those states can be conscious only if the children have HOTs about them." I'm a bit confused about what it means to have an experience of something and to _not_ have a HOT about it, or is Rosenthal just saying that the young kids actually have HOTs that are not verbally expressed.

Yes, Rosenthal (almost) says that children have the HOTs about experience required for consciousness. A few lines after the passage cited by Peter, Rosenthal says that the essential difference is between thought and report. Even adults have thoughts that they cannot formulate as reports, so presumably, children do too. Some such thoughts may be HOTs—"So it may well be that these children [three and younger] have the relevant HOTs even though they do not express them verbally."

This line of thought has the interesting consequence of committing one to nativism about mentalese if one is to maintain that infants are conscious. If there's conscious experience, after all, it is so because it bears the imprint of a thought, and a thought implicates at least one concept. Regarding developing children who have not yet gained a large conceptual repertoire (expressed in a natural language), nativism might be invoked to explain the apparently rich conscious experience that children enjoy. It would not be *required* to explain consciousness, but it does seem like the natural direction to go if one is committed to nativism for infants.

On a separate note, Rosenthal poses one argument for the HOT theory as a disjunctive syllogism: We have conscious content either by virtue of sensing it or thinking about it. It cannot be the former; therefore, it is the latter. This conclusion depends, of course, on the original disjunction's being exhaustive and otherwise accurate.

For my part, I do not believe it to be either. I think Austin's argument that we do not sense sense data (else a regress follows) is essentially
correct. We sense external objects that are internally represented. The internal representations, as far as I can see, do not require a further act of sensing to confer phenomenality on them. Perhaps Rosenthal would take this as evidence in his favor, since it is an argument against our sensing conscious content. However, I take it as an argument against his beginning supposition, since it makes one disjunct out to be not merely wrong, but implausible. To declare cognition as the gatekeeper of consciousness because it excels a plausible contender would be decent argumentation. However, if the competition is downright implausible and not clearly exhaustive (with cognition) of the field, a victory by default seems not to be decisive. (I must confess ignorance of Rosenthal's arguments for HOT cited in note 11.)

P.S.--
It just occurred to me that I really didn't know what I meant in saying that a disjunction ought to be exhaustive and "otherwise correct." If it's exhaustive, the DS argument should go thru. So I guess what I mean about Rosenthal's disjunction is that it is simply not exhaustive. On my (Austinian) understanding, sensing and thinking are not jointly exhaustive, because I think there is a third option: *having* conscious experience. This will appear question-begging, since we are trying to give the criteria for *having* conscious experience, but suffice it to say for the moment that...
I believe it can be had independently of second-order thoughts or sensations. To put it another way, I do not think that second-order mentation is required for conscious mentation. Hope that helps.

Matt

The outcome of the last discussion has led me back to the talk Block was giving to the Consciousness Studies meeting couple weeks ago. For those who haven't been there, his message was somehow close to what we have discussed, but he said there is a way how to save HOT theories from common objections.

Block however suggests that if we enrich the notion of HOT, we might be able to save the theory. Here is how:

P-consciousness is phylogenetically much older than any higher order cognition. Therefore in order for HOT to bridge the gap between higher level cognition and phenomenality, HOT has to accommodate P-consciousness. Here is a quote from Block's handout: "S is an R-conscious state iff S is phenomenally represented in a thought about S."

Just to remind you that R consciousness is in Block's terms just equivalent to HOT. Is this gonna move us anywhere? I have some doubts about it. Let us forget for now my general worry as to what exactly is meant here by "being phenomenally represented"

The issue which puzzles me in this respect is a following one. Let us take Rosenthal's example of Tip-of-Tongue experience. I am afraid that introduction of phenomenality at this stage is going to produce more harm
than benefit. I grant that all conscious beliefs have some phenomenality. But is the phenomenality in the case of different TOTs also different? Do I experience the same thing as I am having TOT answering question WHAT IS THE CAPITAL OF FRANCE as opposed to WHAT IS THE DIAMETER OF THE EARTH? It seems like I have to, because my access goes to different ideas (although it does not reach their content). But at least to me, the feeling is just about the same - I think I know the answer, but I just can't produce it now.

So it seems like we might face a case of (potentially infinite) cases of access consciousness accompanied with a single experience. But that contradicts all our effort to keep them together...

Surely one can reply by saying that in fact all my individual TOTs are different (in the first case I feel that I know what is the capital of France, but I just can't say it, other time I feel like I know what the diameter is, but just can't say it...)

But what if my phenomenality does not go that far and I only feel that I know the answer, but I am just stuck.

At least it is an interesting open possibility...

Juraj
I too have trouble understanding exactly what Rosenthal means here. What is the phenomenality of a TOT? Perhaps his discussion of the difference between being conscious of a particular informational state and being conscious of the same state *in the relevant way* may be of help here.

Rosenthal uses the example of having Mark Twain's real name on the tip of one's tongue. The feeling of <knowing *what* Mark Twain's real name is> is different from the feeling of <knowing *that* Mark Twain's real name is Samuel Clemens>.

Is it possible to extend this sort of example to two different TOTs? I don't see why not. Would'n't the feeling of knowing <what the capital of France is> be phenomenally different from the feeling of knowing <what the diameter of the earth is>? I think so. If that is right then Rosenthal is not committed to a number of different A-conscious states having the same phenomenology; something which Juraj was worried about.

On second thought, I am not sure why I think there is a phenomenological difference here. I suppose all I am really doing in this posting is presenting, in Rosenthal's terms, the opposing intuition to Juraj's. But, there might be more of an argument here. If there is a difference in phenomenology between TOT's I submit that it arises from a difference in description. That is, in TOT-A the relevant informational state bears the description <the capital of France> in TOT-B the relevant informational state bears the description <the diameter of the earth>. Is this enough to give us different phenomenology?

If you hold that all conscious beliefs have some phenomenology, then you need to explain what accounts for the phenomenological difference between two different conscious beliefs. It seems that description could play a role here. That is, two different conscious belief states have different phenomenology just in case they contain different descriptions. If one buys this claim for any conscious belief, it seems to me that one would have to buy it in the case of TOTs. For, TOT-A and TOT-B contain two different descriptions.

(Note: there may be a counter example to my account. Consider the following two TOTs:

1) <knowing the name of the planet to which "the evening star" refers.>
2) <knowing the name of the planet to which "the morning star" refers.>

The above two TOTs contain different descriptions. However, it may seem odd to say that the phenomenality is different, since in both cases one has "Venus" on the tip of one's tongue. I am not sure what to say about this yet, since I just thought of it.)

- Spinoza, The Ethics
Hello all.

I was thinking about the discussion in class concerning the distinction between a conscious mental state and being conscious of a mental state. Dave gave a good example of this distinction (I am describing this from memory, so if I have this example wrong please let me know): show a subject a visual stimulus consisting of a large number of dots for a brief period of time, and then follow this with a second presentation of a group of dots whose number is one less than that of the original presentation. In most cases people would be unaware that there is a difference between the two sets of stimuli, and thus would report that the two sets are the same. It was argued in class that during the first stimulus presentation the extra dot was present in the person's phenomenology (i.e. the visual state corresponding to perception of the dot was conscious) but that the person was not aware of this change because they don't have access to, or cannot discriminate, the change. But if one says this, then couldn't one also say that, in a sense, the experience of the dot is unconscious (or to be more precise un-access conscious)? If one can say this, then it leads naturally to the following questions: is it possible that all the mental processes...
that are currently considered to be unconscious or nonconscious could be in fact conscious, but we have no access to them? Could these processes have experiential aspects that remain un-access conscious?

If one wished to deny this, how could one build a case from the evidence? Consider the case of a cognitive task where one wishes to infer that some unconscious process played a role in the instantiation of that task because the subjects undergoing the task had no awareness of the processes themselves. However one could equally say that the process is conscious (in a phenomenological sense) but that the subjects have no consciousness of the process (i.e. the process is un-access conscious). How could one empirically distinguish between these two interpretations?

In light of the strong arguments for the existence of the hard problem, it seems to me that the latter interpretation may be more metaphysically parsimonious. Instead of trying to figure out how qualia arises from certain brain processes while not arising from others, one posits that qualia arises from all brain processes. However, not all of these brain processes are in the category of which one is conscious of those processes. Of course this requires an explanation of why some processes make it into conscious access and others do not. However this may be a more tractable problem then the one suggested by denying that qualia is ubiquitous to all brain processes.

Take a look around you right now at your present visual scene. All the processes that enabled you to perceive that scene may contribute qualia to your overall visual phenomenology. The fact that we are not conscious of most of those processes does not argue against the possibility that such processes are conscious, with a rich phenomenology interwoven with the phenomenology of those processes to which we may be conscious of.

Hi, a couple of notes:

(1) In response to Joel, one might try to make a case that the actual information that is on the tip of one's tongue can make a difference in phenomenology. E.g., if one is trying to think of the capital of Wyoming, it might feel different to have Cheyenne on the tip of one's tongue compared to having Laramie there. After all, there is often the feeling that some of the information is vaguely present -- maybe
the first letter of the world, or some of the feel. On the other hand, this feeling might be fairly coarse-grained, so it might be that e.g. Casper and Canter would feel the same?

(2) Logan suggests that in the dot case, the extra dot seems to be phenomenally conscious but not access conscious. I think one could make a case that we are access conscious of the extra dot -- it's visually there and available to play a role in our reasoning (e.g. counting the dots) and action (e.g. pointing to it). What it seems that we're not access conscious of is the fact that it *is* an extra dot -- i.e. the fact that the two displays contain different numbers of dots. But that's a slightly different thing.

The idea that lots of our supposedly "unconscious" mental states might be phenomenally conscious but access unconscious is interesting. But I don't think it gets support from this analogy, since we can point to and talk about the dot in the case above, but we can't point to and talk about typical "unconscious" information.

The motivation of suggesting that qualia are associated with all brain processes is interesting; but note that that doesn't force us into holding that they are all phenomenally conscious for me (the person with the brain). Another alternative might be that those qualia are not part of my phenomenal consciousness, but are part of another subject's consciousness (e.g., a proto-subject corresponding to an individual neuron, or neural system). Given that we're going to have qualia or proto-qualia all over, maybe it's not so bad to have subjects or proto-subjects all over, too. And this way we avoid the consequence that we as subjects experience a whole lot of qualia that we can never know about.

--Dave.

Matt writes:

> Yes, Rosenthal (almost) says that children have the HOTs about experience required for consciousness. A few lines after the passage cited by Peter, Rosenthal says that the essential difference is between thought and report. Even adults have thoughts that they cannot formulate as reports, so presumably, children do too. Some such thoughts may be HOTs-- "So it may well be that these children [three and younger] have the relevant HOTs even though they do not express them verbally."

> This line of thought has the interesting consequence of committing one to nativism about mentalese if one is to maintain that infants are conscious. If there's conscious experience, after all, it is so because it bears the imprint of a thought, and a thought implicates at least one concept. Regarding developing children who have not yet gained a large conceptual repertoire (expressed in a natural language), nativism might be invoked to explain the apparently rich conscious experience that children enjoy. It would not be *required* to explain consciousness, but it does seem like the natural direction to go if one is committed to nativism for infants.

I took it that Rosenthal wanted to go in a different direction. That is, it seems that rather than say that children under three have a mentalese (which, as an aside, does not commit one to nativism with respect to mentalese since it seems prima facie plausible that a mental natural language could form after birth and before verbalization) Rosenthal wants to say that the relevant concepts necessary for a consciousness-bestowing HOT (a concept of self and of mental states (mental state types and mental states in general) are merely content based. In other words, instead of a HOT with the content "I am in M." where M is some mental state and where the sentence "I am in M." is considered a mentalese sentence, the concept "I" and "M" are minimalistic concepts filled out by a pre-linguistic content.

Exactly how this is to be cashed out is presumably left up to us since Rosenthal doesn't give us much of a story. In "A Theory of Consciousness" he says that

[a] minimal concept of self will suffice; no more than a concept that allows distinguishing between oneself and other things...

Nor is there reason to suppose that rich conceptual resources are necessary for a thought to refer to one's own mental states. We refer in thought to physical objects by way of their position in our visual field. It is natural to suppose that a thought can similarly refer to sensory states by way of their position in the relevant sensory field.

So it seems that here he wants to put forth some sort of demonstrative reference story where a HOT merely points to a mental state (here a sensory mental state). Mental state concepts (at least sensory ones) are differentiated merely with respect to their content (e.g., a sensory mental states S with the (phenomenal) content "reddish sphere" is different from a sensory mental states M with (phenomenal) content "greenish cube"). Since Rosenthal thinks one needs only a minimal concept of self (presumably in the background of all thought-pointing events--as Brad pointed out in class) children under three have all that they need to form the relevant HOTs necessary for making mental states conscious without the need to posit an infant pre-verbalized mentalese.

HOTs, then, for children under three, are, according to Rosenthal, merely pointers to mental states. But, as Dave stated in class, it seems Rosenthal is going to have to employ HOTs in this role even in adults.

Rosenthal writes (in ATOC):

http://www.u.arizona.edu/~chalmers/class/596v/week10.txt (10 of 16) [4/7/2002 1:55:10 PM]
In any case, conscious differentiation of sensory detail quickly outstrips one's conceptual resources; so some such means of referring to sensory states is necessary.

In other words, even as adults our sensory concepts are incommensurate with our sensory consciousness. We are conscious of sensory detail of which we have no corresponding sensory concept. So the HOTs in virtue of which we are conscious of our sensory mental states must "fill-in" by means of this demonstrative referring to which Rosenthal alludes.

There is, however, more story-telling to be told. For instance, if it is the richness of our mental state concepts that determines the richness of our conscious experience when HOTs are construed as mentalese sentences (which it seems Rosenthal is committed to claiming) then what is it that determines the richness of the "gaps" that are filled-in by these referring HOTs? Or, as is more glaringly problematic, what determines the richness of the conscious lives of children under three (since all of their HOTs are of this referring kind)?

dot -- i.e. the fact that the two displays contain different numbers
> of dots. But that's a slightly different thing.
Perhaps the idea of access consciousness was the wrong thing to use to contrast against the phenomenality in this case, but it does seem that there is a distinction to be made. We can only point to and talk about the dot if there is an opportunity for our attention to make the dot's existence plain to us. Yes the dot is available for reasoning, etc., but such processes do not occur until conscious access to the dot is instantiated. Until then, the dot remains phenomenally present, but not accessed. Perhaps there could be a distinction between potential for access and actual access? Certainly the former obtains in this example, but does the latter? (I am admittedly out on a limb here).

> The idea that lots of our supposedly "unconscious" mental states might be phenomenally conscious but access unconscious is interesting. But I don't think it gets support from this analogy, since we can point to and talk about the dot in the case above, but we can't point to and talk about typical "unconscious" information.

Again, per the discussion above, I am not entirely convinced that the dot is access conscious before it is actually accessed. Thus the fact that we have the potential to point to the dot is not directly relevant to the current state of consciousness of actual access during the period before this occurs. Furthermore wouldn't evidence from biofeedback and studies of meditation that purport to demonstrate effects of conscious intention upon autonomic physiology (processes usually considered to be unconscious) seem to indicate that in the case of some unconscious processes we can "point and talk" to them (metaphorically)? Perhaps states of consciousness exist where access is available to other typical unconscious processes? Such states certainly wouldn't be considered normal consciousness, but then normal conscious states are considered as such because the majority of people tested exhibit the inability to access information considered unconscious.

> The motivation of suggesting that qualia are associated with all brain processes is interesting; but note that that doesn't force us into holding that they are all phenomenally conscious for me (the person with the brain). Another alternative might be that those qualia are not part of my phenomenal consciousness, but are part of another subject's consciousness (e.g., a proto-subject corresponding to an individual neuron, or neural system). Given that we're going to have qualia or proto-qualia all over, maybe it's not so bad to have subjects or proto-subjects all over, too. And this way we avoid the consequence that we as subjects experience a whole lot of qualia that we can never know about.

This is a very interesting idea, perhaps closer to the idea I was trying to get across in my post. I think that such a situation is intimately associated with the problem of phenomenal/perceptual/cognitive binding. Perhaps binding regulates what qualia is associated with which subject. However whether or not this could be empirically tested remains to be seen.

Thanks Dave. As usual your comments and observations are astute and clarifying.

Logan T.
Joel's post got me thinking about the need for HOTs to make sensory data conscious. Perhaps we can modify Rosenthal's proposal to make it more acceptable in the following manner: we remove the requirement that HOTs are necessary to make incoming sensory data conscious, but are required for all other conscious thoughts.

Allow me to present an analogy to make my point. Imagine that memories are like data files. In order to become conscious, a memory must be 'copied' into the cache (working memory). The HOT is the equivalent of the copied file in the cache. Now files come in two parts, an index and a content part. The index segment contains information about the file, things like (in a computer) its size and origin and type. Perhaps our memories also contain an index, and when we have a TOT experience, we only have the index (or maybe even part of the index) copied into the cache, and that is why we have only partial consciousness. Only when the content part of the file is copied into memory will we be fully conscious of it. Of course, the problem is that, even on this generous analogy, sensory data will not seem to require a HOT to be conscious, because the computer equivalent of sense data, data from peripherals that lie outside the bus (the information exchange, or CNS of a computer) is not copied into the cache via a subroutine, but is rather streamed into the cache through the bus. Perhaps this is what happens with sense data, then. Rather than eliciting an HOT, like other conscious experiences, sensory experiences would have a free ride to consciousness, as it were.

Although, this limitation might not be as devastating as it seems, since Rosenthal might argue that attending to sense data inevitably results in HOTs. Perhaps if we concentrate on a stream of incoming sense data, we, as a matter of empirical fact, begin to process the stream in a manner that requires the use of memory, and thus the production of HOTs. It is not implausible that the simple act of turning our attention to an incoming sensory stream results in our processing the units of the stream for memory matches, or trying to anticipate the upcoming units in the stream, or comparing past units looking for patterns, or any number of processes that would require HOTs on this formulation. So the HOT theorist can say that HOTs are necessary for a vast number of conscious experiences, including most of those inside attention. Of course, this argument is offered in the spirit of science fiction, and I don't have a good reason to think that human cognition is sufficiently similar to
Juraj's post regarding the homogeneity of TOT phenomenology was interesting. There does seem to be significant commonality between all experiences of this. There is something distinctive about the brain stalling out because of (what I think might be described as) informational inadequacy. And Juraj's suggestion that the phenomenality of every "brain stall" is roughly the same is both intuitive and helpful. Yet it is hard to deny that tip-of-the-tongue experiences are strongly intentional. If we separate the TOT experience from the information a quest for which resulted in the TOT, and call all TOT phenomenologically equivalent, then it seems *any* answer to the frustrated search would dissolve the block, give that distinctive catharsis (and post-catharsis self-reprimand for having forgotten.) This is manifestly not the case, so it seems that paralyzing TOTs must need be chained to their antidotes, the informational states that are the TOTs' resolutions.

But to say the question, the quest, and the answer are linked is not yet to describe the phenomenological nature of the link. A TOT is like being lost. You've departed with a set of directions, but the directions are inadequate. There is a phenomenality that is specific to being lost with *this* set of directions (which corresponds to Joel's "description" and to Dave's "course-grained" "feel"), but the overwhelming feeling is simply that of being lost (which corresponds to Juraj's intuition that TOT phenomenology is all roughly the same). There is a sort of access consciousness, but what is available for verbal report is only that the access failed, the destination was not reached--along with some vague, "course-grained" information about where the destination "should be." The phenomenology of reaching the destination, of remembering the answer, is very little like that of being lost; the catharsis that comes with the answer arises because of this large disparity.
Or else a TOT is like having an adequate set of directions, but an outdated one. A metaphor that seems more apt is getting lost when driving home after a long time away and after the surroundings have changed. I'm originally from Phoenix, which has been spreading, mutating, and losangelizing for the past couple of years: eight months is time enough for any number of gaudy strip malls to swell like lumps on the desert. So when I meant to drive home after a stay abroad, and looked for the old clues, I was disoriented by the faux adobe franchises. The city planning of the mind is also in flux (please correct me if I'm wrong on this) which can disorient quests for information, apart from any consideration of the quality of the set of directions, and whether the ink has faded or the page has torn.

Last, the getting lost metaphor can be extended to be suggestive in the case of overconfident feeling-of-knowledge. The executive "manages" all the business of the mind with the outside. He takes the request for a memory and sets his people working. If the only answer his consulting firm is able to come up with is that they can't get the requested information, but they can describe some characteristics of it, the executive, in order to save face and continue to legitimize his high fees, claims he's eighty percent sure of his guess. Or else the executive is a nimwit who doesn't understand what his techies and sundry minions do in their cubicles, but is confident and dependent upon them, regardless of their troubles—indeed, he can't understand their troubles. Whatever the case, the executive is clearly male, and hates getting lost.

Nick

Dear Dave,
I wrote this message last Thursday. I thought that I had sent it out but instead I had hit 'postpone'. This whole time I have been thinking that I had posted to the listserve with plenty of time. (happy
that I hadn't procrastinated until Sunday.) When I was talking with Adam last night I figured out that he hadn't gotten my post and that further, it hadn't been sent. So here it is. Sorry that it is late but know that I did finish writing it on time. If you decide to send it on to the listserv please take off this excuse (its an embarrassing mistake to make.)
Thanks, Rachael

Our discussion on Tuesday raised another concern that I had with the Johnson and Reeder article. In the section, Consciousness and Attention, on page 283, they make some pretty interesting claims about consciousness and attention. In this section, they say that the familiar example of driving the car to work is one where the person is paying attention but is not necessarily conscious. This is because consciousness can be distinguished from attention "in that consciousness includes the idea that processes are engaged and monitored by another subsystem, whereas attention does not necessarily involve transactions across subsystems."

So it appears that Johnson and Reeder want to claim that what is going on when we are 'unconsciously' driving to work is that transactions are taking place across one subsystem but processes are not being engaged and monitored across subsystems. But recall, theirs is a picture in which the fulfilling of agendas requires control and monitoring *across* subsystems. (Strangely, the MEM framework doesn't leave room for these functions within a particular subsystem). So what they would have to say about the experience of driving 'unconsciously', while 'paying attention' is one in which no agendas are being carried out, that is, where no control or monitoring is taking place. Anyone who has driven to the store, even 'unconsciously' should recognize that some controlling and monitoring must take place as accomplishing this task requires heading in a basic direction, changing lanes, and in general, not being killed. Even on 'automatic' there must be some control/monitoring processes taking place for us to accomplish our goal.

There are a number of ways Johnson and Reeder could adjust their position to make it more tenable. First, as I pointed to before, they could allow for control and monitoring to take place across a particular subsystem. Secondly, as Liz pointed out, their description of the driving example seems to get things backwards. Most of our intuitions seem to suggest that we are conscious but not paying attention in those scenarios, not the other way around. I am not sure that this claim about consciousness and attention coming apart is that important for Johnson and Reeder's overall project anyway. The claim that consciousness arises from meta-processing (though problematic in itself) is better supported without tacking it to the stronger claim about what attention involves.

Just some thoughts...
I had a discussion with someone this morning about Nagel and some interesting stuff seemed to come out of it. I haven't reread Nagel, so it may not be true to his intent.

(1) Think of an objective phenomenology as something like an (allocentric) space-time map of the world. Every physical thing in the world is at some space-time distance from every other thing. Distinct beings can share this conception of the world. Similarly, a phenomenological dimensional space is a framework onto which all (possible?) phenomenal states can be mapped. Our own (actual and possible) experiences fall somewhere in this multi-dimensional space. The bat's experiences will occur somewhere within this space too.

(2) First problem: what is the structure of this phenomenal space? At least two parts to that problem: (a) what is the structure of our own phenomenal space? (b) how does the structure of our phenomenal experience relate to that of any possible phenomenal experience?

(3) Second problem: where on this phenomenal map does the bat fall? Tough one, but interestingly distinct from (2).

(4) First thesis: having experience x is not sufficient for knowing what it's like to experience x. Knowing what it's like to experience x involves understanding the dimensional structure of x, but one can have x without appreciating this dimensional structure. A being that only experienced a single shade of blue might have no appreciation of the structure of color.

(5) Second thesis: Having an understanding of some structural aspect of experience x might enable you to partially know what it's like to experience x. The sound of trumpets and red might share a high-level structural feature, which makes this analogy partially illuminating.

(6) Third thesis: The richer your understanding of the structure of an experience, the closer you can get to understanding it without having it. Thus, Hume on the missing shade of blue: if you have experienced the other shades, then you probably have an understanding of most of the dimensions that will structure the missing shade.
Fourth thesis: An objective phenomenology enables you to go from understanding what it's like to experience x to understanding what it's like to experience anything else (perhaps given that there's some structural similarity), but it doesn't bootstrap you into understanding phenomenal states from an absence of phenomenal states. That is, if we had this objective phenomenal map, we could understand what it's like to be a bat (or anything else), but zombies couldn't use this map, 'cos they can't get positioned on it at all. Objective phenomenology allows you to get from one phenomenal state to others, it doesn't allow you to go from merely physical states to phenomenal states. Thus, Mary can use it to know what it's like to see red (without seeing red), but Zombie Mary can't.

Part 1. Gallup is confused, and it's not about consciousness at all.
The term consciousness is used loosely in Gallup's article, and the real debate between Gallup and Povinelli concerns whether the animals they study have a theory of mind or 'empathy' (also rather loosely conceived). Specifically, do they have the sort of self-concepts that allow for understanding of their own mental states as mental states, and can they extend this knowledge to encompass an appreciation that other creatures like themselves have mental states like their own? The relationship between theory of mind and consciousness, according to Gallup, seems at first to go something like this: If animals have a theory of other minds, then they must first have a theory of their own minds, and having such a theory makes them likely possessors of consciousness (presumably because if they're thinking about all these mental states, they must be doing it consciously). Later, in some sweeping claims at the end of the article, Gallup equates consciousness and self-consciousness. He suggests that creatures without self-consciousness may have "clever brains but blank minds." Having a blank mind is more than not having a theory of other minds; it is compared to sleepwalking or blindsight, states in which sensory inputs can influence behavior, without any phenomenal consciousness of that input. Blank minds are really phenomenally empty. The link between self-consciousness and phenomenal consciousness turns out to be causal, according to Gallup, who (revealing his Cartesian allegiance) writes, "Being able to conceive of oneself in the first place is what makes consciousness and thinking possible."

Povinelli's statement of the focus of the debate is more clear, and he avoids the term consciousness altogether. He asks, "[W]hat excludes the possibility that evolution has simply produced "mind-blind" mechanisms that lead social primates to look where other animals look, without entertaining any ideas about their visual perspective?" Why ascribe a theory of mind to these creatures, he asks, when a more parsimonious explanation of their behaviors will suffice? He offers the idea of a kinesthetic self-concept to account for the behavior of animals in the mirror task, rejecting interpretations of this ability that infer an understanding of psychological states as psychological states on the animal's part. Povinelli doesn't seem to share Gallup's intuitions about the relationship between theory of mind and consciousness. What the animals lack, he says, is the ability to use their own experiences (phenomenally conscious, I presume) to make inferences about the experiences of others. Povinelli might interpreted as sharing Nagel's assumption that animals have conscious experiences.

Part 2. But since Gallup brought it up, let's talk about it anyway.

What does this discussion reveal about debates about animal consciousness? In particular, what exactly are these investigators imagining when they talk about "blank minds" filled with "mind-blind" mechanisms? Are such minds phenomenally conscious, but merely lacking in a theory of other minds? Or lacking a theory of mind, are these animals not conscious at all, as Gallup suggests?

There are some fundamental assumptions lurking behind the idea that the burden of proof in discussions of animal consciousness lies with those who would argue for it, as opposed to those who would argue against. Morgan's Cannon, as we learned on Tuesday, cautions us to be parsimonious. We should refrain from offering complex explanations when more simple explanations suffice, therefore, we should not claim that consciousness exists in animals if simpler explanations can account for the observed behaviors. The assumption here is that there is an ascending hierarchy of mental capabilities or functions, with consciousness at the top. On Gallup's view we have consciousness, self-consciousness and consciousness of other minds stacked at the top. Beneath this top level are abilities like learning,
memory, and so on that can occur in blank minds. Phenomenal consciousness does not constitute a level of its own. For Povinelli, phenomenal consciousness may have a its own level, beneath the level where we find theory of mind and self-consciousness. Both investigators make the common assumption that many mental functions are mere mechanisms requiring no awareness for their function, mechanisms that inhabit lower levels of the hierarchy. Animal minds should be explained at the lowest level of the hierarchy that can account for the observed behaviors.

This highly mechanistic view of animal minds is a direct inheritance from certain recurrent themes in our western intellectual tradition. It has ancient roots (both in Greek philosophy and Christianity) in a form of speciesism that places humans at the top of the psychological and biological heap. In Descartes, this view takes the form of a mind-body dualism in which our mental nature is markedly different from and superior to our bodily nature. When cast in evolutionary terms it is the view that human consciousness is the most highly evolved mental function in the animal kingdom. Combined with the notion that animals don't have minds (or souls) at all, such views helped to justify the beginnings of animal experimentation. We essentially have two parallel hierarchies that are assumed to map onto one another. The biological hierarchy has humans at the top, followed by other primates, then 'lower animals' of all sorts. The psychological hierarchy has consciousness at the top (maybe self-consciousness above it), complex cognition (memory, learning, etc.) below, and behavior at the bottom. The assumptions here are that the higher levels are more complex. This assumption is incorporated into cognitive models of consciousness that place consciousness at the center or top of the information processing system, and in evolutionary explanations of consciousness that argue for its role in dealing with the demands of more complex information processing systems interacting with more complex environments.

In a recent article in the Journal of Consciousness Studies (1998, Volume 5, 3) entitled "Consciousness: A Natural History", Maxine Sheets-Johnstone questions the correctness of these hierarchical conceptions and of the assumption that "unconsciousness historically preceded consciousness" in animals. She suggests that proprioception may be the first evolved form of consciousness. The evolution of proprioception, she proposes, parallels the evolution of animate forms, such that from the very beginning of the ability of organisms to move, there was a need for a kind of flexible responsivity to external stimuli. It is arbitrary, she argues, to call this responsivity behavioral or cognitive when referring to 'lower animals' and conscious when referring to humans or 'higher animals.' The fact that this is frequently done has much to do, she claims, with our brain-centered notions of consciousness that disregard more embodied sensory abilities. She notes that the first human sense to develop is proprioception (it develops prenatally with the early development of motor pathways), and it is through this sense that we initially come to learn to move our bodies and to feel ourselves. This is a sense that we share with many 'simple' creatures. Sheets-Johnstone provides a description of the proprioceptive abilities of invertebrates that makes the assumption that unconscious mechanisms explain the behaviors of these 'lower animals' look disturbingly ad hoc. In response to Dennett, who claims that in simple organisms "there is really nothing much to self-knowledge beyond the rudimentary biological wisdom enshrined in such maxims as 'When Hungry, Don't Eat Yourself!' and 'When there's a Pain, It's Yours!'" she questions the parsimony of explaining animal behaviors in terms of such mechanisms. I'll close with the following quotation in which she makes this point:

"[W]e should ask what it means to say that a lobster will eat another's claws but that conveniently, as Dennett puts it, it finds eating one of its
own claws unthinkable. Does it mean that there is actually a rule 'Don't eat your own claws!' wired into the lobster's neurological circuitry? But it is patently unparsimonious to think that there is such a rule and just as patently absurd to think that every creature comes prepared with an owner's manual, as it were, a rulebook replete with what Dennett calls 'maxims'. Such a maxim, for example would be only one of an indefinitely great number of maxims that a lobster (or, in analogous terms, any other 'simpler organism') could be said to carry around in the neural machinery that counts as its 'Headquarters'; 'Don't try to go on land!' 'Don't try to eat a squid!' 'Shovel in new sand grains after molting!' 'The large claw is for crushing!' 'The small claw is for seizing and tearing!' And so on. ... What makes eating its own claws 'conveniently unthinkable' is clearly something other than a rule of conduct. 'Convenience' is not a matter of an opportune adaptation but of an astoundingly varied and intricately detailed biological faculty that allows a creature to know its own body and its own body in movement. ... These kinetic cognitional abilities constitute a corporeal consciousness. ... A moment's serious reflection ... discloses a major reason why ... sensitivity to movement is both basic and paramount: no matter what the particular world in which an animal lives, it is not an unchanging world. Hence, whatever the animal, its movement cannot be absolutely programmed such that, for example, at all times its particular speed and direction of movement, its every impulse and stirring, its every pause and stillness, run automatically on something akin to a lifetime tape" (Sheets-Johnstone, 1998, pp. 274-8).

Offering mechanistic explanations for animal behaviors may reveal more about one's commitment to certain assumptions about the mappings between certain presupposed biological and psychological hierarchies of complexity than it does about one's commitment to parsimony of explanation.

All,

Here are some thoughts regarding the hypothesis (as discussed during our last class) that a basic understanding of mirrors plus what we were calling a self-schema might allow chimps to pass the Mirror test just as well as a full-fledged self concept. Dave seemed intrigued by this idea, but rightly pointed out that it was unclear whether the difference between the two views is empirically detectable. During the break, Juraj and I tossed around a few ideas about how an empirical test might work, but didn't really get very far. After a bit more thought, though, I think something along the lines of what we were talking about might work.

To clarify the hypothesis, the idea is that mirrors give a sighted creature visual information about areas of space that are not in the direction the creature's eyes are pointing. In particular, they give us information about areas of space defined by Newton's laws of optics (angle of incidence = angle of reflection). Obviously, chimps don't understand optics, but they might be able to learn by trial and error how to coordinate mirror information with the rest of their visual information in such a way that they could locate objects seen in a mirror, grasp them, and so on. If so, locating the blue spot on their forehead is just a special case of using mirrors to locate things. Once the chimp realizes that the spot is located in a region of space that coincides with its skin, the self-schema can take over. That is, chimps may just be designed in such a way that they take a special interest in the region of space that coincides with their bodies without realizing that it is "their" body.

Falsification of this hypothesis doesn't seem to be a problem. Since the hypothesis sees success in the Mirror test as just a special case of using mirrors to locate things, if chimps can't generally use mirrors to locate things other than themselves, it would be clear that something else was involved in the Mirror test. We might not want to require that they be able to use mirrors at all angles, since arguably the information they get from a mirror at, say, 45 degrees to their line of sight is harder to interpret than the information they get from a mirror that's close to perpendicular to their line of sight. But if it turns out that a chimp can locate spots on his body using the mirror, but not the banana right next to him (hidden from direct line of sight) that would tend to disprove the claim that chimps have a general ability to understand the visual information in mirrors.

Confirming the hypothesis seems to be the hard part. The general trend in the ideas that Juraj and I discussed involved introducing various sorts of degraded visual conditions. The idea was that one of the two competing methods (self-concept vs. self-schema plus an understanding of mirrors) was likely to be harder to adapt to degraded conditions than the other. If so, then we might be able to figure out which method was being used from the way that performance dropped off as a function of the visual degradation. One way of degrading the visual conditions would be to introduce distorting mirrors (i.e. like the ones in fun-houses at carnivals).

Of course, the problem is that I have no idea which of these methods is more/less adaptable to these sorts of conditions. Juraj and I
tried to come up with a priori reasons to think that one task would be
harder than the other, but didn't come up with anything convincing.  The
alternative I've come up with is to use human performance as a baseline
for the relative difficulty of the adaptive tasks.  Presumably, human
beings have both a self-concept and a self-schema with
mirror-understanding.  If we can test these abilities separately in
humans, we might get a quasi-objective measure of which type of process is
more adaptable to fun-house mirrors.  Then we test the chimps and compare
their drop in performance to the way that performance dropped off in
humans to see whether it was more like the drop off on the self-concept
test or the self-schema test.  Here's what I have in mind:

1.  Human self-concept test.  We can't use humans looking at their
own reflections in distorted mirrors, because even the densest human
understands mirrors well enough know that the distorted image is of
himself, even if it is totally unrecognizable.  Instead, we set up a
hidden video camera right on top of a monitor which displays its output.
Now the subject can't rely on his knowledge of the mechanism producing the
image to identify it.  Of course, as soon as he does identitify it, he
will realize that there is a camera somewhere, but  by then we have our
data.  This task should be tried with varying amounts of distortion,
preferably distortion that mimics the distorted mirrors used in the rest
of the test.

2.  Human mirror location test.  Set the mirror up in such a way that
the subject has to use the mirror to locate and grasp some object that he
can't see directly.  Again, we try this with increasingly distorted
mirrors.

The data we get from these two trials should be a learning curve for each
of the tasks.  How long does it take the subjects to figure out how to use
the new (increasingly) distorted mirrors to accomplish 1 and 2?
Presumably, both tasks will get more difficult as the mirrors get more
distorted.  Hopefully, they will get more difficult in characteristically
different ways.  For example, one ability might decline geometrically,
while the other declines linearly, or whatever.  Then, it's the chimps' turn:

3.  Give the Mirror test to the chimps using increasingly distorted
mirrors.  Again, their performance on the test should get worse as the
test gets harder.  If we are lucky, their learning curve for this task
will strongly resemble one, but not the other, of the curves obtained from
1 or 2.  We would then have at least some evidence that the chimp was
using that method.

Obviously, there are some serious experimental difficulties
(comparing the human and chimp data, getting curves that are clearly
different enough to strongly support one hypothesis over the other, just
to name a couple).  The whole thing may just be unworkable, but I thought
I'd throw it out in the open where other more experimentally minded folks
might either find ways to improve it or put it out of its misery.
Suggestions?

Experimentally,
Joel
Since I had to miss out on the discussion of Tuesday, due to illness, I hope that these comments aren't too far off the discussion there. They are a bit tangential, but I think of general interest for assessing the evidential support of primate studies.

In the section "The Meaning of Self-Recognition" Povinelli ties his research together, and comes to the conclusion that great apes have a kinesthetic self-concept, and not a robust psychological self-concept. After reaching this conclusion he tacks on an extra theory about the evolutionary source of a kinesthetic self-concept. My concern is that this add-on is not just another theory which is related and supported by the same evidence, but rather used as a support for Povinelli's primary conclusion. If Povinelli wants the evolutionary theory to play this supporting role, then I think that we must analyze the sort and strength of support that such explanations can give to a theory of current processing.

So we have a story according to which it is of benefit to the great apes to develop a kinesthetic self-concept. They got so big, so fast, maneuvering around in the treetops required a new self-regulation, and a kinesthetic self-concept can play the regulating role. Further it is all that is needed; a psychological self-concept does not help one swing from the trees any better. But what about gorillas? They are an anomaly, being both large, and failing the self-recognition tasks. Is this a counterexample? No, since gorillas are primarily land-dwelling. As land dwellers, they lost the need for fine-grained self-regulation, and lost the kinesthetic self concept. Thus Povinelli's theory can explain the source of the self-concept and its exceptions, and this seems like an additional virtue of the theory.

But is it? While kinesthetic self-regulation can be worked into a historical story, so can psychological self-regulation. Even if the simpler form of self-regulation will do for regulating tree swinging behavior, that does not count against possibility of a more complex form. Only if we accept a further claim (which is often not clearly articulated in these sorts of arguments) that natural selection will pick the minimal way of achieving an ability. To argue in this way is to ignore the real possibility of spandrels, or free-riders, in the evolutionary game. But
while certain theories play this possibility up or down, none deny that we can have an occasional spandrel; appeals to simplicity (particularly when the alternatives are close in complexity) can't be decisive.

While this objection doesn't undermine Povinelli's other arguments, I do think that the introduction of evolutionary explanations (here and elsewhere) can be done in such a way to suggest support without actually giving any. Perhaps support isn't Povinelli's aim in giving his evolutionary explanation. But I think in this case, and in others where support is suggested, we should be critical.

Any comments?
Sarah

I wanted to address some of Sarah's concerns. When Povinelli is talking about kinesthetic self-concept, it actually seems as though he has two arguments in mind, and it is not at all clear that they are compatible.

(2) Heavy Tree Dwellers vs Light Tree Dwellers.
According to Povinelli, those animals which are relatively heavy (ie. 40-80kg) encounter "qualitatively different" problems when moving from tree to tree than do those animals which are lighter. It is not made clear as to exactly what these problems are, but presumably they have something to do with the fact that there are not as many options (with respect to those parts of the tree that can be safely held) for a heavy animal as there are for a light animal. Povinelli hypothesises that the increase in body size of the great apes might have necessitated a "high-level self-representational system" in order to plan their inter- and intra-arboreal movements. This system of self-representation is a "kinesthetic self-concept". Thus self-concept is "an explicit representation of the position and movement of their own bodies".

(2) Tree Dwellers vs Ground Dwellers.
Those great apes which did not remain in the trees will presumably not have required the kinesthetic self-concept. If they are primarily ground-dwellers, then such a self-representation (which is designed to enable inter- and intra-arboreal movement) will be superfluous. Thus we can see how gorillas would not have needed to acquire such a self-concept.

It seems reasonable to assume that tree dwellers need a kinesthetic self-concept that is adequate to enable them to move through trees (although not literally of course!). The idea that this self-concept needs to be somehow better than ground-dweller's seems to me to be in need of further justification, beyond that given in the paper (I don't know - has this been done elsewhere?). Likewise, the idea that heavy animals need a greater self-concept than lighter ones also seems not uncontroversial. I take it, however, that (2) is the more controversial.

According to the logic of (2), it would seem that humans should have less of a kinesthetic concept than do orangutan's, in just the same way as gorillas. Povinelli, however, says that "[h]umans, in contrast, slowed down their growth rate, allowing more years for cognitive development". But why would slowing growth enable cognitive development? It seems in (1) that Povinelli is saying that it is *increased* growth, along with the issues involved with being a tree-dweller that gave rise to the kinesthetic self-concept. Now, however, he asserts that *slower* growth, combined with living on the ground lead to increased cognitive development. It is far from clear that these claims are compatible. In (1), the reason why the kinesthetic self-concept arised was because of the increase in size. In (2) it seems as though cognitive development is possible only given a lack of growth. What is going on here? Perhaps when Povinelli talks about a kinesthetic self-concept, he is talking about something different from cognitive development. But if this is so, then it would seem that humans are a counter-example to his argument. If not, then it is unclear what force his argument has.

Any suggestions?
Simon.

I agree completely with Lis' contention that Gallup's assimilation of consciousness with what he calls "self-consciousness" is confused and more importantly mistaken. If "self-consciousness" in his mouth refers to the kind of thing that the mirror test *might* test for (having a self concept etc.) then self-consciousness has nothing fundamental to do with consciousness. [I add the qualification of "fundamental" here because of course if the deployment of a self concept or a theory of mind is a conscious activity, then it will trivially have *something* to do with consciousness]. With her point against Povinelli and with her discussion of the assumptions regarding complexity, I think Lis is pointing to the fact that questions of animal consciousness are distinct from questions of the complexity of animal cognition. The question of theory of mind in animals, along with matters regarding representation and intentionality, belong in the second category.

It is easy to want to draw conclusions about the presence of consciousness from the degree of representational complexity in an animal species. I know that reading about vervet monkeys in Cheney and Seyfarth's "How Monkeys See the World" (which I highly recommend) had this effect on me, as did seeing a documentary about orangutans. It appears that we pre-theoretically do base our assessment of consciousness on representational or behavioral complexity. The question is whether this is legitimate. I think that there has to be *some* relationship here. One might start by saying that some sort of representational capacity is required for consciousness--maybe only representations are the kinds of things that can be conscious. This would atleast justify not attributing consciousness to rocks. And it might justify the position that anything that is merely a behaviorist organism with no internal representations lacks consciousness. I think this might still be compatible with Lis' suggestion that crabs are conscious, depending on what constraints we place on counting as a representation. But it looks like we need something like this connection between consciousness and representation in order to avoid panpsychism.

I think we also need some kind of assumption about the relationship between consciousness and representation or cognitive complexity in order to even begin an empirical investigation of animal consciousness. I know that I'm conscious directly, and I assume that other human beings are conscious because they are physically similar to me. But what is my inroad to asking whether my cat is conscious? I could notice that she has a brain and base my answer on that--but this would be due to an assumption about what it is that makes me conscious (namely, having a brain). But you might think that having a brain makes me conscious because of what my brain *does*, and something other than a bunch of neurons could perform the same function. And one of the things that my brain does, and which seems closely connected to consciousness, is that it represents states in the environment. So maybe it is this representational capacity that we should look for in non-human animals in order to determine if they are conscious.

Perhaps increased degrees of representational complexity are correlated with different types or degrees of consciousness. This would be a very substantive claim, but if it were true it might justify looking into theory of mind as an insight into something relating to consciousness. Unfortunately I don't think this is what is going on with Gallup's
reasoning.

This leads me to what may be a point of disagreement with Lis. I would want to defend Morgan's Cannon and its use in the case of the mirror test. But this is separable from the first issue Lis points to about conflating consciousness with empathy or self-consciousness. Maybe Gallup is assuming that there is a hierarchy and that consciousness is at the top (such that "lower levels" don't involve consciousness) but this does not follow from his adherence to Morgan's Cannon alone. The placement of consciousness at the top of the purported hierarchy would be the culprit here in my opinion. But the idea of a hierarchy is not problematic, assuming that all is meant here is degree of complexity, etc. Perhaps the term "hierarchy" has moral connotations that are misleading—I would suggest abandoning the term then and just speaking of computational complexity. But it seems to me that Morgan's Cannon is appropriate for asking questions about the computational complexity of various cognitive activities in animals AND in humans. But I agree with Lis that we should be careful about making assumptions about where consciousness fits in with this matter of computational complexity.

Let me emphasize again that I think we should not attribute more complexity than necessary to explain behavior to either animals or humans. This is just Occam's Razor, as Dave mentioned. So my wanting to defend Morgan's Cannon is not the result of human-centrism. And as I suggested earlier, this is especially true given my agreement with Lis that consciousness is not some extra thing at the top of a hierarchy which only humans and maybe "higher" animals possess. Even after applying Morgan's Cannon and offering a "lower level" (in info-processing terms) explanation of an animal's behavior, we might *still* want to attribute consciousness to that animal and even to the processes in question.

Regarding the apparent contradiction between the human possession of a self-concept and the gorillas' apparent lack of one, it seems there is a perfectly good evolutionary explanation for this. It is true that both humans and gorillas are land dwellers rather than tree dwellers. So, by Povinelli's argument, neither has a need for a self-concept. However, gorillas diverged from humans earlier than chimpanzees, which do live in trees. So our self-concept may have developed after our gorilla cousins had already "descended from the trees." When our ancestors adopted a non-tree lifestyle, they already had a self-concept, unlike the gorillas. At first, this self-concept might not have been essential to our survival, but self-concepts are generally useful, so as long as the cost of keeping it isn't too high, it probably won't be bred out. In fact, Povinelli would probably argue that our purportedly more robust sense of self evolved out of the old one because it turned out to be the case that self-concepts are valuable in a wide variety of environments.

Lis' suggestion not to be too anthropocentric reminded me of a wonderful idea that was discussed in class last Tuesday. It was that maybe gorillas notice the spot, but just don't get bothered about it. We seem most able to empathize and then impute consciousness to those species that share our vanities. I, too, will become agitated when my teeth start falling out, and would freak out if someone dyed my hair pink while I was sleeping. If a tell-tale sign of self-consciousness is vanity(and we might recall the pre-university, round about middle- to high-school, use of the word 'self-conscious'), then indeed we might be embarrassed to put self-consciousness at the top of the hierarchy of cognitive complexity.
I wonder not about chimps learning, which is generally considered not to require consciousness, but about chimps teaching. Might not chimps have to empathize with their pupils, believe that the pupils' worldviews are rather akin to their own? Otherwise, it seems chimps couldn't be all that hopeful of success in teaching.

I still find Nagel's article to be rather defeatist. First of all there exists an essential otherness to another subject's point of view that prevents me from ever fully comprehending that subject's experience, at least as far as imagination might be a means of getting closer to what it is like for a subject to experience something as that subject. And Nagel thinks this, imagination or "adopting [the subject's] point of view", is most natural way we go about answering the question What is it like...? Imagination gets us part of the way because it is something like experience, which is the means by which we know "what it is like to be us." Indeed, in trying to access the phenomenality of a bat, "The best evidence would come from the experience of bats, if we only knew what they were like." Experience or the imagination of experience, and not explanation, is the most common way of answering What is it like? And although, because in part of a recognition of the constraints on our capacities for experience and imagination, we realize we must turn to explanations in order to answer the question in the case of other subjects, especially those from other species, still we are frustrated by the unfeeling answers of a primitive science. So when we measure them against our expectations of a true and robust answer, we inevitably find objective answers lacking. "If the subjective character of experience is fully comprehensible only from one point of view, then any shift to greater objetivity--that is, less attachment to a specific viewpoint--does not take us nearer to the real nature of the phenomenon: it takes us farther away from it."

This last quote of Nagel's is bleak. Moving towards a more objective perspective is wrongheaded, and gaining the subject's point of view is impossible. I think Nagel recognizes that a move towards the objective is wrongheaded only insofar as such a move is presently counterintuitive. But our present intuition is that the only satisfactory answer to What is it like...? is an experience or imagination thereof. If a science of consciousness could explain "_how_" the physical and the mental are linked, maybe one could learn to accept physicalist answers, which should in turn allow robust answers to Nagel's title question, and others like it. Akins' article demonstrates the substantial success one can have in moving towards the objective, and incidentally, as we explored in class, give us a much more accurate idea of what we might try to imagine.

But I did have one problem with Akins' article. How are decibels measured? The mustached bat emits beeps and swooping screeches at 100 decibels, "as loud as a rock concert." The jungle must be a terrifying place at night! But how is this supposed to work, since a rock concert can be heard for miles, but a bat can only count on its music carrying a measly six feet?

INDV 101 - PHILOSOPHICAL PERSPECTIVES ON THE INDIVIDUAL - PAPER TOPICS

SECOND PAPER

Due at the beginning of class (2pm), Wednesday December 1, 1999. This should be a 4-5 page typed, doubled-spaced paper. Include your name and your TA's name on the front. Late papers will be penalized at a rate of one letter-grade per day.

You have the option of submitting a rough draft of your paper to your TA by 2pm on Monday November 22. Your TA will return it to you with comments on Monday November 29, and the final draft will be due at the normal time. Assessment is based on the final draft. This process is optional but recommended, both to improve your paper and to improve your grade.

For instructions on how to write a philosophy paper, read the following carefully!

- Writing a Philosophy Paper (Peter Horban)
- Guide to the Study of Philosophy (Garth Kemerling)
- What Does He Want? (Geoffrey Payzant)
- Undergraduate Philosophical Writing (Martin Young)
- Guidelines on Writing a Philosophy Paper (James Pryor)

1. Present and explain Jackson's argument against materialism. Critically assess the argument. Is it valid? Are the premises true? What would an intelligent opponent (say, Jackson if you are arguing against him, or a smart materialist if you agree with Jackson) say to rebut your analysis? Present their case as strongly as possible, then rebut it.

2. Present and explain Chalmers' distinction between the "easy" and the "hard" problems of consciousness, and his argument that no purely physical approach can solve the hard problem. Critically assess the argument. Does it establish its conclusion? What would an intelligent opponent say to rebut your analysis? Present their case as strongly as possible, then rebut it.

3. Present and explain either the "perfect actor" or "super-Spartan" argument against behaviorism. Put the argument in the form of a formal argument, and then critically assess it. Is it valid? Are the premises true? What would an intelligent opponent say to rebut your analysis? Present their case as strongly as possible, then rebut it.

4. An argument against free will runs as follows: (1) If determinism is true, we have no free will, (2) Determinism is true, so (3) We have no free will. Assess the argument. If you do not accept the conclusion, which premise do you reject, and why? Depending on your choice, defend your position by answering the following questions, with reasons:
If you reject premise 1: How can free will be compatible with determinism? Isn't a deterministic life like a boat that is steering down a single underlying track with no freedom? How can we make sense of moral responsibility and choice if all actions are predetermined?

If you reject premise 2: How can nondeterminism support free will any better? If decisions are determined by random dice-rolling, is this really something that we have control over? And if we control the dice-rolling, isn't that determinism after all?

If you accept the conclusion: If there is no free will, how can there be moral responsibility? What is the difference between actions we are responsible for and actions we are not responsible for, if it is not the fact that we chose freely? If there is no freedom or moral responsibility, is it fair to punish people for acts for which they were not responsible?

**FIRST PAPER**

Due at the beginning of class (2pm), Monday October 4, 1999. This should be a 4-5 page typed, doubled-spaced paper. Include your name and your TA's name on the front. Late papers will be penalized at a rate of one letter-grade per day.

1. Present and explain one of Descartes' arguments for his version of dualism. Critically assess the argument. Is it valid? Are the premises true? What would an intelligent opponent (say, Descartes if you are arguing against him, or a smart materialist if you agree with Descartes) say to rebut your analysis? Present their case as strongly as possible, then rebut it.

2. Smullyan's piece "An Unfortunate Dualist" is intended to cast doubt on dualism. Set out explicitly the argument that you think is underlying Smullyan's reasoning. Critically assess this argument (validity and premises). How would a (smart) interactionist respond? How would a (smart) epiphenomenalist respond? What do you think the upshot is?

3. Present Descartes' skeptical challenge (for the conclusion that we cannot know about external reality) in the form of an argument. Critically assess this argument (validity and premises). If you think the argument fails and that you can know that external reality exists, say how you think this knowledge is possible. If you think the argument succeeds, what do you think the upshot is? Either way: what would an intelligent opponent say to rebut your analysis, and how would you respond?

4. You are Keanu Reeves (Neo) in "The Matrix". Laurence Fishburne (Morpheus) finds you and tells you that you are in the Matrix, and says he will help you return to the real world. Is there any way for you to truly know that you are in the Matrix to start with, or that you are in reality later? If yes, could the movie situation be modified so that you could not know these things? If you cannot truly know, is it rational for you to believe that you are in the Matrix at the beginning or that you are in the reality later? Give reasons in every case, present at least some aspect of your reasoning in the form of a formal argument, and
answer objections from an intelligent opponent who would disagree with you. What does this situation teach us about knowledge and external reality, and why?

Bonus question: (no formal credit for this, but fun): Are there any philosophical flaws in the movie "The Matrix"? Give reasons.

Consciousness has scientists of all kinds scheming. Dr. Piet Hut, a physicist, offers this sketch: the objective world (o), with person and chair; the subjective experience of the world (s), in the balloon; the empirical understanding of the world, including physics (o prime), in the smaller rectangle; and the empirical understanding of subjective experience, including psychology, (s prime), in the really small balloon. Dr. Hut argues that when s and s prime are conflated, confusion reigns.
