Experimental researchers don't rely only on these principles of verbal report and reportability. These principles can be somewhat limiting when we want to do broader experiments. In particular, we don't want to just restrict our studies of consciousness to subjects that have language. In fact just this morning we saw a beautiful example of research on consciousness in language-free creatures. I'm referring to the work of Nikos Logothetis and his colleagues (e.g. Logothetis & Schall 1989; Leopold & Logothetis 1996). This work uses experiments on binocular rivalry in monkeys to draw conclusions about the neural processes associated with consciousness. How do Logothetis et al manage to draw conclusions about a monkey's consciousness without getting any verbal reports? What they do is rely on a monkey's pressing bars: if a monkey can be made to press a bar in an appropriate way in response to a stimulus, we'll say that that stimulus was consciously perceived.

The criterion at play seems to be require that the information be available for an arbitrary response. If it turned out that the monkey could press a bar in response to a red light but couldn't do anything else, we would be tempted to say that it wasn't a case of consciousness at all, but some sort of subconscious connection. If on the other hand we find information that is available for response in all sorts of different ways, then we'll say that it is conscious. Actually Logothetis and his colleagues also use some subtler reasoning about similarities with binocular rivalry in humans to buttress the claim that the monkey is having the relevant conscious experience, but it is clearly the response that carries the most weight.

The underlying general principle is something like this: When information is directly available for global control in a cognitive system, then it is conscious. If information is available for response in many different motor modalities, we will say that it is conscious, at least in a range of relatively familiar systems such as humans and primates and so on. This principle squares well with the previous principle in cases where the capacity for verbal report is present: availability for verbal report and availability for global control seem to go together in such cases (report is one of the key aspects of control, after all, and it is rare to find information that is reportable but not available more widely). But this principle is also applicable more widely.

A correlation between consciousness and global availability (for short) seems to fit the first-person evidence - the evidence gleaned from our own conscious experience - quite well. When information is present in my consciousness, it is generally reportable, and it can generally be brought to bear in the control of behavior in all sorts of different ways. I can talk about it, I can point in the general direction of a stimulus, I can press bars, and so on. Conversely, when we find information that is directly available in this way for report and other aspects of control, it is generally conscious information. I think one can bear this out by consideration of cases.

There are some interesting puzzle cases to consider, such as the case of blindsight, where one has some kind of availability for control but arguably no conscious experience. Those cases might best be handled by invoking the directness criterion: insofar as the information here is available for report and other control processes at all, it is available only indirectly, by comparison to the direct and automatic
availability in standard cases. One might also stipulate that it is availability for voluntary control that is relevant, to deal with certain cases of involuntary unconscious response, although that is a complex issue. I discuss a number of puzzle cases in more detail elsewhere (Chalmers 1996, forthcoming), where I also give a much more detailed defence of the idea that something like global availability is the key pre-empirical criterion for the ascription of consciousness.

But this remains at best a first-order approximation of the functional criteria that come into play. I'm less concerned today to get all the fine details right than to work with the idea that some such functional criterion is required and indeed is implicit in all the empirical research on the neural correlate of consciousness. If you disagree with the criterion I've suggested here - presumably because you can think of counterexamples - you may want to use those counterexamples to refine it or to come up with a better criterion of your own. But the point I want to focus on here is that in the very act of experimentally distinguishing conscious from unconscious processes, some such criterion is always at play.

So the question I want to ask is: if something like this is right, then what follows? That is, if some such bridging principles are implicit in the methodology of the search for the NCC, then what are the consequences? I will use global availability as my central functional criterion in the discussion that follows, but many of the points should generalize.

The first thing one can do is produce what philosophers might call a rational reconstruction of the search for the neural correlate of consciousness. With a rational reconstruction we can say, maybe things don't work exactly like this in practice, but the rational underpinnings of the process have something like this form. That is, if one were to try to justify the conclusions one has reached as well as one can, one's justification would follow the shape of the rational reconstruction. In this case, a rational reconstruction might look something like this:

(1) Consciousness <-> global availability (bridging principle)

(2) Global availability <-> neural process N (empirical work)

so

(3) Consciousness <-> neural process N (conclusion).

According to this reconstruction, one implicitly embraces some sort of pre-experimental bridging principle that one finds plausible on independent grounds, such as conceptual or phenomenological grounds. Then one does the empirical research. Instead of measuring consciousness directly, we detect the functional property. One sees that when this functional property (e.g. global availability) is present, it is correlated with a certain neural process (e.g. 40-hertz oscillations). Combining the pre-empirical premise and the empirical result, we arrive at the conclusion that this neural process is a candidate for the NCC.
Of course it doesn't work nearly so simply in practice. The two stages are very intertwined; our pre-experimental principles may themselves be refined as experimental research goes along. Nevertheless I think one can make a separation, at least at the rational level, into pre-empirical and experimental components, for the sake of analysis. So with this sort of rational reconstruction in hand, what sort of conclusions follow? There are about six consequences that I want to draw out here.

(1) The first conclusion is a characterization of the neural correlates of consciousness. If the NCC is arrived at through this sort of methodology, then whatever it turns out to be, it will be a mechanism of *global availability*. The presence of the NCC wherever global availability is present suggests that it is a mechanism that *subserves* the process of global availability in the brain. The only alternative that we have to worry about is that it might be a *symptom* rather than a *mechanism* of global availability; but that possibility ought to be addressable in principle by dissociation studies, by lesioning, and so on. If a process is a mere symptom of availability, we ought to be able to empirically dissociate it from the process of global availability while leaving the latter intact. The resulting data would suggest to us that consciousness can be present even when the neural process in question is not, thus indicating that it wasn't a perfect correlate of consciousness after all.

(A related line of reasoning supports the idea that a true NCC must be a mechanism of *direct* availability for global control. Mechanisms of indirect availability will in principle be dissociable from the empirical evidence for consciousness, for example by directly stimulating the mechanisms of direct availability. The indirect mechanisms will be "screened off" by the direct mechanisms in much the same way as the retina is screened off as an NCC by the visual cortex.)

In fact, if one looks at the various proposals that are out there, this template seems to fit them pretty well. For example, the 40-hertz oscillations discussed by Crick and Koch were put forward precisely because of the role they might play in binding and integrating information into working memory, and working memory is of course a central mechanism whereby information is made available for global control in a cognitive system. Similarly, it is plausible that Libet's extended neural activity is relevant precisely because the temporal extendedness of activity is what gives certain information the capacity to dominate later processes that lead to control. Baars' global workspace is a particularly explicit proposal of a mechanism in this direction; it is put forward explicitly as a mechanism whereby information can be globally disseminated. All of these mechanisms and many of the others seem to be candidates for mechanisms of global availability in the brain.

(2) This reconstruction suggests that a full story about the neural processes associated with consciousness will to do two things. Firstly, it will *explain* global availability in the brain. Once we know all about the relevant neural processes, we will know precisely how information is made directly available for global control in the brain, and this will be an explanation in the full sense. Global availability is a functional property, and as always the problem of explaining the performance of a function is a problem to which...
mechanistic explanation is well-suited. So we can be confident that in a century or two global availability will be straightforwardly explained. Secondly, this explanation of availability will do something else: it will isolate the processes that *underlie* consciousness itself. If the bridging principle is granted, then mechanisms of availability will automatically be correlates of phenomenology in the full sense.

Now, I don't think this gives us a full *explanation* of consciousness. One can always raise the question of why it is that these processes of availability should give rise to consciousness in the first place. As yet we have no explanation of why this is, and it may well be that the full details concerning the processes of availability still won't answer this question. Certainly, nothing in the standard methodology I have outlined answers the question; that methodology *assumes* a relation between availability and consciousness, and therefore does nothing to *explain* it. The relationship between the two is instead taken as something of a primitive. So the hard problem still remains. But who knows: somewhere along the line we may be led to the relevant insights that show why the link is there, and the hard problem may then be solved. In any case, whether or not we have solved the hard problem, we may nevertheless have isolated the *basis* of consciousness in the brain. We just have to keep in mind the distinction between correlation and explanation.

(3) Given this paradigm, it is likely that there are going to be many different neural correlates of consciousness. I take it that this is not going to surprise many people; but the rational reconstruction gives us a way of seeing just why such a multiplicity of correlates should exist. There will be many neural correlates of consciousness because there may well be many different mechanisms of global availability. There will be mechanisms of availability in different modalities: the mechanisms of visual availability may be quite different from the mechanisms of auditory availability, for example. (Of course they *may* be the same, in that we could find a later area that integrates and disseminates all this information, but that's an open question.) There will also be mechanisms at different stages of the processing path whereby information is made globally available: early mechanisms and later ones. So these may all be candidates for the NCC. And there will be mechanisms at many different levels of description: for example, 40-hertz oscillations may well be redescribed as high-quality representations, or as part of a global workspace, at a different level of description. So it may turn out that a number of the animals in the zoo, so to speak, can co-exist, because they are compatible in one of these ways.

I won't speculate much further on just what the neural correlates of consciousness *are*. No doubt some of the ideas in the initial list will prove to be entirely off-track, while some of the others will prove closer to the mark. As we philosophers like to say, humbly, that's an empirical question. But I hope the conceptual issues are becoming clearer.

(4) This way of thinking about things allows one to make sense of a idea that is sometimes floated: that of a *consciousness module*. Sometimes this notion is disparaged; sometimes it is embraced. But this picture of the methodology in the search for an NCC suggests that it is at least possible that there could
turn out to be such a module. What would it take? It would require that there turns out to be some sort of functionally localizable, internally integrated area, through which all global availability runs. It needn't be anatomically localizable, but to qualify as a module it would need to be localizable in some broader sense. For example, the parts of the module would have to have high-bandwidth communication among themselves, compared to the relatively low-bandwidth communication that they have with other areas. Such a thing could turn out to exist. It doesn't strike me as especially likely that things will turn out this way; it seems just as likely that there will be multiple independent mechanisms of global availability in the brain, scattered around without any special degree of mutual integration. If that's so, we will likely say that there doesn't turn out to be a consciousness module after all. But that's another one of those empirical questions.

If something like this does turn out to exist in the brain, it would resemble Baars' conception of a global workspace: a functional area responsible for the integration of information in the brain and for its dissemination to multiple nonconscious specialized processes. In fact I should acknowledge that many of the ideas I'm putting forward here are compatible with things that Baars has been saying for years about the role of global availability in the study of consciousness. Indeed, this way of looking at things suggests that some of his ideas are almost forced on one by the methodology. The special epistemological role of global availability helps explain why the idea of a global workspace provides a useful way of thinking about almost any empirical proposal about consciousness. If NCC's are identified as such precisely because of their role in global control, then at least on a first approximation, we should expect the global workspace idea to be a natural fit.

(5) We can also apply this picture to a question that has been discussed frequently at this conference: are the neural correlates of visual consciousness to be found in V1, in the extrastriate visual cortex, or elsewhere? If our picture of the methodology is correct, then the answer will presumably depend on which visual area is most directly implicated in global availability.

Crick and Koch have suggested that the visual NCC is not to be found within V1, as V1 does not contain neurons that project to the prefrontal cortex. This reasoning has been criticized by Ned Block for conflating access consciousness and phenomenal consciousness (see Block, this volume); but interestingly, the picture I have developed suggests that it may be good reasoning. The prefrontal cortex is known to be associated with control processes; so if a given area in the visual cortex projects to prefrontal areas, then it may well be a mechanism of direct availability. And if it does not project in this way, it is less likely to be such a mechanism; at best it might be indirectly associated with global availability. Of course there is still plenty of room to raise questions about the empirical details. But the broader point is that for the sort of reasons discussed in (2) above, it is likely that the neural processes involved in explaining access consciousness will simultaneously be involved in a story about the basis of phenomenal consciousness. If something like this is implicit in their reasoning, Crick and Koch might escape the charge of conflation. Of course the reasoning does depend on these somewhat shaky bridging principles, but then all work on the neural correlates of consciousness must appeal to such principles somewhere, so this can't be held against Crick and Koch in particular.
(6) Sometimes the neural correlate of consciousness is conceived of as the Holy Grail for a theory of consciousness. It will make everything fall into place. For example, once we discover the NCC, then we'll have a definitive test for consciousness, enabling us to discover consciousness wherever it arises. That is, we might use the neural correlate itself as a sort of consciousness meter. If a system has 40-hertz oscillations (say), then it is conscious; if it has none, then it is not conscious. Or if a thalamocortical system turns out to be the NCC, then a system without that system is unlikely to be conscious. This sort of reasoning is not usually put quite so baldly as this, but I think one finds some version of it quite frequently.

This reasoning can be tempting, but one should not succumb to the temptation. Given the very methodology which comes into play here, there is no way to definitely establish a given NCC as an independent test for consciousness. The primary criterion for consciousness will always remain the functional property we started with: global availability, or verbal report, or whatever. That's how we discovered the correlations in the first place. 40-hertz oscillations (or whatever) are relevant only because of the role they play in satisfying this criterion. True, in cases where we know that this association between the NCC and the functional property is present, the NCC might itself function as a sort of "signature" of consciousness; but once we dissociate the NCC from the functional property, all bets are off. To take an extreme example, if we have 40-hertz oscillations in a test tube, that almost certainly won't yield consciousness. But the point applies equally in less extreme cases. Because it was the bridging principles that gave us all the traction in the search for an NCC in the first place, it's not clear that anything follows in cases where the functional criterion is thrown it away. So there's no free lunch here: one can't get something for nothing.

Once one recognizes the central role that pre-experimental assumptions play in the search for the NCC, one realizes that there are some limitations on just what we can expect this search to tell us. Still, whether or not the NCC is the Holy Grail, I hope that I have said enough to make it clear that the quest for it is likely to enhance our understanding considerably. And I hope to have convinced you that there are important ways in which philosophy and neuroscience can come together to help clarify some of the deep problems involved in the study of consciousness.

It was first presented at Association for the Scientific Study of Consciousness conference on "Neural Correlates of Consciousness" in Bremen, June 1998.]]

1 Introduction

The search for neural correlates of consciousness (or NCCs) is arguably the cornerstone in the recent resurgence of the science of consciousness. The search poses many difficult empirical problems, but it seems to be tractable in principle, and some ingenious studies in recent years have led to considerable progress. A number of proposals have been put forward concerning the nature and location of neural correlates of consciousness. A few of these include:

- 40-hertz oscillations in the cerebral cortex (Crick and Koch 1990)
- Intralaminar nuclei in the thalamus (Bogen 1995)
- Re-entrant loops in thalamocortical systems (Edelman 1989)
- 40-hertz rhythmic activity in thalamocortical systems (Llinas et al 1994)
- Extended reticular-thalamic activation system (Newman and Baars 1993)
- Neural assemblies bound by NMDA (Flohr 1995)
- Certain neurochemical levels of activation (Hobson 1997)
- Certain neurons in inferior temporal cortex (Sheinberg and Logothetis 1997)
- Neurons in extrastriate visual cortex projecting to prefrontal areas (Crick and Koch 1995)
- Visual processing within the ventral stream (Milner and Goodale 1995)

(A longer list can be found in Chalmers 1998. Review articles on neural correlates of consciousness, especially visual consciousness, can be found in Crick and Koch 1998 and Milner 1995.)

As the full title of this book ("Neural Correlates of Consciousness: Empirical and Conceptual Issues") suggests, all this activity raises a number of difficult conceptual and foundational issues. I can see at least five sorts of foundational questions in the vicinity.

- (1) What do we mean by 'consciousness'?
What is a Neural Correlate of Consciousness?

- (2) What do we mean by 'neural correlate of consciousness'?
- (3) How can we find the neural correlate(s) of consciousness?
- (4) What will a neural correlate of consciousness explain?
- (5) Is consciousness reducible to its neural correlate(s)?

The first two questions here are conceptual questions, the third is an epistemological or methodological question, the fourth is an explanatory question, and the fifth is an ontological question. The first, fourth, and fifth are versions of general questions that philosophers have discussed for a long time (my own view on them is in Chalmers (1995; 1996)). The second and third questions are more specific to the NCC investigation. I have discussed the third question in Chalmers (1998). Here I want to focus on the second question.

What does it mean to be a neural correlate of consciousness? At first glance, the answer might seem to be so obvious that the question is hardly worth asking. An NCC is just a neural state that directly correlates with a conscious state, or which directly generates consciousness, or something like that. One has a simple image: when your NCC is active, perhaps, your consciousness turns on, and in a corresponding way. But a moment's reflection suggests that the idea is not completely straightforward, and that the concept needs some clarification.

Here, I will attempt a little conceptual spadework in clarifying the concept of an NCC. I don't know that this is the deepest problem in the area, but it seems to me that if we are looking for an NCC, it makes sense to get clear on what we are looking for. On the way I will try to make contact with some of the empirical work in the area, and see what concept of NCC is at play in some of the central work in the field. I will also draw out some consequences for the methodology of empirical work in the search. Most of this is intended as a first step rather than a last word. Much of what I say will need to be refined, but I hope at least to draw attention to some interesting issues in the vicinity.

As a first pass, we can use the definition of a neural correlate of consciousness given in the program of the ASSC conference. This says a neural correlate of consciousness is a "specific system in the brain whose activity correlates directly with states of conscious experience". This yields something like the following:

A neural system N is an NCC if the state of N correlates directly with states of consciousness.

There are at least two things to get clear on here. First, what are the relevant "states of consciousness"? Second, what does it mean for a neural state to "correlate directly" with states of consciousness? I'll look into both these things in turn.

2 States of consciousness

I will take it that the states of consciousness we are concerned with here are all states of subjective experience, or equivalently, states of phenomenal consciousness. But what sort of states are relevant? In
What is a Neural Correlate of Consciousness?

in the NCC literature, I can see a few different classes of state that are sometimes considered.

(i) Being conscious

The first option is that the states in question are just those of being conscious and of not being conscious. The corresponding notion of an NCC will be that of a neural system whose state directly correlates with whether a subject is conscious or not. If the NCC is in a particular state, the subject will be conscious. If the NCC is not in that state, the subject will not be conscious.

This is perhaps the idea that first comes to mind when we think about an NCC. We might think about it as the "neural correlate of creature consciousness", where creature consciousness is the property a creature has when it is conscious, and lacks when it is not conscious.

Although this is an interesting notion, it does not seem to capture the sort of NCC that most work in the area is aimed at. As we'll see, most current work is aimed at something more specific. There are some ideas that can be taken as aiming at least in part at this notion, though. For example, the ideas of Bogen (1995) about the intralaminar nucleus seem to be directed at least in part at this sort of NCC.

Examining current work, it's interesting to note that insofar as there is any consensus at all about the location of this sort of NCC, the dominant view seems to be that it should be in or around the thalamus, or at least that it should involve interactions between the thalamic and cortical systems in a central role. Penfield (1937) argued that "the indispensable substratum of consciousness" lies outside the cerebral cortex, and probably lies in the diencephalon (thalamus, hypothalamus, subthalamus, epithalamus). This theme has been taken up in recent years by Bogen, Newman and Baars (1993), and others.

(ii) Background state of consciousness

A related idea is that of the neural correlate of what we might call the background state of consciousness. A background state is an overall state of consciousness such as being awake, being asleep, dreaming, being under hypnosis, and so on. Exactly what counts as a background state is not entirely clear, as one can divide things up in a number of ways, and with coarser or finer grains, but presumably the class will include a range of normal and of "altered" states.

We can think of this as a slightly more fine-grained version of the previous idea. Creature consciousness is the most coarse-grained background state of consciousness: it is just the state of being conscious. Background states will usually be more fine-grained than this, but they still will not be defined in terms of specific contents or modalities.

A neural correlate of the background state of consciousness, then, will be a neural system N such that the state of N directly correlates with whether a subject is awake, dreaming, under hypnosis, and so on. If N is in state 1, the subject is awake; if N is in state 2, the subject is dreaming; if N is in state 3, the subject is under hypnosis; and so on.
It may well be that some of the thalamocortical proposals discussed above are intended as, or might be extended into proposals about this sort of NCC. A more direct example is given by Hobson's (1997) ideas about neurochemical levels of activation. Hobson holds that these levels can be grouped into a three-dimensional state-space, and that different regions in this space correspond to different overall states of consciousness: wakefulness, REM sleep, nonREM sleep, and so on. When chemical levels are in a particular region in this space, the subject will be awake; when in another region, the subject will be in REM sleep; and so on. On this reading, one might see the neurochemical system as an NCC of the sort characterized above, with the different regions in state space corresponding to correlates of the various specific background states.

(iii) Contents of consciousness

There is much more to consciousness than the mere state of being conscious, or the background state of consciousness. Arguably the most interesting states of consciousness are specific states of consciousness: the fine-grained states of subjective experience that one is in at any given time. Such states might include the experience of a particular visual image, of a particular sound pattern, of a detailed stream of conscious thought, and so on. A detailed visual experience, for example, might include the experience of certain shapes and colors in one's environment, of specific arrangements of objects, of various relative distances and depths, and so on.

Specific states like these are most often individuated by their content. Most conscious states seem to have some sort of specific representational content, representing the world as being one way or another. Much of the specific nature of a visual experience, for example, can be characterized in terms of content. A visual experience typically represents the world as containing various shapes and colors, as containing certain objects standing in certain spatial relations, and so on. If the experience is veridical, the world will be the way the experience represents it as being. If the experience is an illusion or is otherwise misleading, the world will be other than the experience represents it as being. But either way, it seems that visual experiences typically have detailed representational content. The same goes for experiences in other sensory modalities, and arguably for many or most nonsensory experiences as well.

Much of the most interesting work on NCCs is concerned with states like these. This is work on the neural correlates of the contents of consciousness. Much work on the neural correlates of visual consciousness has this character, for example. This work is not concerned merely with the neural states that determine that one has visual consciousness; it is concerned with the neural states that determine the specific contents of visual consciousness.

A nice example is supplied by the work of Logothetis and colleagues on the NCC of visual consciousness in monkeys (Logothetis and Schall 1989; Leopold and Logothetis 1996; Sheinberg and Logothetis 1997). In this work, a monkey is trained to press various bars when they are confronted with various sorts of images: horizontal and vertical gratings, for example, or gratings drifting left and right, or faces and sunbursts (I will use horizontal and vertical gratings for the purposes of illustration). After training is complete, the monkey is presented with two stimuli at once, one to each eye. In humans, this usually
What is a Neural Correlate of Consciousness?

produces binocular rivalry, with alternating periods of experiencing a definite image, and occasional partial overlap. The monkey responds by pressing bars, in effect "telling" the experimenter what it is seeing: a horizontal grating, or a vertical grating, or an interlocking grid.

At the same time, neurons in the monkey's cortex are being monitored by electrodes. It is first established that certain neurons respond to certain stimuli: to horizontal lines, for example, or to flowers. Then these neurons are monitored in the binocular rivalry situation, to see how well they correlate with what the monkey seems to be seeing. It turns out that cells in primary visual cortex (V1) don't correlate well: when the monkey is stimulated with horizontal and vertical gratings but "sees" horizontal, a large number of "vertical" cells in V1 fire, as well as "horizontal" cells. At this point, most cells seem to correlate with retinal stimulus, not with visual percept. But further into the visual system, the correlation increases, until in inferior temporal cortex, there is a very strong correlation. When the monkey is stimulated with horizontal and vertical grating but "sees" horizontal, almost all of the relevant horizontal cells in IT fire, and almost none of the vertical cells do. When the monkey's response switches, indicating that it is now "seeing" vertical, the cell response switches accordingly.

These results lend themselves naturally to speculation about the location of a visual NCC. It seems that V1 is unlikely to be or involve an NCC, for example, due to the failure of V1 cells to correlate with the contents of consciousness. Of course there are still the possibilities that some small subset of V1 is an NCC, or that V1 is a neural correlate of some aspects of visual consciousness but not of others, but I leave those aside for now. On the other hand, IT seems to be a natural candidate for the location of an NCC, due to the strong correlation of its cells with the content of consciousness. At least it is natural to suppose that IT is a "lower bound" on the location of a visual NCC (due to the failure of strong correlation before then), though the NCC itself may be further in. None of this evidence is conclusive (and Logothetis and colleagues are appropriately cautious), but it is at least suggestive.

It is clear that this work is concerned with the neural correlates of the contents of visual consciousness. We are interested in finding cortical areas whose neural activity correlates with and predicts specific contents of consciousness, such as experiences of horizontal or vertical lines, or of flowers or sunbursts. The ideal is to find a neural system from whose activity we might determine the precise contents of a visual experience, or at least of its contents in certain respects (shape, color, and the like).

Interestingly, it seems that in doing this we are crucially concerned with the the representational contents of the neural systems themselves. In the Logothetis work, for example, it is important to determine the receptive fields of the cells (whether they respond to horizontal or vertical gratings, for example), in order to see whether the receptive fields of active cells matches up with the apparent contents of visual consciousness. In essence, the receptive field is acting at least as a heuristic way of getting at representational content in the neurons in question. Then, the crucial question is whether the representational content in the neural system matches up with the representational content in visual consciousness.

This suggests a natural definition of a neural correlate of the contents of consciousness.
A neural correlate of the contents of consciousness is a neural representational system N such that representation of a content in N directly correlates with representation of that content in consciousness.

Or, more briefly:

A content NCC is a neural representational system N such that the content of N directly correlates with the content of consciousness.

For example, the Logothetis work lends itself to the speculation that IT might contain a content NCC for visual consciousness, since the content of cells in IT seems to directly correlate (at least in these experiments) with the contents of visual consciousness. (Much more investigation is required to see whether this correlation holds across the board, of course.)

This definition requires that we have some way of defining the representational content of a neural system independent of the contents of consciousness. There are various ways to do this. Using a cell's receptive field to define its representational content is probably the simplest. A more refined definition might also give a role to a system's projective field, and the sort of behavior that activity in that system typically leads to. And there may be more complex notions of representational content still, based on complex correlations with environment, patterns of behavior, and activity in other cells. But even a crude definition of representational content (e.g., the receptive field definition) is good enough for many purposes, and can yield informative results about the visual NCC.

It's arguable that much work on the visual NCC tacitly invokes this sort of definition. Another example is Milner and Goodale's work on the two pathways of visual perception. They suggest that the ventral stream is largely for cognitive identification and decision, while the dorsal stream is largely for online motor response, and the visual consciousness correlates with activity in the ventral stream.

Much of the support for this work lies with patients who have dissociations between specific contents of conscious perception and the contents involved in motor response. For example, a subject with visual form agnosia (e.g. Milner and Goodale's patient D.F.) cannot consciously identify a vertical slot, but can "post" an envelope through it without problem; while subjects with optic ataxia (e.g. those with Balint's (1909) syndrome) can identify an object but cannot act appropriately toward it. The dissociations here appear to go along with damage to the ventral and dorsal pathways respectively.

What seems to be going on, on a natural interpretation of these results and of Milner and Goodale's hypothesis, is that for these subjects, there is a dissociation between the contents represented in the ventral pathways and those represented in the dorsal pathway. In these cases, the character of a motor response appears to be determined by the contents represented in the dorsal pathway, but the character of conscious perception appears to be determined by the contents represented in the ventral pathway.

Thus one can see Milner and Goodale's hypothesis as involving the suggestion that the ventral stream
What is a Neural Correlate of Consciousness?

contains the neural correlates of the contents of visual consciousness. The hypothesis is quite speculative, of course (though it is interesting to note that IT lies in the ventral stream), but it seems that the content-based analysis provides a natural interpretation of what the hypothesis is implicitly claiming regarding the visual NCC, and of what may follow if the hypothesis turns out to be correct.

One could give a similar analysis of much or most work on the visual NCC. When Crick and Koch (1998) propose that the visual NCC lies outside V1, for example, much of the experimental evidence they appeal to involves cases where some content is represented in consciousness but not in V1, or vice versa. For example, Gur and Snodderly (1997) show that for some quickly alternating isoluminant color stimuli, color cells in V1 flicker back and forth even though a single fused color is consciously perceived. And results by He et al (1996) suggest that orientation of a grating can fade from consciousness even though orientation cells in V1 carry the information. The results are not entirely conclusive, but they suggest a mismatch between the representational content in V1 and the content of consciousness.

One can apply this sort of analysis equally to NCCs in other sensory modalities. An NCC of auditory consciousness, for example, might be defined as a neural representational system whose contents correlate directly with the contents of auditory consciousness: loudness, direction, pitch, tone, and the like. The idea can arguably apply to defining the neural correlates of bodily sensations, of conscious mental imagery, and perhaps of conscious emotion and of the stream of conscious thought. All these aspects of consciousness can be naturally analyzed (at least in part) in terms of their content. In looking for their respective NCCs, we may ultimately be looking for neural systems whose content correlates with the contents of these aspects of consciousness.

(iv) Arbitrary phenomenal properties

(This section is a little more technical than those above, and might be skipped by those not interested in philosophical details.)

One might try to give a general definition of an NCC of various states of consciousness, of which each of the above would be a special case. To do this, one would need a general way of thinking about arbitrary states of consciousness. Perhaps the best way is to think in terms of arbitrary phenomenal properties. For any distinctive kind of conscious experience, there will be a corresponding phenomenal property: in essence the property of having a conscious experience of that kind. For example, being in a hypnotic state of consciousness is a phenomenal property; having a visual experience of a horizontal line is a phenomenal property; feeling intense happiness is a phenomenal property; feeling a throbbing pain is a phenomenal property; being conscious is a phenomenal property. Phenomenal properties can be as coarse-grained or as fine-grained as you like, as long as they are wholly determined by the current conscious state of the subject.

With this notion in hand, one might try to define the neural correlate of an arbitrary phenomenal property P.

A state N1 of system N is a neural correlate of phenomenal property P if N's being in N1
What is a Neural Correlate of Consciousness?

Note that we here talk of a state being an NCC. Given a specific phenomenal property - experiencing a horizontal line, for example, it is no longer clear that it makes sense to speak of a given system being the NCC of that property. Rather, it will be a particular state of that system. Neural firing in certain horizontal cells in IT (say) might be a neural correlate of seeing a horizontal line, for example; and having one's neurochemical system in a certain region of state space might be a neural correlate of waking consciousness, on Hobson's hypothesis. These are specific states of the neural systems in question.

Most of the time, we are not concerned with neural correlates of single phenomenal properties, but of families of phenomenal properties. Hobson is concerned not just with the neural correlate of waking consciousness, for example, but with the neural correlate of the whole family of background states of consciousness. Work on the visual NCC is not concerned with just the neural correlate of horizontal experience, but with the neural correlates of the whole system of visual experiential contents.

We might say a phenomenal family is a set of mutually exclusive phenomenal properties that jointly partition the space of conscious experiences, or at least some subset of that space. That is, any subject having an experience (of a certain relevant kind) will have a phenomenal property in the family, and will not have more than one such property. Specific contents of visual consciousness make for a phenomenal family, for example: any visually conscious subject will have some specific visual content, and they will not have two contents at once (given that we are talking about overall visual content). The same goes for contents at a particular location in the visual field: anyone with an experience as of a certain location will have some specific content associated with that location (a red horizontal line, say), and not more than one. (Ambiguous experiences are not counterexamples here, as long as we include ambiguous contents as members of the family in question.) The same again goes for color experience at any given location: there will be a phenomenal family (one property for each color quality) for any such location. And the same goes for background states of consciousness. All these sets of phenomenal properties make phenomenal families.

We can then say:

A neural correlate of a phenomenal family S is a neural system N such that the state of N directly correlates with the subject's phenomenal property in S.

For any phenomenal family S, a subject will have at most one property in S (one background state, or one overall state of visual consciousness, or one color quality at a location). Neural system N will be an NCC of S when there are a corresponding number of states of N, one for every property in P, such that N's being in a given state directly correlates with the subject's having the corresponding phenomenal property. This template can be seen to apply to most of the definitions given above.

For the neural correlate of creature consciousness, we have a simple phenomenal family with two properties: being conscious and not being conscious. An NCC here will be a system with two states that
correlate with these two properties.

For the neural correlate of a background state of consciousness, we have a phenomenal family with a few more properties: dreaming, being in an ordinary waking state, being under hypnosis, etc. An NCC here will be a neural system with a few states that correlate directly with these properties. Hobson's neurochemical system would be an example.

For the neural correlate of contents of consciousness, one will have a much more complex phenomenal family (overall states of visual consciousness, or states of color consciousness at a location, or particular conscious occurrent thoughts), and a neural representational system to match. The state of the NCC will directly correlate with the specific phenomenal property.

Notice that in the content case, there is an extra strong requirement on the NCC. In the other cases, we have accepted an arbitrary match of neural states to phenomenal states - any state can serve as the neural correlate of a dreaming state of background consciousness, for example. But where content is concerned, not any neural state will do. We require that the content of the neural state in question must match the content of consciousness. This is a much stronger requirement.

It is arguable that this requirement delivers much greater explanatory and predictive power in the case of neural correlates of conscious content. The systematicity in the correlation means that it can be extended to predict the presence or absence of phenomenal features that may not have been present in the initial empirical data set, for example. And it also will dovetail more nicely with finding a mechanism and a functional role for the NCC that matches the role that we associate with a given conscious state.

It is this systematicity in the correlation that makes the current work on neural correlate of visual consciousness particularly interesting. Without it, things would be much more untidy. Imagine that we find arbitrary neural states that correlated directly with the experience of horizontal lines, etc, such that there was no corresponding representational content in the neural state. Instead, we match seemingly arbitrary states N1 with horizontal, N2 with vertical, and so on. Would we count this as a neural correlate of the contents of visual consciousness? If we did, it would be in a much weaker sense, and in a way that would lead to much less explanatory and predictive power.

One might then hope to extend this sort of systematicity to other, non-content-involving phenomenal families. For example, one might find among background states of consciousness some pattern, or some dimension along which they systematically vary (some sort of intensity dimension, for example, or a measure of alertness). If we could then find a neural system whose states do not just arbitrarily correlate with the phenomenal states in question, but which vary along a corresponding systematic dimension, then the NCC in question will have much greater potential explanatory and predictive power. So this sort of systematicity in phenomenal families is something that we should look for, and something that we should look to match in potential neural correlates.

Perhaps one could define a "systematic NCC" as a neural correlate of a phenomenal family such that states correlate with each other in some such systematic way. I will not try to give a general abstract
What is a Neural Correlate of Consciousness?

definition here, as things are getting complex enough already, but I think one can see a glimmer of how it might go. I will, however, keep using the case of neural correlate of the contents of consciousness (especially visual consciousness) as the paradigmatic example of an NCC, precisely because its definition builds in this such a notion of systematicity, with the corresponding explanatory and predictive power.

3 Direct correlation

The other thing that we need to clarify is the notion of "direct correlation". We have said that an NCC is a system whose state directly correlates with a state of consciousness, but what does direct correlation involve, exactly? Is it required that the neural system be necessary and sufficient for consciousness, for example, or merely sufficient? And over what range of cases must the correlation obtain for the system to count as an NCC? Any possible case? A relevantly constrained set of cases? And so on.

The paradigmatic case will involve a neural system N with states that correlate with states of consciousness. So we can say that

\[
\text{state of N} \rightarrow \text{state of consciousness}
\]

and specifically

\[
N \text{ is in state } N_1 \rightarrow \text{subject has conscious state } C.
\]

In the case of the contents of consciousness, we have a system N such that representing a content in N directly correlates with representation in consciousness. So we can say

\[
\text{representing } C \text{ in N} \rightarrow \text{representing } C \text{ in consciousness.}
\]

The question in all these cases concerns the nature of the required relation. How strong a relation is required here for N to be a NCC?

(A) Necessity, sufficiency?

The first question is whether the NCC state is required to be necessary and sufficient for the conscious state, merely sufficient, or something else in the vicinity.

(A1) Necessity and sufficiency. The first possibility is that the state of N is necessary and sufficient for the corresponding state of consciousness. This is an attractive requirement for an NCC, but it is arguably too strong. It might turn out that there is more than one neural correlate of a given conscious state. For example, it may be there there are two systems, M and N, such that a certain state of M suffices for being in pain and a certain state of N also suffices for being in pain, where these two states are not themselves always correlated. In this case, it seems that we would likely say that both M and N (or their
corresponding states) are neural correlates of pain. But it is not the case that activity in M is necessary and sufficient for pain (as it is not necessary), and the same goes for N. If both M and N are to count as NCCs here, we cannot require an NCC to be necessary and sufficient.

(A2) **Sufficiency.** From the above, it seems plausible that we require only that an NCC state be *sufficient* for the corresponding state of consciousness, not necessary. But is any sufficient state enough? If it is, then it seems that the whole brain will count as an NCC of any state of consciousness. The whole brain will count as an NCC of pain, for example, since being in a certain total state of the whole brain will suffice for being in pain. Perhaps there is some very weak sense in which this makes sense, but it does not seem to capture what researchers in the field are after when looking for an NCC. So something more than mere sufficiency is required.

(A3) **Minimal sufficiency.** The trouble with requiring mere sufficiency, intuitively, is that it allows irrelevant processes into a NCC. If N is an NCC, then the system obtained by conjoining N with a neighboring system M will also qualify as an NCC by the previous definition, since the state of N+M will suffice for the relevant states of consciousness.

The obvious remedy is to require that an NCC has to be a *minimal sufficient system*: that is, a minimal system whose state is sufficient for the corresponding conscious state. By this definition, N will be an NCC when (1) the states of N suffice for the corresponding states of consciousness, and (2) no proper part M of N is such that the states of M suffice for the corresponding states of consciousness. In this way, we pare down any potential NCC to its core: any irrelevant material will be whittled away, and an NCC will be required to contain only the core processes that suffice for the conscious state in question.

Note that on this definition, there may be more than one NCC for a given conscious state. It may be that there is more than one minimal sufficient system for a given state, and both of these will count as a neural correlate of that state. The same goes for systems of phenomenal states. This seems to be the right result: we cannot know a priori that there will be only one NCC for a given state or system of states. Whether there will actually be one or more than one for any given state, however, is something that can be determined only empirically.

There is a technical problem for the minimality requirement. It may turn out that there is significant redundancy in a neural correlate of consciousness, such that for example a given conscious visual content is represented redundantly in many cells in a given area. If this is so, then that visual area as a whole might not qualify as a minimal sufficient system, as various smaller components of it might all themselves correlate with the conscious state. In this case the definition above would imply that various such small components would each be an NCC. One could deal with this sort of case by noting that the problem arises only when the states of the various smaller systems are themselves wholly correlated with each other. (If their mutual correlation can be broken, so will their correlation with consciousness, so that the overall system or some key subsystem will again emerge as the true NCC). Given this, one could stipulate that where states of minimal sufficient systems are wholly correlated with each other, it is the union of the system that should be regarded as an NCC, rather than the individual systems. So an NCC would be a minimal system whose state is sufficient for a given conscious state and whose state is not wholly
correlated with the state of any other system. I will pass over this complication in what follows, however.

(B) What range of cases?

An NCC will be a minimal neural system N such that the state of N is sufficient for a corresponding conscious state C. This is to say: if the system is in state N1, the subject will have conscious state C. But the question now arises: over what range of cases must the correlation in question hold?

There is sometimes a temptation to say that this question does not need to be answered: all that is required is to say that in this very case, neural state N1 suffices for or correlates with conscious state C. But this does not really make sense. There is no such thing as a single-case correlation. Correlation is always defined with respect to a range of cases. The same goes for sufficiency. To say that neural state N1 suffices for conscious state C is to say that in a range of cases, neural state N1 will always be accompanied by conscious state C. But what is the range of cases?

(B1) Any possible case. It is momentarily tempting to suggest that the correlation should range across any possible case: if N is an NCC it should be impossible to be in a relevant state of N without being in the corresponding state of consciousness. But a moment's reflection suggests that this is incompatible with the common usage in the field. NCCs are often supposed to be relatively limited systems, such as the inferior temporal cortex or the intralaminar nucleus. But nobody (or almost nobody) holds that if one excises the entire inferior temporal cortex or intralaminar nucleus and puts it in a jar, and puts the system into a relevant state, it will be accompanied by the corresponding state of consciousness.

That is to say, for a given NCC, it certainly seems possible that one can have the NCC state without the corresponding conscious state, for example by performing sufficiently radical lesions. So we cannot require that the correlation range over all possible cases.

Of course, one could always insist that a true NCC must be such that it is impossible to have the NCC state without the corresponding conscious state. The consequence of this would be that an NCC would almost certainly be far larger than it is on any current hypothesis, as we would have to build in a large amount of the brain to make sure that all the background conditions are in place. Perhaps it would be some sort of wide-ranging although skeletal brain state, involving aspects of processes from a number of regions of the brain. This might be a valid usage, but it is clear that this is not what researchers in the field are getting at when they are talking about an NCC.

We might call the notion just defined a total NCC, as it builds in the totality of physical processes that are absolutely required for a given conscious state. The notion that is current in the field is more akin to that of a core NCC. (I adapt this terminology from Shoemaker's (1979) notion of a "total realization" and a "core realization" of a functional mental state.) A total NCC builds in everything and thus automatically suffices for the corresponding conscious states. A core NCC, on the other hand, contains only the "core" processes that correlate with consciousness. The rest of the total NCC will be relegated to some sort of background conditions, required for the correct functioning of the core.
What is a Neural Correlate of Consciousness?

(Philosophical note: The sort of possibility being considered here is natural or nomological possibility, or possibility compatible with the laws of nature. If we required correlation across all logically possible cases, there might be no total NCC at all, as it is arguably logically possible (or coherently conceivable) to instantiate any physical process at all without consciousness. But it is probably not naturally possible. It is almost certainly naturally necessary that a being with my brain state will have the same sort as conscious state as me, for example. So natural possibility and necessity is the relevant sort for defining the correlation here.)

The question is then how to distinguish the core from the background. It seems that what is required for an NCC (in the "core" sense) is not that it correlate with consciousness across any possible conditions, but rather that it correlate across some constrained range of cases in which some aspects of normal brain functioning are held constant. The question then becomes, what is to be held constant? Across just what constrained range of cases do we require than an NCC correlate with consciousness?

(B2) Ordinary functioning brain in ordinary environments.

One might take the moral of the above to be that one cannot require an NCC to correlate with consciousness in "unnatural" cases. What matters is that the NCC correlates with consciousness is "natural" cases, those that actually occur in the functioning of a normal brain. The most conservative strategy would be to require correlation only across cases involving a normally functioning brain in a normal environment, receiving "ecologically valid" inputs of the sort received in a normal life.

The trouble with this criterion is that it seems too weak to narrow down the NCC. It may turn out that this way, we find NCCs at all stages of the visual system, for example. In normal visual environment, we can expect that the contents of visual systems from V1 through IT will all correlate with the contents of visual consciousness, and that even the contents of the retina will to some extent. The reason is that in normal cases all these will be linked in a straightforward causal chain, and the systems in question will not be dissociated. But it seems wrong to say that merely because of this, all the systems (perhaps even the retina) should count as an NCC.

The moral of this is that we need a more fine-grained criterion to dissociate these systems and to distinguish the core NCC from processes that are merely causally linked to it. To do this, we are have to require correlation across a range of unusual cases as well as across normal cases, as it is these cases that yield interesting dissociations.

(B3) Normal brain, unusual inputs. The next most conservative suggestion is that we still require a normal brain for our range of cases, but that we allow any possible inputs, including "ecologically invalid" inputs. This would cover the Logothetis experiments, for example. The inputs that evoke binocular rivalry are certainly unusual, and not encountered in a normal environment. But it is precisely these that allow the experiments to make more fine-grained distinctions than we normally can. The experiments suggest that IT is more likely than V1 to be an NCC precisely because it correlates with consciousness across the wider range of cases. If states of V1 truly do not match up with states of

What is a Neural Correlate of Consciousness?

consciousness in this situation, then it seems that V1 cannot be an NCC. If that reasoning is correct, then it seems that we require an NCC to correlate with consciousness across all unusual inputs, and not just across normal environments.

The extension of the correlation requirement from normal environments to unusual inputs is a relatively "safe" extension and seems a reasonable requirement, though those who place a high premium on ecological validity might contest it. But it is arguable that this is still too weak to do the fine-grained work in distinguishing an NCC from systems linked to it. Presumably unusual inputs will go only so far in yielding interesting dissociations, and some systems (particularly those well down the processing pathway) may well stay associated on any unusual inputs. So it is arguable that we will need more fine-grained tools to distinguish the NCC.

(B4) Normal brain, vary brain stimulation. The next possibility is to allow cases involving not just unusual inputs, but involving direct stimulation of the brain. Such direct stimulation might include both electrode stimulation and transcranial magnetic stimulation. On this view, we will require that an NCC correlates with consciousness across all cases of brain stimulation, as well as normal functioning. So if we have a potential NCC state that does not correlate with consciousness in the right way in a brain stimulation condition, that state will not be a true NCC.

This requirement seems to fit some methods used in the field. Penfield (e.g. Penfield and Rasmussen 1950) pioneered the use of brain stimulation to draw conclusions about the neural bases of consciousness. Libet (1982) has also used brain stimulation to good effect, and more recently Newsome and colleagues (e.g. Salzman et al 1990) have used brain stimulation to draw some conclusions about neural correlates of motion perception in monkeys. (See also Marge 1991 for a review of transcranial magnetic stimulation in vision.)

Brain stimulation can clearly be used to produce dissociations more fine-grained than can be produced merely with unusual inputs. One might be able to dissociate activity in any system from that in a preceding system by stimulating that system directly, for example, as long as there are not too many backwards connections. Given a candidate NCC - inferior temporal cortex, say - one can test the hypothesis by stimulating an area immediately following the candidate in the processing pathway. If that yields a relevant conscious state without relevant activity in IT (say), that indicates that IT is probably not a true NCC after all. Rather, the NCC may lie in a system further down the processing chain. (I leave aside the possibility that there might be two NCCs at different stages of the chain.)

This reasoning seems sound, suggesting that we may tacitly require an NCC to correlate with consciousness across brain stimulation conditions. There is no immediately obvious problem with the requirement, at least when the stimulation in question is relatively small and localized. If one allows arbitrary large stimulation, there may be problems. For example, one could presumably use brain stimulation at least in principle to disable large areas of the brain (by overstimulating those areas, for example) while leaving NCC activity intact. In this case, it is not implausible to expect that one will have the relevant NCC activity without the usual conscious state (just as in the case where one lesions the whole NCC and puts it in a jar), so the correlation will fail in this case. But intuitively, this does not seem
to disprove the claim that the NCC in question is a true NCC, at least before the stimulation. If so, then we cannot allow unlimited brain stimulation in the range of cases relevant to the correlation; and more generally, some of the problems for lesions (discussed below) may apply to reasoning involving brain stimulation. Nevertheless, one might well require that an NCC correlate with consciousness at least across cases of limited stimulation, in the absence of strong reason to believe otherwise.

(B5) Abnormal functioning, due to lesions. In almost all of the cases above, we have retained a normally functioning brain; we have just stimulated it in unusual ways. The next logical step is to allow cases where the brain is not functioning normally, due to lesions in brain systems. Such lesions might be either natural (e.g. due to some sort of brain damage) or artificial (e.g. induced by surgery). On the latest view, we will require that an NCC correlates with states of consciousness not just over cases of normal functioning, but over cases of abnormal functioning as well.

This certainly squares with common practice in the field. Lesion studies are often used to draw conclusions about the neural correlates of consciousness. In Milner and Goodale's work, for example, the fact that consciousness remains much the same upon lesions to the dorsal stream but not to the ventral stream is used to support the conclusion that the NCC lies within the ventral stream. More generally, it is often assumed that if some aspect of consciousness survives relatively intact with a given brain area is damaged, then that brain area is unlikely to be or contain an NCC.

The tacit premise in this research is that an NCC should correlate with consciousness but just in cases of normal functioning but in cases of abnormal functioning as well. Given this premise, it follows that if we find an abnormal case in which neural system N is damaged but a previously corresponding conscious state C is preserved, then N is not a neural correlate of C. Without this premise, or a version of it, it is not clear that any such conclusion can be drawn from lesion studies.

The premise may sound reasonable, but we already have reason to be suspicious of it. We know that for any candidate NCC, sufficiently radical changes can destroy the correlation. Preserving merely system N, cut off from the rest of the brain, for example, is unlikely to yield a corresponding conscious state; but intuitively, this does not imply that N was not an NCC in the original case.

Less radically, one can imagine placing lesions immediately downstream from a candidate NCC N, so that N's effects on the rest of the brain are significantly reduced. In such a case, it is probable that N can be active without the usual behavioral effects associated with consciousness, and quite plausibly without consciousness itself. It's not implausible that an NCC supports consciousness largely in virtue of playing the right functional role in the brain; by virtue of mediating global availability, for example (see Baars 1988 and Chalmers 1998). If so, then if the system is changed so that the NCC no longer plays that functional role, then NCC activity will no longer correlate with consciousness. But the mere fact that correlation can be destroyed by this sort of lesion does not obviously imply that N is not an NCC in a normal brain. If that inference could be made, then almost any candidate NCC could be ruled out by the right sort of lesion.

It may be that even smaller lesions can destroy a correlation in this way. For example, it is not implausible
that for any candidate NCC N, there is some other local system in the brain (perhaps a downstream area) whose proper functioning is required for activity in the N to yield the usual effects that go with consciousness, and for N to yield consciousness itself. This second system might not itself be an NCC in any intuitive sense; it might merely play an enabling role, in the way that proper functioning of the heart plays an enabling role for functioning of the brain. If so, then if one lesions this single area downstream, then activity in the N will no longer correlate with consciousness. In this way, any potential NCC might be ruled out by a localized lesion elsewhere.

The trouble is that lesions change the architecture of the brain, and its quite possible that changes to brain architecture can change the very location of an NCC, so that a physical state that was an NCC in a normal brain will not be an NCC in the altered brain. Given this possibility, it seems too strong to require that an NCC correlate with consciousness across arbitrary lesions and changes in brain functioning. We should expect an NCC to be architecture-dependent, not architecture-independent.

So an NCC should not be expected to correlate with consciousness across arbitrary lesion cases. There are now two alternatives. Either we can require correlation across some more restricted range of lesion cases, or one can drop the requirement of correlation in abnormal cases altogether.

For the first alternative to work, we would have to find some way to distinguish a class of "good" lesions from the class of "bad" lesions. An NCC would be expected to correlate with consciousness across the good lesions but not the bad lesions. If one found a "good" lesion case where activity in system N was present without the corresponding consciousness state, this would imply that N is not an NCC; but no such conclusion could be drawn from a "bad" lesion case.

The trouble is that it is not at all obvious that such a distinction can be drawn. It might be tempting to come up with an after-the-fact distinction, defined as the range of lesions in which correlation with an given NCC N is preserved, but this will not be helpful at all, as we are interested in precisely the criterion that makes N qualify as an NCC in the first place. So a distinction will have to be drawn on relatively a priori grounds (it can then be used to determined whether a given correlation-pattern qualifies an arbitrary system as an NCC or not). But it is not clear how to draw the distinction. One might suggest that correlation should be preserved across small lesions but not large ones; but we have seen above that even small lesions might destroy a potential NCC. Or one might suggest that lesions in downstream areas are illegitimate, but upstream and parallel lesions are legitimate. But even here, it is not clear that indirect interaction with an upstream or parallel area might be required to support proper functioning of an NCC. Perhaps with some ingenuity one might be able to come up with a criterion, but it is not at all obvious how.

The second alternative is to hold that correlation across cases of normal functioning (perhaps with unusual inputs and brain stimulation) is all that is required to be an NCC. If this is so, one can never infer directly from the fact that N fails to correlate with consciousness in a lesion case to the conclusion that N is not an NCC. On this view, the location of an NCC is wholly architecture-dependent, or entirely dependent on the normal functioning of the brain. One cannot expect an NCC to correlate with consciousness in cases with abnormal functioning or different architecture, so no direct conclusion can be drawn from failure of
correlation across lesion cases. Of course, one can still appeal to cases with unusual inputs and brain stimulation to make fine-grained distinctions among NCCs.

The main conceptual objection to the second alternative is that one might need lesion cases to make the most fine-grained distinctions that are required. Consider a hypothetical case in which we have two linked systems N and M which correlate equally well with consciousness across all normal cases, including all unusual inputs and brain stimulation, but such that in almost all relevant lesion cases, consciousness correlates much better with N than with M. In this case, might we want to say that N rather than M is an NCC? If so, we have to build in some allowance for abnormal cases into the definition of an NCC. An advocate of the second alternative might reply by saying that such cases will be very unusual, and that if N and M are dissociable by lesions, there is likely to be some unusual brain stimulation that will bring out the dissociation as well. In the extreme case where no brain stimulation leads to dissociation, one might simply bite the bullet and say that both N and M are equally good NCCs.

Taking everything into consideration, I am inclined to think the second alternative is better than the first. It seems right to say that "core" NCC location depends on brain architecture and normal functioning, and it is unclear that correlation across abnormal cases should be required, especially given all the associated problems. A problem like the one just mentioned might provide some pressure to investigate the first alternative further, and I do not rule out the possibility that some way of distinguishing "good" from "bad" lesions might be found, but all in all it seems best to say that an NCC cannot be expected to correlate with consciousness across abnormal cases.

Of course this has an impact on the methodology in the search for an NCC. As we have seen, lesion studies are often used to draw conclusions about NCC location (as in the Milner and Goodale research, for example, and also in much research on blindsight), and failure of correlation in lesion cases is often taken to imply that a given system is not an NCC. But we have seen that the tacit premise of this sort of research - that an NCC must correlate across abnormal as well as normal cases - is difficult to support, and leads to significant problems. So it seems that lesion studies are methodologically dangerous here. One should be very cautious in using them to draw conclusions about NCC location.

This is not to say that lesion studies are irrelevant in the search for an NCC. Even if correlation across abnormal cases is not required for system N to be an NCC, it may be that correlation across abnormal cases can provide good evidence that N is an NCC, and that failure of such correlation in some cases provides good evidence that N is not an NCC. Say we take the second alternative above, and define an NCC as a system that correlates with consciousness across all normal cases (including unusual input and stimulation). It may nevertheless be the case that information about correlations across all these normal cases with unusual stimulation is difficult to come by (due to problems in monitoring brain systems at a fine grain, for example), and that information about correlation across lesion cases is easier to obtain. In this case, one might sometimes take correlation across abnormal cases as evidence that a system will correlate across the normal cases in question, and thus as evidence that the system is an NCC. Similarly, one might take failure of correlation across abnormal cases as evidence that a system will fail to correlate across certain normal cases, and thus as evidence that the system is not an NCC.
The question of whether a given lesion study can serve as evidence in this way needs to be taken on a case-by-case basis. It is clear that some lesion studies will not provide this sort of evidence, as witnessed by the cases of severe lesions and downstream lesions discussed earlier. In the cases, failure of correlation across abnormal cases provides no evidence of failure of correlation across normal cases. On the other hand, it does not seem unreasonable that the Milner and Goodale studies should be taken as evidence that even in normal cases, the ventral stream will correlate better with visual consciousness than the dorsal stream. Of course the real "proof" would come from a careful investigation of the relevant processes across a wide range of "normal" cases involving both standard environments, unusual inputs, and brain stimulation; but in the absence of such a demonstration, the lesion cases at least provide suggestive evidence.

In any case, the moral is that one has to be very cautious when drawing conclusions about NCC location from lesion studies. At best these studies serve as indirect evidence rather than as direct criteria, and even as such there is a chance that the evidence can be misleading. One needs to consider the possibility that the lesion in question is changing brain architecture in such a fashion that what was once an NCC is no longer an NCC, and one needs to look very closely at what is going on to rule out the possibility. It may be that this can sometimes be done, but it is a nontrivial matter.

4 Overall definition

With all this, we have come to a more detailed definition of an NCC. The general case is something like the following:

An NCC is a minimal neural system \( N \) such that there is a mapping from states of \( N \) to states of consciousness, where a given state of \( N \) is sufficient, under conditions \( C \), for the corresponding state of consciousness.

The central case of the neural correlate of the content of consciousness can be put in more specific terms.

An NCC (for content) is a minimal neural representational system \( N \) such that representation of a content in \( N \) is sufficient, under conditions \( C \), for representation of that content in consciousness.

One might also give a general definition of the NCC for an arbitrary phenomenal property or for a phenomenal family, but I will leave those aside here.

The "conditions \( C \)" clause here represents the relevant range of cases, as discussed above. If the reasoning above is on the right track, then conditions \( C \) might be seen as conditions involving normal brain functioning, allowing unusual inputs and limited brain stimulation, but not lesions or other changes in architecture. Of course the precise nature of conditions \( C \) is still debatable. Perhaps one could make a case for including a limited range of lesion cases in the definition. In the other direction, perhaps one might make a case that the requirement of correlation across brain stimulation or unusual inputs is too strong, due to the abnormality of those scenarios. But I think the conditions \( C \) proposed here are at least a
What is a Neural Correlate of Consciousness?

reasonable first pass, pending further investigation.

Of course, to some extent, defining what "really" counts as an NCC is a terminological matter. One could quite reasonably say that there are multiple different notions of NCC, depending on just how one understands the relevant conditions C, or the matter of necessity and sufficiency, and so on; and not much really rests on which of these is the "right" definition. Still, we have seen that different definitions give very different results, and that many potential definitions have the consequence that systems that intuitively seem to qualify as an NCC do not qualify after all, and that NCC hypotheses put forward by researchers in the field could be ruled out on trivial a priori grounds. Those consequences seem undesirable. It makes sense to have a definition of NCC that fits the way the notion is generally used in the field, and that can make sense of empirical research in the area. At the same time we want a definition of NCC to be coherent and well-motivated in its own right, such that an NCC is something worth looking for, and such that the definition can itself be used to assess various hypotheses about the identity of an NCC. It seems to me that the definition I have given here is at least a first pass in this direction.

5 Methodological consequences

The discussion so far has been somewhat abstract, and the definitions given above may look like mere words, but from these definitions and the reasoning that went into them, one can straightforwardly extract some concrete methodological recommendations for the NCC search. Many of these recommendations are plausible or obvious in their own right, but it is interesting to see them emerge from the analysis.

(i) **Lesion studies are methodologically dangerous.** Lesion studies are often used to draw conclusions about neural correlates of consciousness, but we have seen that their use can be problematic. The identity of an NCC is arguably always relative to specific brain architecture and normal brain functioning, and correlation across abnormal cases should not generally be expected. In some cases, lesion studies can change brain architecture so that a system that was previously an NCC is no longer an NCC. So one can never infer directly from failure of correlation between a system and consciousness in a lesion case to the conclusion that that system is an NCC. Sometimes one can infer this indirectly, by using the failure of correlation here as evidence for failure of correlation in normal cases, but one must be cautious.

(ii) **There may be many NCCs.** On the definition above, an NCC is a system whose activity is sufficient for certain states of consciousness. This allows for the possibility of multiple NCCs, in at least two ways. First, different sorts of conscious states may have different corresponding NCCs; there may be different NCC for visual and auditory consciousness, for example, and perhaps even for different aspects of visual consciousness. Second, even for a particular sort of conscious state (such as pain), we cannot rule out the possibility that there will be two different systems whose activity is sufficient to produce that state.

Of course it could turn out that there is only a small number of NCCs, or perhaps even one. For all that I have said here, it is possible that there is some central system which represents the contents of visual consciousness, auditory consciousness, emotional experience, the stream of conscious thought, the background state of consciousness, and so on. Such a system might be seen as a sort of "consciousness
module”, or perhaps as a "Cartesian theater" (Dennett 1991) or a "global workspace" (Baars 1988), depending on whether one is a foe or a friend of the idea (see Chalmers 1998 for some discussion). But it is by no means obvious that there will be such a system, and I think the empirical evidence so far is against it. In any case, the matter cannot be decided a priori, so our definition should be compatible with the existence of multiple or many NCCs.

(3) **Minimize size of an NCC.** We have seen that an NCC should be understood as a minimal neural system that correlates with consciousness. Given this, we should constrain the search for the NCC by aiming to find a neural correlate that is as small as possible. Given a broad system that appears to correlate with consciousness, we need to isolate the core relevant parts and aspects of that system that underlie the correlation. And given the dual hypotheses that consciousness correlates with a broad system or a narrower system contained within it, we might first investigate the "narrow" hypothesis, as if it correlates with consciousness, the broad system cannot be a true NCC.

So it some extent it makes sense to "start small" in the search for an NCC. This fits the working methodology proposed by Crick and Koch (1998). Crick and Koch suggest that an NCC may perhaps involve a very small number of neurons (perhaps in the thousands) with certain distinctive properties. There is no guarantee that this is correct (and my own money is against it), but it makes a good working hypothesis in the NCC search. Of course one should simultaneously investigate broad systems for correlation with consciousness, so that one can then focus on those areas and try to narrow things down.

(4) **Distinguish NCC for background state and for content.** We have seen that there may be different NCCs for different sorts of states of consciousness. An important distinction in this class is that between the neural correlate of background state of consciousness (wakefulness, dreaming, etc) and the neural correlate of specific contents. It may be that these are quite different systems. It is not implausible on current evidence that an NCC for background state involves processes in the thalamus, or thalamocortical interactions, while an NCC for specific contents of consciousness involves processes in the cortex. These different sorts of NCC will require quite different methods for their investigation.

(5) **NCC studies need to monitor neural representational content.** Arguably the most interesting part of the NCC search is the search for neural determinants of specific contents of consciousness, such as the contents of visual consciousness. We have seen that an NCC here will be a neural representational system whose contents are correlated with the contents of consciousness. To determine whether such a system is truly an NCC, then, we need methods that monitor the representational content of the system. This is just what we find in Logothetis's work, for example, where it is crucial to keep track of activity in neurons with known receptive fields.

This gets at a striking aspect of the NCC search in practice, which is that the most informative and useful results usually come from single-cell studies on monkeys. Large claims are sometimes made for brain imaging on humans, but it is generally difficult to draw solid conclusions from such studies, especially where an NCC is concerned. We can trace the difference to the fact that single-cell studies can monitor representational content in neural systems, whereas imaging studies cannot (or at least usually do not). The power of single-cell studies in the work of Logothetis, Andersen, Newsome and colleagues (e.g. the
What is a Neural Correlate of Consciousness?

works of Logothetis and Newsome already cited, and Bradley, Chang, and Andersen 1998) comes precisely from the way that cells can be monitored to keep track of their activity profile of neurons with known representational properties, such as receptive and projective fields. This allows us to track representational content in these neural systems and to correlate it with the apparent contents of consciousness. This is much harder to do in a coarse-grained brain imaging study, which generally tells one that there is an activity in a region while saying nothing about specific contents.

A moral is that it makes sense to concentrate on developing methods that can track neural representational content, especially in humans (where invasive studies are much more problematic, but where evidence for conscious content are much more straightforward). There has been some recent work on the using imaging methods to get at certain aspects of the content of visual consciousness, such as colors and shapes in the visual field (e.g. Engel et al 1997), and different sorts of objects that activate different brain areas (e.g. Tong et al 1998). There is also some current work on using invasive methods in neurosurgery patients to monitor the activity of single cells. One can speculate that if a noninvasive method for monitoring single-cell activity in humans is ever developed, the search for an NCC (like most of neuroscience) will be transformed almost beyond recognition.

(6) Correlation across a few situations is limited evidence. According to the definition above, an NCC is a system that correlates with consciousness across arbitrary cases of normal functioning, in any environment, with any unusual input or limited brain stimulation. In practice, though, evidence is far weaker than this. Typically one has a few cases, involving either a few subjects with different lesions, or study in which subjects are given different stimuli, and one notes an apparent correlation. This is only to be expected, given the current technological and ethical constraints on experimental methods. But it does mean that the evidence that current methods give is quite weak. To truly demonstrate that a given system is an NCC, one would need to demonstrate correlation across a far wider range of cases than is currently feasible. Of course current methods may give good negative evidence about systems that fail to correlate and thus are not NCCs, but strong positive evidence is harder to find. Positive hypotheses based on current sorts of evidence should probably be considered suggestive but highly speculative.

(7) We need good criteria for the ascription of consciousness. To find an NCC, we need to find a neural system that correlates with certain conscious states. To do this, we first need a way to know when a system is in a given conscious state. This is famously problematic, given the privacy of consciousness and the philosophical problem of other minds. In general, we rely on indirect criteria for the ascription of consciousness. The most straightforward of these criteria is verbal report in humans, but other criteria are often required. Where nonhuman subjects are involved, one must rely on quite indirect behavioral signs (voluntary bar-pressing in Logothetis's monkeys, for example).

A deep problem for the field is that our ultimate criteria here are not experimentally testable, as the results of any experiment will itself requires such criteria for its interpretation. (First-person experimentation on oneself as subject may be an exception, but even this has limitations.) So any experimental work implicitly relies on pre-empirical principles (even "philosophical" principles) for its interpretation. Given this, it is vital to refine and justify these pre-empirical principles as well as we can. In the case of verbal report, we may be on relatively safe ground (though even here there may be some grounds for doubt, as
witnessed in the debates over "subjective threshold" criteria in unconscious perception research; see e.g. Merikle and Reingold (1992). In other cases, especially nonhuman cases, careful attention to the assumptions involved here are required. I don't think this problem is insurmountable, but it deserves careful attention. Our conclusions about NCC location will be no better than the pre-experimental assumptions that go into the search. (I consider this problem, and its consequences for the NCC search, in much more detail in Chalmers 1998.)

Methodological summary: We can use all this to sketch a general methodology for the NCC search. First, we need methods for determining the contents of conscious experience in a subject, presumably by indirect behavioral criteria or by first-person phenomenology. Second, we need methods to monitor neural states in a subject, and in particular to monitor neural representational contents. Then we need to perform experiments in a variety of situations to determine which neural systems correlate with conscious states and which do not. Experiments involving normal brain functioning with unusual inputs and limited brain stimulation are particularly crucial here. Direct conclusions cannot be drawn from systems with lesions, but such systems can sometimes serve as indirect evidence. We need to consider multiple hypotheses in order to narrow down a set of minimal neural systems that correlate with consciousness across all relevant scenarios. We may well find many different NCCs in different modalities, and different NCCs for background state and conscious contents, although it is not out of the question that there will be only a small number. If all goes well, we might expect to eventually isolate systems that correlate strongly with consciousness across any normally functioning brain.

6 Should we expect an NCC?

One might well ask: given the notion of an NCC as I have defined it, is it guaranteed that there will be a neural correlate of consciousness?

In answering, I will assume that states of consciousness depend systematically in some way on overall states of the brain. If this assumption is false, as is held by some Cartesian dualists (e.g. Eccles 1994) and some phenomenal externalists (e.g. Dretske 1995), then there may be no NCC as defined here, as any given neural state might be instantiated without consciousness. (Even on these positions, an NCC could be possible, if it were held that brain states at least correlate with conscious states in ordinary cases). But if the assumption is true, then there will at least be some minimal correlation of neural states with consciousness.

Does it follow that there will be an NCC as defined here? This depends on whether we are talking about neural correlates of arbitrary conscious states, or about the more constrained case of neural correlates of conscious contents. In the first case, it is guaranteed that the brain as a whole will be a neural system which has states that suffice for arbitrary conscious states. So the brain will be one system whose state is sufficient for a given conscious state; and given that there is at least one such system for a given state, there must be at least one such minimal system for that state. Such a system will be an NCC for that state. Of course this reasoning does not guarantee that there will be only one NCC for a given state, or that the NCC for one state will be the same as the NCC for another, but we know that an NCC will exist.
What is a Neural Correlate of Consciousness?

In the case of neural correlates of the content of consciousness, things are more constrained, since a neural correlate is required not just to map to a corresponding state of consciousness, but to match it in *content*. This rules out the whole brain as even a non-minimal neural correlate, for example, since representing a content in the brain does not suffice to represent that content in consciousness (much of the brain’s representational content is unconscious). Of course we may hope that there will be more constrained neural systems whose content systematically matches the contents of some aspect of consciousness. But one might argue that it is not obvious that such a system *must* exist. It might be held, for example, that the contents of consciousness are an emergent product of the contents of various neural systems, which together suffice for conscious content in question, but none of which precisely mirrors the conscious content.

I think one can plausibly argue that there is reason to expect that conscious contents will be mirrored by the contents of a neural representational system at *some* level of abstraction. In creatures with language, for example, conscious contents correspond well with contents that are made directly available for verbal report; and in conscious creatures more generally, one can argue that the contents of consciousness correspond to contents that are made directly available for the global voluntary control of behavior (see e.g. Chalmers 1998). So there is a correlation between the contents of consciousness and contents revealed or exhibited in certain functional roles within the system.

Given that these contents are revealed in verbal report and are exhibited in the control of behavior, there is reason to believe that they are represented at some point within the cognitive system. Of course this depends to some extent on just what "representation" comes to. On some highly constrained notions of representation - if it is held that the only true representation is symbolic representation, for example - then it is far from clear that the content revealed in behavior must be represented. But on less demanding notions of representation - on which, for example, systems are assigned representational content according to their functional role - then it will be natural to expect that the content revealed in a functional role will be represented in a system that plays that functional role.

This does not guarantee that there will be any single neural system whose content always matches the content of consciousness. It may be that the functional role in question is played by multiple systems, and that a given system may sometimes play the role, and sometimes not. If this is so, we may have to move to a higher level of abstraction. If there is no localizable neural system that qualifies as a correlate of conscious content, we may have to look at a more global system - the "global availability" system, for example, whereby contents are made available for report and global control - and argue that the contents of consciousness correspond to the contents made available in this system. If so, it could turn out that what we are left with is more like a "cognitive correlate of consciousness" (CCC?), since the system may not correspond to any neurobiological system whose nature and boundaries are independently carved out. But it can still function as a correlate in some useful sense.

In this context, it is important to note that an NCC need not be a specific anatomical area in the brain. Some of the existing proposals regarding NCCs involve less localized neurobiological properties. For example, Libet (1994) argues that the neural correlate of consciousness is temporally extended neural firing; Crick and Koch (1998) speculate that the NCC might involve a particular sort of cell, throughout

What is a Neural Correlate of Consciousness?

the cortex; Edelman (1988) suggests that the NCC might involve re-entrant thalamocortical loops; and so on. In these cases, NCCs are individuated by temporal properties, or by physiological rather than anatomical properties, or by functional properties, among other possibilities. If so, the "neural representational system" involved in defining a neural correlate of conscious content might also be individuated more abstractly: the relevant neural representational contents might be those represented by temporally extended firings, or by certain sorts of cells, or by re-entrant loops, and so on. So abstractness and failure of localization is not in itself a bar to a system's qualifying as an NCC.

It seems, then, that there are a range of possibilities for the brain-based correlates of conscious states, ranging from specific anatomical areas, through more abstract neural systems, to purely "cognitive" correlates such as Baars' (1988) "global workspace". Just how specific an NCC may turn out to be is an empirical question. One might reasonably expect that there will be some biological specificity. Within a given organism or species, one often funds a close match between specific functions and specific physiological systems, and it does not seem unlikely that particular neural systems and properties in the brain should be directly implicated in the mechanisms of availability for global control. If so, then we may expect specific neural correlates even of conscious contents. If not, we may have to settle for more abstract correlates, individuated at least partly at the cognitive level, though even here one will expect that some neural systems will be much more heavily involved than others. In any case it seems reasonable to expect that we will find informative brain-based correlates of consciousness at some level of abstraction in cognitive neurobiology.

Some have argued that we should not expect neural correlates of consciousness. For example, in their discussion of neural "filling-in" in visual perception, Pessoa, Thompson, and Noe (1998) argue against the necessity of what Teller and Pugh (1983) call a "bridge locus" for perception, which closely resembles the notion of a neural correlate of consciousness. Much of their argument is based on the requirement that such a locus must involve a spatiotemporal isomorphism between neural states and conscious states (so a conscious representation of a checkerboard would require a neural state in a checkerboard layout, for example). These arguments do not affect neural correlates of conscious contents as I have defined them, since a match between neural and conscious content does not require such a spatiotemporal correspondence (a neural representation of a shape need not itself have that shape). Pessoa et al also argue more generally against a "uniformity of content" thesis, holding that one should not expect a match between the "personal" contents of consciousness and the "subpersonal" contents of neural systems. I agree that the existence of such a match is not automatic, but as above I think that the fact that conscious contents are mirrored in specific functional roles gives reason to believe that they will be subpersonally represented at least at some level of abstraction.

It has also been argued (e.g. by Güzeldere 1999) that there is probably no neural correlate of consciousness, since there is probably no area of the brain that is specifically dedicated to consciousness as opposed to vision, memory, learning, and so on. One may well agree that there is no such area, but it does not follow that there is no neural correlate of consciousness as defined here. An NCC (as defined here) requires only that a system be correlated with consciousness, not that it be dedicated solely or mainly to consciousness. The alternative notion of an NCC is much more demanding that the notion at issue in most empirical work on the subject, where it is often accepted that an NCC may be closely bound
What is a Neural Correlate of Consciousness?

up with visual processing (e.g. Logothetis, Milner and Goodale), memory (e.g. Edelman), and other processes. This becomes particularly clear once one gives up on the requirement that there be a single NCC, and accepts that there may be multiple NCCs in multiple modalities.

7 Conclusion

The discussion in the previous section helps bring out what an NCC is not, or at least what it might turn out not to be. An NCC is defined to be a correlate of consciousness. From this, it does not automatically follow that an NCC will be a system solely or mainly dedicated to consciousness, or even that an NCC will be the brain system most responsible for the generation of consciousness. It certainly does not follow that an NCC will itself yield an explanation of consciousness, and it is not even guaranteed that identifying an NCC will be the key to understanding the processes underlying consciousness. If were to define an NCC in these stronger terms, it would be far from obvious that there must be an NCC, and it would also be much less clear how to search for an NCC.

Defining an NCC in terms of correlation seems to capture standard usage best, but it also makes the search more clearly defined, and makes the methodology clearer. Correlations are easy for science to study. It also means that the search for an NCC can be to a large extent theoretically neutral, rather than theoretically loaded. Once we have found an NCC, one might hope that it will turn out to be a system dedicated to consciousness, or that it will turn out to yield an explanation of consciousness, but these are further questions. In the meantime the search for an NCC as defined poses a tractable empirical question with relatively clear parameters, one which researchers of widely different theoretical persuasions can engage in.

There are certain rewards of the search for an NCC that one might reasonably expect. For example, these systems might be used to monitor and predict the contents of consciousness in a range of novel situations. For example, we may be able to use them to help reach conclusions about conscious experience in patients under anesthesia, and in subjects with "locked-in syndrome" or in coma. In cases where brain architecture differs significantly from the original cases (perhaps some coma cases, infants, and animals), the evidence will be quite imperfect, but it will at least be suggestive.

These systems might also serve as a crucial step toward a full science of consciousness. Once we know which systems are NCCs, we can investigate the mechanisms by which they work, and how they produce various characteristic functional effects. Just as isolating the DNA basis of the gene helped explain many of the functional phenomena of life, isolating NCC systems may help explain many functional phenomena associated with consciousness. We might also systematize the relationship between NCCs and conscious states, and abstract general principles governing the relationship between them. In this way we might be led to a much greater theoretical understanding.

In the meantime, the search for a neural correlate of consciousness provides a project that is relatively tractable, clearly defined, and theoretically neutral, whose goal seems to be visible somewhere in the middle distance. Because of this, the search makes an appropriate centerpiece for a developing science of
What is a Neural Correlate of Consciousness?

consciousness, and an important springboard in the quest for a general theory of the relationship between physical processes and conscious experience.

References

Here are a few very general thoughts about how I see the shape of a science of consciousness, focusing on the issue of first-person methodology. At the end I will make a few remarks about how this might apply to the study of emotion.

As I see it, the science of consciousness is all about relating third-person data - about brain processes, behavior, environmental interaction, and the like - to first-person data about conscious experience. I take it for granted that there are first-person data. It's a manifest fact about our minds that there is something it is like to be us - that we have subjective experiences - and that these subjective experiences are quite different at different times. Our direct knowledge of subjective experiences stems from our first-person access to them. And subjective experiences are arguably the central data that we want a science of consciousness to explain.

I also take it that the first-person data can't be expressed wholly in terms of third-person data about brain processes and the like. There may be a deep connection between the two - a correlation or even an identity - but if there is, the connection will emerge through a lot of investigation, and can't be stipulated at the beginning of the day. That's to say, no purely third-person description of brain processes and behavior will express precisely the data we want to explain, though they may play a central role in the explanation. So as data, the first-person data are irreducible to third-person data.

The job of a science of consciousness, then, is to connect the first-person data to third-person data: perhaps to explain the former in terms of the latter, or at least to come up with systematic theoretical connections between the two. We ought at least to be able to come up with broad connecting principles, saying e.g. that certain sorts of experiences go along with certain sorts of processes in the brain (and/or vice versa), or that certain sorts of experiences go along with certain sorts of information-processing (and/or vice versa), and so on. If we're successful with this, perhaps we'll eventually be able to formulate simple and universal laws that underlie these broad connecting principles. That would be what I've called a "fundamental theory" of consciousness. We're a long way from that now, but we can at least make a start on connecting third-person data to first-person data at a broad level.
To do this, we need good methodologies for collecting the data and good languages and formalisms for expressing them. When it comes to the third-person data, these methods are very well-developed. Psychologists have developed sophisticated methods for studying behavior, for example, and neuroscientists have developed an ever-expanding group of ingenious methods for getting at what is going on in the brain: EEG, brain imaging, single-cell studies, and many others. And there are multiple formalisms for expressing these data: plain language, neurophysiological classification, various sorts of images and diagrams, computational models, and more. It seems fair to say that on the third-person side of things, the central constraints on data gathering and expression stem from technological (and ethical) limitations rather than conceptual barriers.

When it comes to first-person data, things aren't nearly so well-developed. Here methodologies for investigating the data are relatively thin on the ground, and formalisms for expressing them are even thinner. When it comes to methodologies, there have been various ideas: the 19th-century psychological introspectionists, 20th-century philosophical phenomenologists, and centuries of meditative studies in Eastern thought have all developed sophisticated frameworks, but all are widely held to have serious limitations, and none has been much integrated into contemporary science.

Contemporary scientists quite often do rely on first-person data in central ways, for example in psychophysics, where first-person experience of various phenomena such as illusions seems to be the coin of the realm in capturing the data that need to be explained. The methodology here seems to be that of simple untutored introspection and verbal report. This is not bad for capturing gross and simple features of conscious experience - does one see a pink splotch? - and maybe such methods will take us a fair way, but eventually we will need more to investigate that manifold intricacies of conscious experience.

When it comes to formalisms for expressing the first-person data, we are even worse off. Mostly we rely on simple language - an experience of red, of a horizontal line, a feeling of happiness, a sharp pain. But this sort of language is obviously coarse-grained and imprecise, and usually relies on an interlocutor's experience of the same phenomena to carry any communicative content at all. There have been a few attempts at developing more structured formalisms - the quantitative methods used in measurement of sensation in psychophysics, for example, or the structured phenomenal fields of Husserlian phenomenologists - but nothing with remotely the precision and scope of formalisms in the third-person domain.

In my opinion, the development of more sophisticated methodologies for investigating first-person data and of formalisms for expressing them is the greatest challenge now facing a science of consciousness. Only by developing such methodologies and formalisms will we be able to collect and express first-person data in such a way that it is on a par with third-person data, so that we can find truly systematic and detailed connections between the two.

When it comes to first-person methodologies, there are well-known obstacles: the lack of incorrigible access to our experience; the idea that introspecting an experience changes the experience; the impossibility of accessing all of our experience at once, and the consequent possibility of "grand
I don't have much that's new to say about these. I think that could end up posing principled limitations, but none provide in-principle barriers to at least initial development of methods for investigating the first-person data in clear cases. I hope to see ideas from Western and Eastern philosophy and from contemporary and historical psychology integrated with a series of new ideas in coming years.

When it comes to first-person formalisms, there may be even greater obstacles: can the content of experience be wholly captured in language, or in any other formalism, at all? Many have argued that at least some experiences are "ineffable". And if one has not had a given experience, can any description be meaningful to one? Here again, I think at least some progress ought to be possible. We ought at least to be able to develop formalisms for capturing the structure of experience: similarities and differences between experiences of related sorts, for examples, and the detailed structure of something like a visual field. I don't know what exactly such a formalism would look like, but perhaps something bringing in ideas from geometry or topology, or from information theory, might be useful.

As for the intrinsic non-structural aspects of experience (the sensation of red, for example), things are more difficult. But even here one could arguably find some underlying structure: e.g. color experiences can arguably be decomposed into experiences of brightness, saturation, and hue. Perhaps - let's speculate - one might develop a theory of "proto-qualia" from which the qualia we experience are systematically built up? Or perhaps not, in which case we'll need other ideas. The idea of simple building blocks might help to some extent with the problem of communication, though: although different individuals may have different experiences, arguably some of the same building blocks might be present in each case. So perhaps they could abstract the primitive elements through inference from their own experience, and then get some idea of others' experience through the idea of recombination. Perhaps this could even eventually (when connected appropriately to third-person data) give us some clue about the subjective lives of animals. Or again, perhaps not.

What about emotions, in particular? Here I don't have much to say, and I expect that other participants in this symposium have thought about the issue in far more sophisticated ways than I have. But I hope I will be forgiven for entering into the spirit of things with a little uninformed speculation.

It's clear at a glance that when it comes to first-person study of emotion, the issues of both methodology and formalism are relevant. How does one collect first-person data about emotional experience? There are presumably particular difficulties with reliability here. How reliable can one expect an observer in a red-hot rage to be? In the domain of emotion, isn't self-deception likely to be ubiquitous? And presumably there will be observer effects all over the place: it doesn't seem implausible that cultivating a detached perspective on emotional experience will change the character of the experience significantly.

On the positive side, many people seem to be quite good at investigating their own emotional states, and it is a particularly interesting project. In this area, going beyond gross features to subtleties may be particularly rewarding. This is illustrated in the rich investigations of novelists such as Proust. Perhaps there is some way to tap into this sort of thing for scientific purposes?

I don't know much about the field, but my guess is that right now, the dominant methods for accessing
first-person data in scientific experiments on emotion involve relatively untutored introspection of relatively gross features: asking a subject whether they are having experiences of happiness and sadness, and the like. And I imagine that even this provides a productive source of data to be going on with, and with which a lot of interesting science can be done. I imagine that participants in this symposium will be talking about some more developed methodologies for the first-person study of emotion, though, and I will be interested to hear what they have to say.

As for formalisms, this seems to be more of a question mark. Emotions seem to be particularly inexpressible, especially to one who hasn't experienced the emotion in question before. Even where two individuals have emotional experience in common, it can be hard to find the right language to describe it. At the same time, our experiences clearly vary on a number of clear dimensions: duration, intensity, positive or negative affect, and numerous others. And I imagine that most of these things are already exploited by experimenters in the field. It's far from clear (to me, at least) just how much of the complex character of emotions can be captured in such quantitative and structural measures, but it's at least a start. And perhaps we will be able to develop more and more sophisticated formalisms for expressing more and more of the complex structure of emotion, so the unexpressed residue will at least shrink considerably. I imagine there are a good number of ideas along these lines out there already.

As to what to do with that unexpressed residue: perhaps we'll have to rely on common language to bootstrap our understanding of common elements of experience, or perhaps we'll be able to go further with some sort of building-block methodology. Or perhaps we'll come to the conclusion that formalisms can only tell us so much about emotions, and that novelists are needed to tell us the rest. I don't have any firm expectations here myself, but I'll be very interested to see how thing play out, both in this conference and in coming years.
John Perry's book *Knowledge, Possibility, and Consciousness* is a lucid and engaging defense of a physicalist view of consciousness against various anti-physicalist arguments. It will come as no surprise to Perry to learn that I think his defense does not succeed. In what follows, I will address Perry's responses to the three main anti-physicalist arguments he discusses: the zombie argument (focusing on insentience), the knowledge argument (focusing on indexicality), and the modal argument (focusing on intensions).

### 1 The Zombie Argument

Zombies are unconscious creatures that are microphysically identical to conscious beings such as ourselves. If zombies are metaphysically possible, then materialism is false. The zombie arguments aims to establish that zombies are conceivable, infers that they are metaphysically possible, and concludes that materialism is false.

Perry's response is straightforward. He says (pp. 77-80) that zombies will be possible if and only if epiphenomenalism is true. And he says that he cannot see any reason why one would think that zombies (and zombie worlds) are possible unless one were already an epiphenomenalist. So the zombie argument begs the question, by tacitly assuming epiphenomenalism as a premise.

I think that Perry is clearly wrong here. Whatever the merits of the zombie argument, it does not beg the question. To see this, note that the zombie argument is not based on a *single* premise - the possibility of zombies - but rather on two premises. The first premise is that zombies are conceivable, roughly in the sense that there is no a priori contradiction in the idea of a zombie. The second premise is that if zombies are conceivable in this sense, then they are possible. (Or they are "primarily possible", in that there is a possible world satisfying the relevant primary intension).

Each of these premises is accepted by many philosophers who clearly reject epiphenomenalism. For
example, the first premise is accepted by many "type-B" materialists (those who accept an epistemic gap between the physical and the phenomenal but deny an ontological gap), all of whom deny epiphenomenalism: e.g., Ned Block, Chris Hill, Joe Levine, Brian Loar, and many others. The second premise is accepted by many "type-A" materialists (those who deny an epistemic gap between physical and phenomenal) and interactionists, all of whom deny epiphenomenalism: e.g., Frank Jackson (current incarnation), David Lewis, Richard Swinburne, and others. Of course few or none of these people accept both premises. But their mere existence shows that the premises have support that is independent of a prior acceptance of epiphenomenalism.

To go beyond a roll-call, it can be seen straightforwardly that each premise has substantive support that goes beyond epiphenomenalism. The second premise rests on general considerations linking conceivability and possibility. The first premise rests partly on prima facie conceivability intuitions that many share, and partly on deeper considerations concerning the absence of any conceptual linkage between microphysical concepts (which are structural-functional in nature) and phenomenal concepts (which are not). In both cases, whether or not these premises are correct, their support presupposes nothing about epiphenomenalism.

I suppose that Perry might try to argue that the first premise tacitly builds in epiphenomenalism. Given all the non-epiphenomenalists who accept the premise, however, this would seem unlikely: it would require that they be deeply irrational, or have deeply divided minds. Further, Perry says a number of things elsewhere in the book that seem to come close to embracing the first premise (in the relevant sense of conceivability). For example, although he embraces an identity between phenomenal and physical properties, he denies (pp. 87-88) that consciousness supervenes logically on the microphysical (i.e., he denies a conceptual entailment from microphysical truths to phenomenal truths), which suggests that there will be no a priori contradiction in the notion of a zombie. And even in raising questions about zombies, he points to nothing like an incoherence in the notion; at best he points to a tension with certain a posteriori beliefs about the causal role of our own conscious states.

In any case, it seems clear that to reject the argument, Perry has to go beyond considerations about begging the question, and instead give substantive reasons to reject one of the premises. From Perry's overall position, I would expect him to be more likely to reject the second premise than the first. Like other type-B materialists, he can accept that zombies are conceivable in the relevant sense, but deny the principle linking conceivability (in this sense) with possibility. I will return to this matter in the last section.

One final point: it is worth noting that even the possibility of zombies does not obviously entail epiphenomenalism. To see this, note that an interactionist dualist can accept the possibility of zombies, by accepting the possibility of physically identical worlds in which physical causal gaps (those filled in the actual world by mental processes) go unfilled, or are filled by something other than mental processes. The first possibility would have many unexplained physical events, but there is nothing metaphysically impossible about unexplained physical events. Also: a Russelian "panprotopsychist", who holds that consciousness is constituted by the unknown intrinsic categorical bases of microphysical dispositions, can accept the possibility of zombies by accepting the possibility of worlds in which the microphysical
dispositions have a different categorical basis, or none at all. So even if the argument had the one-premise structure that Perry suggests, then as long as it was appropriately neutral on the physical character of the world, it would not obviously beg the question in favor of epiphenomenalism.

2 The Knowledge Argument

The knowledge argument holds that there is phenomenal knowledge (e.g. concerning what it is like to see red) that is not deducible from physical knowledge, and infers that phenomenal facts are non-physical facts. Perry's response, essentially, is to analyze phenomenal knowledge as a sort of indexical knowledge. We know that there is indexical knowledge (e.g. concerning my current location) that is not deducible from complete physical knowledge, but this indexical knowledge does nothing to falsify physicalism. If phenomenal knowledge is indexical knowledge, then we can straightforwardly explain the epistemic gap between the physical and phenomenal domains, without requiring any non-physical ontology.

Perry applies this strategy to the new knowledge that (physically omniscient) Mary gains when she sees red for the first time, roughly as follows. Mary gains new knowledge of the form "red things cause experiences of type $P$". This knowledge crucially involves a phenomenal concept $P$ - a concept of what it is like to have a certain sort of experience. Perry's strategy (pp. 145-48) is to analyze Mary's phenomenal concept $P$ as a demonstrative concept - which he labels $\text{this}_i$ - that functions, like other demonstrative concepts, to pick out whatever sort of experience she is currently attending to. Because of an underlying indexical character, knowledge involving demonstrative concepts cannot usually be inferred from complete objective knowledge. So Mary's epistemic gap is reduced to the familiar epistemic gap for indexicals and demonstratives.

My response is straightforward. I think that there are clear reasons to hold that phenomenal knowledge (of the crucial sort) is not indexical knowledge, and that phenomenal concepts (of the crucial sort) are not demonstrative concepts of this sort; so this analysis of the epistemic gap fails. Mary does gain indexical knowledge involving a demonstrative concept, but this indexical knowledge is not the phenomenal knowledge that is central to the knowledge argument, and this demonstrative concept is not the concept that Mary's central new knowledge involves. I have argued for this based on an independently-grounded analysis of phenomenal concepts elsewhere (Chalmers 2002a), but I will give some reasons here.

It is useful to consider analogies with other demonstrative knowledge of types. Let $\text{this}_S$ be a demonstrative concept of certain shapes. Jill might tell Jack that she is about to show him her favorite shape. When she shows him a circle, he might form the thought "Jill's favorite shape is $\text{this}_S$", where $\text{this}_S$ refers to circles. This is a clearly demonstrative thought. He might also form the thought "Jill's favorite shape is a circle". This is a clearly nondemonstrative thought: the right hand side is not a demonstrative concept, but what we might call a qualitative concept. Finally, he might form the thought "$\text{this}_S$ is a circle". This is a substantive, nontrivial thought, taking the form of an identity involving a demonstrative concept and a qualitative concept. This sort of thought is very common with demonstratives - one conceives the object of a demonstration as the object of a demonstration, and at the same time attributes it substantive qualitative properties, conceived non-demonstratively.
On the face of it, Mary's situation is precisely analogous. She knows that she is about to have an experience of the sort usually caused by red things. Upon having the experience, she might form the thought "The experience usually caused by red things is this_I". But at the same time, she might form the thought "The experience usually caused by red things is R", where R is a qualitative concept of the sort of experience she is now having. This is brought out by the fact that just as Jack might think the substantive thought "this_S is a circle", Mary might think the substantive thought "this_I is R". Like Jack's thought, Mary's thought involves attributing a certain substantive qualitative nature to an object that is identified demonstratively. The concept R - her qualitative concept of the sort of experience in question - is not a demonstrative concept at all, as witnessed by the nontriviality of the identity involving the demonstrative concept this_I and R. And Mary's crucial new knowledge in the thought-experiment, the new knowledge that the knowledge argument turns on, is the substantive qualitative knowledge involving R (e.g. that red things cause R experiences), not the relatively uninteresting indexical knowledge involving this_I.

One might be distracted by the fact that Mary's concept R is a new concept, acquired upon having the experience, while Jack's concept "circle" is an old concept. But this is inessential to Jack's case. We can imagine that Jack has never seen a circle before (if one is worried about plausibility, make it another shape), but that on seeing a circle for the first time, he acquires the qualitative concept of circularity. He will then be in the position to think the qualitative thought "Jill's favorite shape is a circle", and to think the substantive demonstrative-qualitative thought "This_S is a circle. Mary's situation is just the same. Upon seeing red for the first time, she is able to form a qualitative concept of that sort of experience (based on her exposure to it), to think qualitative thoughts involving that concept, and to think demonstrative-qualitative thoughts in which both a demonstrative and a qualitative concept are deployed.

Perry might respond by holding that the cases are deeply disanalogous, and that where Joe has two concepts ("this_S" and "circle"), Mary has only one (this_I). But this seems quite false to the phenomenology of the cases, both of which involve substantive knowledge of the form "this is such-and-such", where "such-and-such" is a qualitative predication based on exposure to a demonstrated entity. We can also note that just as it seems that Joe could have had different thoughts of the form "this_S is a square", if he had been exposed to a different shape, it seems that Mary could have had different thoughts of the form "this_I is G" had she been exposed to a different sort of experience, such as an experience of green. So it seems that the qualitative concept of the experiential type is quite different from the demonstrative concept.

I conclude that Perry gives an adequate analysis of certain subsidiary demonstrative knowledge that Mary gains - knowledge that is analogous to demonstrative knowledge in other domains. But Perry gives no adequate analysis of Mary's substantive new non-indexical, non-demonstrative phenomenal knowledge, and in particular gives no way of reconciling this new phenomenal knowledge with the truth of physicalism.

(In Chalmers (2002a), I distinguish three sorts of phenomenal concepts: pure phenomenal concepts (such as R), demonstrative phenomenal concepts (such as this_I) and relational phenomenal concepts (such as
"the sort of experience typically caused by red things"). Perry's discussion seems to acknowledge only two sorts, the demonstrative and the relational; or at least, it seems to assimilate the pure phenomenal and the demonstrative with each other.)

One can also make a direct case against any analysis of phenomenal knowledge as indexical or demonstrative knowledge, as follows. In the indexical case, any epistemic gaps disappear from an objective perspective. Say that I am physically omniscient, but do not know whether I am in the USA or Australia (let's imagine that there are appropriate qualitative twins in both). Then I have a certain indexical ignorance, and discovering that I am in the USA will constitute new knowledge. But if someone else is watching from the third-person point of view and is also physically omniscient, they will have no corresponding ignorance: they will know that A is in Australia and that B is in the US, and that's that. There is no potential knowledge that they lack: from their perspective, they know everything there is to know about my situation. So my ignorance is essentially indexical, and evaporates from the objective viewpoint. The same goes for indexical ignorance concerning what time it is, for demonstrative ignorance concerning what this is, and so on. In all these cases, the ignorance disappears from the objective viewpoint: an objectively omniscient observer can know everything there is for them to know about my situation, and there will be no doubts for them to settle.

Now consider Mary's ignorance. From her black-and-white room, she is ignorant of all sorts of facts: what it will be like for her to see red for the first time, what it is like for others to see red, and so on. Only the first of these looks even apparently indexical, so let us focus on that. In this case, a physically omniscient observer may have precisely analogous ignorance: even given his complete physical knowledge, he may have no idea what it will be like for Mary to see red for the first time. So this ignorance does not evaporate from the objective viewpoint. The same goes even more strongly for knowledge of what it is like for others to see red. For any observer, regardless of their viewpoint, there will be an epistemic gap between complete physical knowledge and this sort of phenomenal knowledge. This suggests very strongly that phenomenal knowledge is not a variety of indexical or demonstrative knowledge at all. Rather, it is a sort of objective knowledge of the world, not essentially tied to any viewpoint.

If this is right, then any analysis of phenomenal concepts as indexical or demonstrative concepts fails, and any attempt to explain Mary's epistemic gap in terms of the epistemic gap for indexical or demonstrative concepts fails. If this is right, then Perry's substantive account of Mary's epistemic gap, in terms of the "reflexive content" of certain beliefs, will also fail. Reflexive content is essentially indexical content (tied to the relation of this token to the world), so that an analysis in these terms applies only to broadly indexical knowledge.

A similar diagnosis can be applied to analyses of phenomenal knowledge by many other materialists who seek to acknowledge Mary's epistemic gap and to explain it away: any analysis of phenomenal concepts as indexical, demonstrative, or recognitional concepts will fall prey to similar objections. This does not show by itself that no analysis of phenomenal knowledge can be given that saves both physicalism and the epistemic gap but I think that it renders the prospects dim.
3 The modal argument

The third anti-physicalist discussion that Perry discusses is the "modal argument". Of course the zombie argument is itself a sort of modal argument. Presumably Perry intends a more general target here, but I think some of the same issues arise. The chapter is divided into a discussion of "Kripke's argument" and of "Chalmers' argument". His discussion of the latter focuses on my use of the two-dimensional framework in arguing against materialism; so this can be seen as filling in the issues that went unaddressed in his earlier discussion, concerning the relationship between conceivability and possibility. I will focus on this issue here.

Perry's discussion in this chapter is harder to follow than in the other chapters of the book, and it is not easy to clearly identify his responses to the arguments in question. His basic strategy appears to be to agree with his opponents that where there is "apparent contingency" (Kripke) or "conceivability" (me) of some mental-physical dissociation, there is some sort of possibility in the vicinity, but to argue that once the possibility is appropriately understood (in terms of reflexive relations to tokens and the like), it does not threaten materialism. I was left unclear, however, on how this strategy bears on the specific argument I put forward.

To summarize the argument briefly (see Chalmers 2002b for a more detailed treatment): Let us say that S is conceivable when it is not a priori that ~S. Any given statement S can be associated with two intensions: a primary intension, which is a function from centered worlds (worlds plus individuals/times) to truth-values, and a secondary intension which is a function from uncentered worlds to truth-values. When S is necessary, it has a necessary secondary intension (and vice versa); when S is a priori, it has a necessary primary intension (and somewhat controversially, vice versa). Let us say that S is primarily possible when its primary intension is true at some centered world. Let P be the complete microphysical truth about the world. Let Q be a phenomenal truth. Then the anti-materialist argument can be put as follows

(1) P&~Q is conceivable

(2) If S is conceivable, S is primarily possible.

(3) If P&~Q is primarily possible, materialism is false.

--

(4) Materialism is false.

Here, the first premise is simply a statement of the epistemic gap, grounded in the a priori coherence of zombies, or in the a priori coherence of inverted spectra, or in Mary's inability to deduce phenomenal truths from physical truths. The second premise is a core principle of the two-dimensional framework,
linking apriority and primary possibility. The third premise is not completely obvious (since materialism requires the secondary possibility of P&~Q), but some relatively straightforward argument involving the nature of physical and phenomenal concepts takes one from the relevant primary possibility to a relevant secondary possibility.

(On the third premise: If a world satisfies the primary intension of P, it is at least structurally identical to our world. So either (i) the world is completely physically identical to our world but different in mental respects, so materialism is false, or (ii) it differs at most in the intrinsic microphysical properties that underlie this structure. Exploiting (ii) leads directly to the Russellian "panprotopsychist" position, which I count for present purposes as a version of nonmaterialism. The argument also needs supplementing to handle the role of indexicals and centering, but this is not hard: one can argue that premise 1 is true even when one supplements P with full indexical "locating" knowledge (see below for more on this), and then a corresponding version of premise (3) still goes through.)

Despite Perry's extensive discussion of the two-dimensional framework, I was left unclear on which premise of this argument he would reject, and why. For reasons discussed earlier, he seems to be committed to a version of premise 1. Many of Perry's fellow type-B materialists reject premise 2 (often allowing that it applies in all standard cases, but holding that the case of consciousness is exceptional or unique). Perhaps Perry would reject this premise, but he does not discuss it explicitly, so it is hard to tell. Perhaps more likely, given Perry's sympathy for the idea that where there is apparent contingency, there is possibility, it is not out of the question that he accepts the second premise and rejects the third, holding that the relevant possibility does not trouble materialism. But again, it is hard to tell from Perry's discussion, as he does not address the argument directly, and he does not argue against the relevant premises.

Insofar as I understand Perry's response to the two-dimensional argument (on pp. 198-200), it focuses on the status of an identity such as \(Q_R = B_{47}\), where \(Q_R\) is the concept of whatever sort of experience is caused by red things, and \(B_{47}\) is the concept of brain states of a certain sort. He allows that the identity is "apparently contingent" (conceivable in the relevant sense), allows that there is a primary possibility in the vicinity, but explains the relevant primary possibility in terms of the fact that (i) \(Q_R\) might have picked out a different phenomenal property, and (ii) \(B_{47}\) might have picked out a different sensation. In two-dimensional terms (modulo a few complications in the translation that I pass over here), it seems that Perry is accepting: (i) the primary intension of \(Q_R\) picks out a different phenomenal property in some centered worlds, and (ii) the primary intension of \(B_{47}\) picks out a different sensation in some centered world. In effect, this is to explain the primary possibility in terms of the fact that \(Q_R\) and \(B_{47}\) have distinct primary and secondary intensions. As such, it appears that Perry is here allowing premise (2) above, but denying the equivalent of premise (3): there is no argument from the relevant primary possibility to the falsity of materialism.

There are a few things to say here. First, my own argument here is not formulated in terms of identities, precisely because it is hard to mount an argument from the primary possibility of the negation of a physical-phenomenal identity to the falsity of materialism. (Perry characterizes my argument in terms of identity on pp. 188-89, but this is a mischaracterization.) When we invoke the full claim P&~Q, rather
than the mere negation of an identity, the argument from primary possibility to the falsity of materialism is much more straightforward. So Perry is addressing something of a straw figure here.

Second, Perry invocation of the *relational* phenomenal concept $Q_R$ is very odd in this context. This is a deeply extrinsic characterization of the phenomenal property in question, with a very different primary and secondary intension. For the anti-materialist argument it is much better to invoke something closer to a pure phenomenal concept, to accommodate Kripke's insight that for phenomenal concepts, there is no gap between reference-fixers and reference (or between primary and secondary intensions). Perhaps Perry denies that there are any such phenomenal concepts; but if so, he needs to give substantive arguments against the Kripkean claim. In any case, it is clear that by appealing to the relational concept, Perry is making things easy for himself. (At the very least, I would have expected to see the demonstrative concept $this_I$.) If there are phenomenal concepts with the same primary and secondary intension, then Perry's strategy here will fail. (In fact, even if phenomenal concepts have different primary and secondary intensions, the anti-materialist argument still goes through, but things are more complicated.)

Third, Perry appeals to the possibility that there are centered worlds in which (the primary intension of) $B_{47}$ picks out a different sensation. It is hard to see how this is supposed to go, at least if $B_{47}$ gives a full microphysical description of the relevant state. As such, it seems that there is no centered world in which $B_{47}$ picks out a different *physical property*. And presumably Perry holds that there are no centered worlds in which that very physical property is a different sensation (that would deny the necessity of identity). One way out might be to endorse the Russellian claim that physical concepts are topic-neutral, fixing reference to different underlying intrinsic properties depending on the state of the world. But this leads only to the "panprotopsychist" loophole, which I don't think Perry is exploiting. So it is hard to see how this move works for him.

I would have expected Perry to embrace an alternative strategy, suggested by his response to the knowledge argument. If $A$ is "I am in the USA", then $P \& \neg A$ is conceivable and primarily possible, but the the primary possibility simply corresponds to the actual world with a different center. Such a centered world yields no argument against materialism. By analogy, Perry might hold that $P \& \neg Q$ is conceivable because of a tacit indexicality in $Q$, and is primarily possible, but the primary possibility simply corresponds to the actual world with a different center, again yielding no argument against materialism. Here the center would presumably need to be expanded beyond an individual and a time, but that could be justified if phenomenal concepts were truly analogous indexical concepts, so that phenomenal information is a sort of "locating information". For example, one might supplement the "you are here" and "now is here" arrows at the center with "this is here" arrows pointing to certain states as the referents of phenomenal demonstratives. Then the relevant centered world will simply be a world with different locations for the "this is here" arrows.

I think that this move does not work, for more or less the reasons given above. First, phenomenal concepts are not indexical or demonstrative concepts, for reasons given there. Second, phenomenal information does not disappear from the third-person viewpoint, so it is not locating information (it is epistemically objective information), and so not the sort of thing that can be built into the center of a
world. Third, while Mary is in the black and white room, one can supplement her physical information with all the locating information one likes - "you are here", "now is here", and "this is here" with arrows pointing to various of her brain states - and she will still be in complete ignorance of what it is like to see red. So unlike the case of my physical location, the epistemic gap here is not closed by adding any amount of locating information. Still, this is an interesting strategy that is worth exploring, especially in the context of Perry's response to the knowledge argument.

In any case: it is possible that I have misunderstood Perry's intended response to the modal argument here. So I would be interested to see how he responds to the straightforward three-premise argument above.

4 Conclusion

Perry's responses to the anti-materialist arguments are philosophically deep and sophisticated. Nevertheless, I think that upon close examination, these responses fail in straightforward ways. Given Perry's depth and sophistication, I take this to be indirect evidence that the arguments are sound.

[[This was written as a commentary on Ned Block's paper "On A Confusion about a Function of Consciousness". It appeared in Behavioral and Brain Sciences 20:148-9, 1997, and also in the collection The Nature of Consciousness: Philosophical Debates (MIT Press, 1997) edited by Block, Flanagan, and Guzeldere.]]

Introduction

Block's distinction between access consciousness and phenomenal consciousness (or experience) is very useful. There is clearly a conceptual distinction here, as illustrated by the facts that: (1) one can imagine access without experience and vice versa; (2) access can be observed straightforwardly, whereas experience cannot; and, most important, (3) access consciousness seems clearly amenable to cognitive explanation, whereas phenomenal consciousness is quite perplexing in this regard. But the tight empirical link between the two phenomena deserves attention.

Bringing access and experience closer together.

Block himself notes that P-consciousness and A-consciousness often occur together. This is no accident, as one can see by noting that a P-conscious experience is usually reportable, and that reportability implies accessibility of the corresponding information. Block does not think they always occur together, but I think that with appropriate modifications they might. One of the most interesting projects in this area is that of modifying the concept of A-consciousness in such a way as to make it plausible that A-consciousness (in the modified sense) and P-consciousness are perfect correlates.

A good start is the modified notion of direct availability for global control. That is, a content is A-conscious in the modified sense when it is directly available for use in directing a wide range of behaviors, especially deliberate behaviors. I am not sure how different this is from Block's definition: it plays down the role of rationality and reasoning (after all, impairments of rationality probably do not diminish phenomenal consciousness), it relegates verbal report to the status of a heuristic (as Block himself suggests), and there is another important difference that I will come to shortly. The restriction to direct availability works to eliminate contents that can be retrieved with some work but that are not conscious.
To see how well this modified notion of A-consciousness correlates with P-consciousness, we need to see how it handles Block's examples in which one sort of consciousness occurs without the other. Block's examples of A-consciousness without P-consciousness are all mere conceptual possibilities (zombies and super-blindsight, for example), so they are not relevant here, but to illustrate P-consciousness with A-consciousness he gives some real-world examples. One is Sperling's example in which all nine letters in a square array are experienced, but only three can be reported at a time. In this case, only three letter-representations are accessed, but it is nevertheless plausible that each of the nine was available, until the process of access destroyed their availability. This works because the modified notion of A-consciousness is dispositional - not access but accessibility is required. And it is plausible that all nine letter-representations are A-conscious in the modified sense. So even in this case, P-consciousness and modified A-consciousness occur together.

The case of the drilling noise in the background can be handled similarly. Here it seems reasonable to say that the information was directly available all along; it simply wasn't accessed. The case of experience under anesthesia (if this is actual) is trickier, but we might handle it by saying that in these cases the corresponding contents are available for global control; it is just that the control mechanisms themselves are mostly shut down. We might say that the information makes it to a location where it could have been used to direct behavior, had the motor cortex and other processes been functioning normally.

Other cases could be considered and further refinements could be made. A fuller account might flesh out the kind of availability required (perhaps a kind of high-bandwidth availability is required for experience, or at least for experience of any intensity) and might specify the relevant kind of control role more fully. Counterexamples are not threatening but helpful; they allow us to refine the definition further. The details can be left aside here; the point is that this project will lead to a functionally characterized property that might correlate perfectly with P-consciousness, at least in the cases with which we are familiar.

This property - something in the vicinity of direct availability for global control - could then be thought of as the information-processing correlate of P-consciousness, or as the cognitive basis of experience. There are some interesting consequences for the issues that Block discusses.

**Empirical work on consciousness.**

Block notes that researchers on consciousness often start with an invocation of phenomenal consciousness but end up offering an explanation of A-consciousness and leaving P-consciousness to the side. The tight link between the two suggests that a somewhat more charitable interpretation is possible. If experience correlates with availability for global control, much of this work can be interpreted as seeking to explain A-consciousness, but trying to find a basis for P-consciousness. For example, Crick and Koch's oscillations are put forward because of a potential role in binding and working memory; that is, in integrating contents and making them available for control (working memory is itself an availability system, after all). If both the empirical hypothesis (oscillations subserve availability) and the bridging
principle (availability goes along with experience) are correct, then the oscillations are a neural correlate of experience, which is just what Crick and Koch claim.

The same holds elsewhere. Shallice's "selector inputs" for "action systems" (1972) and his "Supervisory System" (1988a; 1988b) are clearly supposed to play a central role in availability and control; if the empirical hypothesis is correct, these could reasonably be regarded as part of the basis for conscious experience. Similarly, the "global workspace" of Baars (1988), the "high-quality representations" of Farah (1994), the "temporally-extended neural activity" of Libet (1993), and many other proposals can be all be seen as offering mechanisms in the process whereby some contents are made available for global control. The common element is striking. Of course, it is an empirical question which of these proposals is correct (although more than one might be, if they offer accounts of different parts of the process or descriptions at different levels). But insofar as these mechanisms play a role in the availability/control process, they are candidates to be neural or cognitive correlates of experience, which is often what the authors suggest (correlation is all that Farah and Libet claim; Shallice and Baars oscillate between "correspondence" and explanation).

The picture is this: (1) we know that availability goes along with experience; (2) we empirically discover that some mechanism plays the central role in the availability process. We may then conclude that the mechanism is part of the explanation of A-consciousness and part of the basis of P-consciousness. Of course, the story about the mechanism does not alone explain P-consciousness, as we still have not explained why availability always goes along with experience; we have simply taken for granted that it does. But if we are prepared to take the link between availability and experience as a kind of background assumption (perhaps for later explanation), this can provide a useful partial explanation of the contents of experience.

A phenomenal consciousness module?

Interestingly, this analysis allows us to make some sense of the idea of a phenomenal consciousness module. If it turns out that there is a single system responsible for mediating the availability of certain contents for global control - something like Baars' global workspace or Shallice's supervisory system - then it might be plausible that the contents of that system correspond precisely to the contents of experience, and maybe we could call it a P-consciousness module. I do not think it is probable that there is such a module - more likely there are many different mechanisms by which contents become available for a control role - but at least the idea makes sense. But the only way there could be a "P-consciousness" module would be for it to be an availability/control module. If a module were dissociable from the relevant role in availability and control, the considerations above suggest that it would be dissociable from P-consciousness too.

In particular, there is something very strange about the idea of an "epiphenomenal" P-consciousness module (Block's Figure 3). The main motivation for epiphenomenalism is surely that experience seems superfluous to any information-processing; but Block's idea suggests an implausible epiphenomenalism within the information-processing story. Indeed, if the module has no effect on other processes, then we
could lesion it with no external change (same reports, even), and no empirical evidence could support the hypothesis. Perhaps Block means to allow that the module has the very limited function of causing phenomenal reports, so that lesioning it eliminates remarks such as "I am having a blue sensation." But now either (1) remarks such as "There is a blue object", confident blue-directed behavior, and so on are all eliminated too - in which case the module had an important function after all - or (2) they are preserved (a kind of ultra-superblindsight), implying an extraordinary independence between the pathways responsible for phenomenal report and those responsible for visual descriptions and normal visual processing. Given the remarkable coherence between visual descriptions and reports of visual experience, one presumes that they are tied more closely than this.

**The function of consciousness?**

The link between P-consciousness and (modified) A-consciousness makes the search for a function for P-consciousness even more hopeless. Given the correlation, any purported function for P-consciousness can be attributed to A-consciousness instead.

Only those who implausibly identify the concept of P-consciousness with that of (modified) A-consciousness have a way out. If one accepts the conceptual distinction, one will accept the conceivability of zombie functional isomorphs (made of silicon, say). To be consistent, one must then accept the conceivability of zombie physical isomorphs, as there is no more of a conceptual entailment from neural stuff to consciousness than there is from silicon stuff. From here, it is easy to see that P-consciousness gives me no functional advantage. After all, I am different from my zombie twin only in that I have P-consciousness and he does not, but we are functionally identical.

Block suggests that P-consciousness might "grease the wheels" of A-consciousness, but this cannot work. P-consciousness is redundant to the explanation of the physical mechanisms of A-consciousness, as the conceivability of the zombie shows: same physical mechanisms, same explanation of A-consciousness, no P-consciousness. The remaining option is to "identify" P-consciousness with modified A-consciousness (empirically but not conceptually), solving the problem by fiat. I think this sort of identification without explanation misunderstands the way that scientific identification works (see Chalmers 1995; Jackson 1994), but in any case it still leaves the concept of P-consciousness with no explanatory role in cognitive functioning. The independent concept of A-consciousness does all the work. I think it best to accept instead that phenomenal consciousness is distinct from any physical or functional property, and that it does not need to have a function to be central to our mental lives.

In Section 5 of his interesting article, Goldman suggests that the consideration of imaginary cases can be valuable in the analysis of our psychological concepts. In particular, he argues that we can imagine a system that is isomorphic to us under any functional description, but which lacks qualitative mental states, such as pains and color sensations. Whether or not such a being is empirically possible, it certainly seems to be logically possible, or conceptually coherent. Goldman argues from this possibility to the conclusion that our concepts of qualitative mental states cannot be analyzed entirely in functional terms.

This thought-experimental methodology seems sound to me, and I agree with Goldman on the logical possibility of these absent-qualia cases (although many functionalists would not; e.g. Armstrong 1968, Dennett 1991, Shoemaker 1975). However, I think that this methodology can be taken further, yielding conclusions that oppose those that Goldman draws elsewhere in the article.

Consider: if it is logically possible that my functional isomorph might lack qualia entirely, it seems equally logically possible that there could be a qualia-free physical replica of me. We have already seen that there is no conceptual entailment relation from the functional properties of a system to the qualitative properties; it seems even clearer that there is no entailment relation from the non-functional implementational details to qualia. (What conceptual entailment could neurophysiological detail possibly provide that silicon, or even Chinese nations, could not?) So let's consider Zombie Dave, my qualia-free physical replica. Zombie Dave is almost certainly not an empirical impossibility, but he is a conceptual possibility.

First, let us ask: Does Zombie Dave have beliefs? It seems to me that he does. If we ask him where his car is, he'll tell us that it's in the driveway. If we ask him whether he likes basketball, he tells us that he does. If we tell him that there's a basketball game starting across town in half an hour, he'll immediately head for the driveway, an action that seems to be best explained by the hypothesis that he wants to go to the basketball game, believes that his car will get him there, and believes that his car is in the driveway. All of the usual principles of psychological explanation sanction attributing beliefs to Zombie Dave; explaining his action without the attribution of beliefs would be a fearsomely complex task. (It might be
objected that Zombie Dave lacks the external grounding required for belief contents, but we can avoid this problem by stipulating that his environment and history are physically indistinguishable from mine.)

Goldman argues in Section 8 that beliefs, like perceptual states, are typically accompanied by qualia; but much more would be required to conclude that qualia are essential to a state's being a belief. (Searle (1990) has given an argument in this direction, but it does not seem to have been widely accepted.) Zombie Dave's beliefs may not be colored by the usual phenomenological tinges, but it seems reasonable to say that they are nevertheless beliefs. Beliefs, unlike qualia, seem to be characterized primarily by the role that they play in the mind's causal economy. (To illustrate the difference, note that it seems coherent to be an epiphenomenalist about qualia, whether or not one finds the position plausible; but there seems to be something conceptually wrong with the idea that beliefs could be epiphenomenal.) So qualia-free believers like Zombie Dave are quite conceptually coherent, and qualia don't seem to be an essential part of our concept of belief.

Even if one resists the idea that Zombie Dave has beliefs, we can still use him to show that qualia cannot be the primary mechanism in the self-ascription of our mental states. For Zombie Dave ascribes precisely the same mental states to himself as I do! By some process or other, he'll tell you that he thinks that Bob Dylan makes good music. How can this ability for self-ascription be explained? Clearly not by appealing to qualia, for Zombie Dave doesn't have any. The story will presumably have to be told in purely functional terms. But once we have this story in hand, it will apply equally to proud possessors of qualia such as ourselves. The self-ascription mechanisms that Zombie Dave uses are equally the mechanisms that we use; at most, the difference consists in the fact that his ascriptions might be wrong, whereas ours are right. Therefore there is no need to invoke qualia in the explanation of how we ascribe mental states to ourselves. Zombie Dave does the job, presumably, either by reasoning from non-qualitative evidence, or by simply being thrown into the appropriate state. It seems likely that we do it the same way, and that qualia are a red herring.

All this seems to lead to a rather epiphenomenalist view of qualia. Note, for instance, that the argument in the above paragraph doesn't apply only to the self-ascription of beliefs, but also to the self-ascription of qualia; so that qualia don't seem to play a primary role in the process by which we ascribe qualia to ourselves! (Zombie Dave, after all, ascribes himself the same qualia; it's just that he's wrong about it.) I am happy enough with the conclusion that qualia are mostly just along for the ride, but I suspect that Goldman and others will not be. It seems to me that the only way to avoid this conclusion is to deny that Zombie Dave is a conceptual possibility; and the only principled way to deny that Zombie Dave is a conceptual possibility is to allow that functional organization is conceptually constitutive of qualitative content. This is probably a step that Goldman doesn't wish to take, as it would negate many of his conclusions, but there may not be any tenable middle ground between functionalism and epiphenomenalism.

[chalmers@arizona.edu](mailto:chalmers@arizona.edu)

How does conscious experience emerge from a physical basis? At a first glance, this is *the* question about the mind that most needs answering. So it is curious that those who study the mind professionally have often avoided the question entirely. In psychology, the cognitive revolution did not make consciousness respectable: most cognitive psychologists have stuck to subjects such as learning, memory, and perception instead. Neuroscientists have been known to speculate on the topic, but usually only late at night, after a few drinks. Even philosophers have been curiously diffident. Some have been exercised by the fact that there is a problem, others have been concerned to deny the problem entirely, but the focus of inquiry has remained elsewhere. As in all these fields, serious theories of consciousness have been hard to come by.

But consciousness is making a comeback. In the last few years, popular books on the subject by Francis Crick, Daniel Dennett, and Roger Penrose have provoked widespread discussion. Not everybody agrees on just what the problems are, and almost nobody agrees on where a solution will lie, but almost everyone has an opinion. Philosophers are having a field day, neuroscientists are speculating a little earlier in the evening, and even psychologists have begun to sheepishly utter the dreaded C-word. At conferences on the subject, researchers from different fields are learning to speak each other's language. New books are appearing every month. And there are now three academic journals devoted to the subject.

The latest and flashiest of these journals is the *Journal of Consciousness Studies*. The first issue boasts interviews with such luminaries as Crick and Penrose, a number of conference reports, and refereed articles on consciousness based in areas as diverse as quantum mechanics and Buddhist philosophy. The journal's center of gravity is outside the mainstream, with the editors admitting a preference for "radical" conceptualizations of the subject. The bulk of the first issue is devoted to scientific approaches of one sort or another, but we are promised a discussion of "ethical, spiritual, and social issues" in the future. All in all, the journal is surprisingly accessible to the general reader, and despite its biases it provides a useful look at the state of play in consciousness research *circa* 1994.

One thing that quickly becomes clear is that the most puzzling questions about consciousness are just as puzzling as ever. A distinction is made a number of times between the "easy" problems of consciousness and the "hard" problem. The easy problems are those of finding neural mechanisms and explaining...
cognitive functions: the ability to discriminate and categorize environmental stimuli, the capacity to verbally report mental states, the difference between waking and sleeping. The hard problem is that of experience: why does all this processing give rise to an experienced inner life at all? While progress is being made on the easy problems, the hard problem remains perplexing. Even Crick and Penrose concede that so far they have little idea how the problem might be solved. They simply hope that if we do enough investigation in neuroscience (for Crick) or in physics (for Penrose), the faint outlines of a solution might be revealed. At this point, such remarks are not much more than an expression of faith.

But even without a solution to the hard problem, there is much of interest in the field of consciousness studies. The papers in this issue range from the conventional to the exotic. The most sober paper concerns the "binding problem" in neuroscience - the problem of how the brain integrates different pieces of information about the same object. A popular hypothesis has been that binding is achieved by groups of neurons oscillating in phase, but philosopher Valerie Hardcastle suggests that the evidence here is weak, and recommends a higher-level approach to the issue. In tying together evidence from a number of different fields, this thoughtful paper illustrates the benefits of an interdisciplinary approach to the science of the mind.

It is the quantum-mechanical papers that will draw the most attention. In a hypothesis that has been endorsed by Penrose, anesthesiologist Stuart Hameroff suggests that the key to consciousness lies in microtubules, large molecules found within the cell wall of a neuron. Noting that these are finely poised between the quantum and neural realms - small enough to maintain a state of quantum coherence, but large enough to affect neural activity - Hameroff argues that these could mediate a quantum role in brain function. This is recommended as a solution to the binding problem (through quantum nonlocality), as an explanation of "intuitive" processing (through quantum superposition) and problem-solving (through wavefunction collapse), and even as the key to the problem of free will (through quantum indeterminacy)! Critics will respond that all of these problems can be handled by orthodox methods, but Hameroff's ideas are at least provocative.

Another paper presents experimental evidence that EEG measurements on the brain affect performance on various cognitive tasks. The authors (Nunn, Clarke, and Blott) suggest that the measurement may cause the brain's quantum wave state to collapse! Perhaps this is related to Benjamin Libet's suggestion in a neighbouring paper that the brain has an associated "conscious mental field", which may affect neural function. In both cases, however, the evidence is quite tenuous, and one might ask for a more rigorous theoretical basis for the strong claims that are made. On the other hand, psychologist John Beloff provides a spirited defense of the claims of parapsychology, and argues that the experimental evidence has been dismissed more quickly than it should have been. There is room for a debate here: just when do well-supported prior convictions justify the easy dismissal of evidence for radically different views? No doubt many mainstream scientists will dismiss the evidence of Nunn et al and of Beloff without qualms. Is this reasonable?

Two of the most interesting papers relate Eastern thought to the study of the mind. Eleanor Rosch uses some ideas from the Buddhist Madhyamika school in developing a theory of the way that people think about causality, and Robert Forman discusses mystical experiences as revealed in the writings of the
Hindu Upanishads. Rosch brings the Buddhist ideas to bear on issues in cognitive psychology, while Forman uses his study to help adjudicate a debate between "constructivists" and "decontextualists" in religious studies. In papers like these, there is no claim that a theory of consciousness is on offer, but the wide-ranging discussion provides useful insights.

To judge from this issue, one would think that researchers on consciousness come in four varieties: neuroscientists, quantum theorists, parapsychologists, and mystics. This makes for a spicy journal, but it would be nice to see contributions from mainstream cognitive psychology and artificial intelligence in there too. It would be a great pity if too much spice caused conventional researchers to dismiss the journal altogether. But it is pleasant that we are promised discussions in the humanities as well as in science, with papers on cultural aspects of consciousness and on the philosophy of mind slated for future issues. The journal will continue to have something for everybody.

So, the question arises: Has consciousness been explained? Is it likely to be explained any time soon? After a while, I found that I had a curious reaction. The approaches here are too wild for the easy problems, but not wild enough for the hard problem. When it comes to the explanation of cognitive functioning, conventional methods seem to do just fine, and it is hard to see why things like quantum mechanics need to be brought in at all. But when it comes to the hard problem of conscious experience, all the quantum mechanics and parapsychology in the world does not add up to a solution. Why should quantum coherence in microtubules give rise to conscious experience? This question seems no easier to answer than the corresponding question about information-processing in neurons. Radical as the approach is, it is ultimately not radical enough.

Still, a journal like this serves a useful function, both in stimulating thought and in letting a thousand flowers bloom. After all, the problem of conscious experience is so hard that when a solution finally appears, it will probably look crazy. With an unconventional journal on the scene, the required craziness will be given room to flourish.
1 The principle of organizational invariance

It is widely accepted that conscious experience has a physical basis. That is, the properties of experience (phenomenal properties, or qualia) systematically depend on physical properties according to some lawful relation. There are two key questions about this relation. The first concerns the strength of the laws: are they logically or metaphysically necessary, so that consciousness is nothing "over and above" the underlying physical process, or are they merely contingent laws like the law of gravity? This question about the strength of the psychophysical link is the basis for debates over physicalism and property dualism. The second question concerns the shape of the laws: precisely how do phenomenal properties depend on physical properties? What sort of physical properties enter into the laws' antecedents, for instance; consequently, what sort of physical systems can give rise to conscious experience? It is this second question that I address in this paper.

To put the issue differently, even once it is accepted that experience arises from physical systems, the question remains open: in virtue of what sort of physical properties does conscious experience arise? Some property that brains can possess will presumably be among them, but it is far from clear just what the relevant properties are. Some have suggested biochemical properties; some have suggested quantum-mechanical properties; many have professed uncertainty. A natural suggestion is that when experience arises from a physical system, it does so in virtue of the system's functional organization. On this view, the chemical and indeed the quantum substrates of the brain are not directly relevant to the existence of consciousness, although they may be indirectly relevant. What is central is rather the brain's abstract causal organization, an organization that might be realized in many different physical substrates.

In this paper I defend this view. Specifically, I defend a principle of organizational invariance, holding that experience is invariant across systems with the same fine-grained functional organization. More precisely, the principle states that given any system that has conscious experiences, then any system that has the same functional organization at a fine enough grain will have qualitatively identical conscious experiences. A full specification of a system's fine-grained functional organization will fully determine any conscious experiences that arise.
To clarify this, we must first clarify the notion of functional organization. This is best understood as the *abstract pattern of causal interaction* between the components of a system, and perhaps between these components and external inputs and outputs. A functional organization is determined by specifying (1) a number of abstract components, (2) for each component, a number of different possible states, and (3) a system of dependency relations, specifying how the states of each component depends on the previous states of all components and on inputs to the system, and how outputs from the system depend on previous component states. Beyond specifying their number and their dependency relations, the nature of the components and the states is left unspecified.

A physical system *realizes* a given functional organization when the system can be divided into an appropriate number of physical components each with the appropriate number of possible states, such that the causal dependency relations between the components of the system, inputs, and outputs precisely reflect the dependency relations given in the specification of the functional organization. A given functional organization can be realized by diverse physical systems. For example, the organization realized by the brain at the neural level might in principle be realized by a silicon system.

A physical system has functional organization at many different levels, depending on how finely we individuate its parts and on how finely we divide the states of those parts. At a coarse level, for instance, it is likely that the two hemispheres of the brain can be seen as realizing a simple two-component organization, if we choose appropriate interdependent states of the hemispheres. It is generally more useful to view cognitive systems at a finer level, however. For our purposes I will always focus on a level of organization fine enough to determine the behavioral capacities and dispositions of a cognitive system. This is the role of the "fine enough grain" clause in the statement of the organizational invariance principle; the level of organization relevant to the application of the principle is one fine enough to determine a system's behavioral dispositions. In the brain, it is likely that the neural level suffices, although a coarser level might also work. For the purposes of illustration I will generally focus on the neural level of organization of the brain, but the arguments generalize.

Strictly speaking, for the purposes of the invariance principle we must require that for two systems to share their functional organization, they must be in corresponding states at the time in question; if not for this requirement, my sleeping twin might count as sharing my organization, but he certainly does not share my experiences. When two systems share their organization at a fine enough grain (including the requirement that they be in corresponding states), I will say that they are *functionally isomorphic* systems, or that they are *functional isomorphs*. The invariance principle holds that any functional isomorph of a conscious system has experiences that are qualitatively identical to those of the original system.

2Absent qualia and inverted qualia

The principle of organizational invariance is far from universally accepted. Some have thought it likely that for a system to be conscious it must have the right sort of biochemical makeup; if so, a metallic robot

http://www.u.arizona.edu/~chalmers/papers/qualia.html (2 of 18) [4/7/2002 1:47:49 PM]
or a silicon-based computer could never have experiences, no matter what its causal organization. Others have conceded that a robot or a computer might be conscious if it were organized appropriately, but have held that it might nevertheless have experiences quite different from the kind that we have. These two sorts of objections are often known as the *absent qualia* and *inverted qualia* objections to broadly functionalist theories of consciousness.

Arguments for the absent qualia objection usually consist in the description of a system that realizes whatever functional organization might be specified, but that is so outlandish that it is natural to suppose that it lacks conscious experience. For example, Block (1980) points out that the functional organization of the brain might be instantiated by the population of China, if they were organized appropriately, and argues that it is bizarre to suppose that this would somehow give rise to a group mind. In a similar way, John Searle (1980) notes that a given organization might be realized by "a sequence of water-pipes, or a set of wind-machines", but argues that these systems would not be conscious.

Arguments for the inverted qualia objection are often illustrated by considerations about experiences of color. According to this line of argument (taken by Shoemaker (1982) and Horgan (1984), among others), it is possible that a system might make precisely the same color discriminations that I do, but that when confronted by red objects it has the kind of experience that I have when confronted by blue objects. Further, it is argued that this might happen even when the systems are functionally isomorphic. If this argument succeeds, then even if the appropriate functional organization suffices for the existence of conscious experiences, it does not determine their specific nature. Instead, the specific nature of experiences must be dependent on non-organizational properties, such as specific neurophysiological properties.

Sometimes these arguments are intended as arguments for "possibility" only in some weak sense, such as logical or metaphysical possibility. These less ambitious forms of the arguments are the most likely to be successful. It seems difficult to deny that the absent qualia and inverted qualia scenarios are at least intelligible. With the aid of certain assumptions about possibility, this intelligibility can be extended into an argument for the logical and perhaps the metaphysical possibility of the scenarios. If successful, even these less ambitious arguments would suffice to refute some strong versions of functionalism, such as analytic functionalism and the view that phenomenal properties are identical to functional properties.

In the present paper I am not concerned with the logical or metaphysical possibility of these scenarios, however, but rather with their *empirical* (or natural, or nomological) possibility. The mere logical or metaphysical possibility of absent qualia is compatible with the claim that in the actual world, whenever the appropriate functional organization is realized, conscious experience is present. By analogy: many have judged it logically possible that a *physical* replica of a conscious system might lack conscious experience, while not wishing to deny that in the actual world, any such replica will be conscious. It is the claim about empirical possibility that is relevant to settling the issue at hand, which concerns a possible lawful relation between organization and experience. Mere intelligibility does not bear on this, any more than the intelligibility of a world without relativity can falsify Einstein's theory.
On the question of empirical possibility, the success of the absent qualia and inverted qualia arguments is unclear. To be sure, many have found it *counterintuitive* that the population of China might give rise to conscious experience if organized appropriately. The natural reply, however, is that it seems equally counterintuitive that a mass of $10^{11}$ appropriately organized neurons should give rise to consciousness, and yet it happens. Intuition is unreliable as a guide to empirical possibility, especially where a phenomenon as perplexing as conscious experience is concerned. If a brain can do the job of enabling conscious experience, it is far from obvious why an appropriately organized population, or indeed an appropriate organized set of water-pipes, could not.

The debate over absent and inverted qualia tends to produce a stand-off, then. Both proponents and opponents claim intuitions in support of their positions, but there are few grounds on which to settle the debate between them. Both positions seem to be epistemic possibilities, and due to the notorious difficulties in collecting experimental evidence about conscious experience, things might seem likely to stay that way.

I believe that the stand-off can be broken, and in this paper I will offer considerations that offer strong support to the principle of organizational invariance, suggesting that absent qualia and inverted qualia are empirically impossible. These arguments involve thought-experiments about gradual neural replacement, and take the form of a *reductio*. The first thought-experiment demonstrates that if absent qualia are possible, then then a phenomenon involving what I will call *Fading Qualia* is possible; but I will argue that we have good reason to believe that Fading Qualia are impossible. The second argument has broader scope and is more powerful, demonstrating that if absent qualia or inverted qualia are possible, then a phenomenon involving what I will call *Dancing Qualia* is possible; but I will argue that we have even better reason to believe that Dancing Qualia are impossible. If the arguments succeed, we have good reason to believe that absent and inverted qualia are impossible, and that the principle of organizational invariance is true.

These arguments do not constitute conclusive *proof* of the principle of organizational invariance. Such proof is generally not available in the domain of conscious experience, where for familiar reasons one cannot even disprove the hypothesis that there is only one conscious being. But even in the absence of proof, we can bring to bear arguments for the plausibility and implausibility of different possibilities, and not all possibilities end up equal. I use these thought-experiments as a *plausibility argument* for the principle of organizational invariance, by showing that the alternatives have implausible consequences. If an opponent wishes to hold on to the possibility of absent or inverted qualia she can still do so, but the thought-experiments show that the cost is higher than one might have expected.

Perhaps it is useful to see these thought-experiments as playing a role analogous to that played by the "Schrödinger's cat" thought-experiment in the interpretation of quantum mechanics. Schrödinger's thought-experiment does not deliver a decisive verdict in favor of one interpretation or another, but it brings out various plausibilities and implausibilities in the interpretations, and it is something that every interpretation must ultimately come to grips with. In a similar, any theory of consciousness must ultimately come to grips with the Fading and Dancing Qualia scenarios, and some will handle them better than others. In this way, the virtues and drawbacks of various theories are clarified.
3 Fading Qualia

The first scenario that I will present is relatively familiar,[*] but it is important to analyze it correctly, and it is a necessary preliminary to the more powerful second argument. In this thought-experiment, we assume for the purposes of reductio that absent qualia are empirically possible. It follows that there can be a system with the same functional organization as a conscious system (such as me), but which lacks conscious experience entirely due to some difference in non-organizational properties. Without loss of generality, suppose that this is because the system is made of silicon chips rather than neurons. Call this functional isomorph Robot. The causal patterns in Robot's processing system are the same as mine, but there is nothing it is like to be Robot.

*[[Neural replacement scenarios along the lines discussed in this section are discussed by Pylyshyn (1980), Savitt (1980), Cuda (1985), and Searle (1992), among others.]]

Given this scenario, we can construct a series of cases intermediate between me and Robot such that there is only a very small change at each step and such that functional organization is preserved throughout. We can imagine, for instance, replacing a certain number of my neurons by silicon chips. In the first such case, only a single neuron is replaced. Its replacement is a silicon chip that performs precisely the same local function as the neuron. We can imagine that it is equipped with tiny transducers that take in electrical signals and chemical ions and transforms these into a digital signal upon which the chip computes, with the result converted into the appropriate electrical and chemical outputs. As long as the chip has the right input/output function, the replacement will make no difference to the functional organization of the system.

In the second case, we replace two neighboring neurons with silicon chips. This is just as in the previous case, but once both neurons are replaced we can eliminate the intermediary, dispensing with the awkward transducers and effectors that mediate the connection between the chips and replacing it with a standard digital connection. Later cases proceed in a similar fashion, with larger and larger groups of neighboring neurons replaced by silicon chips. Within these groups, biochemical mechanisms have been dispensed with entirely, except at the periphery. In the final case, every neuron in the system has been replaced by a chip, and there are no biochemical mechanisms playing an essential role. (I abstract away here from detailed issues concerning whether, for instance, glial cells play a non-trivial role; if they do, they will be components of the appropriate functional organization, and will be replaced also.)

We can imagine that throughout, the internal system is connected to a body, is sensitive to bodily inputs, and produces motor movements in an appropriate way, via transducers and effectors. Each system in the sequence will be functionally isomorphic to me at a fine enough grain to share my behavioral dispositions. But while the system at one end of the spectrum is me, the system at the other end is essentially a copy of Robot.

To fix imagery, imagine that as the first system I am having rich conscious experiences. Perhaps I am at
a basketball game, surrounded by shouting fans, with all sorts of brightly-colored clothes in my environment, smelling the delicious aroma of junk food and perhaps suffering from a throbbing headache. Let us focus in particular on the bright red and yellow experiences I have when I watch the players' uniforms. ("Red experience" should be taken as shorthand for "color experience of the kind I usually have when presented with red objects", and so on throughout.) The final system, Robot, is in the same situation, processing the same inputs and producing similar behavior, but by hypothesis is experiencing nothing at all.

The question arises: What is it like to be the systems in between? For those systems intermediate between me and Robot, what, if anything, are they experiencing? As we move along the spectrum of cases, how does conscious experience vary? Presumably the very early cases have experiences much like mine, and the very late cases have little or no experience, but what of the cases in the middle?

Given that Robot, at the far end of the spectrum, is not conscious, it seems that one of two things must happen along the way. Either consciousness gradually fades over the series of cases, before eventually disappearing, or somewhere along the way consciousness suddenly blinks out, although the preceding case had rich conscious experiences. Call the first possibility Fading Qualia and the second Suddenly Disappearing Qualia.

On the second hypothesis, the replacement of a single neuron could be responsible for the vanishing of an entire field of conscious experience. If so, we could switch back and forth between a neuron and its silicon replacement, with a field of experience blinking in and out of existence on demand. This seems antecedently implausible, if not entirely bizarre. If Suddenly Disappearing Qualia were possible, there would be brute discontinuities in the laws of nature unlike those we find anywhere else. Any specific point for qualia to suddenly disappear (50 percent neural? 25 percent?) would be quite arbitrary. We might even run the experiment at a finer grain within the neuron, so that ultimately the replacement of a few molecules produces a sudden disappearance of experience. As always in these matters, the hypothesis cannot be disproved, but its antecedent plausibility is very low.

*[[One might argue that there are situations in nonlinear dynamics in which one magnitude depends sensitively on another, with large changes in the first arising from small changes in the second. But in these cases the dependence is nevertheless continuous, so there will be intermediate cases in which the dependent magnitude takes on intermediate values; the analogy therefore leads to Fading Qualia, below. And in any case, the sensitive dependence in these cases generally arise from the compound effects of a number of more basic gradual dependencies. In all fundamental laws known to date, the dependence of one magnitude on another is continuous in this fashion, and there is no way to compound continuity into discontinuity. Suddenly Disappearing Qualia, in contrast to nonlinear dynamics, would therefore require brute discontinuities in fundamental laws.]]

This leaves the first hypothesis, Fading Qualia. To get a fix on this hypothesis, consider a system halfway along the spectrum between me and Robot, after consciousness has degraded considerably but before it has gone altogether. Call this system Joe. What is it like to be Joe? Joe, of course, is functionally isomorphic to me. He says all the same things about his experiences as I do about mine. At the basketball game, he exclaims about the vivid bright red and yellow uniforms of the basketball players.
By hypothesis, though, Joe is not having bright red and yellow experiences at all. Instead, perhaps he is experiencing tepid pink and murky brown. Perhaps he is having the faintest of red and yellow experiences. Perhaps his experiences have darkened almost to black. There are various conceivable ways in which red experiences might gradually transmute to no experience, and probably more ways that we cannot conceive. But presumably in each of these transmutation scenarios, experiences stop being *bright* before they vanish (otherwise we are left with the problem of Suddenly Disappearing Qualia). Similarly, there is presumably a point at which subtle distinctions in my experience are no longer present in an intermediate system's experience; if we are to suppose that all the distinctions in my experience are present right up until a moment when they simultaneously vanish, we are left with another version of Suddenly Disappearing Qualia.

For specificity, then, let us imagine that Joe experiences faded pink where I see bright red, with many distinctions between shades of my experience no longer present in shades of his experience. Where I am having loud noise experiences, perhaps Joe is experiencing only a distant rumble. Not everything is so bad for Joe: where I have a throbbing headache, he only has the mildest twinge.

The crucial point here is that Joe is systematically wrong about everything that he is experiencing. He certainly says that he is having bright red and yellow experiences, but he is merely experiencing tepid pink. If you ask him, he will claim to be experiencing all sorts of subtly different shades of red, but in fact many of these are quite homogeneous in his experience. He may even complain about the noise, when his auditory experience is really very mild. Worse, on a functional construal of judgment, Joe will even judge that he has all these complex experiences that he in fact lacks. In short, Joe is utterly out of touch with his conscious experience, and is incapable of getting in touch.

There is a significant implausibility here. This is a being whose rational processes are functioning and who is in fact conscious, but who is completely wrong about his own conscious experiences. Perhaps in the extreme case, when all is dark inside, it is reasonable to suppose that a system could be so misguided in its claims and judgments - after all, in a sense there is nobody in there to be wrong. But in the intermediate case, this is much less plausible. In every case with which we are familiar, conscious beings are generally capable of forming accurate judgments about their experience, in the absence of distraction and irrationality. For a sentient, rational being that is suffering from no functional pathology to be so systematically out of touch with its experiences would imply a strong dissociation between consciousness and cognition. We have little reason to believe that consciousness is such an ill-behaved phenomenon, and good reason to believe otherwise.

To be sure, Fading Qualia may be logically possible. Arguably, there is no contradiction in the notion of a system that is so wrong about its experiences. But logical possibility and empirical possibility are different things. One of the most salient empirical facts about conscious experience is that when a conscious being with the appropriate conceptual sophistication has experiences, it is at least capable of forming reasonable judgments about those experiences. Perhaps there are some cases where judgment is impaired due to a malfunction in rational processes, but this is not such a case. Joe's processes are functioning as well as mine -- by hypothesis, he is functionally isomorphic. It is just that he happens to be
completely misguided about his experience.

There are various cases of fading qualia in everyday life, of course. Think of what happens when one is dropping off to sleep; or think of moving back along the evolutionary chain from people to trilobites. In each case, as we move along a spectrum of cases, conscious experience gradually fades away. But in each of these cases, the fading is accompanied by a corresponding change in functioning. When I become drowsy, I do not believe that I am wide awake and having intense experiences (unless perhaps I start to dream, in which case I very likely am having intense experiences). The lack of richness in a dog's experience of color accompanies a corresponding lack of discriminatory power in a dog's visual mechanisms. These cases are quite unlike the case under consideration, in which experience fades while functioning stays constant. Joe's mechanisms can still discriminate subtly different wavelengths of light, and he certainly judges that such discriminations are reflected in his experience, but we are to believe that his experience does not reflect these discriminations at all.

Searle[*] discusses a thought-experiment like this one, and suggests the following possibility:

...as the silicon is progressively implanted into your dwindling brain, you find that the area of your conscious experience is shrinking, but that this shows no effect on your external behavior. You find, to your total amazement, that you are indeed losing control of your external behavior. You find, for example, that when the doctors test your vision, you hear them say, "We are holding up a red object in front of you; please tell us what you see." You want to cry out, "I can't see anything. I'm going totally blind." But you hear your voice saying in a way that is completely out of your control, "I see a red object in front of me." If we carry the thought-experiment out to the limit, we get a much more depressing result than last time. We imagine that your conscious experience slowly shrinks to nothing, while your externally observable behavior remains the same.

*[[Searle, *The Rediscovery of the Mind*, pp. 66-67.]]

Here, Searle embraces the possibility of Fading Qualia, but suggests that such a system need not be systematically mistaken in its beliefs about its experience. The system might have true beliefs about its experience, but beliefs that are impotent to affect its behavior.[*]

*[[Searle also raises the possibility that upon silicon replacement, the system might be slowly reduced to paralysis, or have its functioning otherwise impaired. Such a scenario is irrelevant to the truth of the invariance principle, however, which applies only to systems with the appropriate functional organization. If a silicon system does not duplicate the organization of the original system, the principle does not even come into play.]]

It seems that this possibility can be ruled out, however. There is simply no room in the system for any new beliefs to be formed. Unless one is a dualist of a very strong variety, beliefs must be reflected in the functioning of a system - perhaps not in behavior, but at least in some process. But this system is identical to the original system (me) at a fine grain. There is no room for new beliefs like "I can't see..."
anything", new desires like the desire to cry out, and other new cognitive states such as amazement. Nothing in the physical system can correspond to that amazement. There is no room for it in the neurons, which after all are identical to a subset of the neurons supporting the usual beliefs; and Searle is surely not suggesting that the silicon replacement is itself supporting the new beliefs! Failing a remarkable, magical interaction effect between neurons and silicon - and one that does not manifest itself anywhere in processing, as organization is preserved throughout - such new beliefs will not arise.

While it might just seem plausible that an organization-preserving change from neurons to silicon might twist a few experiences from red to blue, a change in beliefs from "Nice basketball game" to "I seem to be stuck in a bad horror movie!" is of a different order of magnitude. If such a major change in cognitive contents were not mirrored in a change in functional organization, cognition would float free of internal functioning like a disembodied mind. If the contents of cognitive states supervened on physical states at all, they could do so only by the most arbitrary and capricious of rules (if this organization in neurons, then "pretty colors!"; if this organization in silicon, then "Alas!").

It follows that the possibility of Fading Qualia requires either a bizarre relationship between belief contents and physical states, or the possibility of beings that are massively mistaken about their own conscious experiences despite being fully rational. Both of these hypotheses are significantly less plausible than the hypothesis that rational conscious beings are generally correct in their judgments about their experiences. A much more reasonable hypothesis is therefore that when neurons are replaced, qualia do not fade at all. A system like Joe, in practice, will have conscious experiences just as rich as mine. If so, then our original assumption was wrong, and the original isomorph, Robot, has conscious experiences.

This thought-experiment can be straightforwardly extended to other sorts of functional isomorphs, including those that differ in shape, size, and physical makeup. All we need do is construct a sequence of intermediate cases, each with the same functional organization. In each case the conclusion is the same. If such a system is not conscious, then there exists an intermediate system that is conscious, has faded experiences, and is completely wrong about its experiences. Unless we are prepared to accept this massive dissociation between consciousness and cognition, the original system must have been conscious after all.

We can even extend the reasoning straightforwardly to the case of an appropriately-organized population: we simply need to imagine neurons replaced one-by-one with tiny homunculi, ending up with a network of homunculi that is essentially equivalent to the population controlling a robot. (If one objects to tiny homunculi, they can be external and of normal size, as long as they are equipped with appropriate radio connections to the body when necessary.) Precisely the same considerations about intermediate cases arise. One can also imagine going from a multiple-homunculi case to a single-homunculus case, yielding something like Searle's "Chinese room" example. We need only suppose that the homunculi gradually "double up" on their tasks, leaving written records of the state of each component, until only a single homunculus does all the work. If the causal organization of the original system is preserved, even if it is only among a system of marks on paper, then the same arguments suggest that the system will have experiences. (Of course, we should not expect the homunculus itself to
have the experiences; it is merely acting as a sort of causal facilitator.)

If Absent Qualia are possible, then Fading Qualia are possible. But I have argued above that it is very unlikely that Fading Qualia are possible. It follows that it is very unlikely that absent qualia are possible.

Some might object that these thought-experiment are the stuff of science fiction rather than the stuff of reality, and point out that this sort of neural replacement would be quite impossible in practice. But although it might be technologically impossible, there is no reason to believe that the neural replacement scenario should be nomologically impossible. We already have prosthetic arms and legs. Prosthetic eyes lie within the foreseeable future, and there seems to be no reason why a prosthetic neuron is impossible in principle. Even if it were impossible for some technical reason (perhaps there would not be enough room for a silicon replacement to do its work?), it is entirely unclear what bearing this technical fact would have on the principled force of the thought-experiment. There will surely be some systems between which gradual replacement is possible; will the objector hold that the invariance principle holds for those systems, but no other? If so, the situation seems quite arbitrary; if not, then there must be a deeper objection available.

Others might object that no silicon replacement could perform even the local function of a neuron, perhaps because neural function is uncomputable. There is little evidence for this, but it should be noted that even if it is true, it does not affect the argument for the invariance principle. If silicon really could not even duplicate the function of a neural system, then a functional isomorph made of silicon would be impossible, and the assessment of silicon systems would simply be irrelevant to the invariance principle. To evaluate the truth of the principle, it is only functionally isomorphic systems that are relevant.

Another objection notes that there are actual cases in which subjects are seriously mistaken about their experiences. For example, in cases of blindness denial, subjects believe that they are having visual experiences when they likely have none. In these cases, however, we are no longer dealing with fully rational systems. In systems whose belief-formation mechanisms are impaired, anything goes. Such systems might believe that they are Napoleon, or that the moon is pink. My "faded" isomorph Joe, by contrast, is a fully rational system, whose cognitive mechanisms are functioning just as well as mine. In conversation, he seems perfectly sensible. We cannot point to any unusually poor inferential connections between his beliefs, or any systematic psychiatric disorder that is leading his thought processes to be biased toward faulty reasoning. Joe is an eminently thoughtful, reasonable person, who exhibits none of the confabulatory symptoms of those with blindness denial. The cases are therefore disanalogous. The plausible claim is not that no system can be massively mistaken about its experiences, but that no rational system whose cognitive mechanisms are unimpaired can be so mistaken. Joe is certainly a rational system whose mechanisms are working as well as mine, so the argument is unaffected.

Some object that this argument has the form of a Sorites or "slippery-slope" argument, and observe that these arguments are notoriously suspect. Using a Sorites argument, we can "show" that even a grain of a sand is a heap; after all, a million grains of sand form a heap, and if we take a single grain away from a heap we still have a heap. This objection is based on a superficial reading of the thought-experiment,
however. Sorites arguments gain their force by ignoring the fact that some apparent dichotomy is in fact a continuum; there are all sorts of vague cases between heaps and non-heaps, for instance. The Fading Qualia argument, by contrast, explicitly accepts the possibility of a continuum, but argues that intermediate cases are impossible for independent reasons. The argument is therefore not a Sorites argument.

Ultimately, the only tenable way for an opponent of organizational invariance to respond to this argument is to bite the bullet and accept the possibility of Fading Qualia, and the consequent possibility that a rational conscious system might be massively mistaken about its experience, or perhaps to bite another bullet and accept Suddenly Disappearing Qualia and the associated brute discontinuities. These positions seem much less plausible than the alternative, other things being equal, but they are the only way to avoid it. But there is worse to come: the argument to follow provides an even more powerful case against the possibility of absent qualia, so opponents of organizational invariance cannot rest easily.

4 Dancing Qualia

If the Fading Qualia argument succeeds, it establishes that functional isomorphs of a conscious system will have conscious experience, but it does not establish that isomorphs have the same sort of conscious experience. The preceding argument has no bearing on the possibility of inverted qualia. For all that has gone before, where I am having a red experience, my silicon functional isomorph might be having a blue experience, or some other kind of experience that is quite foreign to me.

One might think that the Fading Qualia argument could be directly adapted to provide an argument against the possibility of inverted qualia, but that strategy fails. If I have a red experience and my functional isomorph has a blue experience, there is no immediate problem with the idea of intermediate cases with intermediate experiences. These systems might be simply suffering from milder cases of qualia inversion, and are no more problematic than the extreme case. These systems will not be systematically wrong about their experiences. Where they claim to experience distinctions, they may really be experiencing distinctions; where they claim to be having intense experiences, they may still be having intense experiences. To be sure, the experiences they call "red" differ from those I call "red", but this is already an accepted feature of the usual inversion case. The difference between these cases and the Fading Qualia cases is that these cases preserve the structure of experience throughout, so that their existence implies no implausible dissociation between experience and cognition.

Nevertheless, a good argument against the possibility of inverted qualia can be found in the vicinity. Once again, for the purposes of *reductio*, assume that inverted qualia are empirically possible. Then there can be two functionally isomorphic systems that are having different experiences. Suppose for the sake of illustration that these systems are me, having a red experience, and my silicon isomorph, having a blue experience (there is a small caveat about generality, which I discuss below).

As before, we construct a series of cases intermediate between me and my isomorph. Here, the argument takes a different turn. We need not worry about the way in which experiences change as we move along
the series. All that matters is that there must be two points $A$ and $B$ in this series, such that no more than one-tenth of the system is replaced between $A$ and $B$, and such that $A$ and $B$ have significantly different experiences. To see that this must be the case, we need only consider the points at which 10 percent, 20 percent, and so on up to 90 percent of the brain has been replaced. Red and blue are sufficiently different experiences that some neighboring pairs here must be significantly different (that is, different enough that the difference would be noticeable if they were experienced by the same person); there is no way to get from red to blue by ten non-noticeable jumps.

There must therefore be two systems that differ in at most one-tenth of their internal makeup, but that have significantly different experiences. For the purposes of illustration, let these systems be me and Bill. Where I have a red experience, Bill has a slightly different experience. We may as well suppose that Bill sees blue; perhaps his experience will be more similar to mine than that, but that makes no difference to the argument. The two systems also differ in that where there are neurons in some small region of my brain, there are silicon chips in Bill's brain. This substitution of a silicon circuit for a neural circuit is the only physical difference between me and Bill.

The crucial step in the thought-experiment is to take a silicon circuit just like Bill's and install it in my head as a backup circuit. This circuit will be functionally isomorphic to a circuit already present in my head. We equip the circuit with transducers and effectors so that it can interact with the rest of my brain, but we do not hook it up directly. Instead, we install a switch that can switch directly between the neural and silicon circuits. Upon flipping the switch, the neural circuit becomes irrelevant and the silicon circuit takes over. We can imagine that the switch controls the points of interface where the relevant circuits affects the rest of the brain. When it is switched, the connections from the neural circuit are pushed out of the way, and the silicon circuit's effectors are attached. (We might imagine that the transducers for both circuits are attached the entire time, so that the state of both circuits evolves appropriately, but so that only one circuit at a time plays a role in processing. We could also run a similar experiment where both transducers and effectors are disconnected, to ensure that the backup circuit is entirely isolated from the rest of the system. This would change a few details, but the moral would be the same.)

Immediately after flipping the switch, processing that was once performed by the neural circuit is now performed by the silicon circuit. The flow of control within the system has been redirected. However, my functional organization is exactly the same as it would have been if we had not flipped the switch. The only relevant difference between the two cases is the physical makeup of one circuit within the system. There is also a difference in the physical makeup of another "dangling" circuit, but this is irrelevant to functional organization, as it plays no role in affecting other components of the system and directing behavior.

What happens to my experience when we flip the switch? Before installing the circuit, I was experiencing red. After we install it but before we flip the switch, I will presumably still be experiencing red, as the only difference is the addition of a circuit that is not involved in processing in any way; for all the relevance it has to my processing, I might as well have eaten it. After flipping the switch, however, I am more or less the same system as Bill. The only difference between Bill and me now is that I have a causally irrelevant neural circuit dangling from the system (we might even imagine that the circuit is
destroyed when the switch is flipped). Bill, by hypothesis, was enjoying a blue experience. After the switch, then, I will have a blue experience too.

What will happen, then, is that my experience will change "before my eyes". Where I was once experiencing red, I will now experience blue. All of a sudden, I will have a blue experience of the apple on my desk. We can even imagine flipping the switch back and forth a number of times, so that the red and blue experiences "dance" before my eyes.

This might seem reasonable at first - it is a strangely appealing image - but something very odd is going on here. My experiences are switching from red to blue, but I do not notice any change. Even as we flip the switch a number of times and my qualia dance back and forth, I will simply go about my business, not noticing anything unusual. My functional organization remains normal throughout. In particular, my functional organization after flipping the switch evolves just as it would have if the switch had not been flipped. There is no special difference in my behavioral dispositions. I am not suddenly disposed to say "Hmm! Something strange is going on!". There is no room for a sudden start, for an exclamation, or even for a distraction of attention. My cognitive organization is just as it usually is, and in particular is precisely as it would have been had the switch not been flipped.

Certainly, on any functional construal of judgment, it is clear that I do not make any novel judgments due to the flip. Even if one were to dispute a functional account of judgment, it is is extremely implausible that a simple organization-preserving replacement of a neural circuit by a silicon circuit could be responsible for the addition of significant new judgments such as "My qualia just flipped". As in the case of Fading Qualia, there is simply no room for such a change to take place, unless it is in an accompanying Cartesian disembodied mind.

We are therefore led once more into a reductio ad absurdum. It seems entirely implausible to suppose that my experiences could change in such a significant way, even with me paying full attention, without my being able to notice the change. It would suggest once again an extreme dissociation between consciousness and cognition. If this kind of thing could happen, then psychology and phenomenology would be radically out of step, much further out of step than even the Fading Qualia scenario would imply.

This "Dancing Qualia" scenario may be logically possible (although the case is so extreme that it seems only just logically possible), but that does not mean we should take it seriously as an empirical possibility, any more than we should take seriously the possibility that the world was created five minutes ago. As an empirical hypothesis, it is far more plausible that when one's experiences change significantly, then as long as one is rational and paying attention, one should be able to notice the change. If not, then consciousness and cognition are tied together by only the most slender of threads.

Indeed, if we are to suppose that Dancing Qualia are empirically possible, we are led to a worrying thought: they might be actual, and happening to us all the time. The physiological properties of our functional mechanisms are constantly changing. The functional properties of the mechanisms are
reasonably robust; one would expect that this robustness would be ensured by evolution. But there is no adaptive reason for the non-functional properties to stay constant. From moment to moment there will certainly be changes in low-level molecular properties. Properties such as position, atomic makeup, and so on can change while functional role is preserved, and such change is almost certainly going on constantly.

If we allow that qualia are dependent not just on functional organization but on implementational details, it may well be that our qualia are in fact dancing before our eyes all the time. There seems to be no principled reason why a change from neurons to silicon should make a difference while a change in neural realization should not; the only place to draw a principled line is at the functional level. The reason why we doubt that such dancing is taking place in our own cases is that we accept the following principle: when one's experiences change significantly, one can notice the change. If we were to accept the possibility of Dancing Qualia in the original case, we would be discarding this principle, and it would no longer be available as a defense against skepticism even in the more usual cases.

It is not out of the question that we could actually perform such an experiment. Of course the practical difficulties would be immense, but at least in principle, one could install such a circuit in me and I could see what happened, and report it to the world. But of course there is no point performing the experiment: we know what the result will be. I will report that my experience stayed the same throughout, a constant shade of red, and that I noticed nothing untoward. I will become even more convinced than I was before that qualia are determined by functional organization. Of course this will not be a proof, but the evidence will be hard to seriously dispute.

I conclude that by far the most plausible hypothesis is that replacement of neurons while preserving functional organization will preserve qualia, and that experience is wholly determined by functional organization.

There are a few small loopholes that the argument leaves open, but none of the loopholes leads to an attractive position. For example, while the Dancing Qualia scenario is straightforwardly extendible to most sorts of functional isomorphs, there are a couple of exceptions involving speed and history. If an isomorph is much faster or slower than the original system, we cannot simply substitute a circuit from one system into the other and expect everything to function normally. We can still perform the experiment on a slowed-down or speeded-up version of the system in question, however, so at most we have left open the possibility that a change in speed might invert qualia. A similar loophole is left open for physical isomorphs that differ in their history: perhaps if I was born in the Southern Hemisphere I experience green, whereas a physical twin born in the North would experience red. History cannot be varied in a Dancing Qualia scenario (although it can be varied in a Fading Qualia scenario), so the argument does not bear on the hypothesis that qualia supervene on the past.

But neither of these hypotheses were very plausible in the first place. It is reasonable that history should affect our qualia by affecting our physical structure, but the history-dependence required above would be much stronger: there would in effect be a "nonlocal" effect of distal history on present qualia, unmediated...
by anything in physical structure or nearby in space and time. As for speed, it would seem quite arbitrary that a change in speed would invert qualia when nothing else could. The hypotheses here are coherent, but there is little reason to embrace them.

Another small caveat is that the argument does not refute the possibility of a very mild spectrum inversion. Between dark red and a slightly darker red, for instance, there may be nine intermediate shades such that no two neighboring shades are distinguishable. In such a case the Dancing Qualia scenario is not a problem; if the system notices no difference on flipping the switch, that is just what we would expect.

Of course, there is nothing special about the figure of one-tenth as the amount of difference between two neighboring systems. But we cannot make the figure too high. If we made it as high as one half, we would run into problems with personal identity: it might reasonably be suggested that upon flipping the switch, we are creating a new person, and it would not be a problem that the new person noticed no change. Perhaps we might go as high as 20 percent or 25 percent without such problems; but that would still allow the possibility of very mild inversions, the kind that could be composed of four or five unnoticeable changes. We can reduce the impact of this worry, however, by noting that it is very unlikely that experience depends equally on all areas of the brain. If color experience depends largely on a small area of the visual cortex, say, then we could perform any qualia inversion in one fell swoop while only replacing a small portion of the system, and the argument would succeed against even the mildest noticeable qualia inversion.

In any case, the possibility of a mild underdetermination of experience by organization is an unthreatening one. If we wished, we could accept it, noting that any differences between isomorphs would be so slight as to be uninteresting. More likely, we can note that this would seem an odd and unlikely way for the world to be. It would seem reasonable that experiences should be invertible across the board, or not invertible at all, but why should the world be such that a small inversion is possible but nothing more? This would seem quite arbitrary. We cannot rule it out, but it is not a hypothesis with much antecedent plausibility.

In a similar way, the argument leaves open the loophole that unattended qualia might be invertible. If we are not attending to the fringes of our visual field, for example, a qualia inversion might take place there without our noticing. But to exploit this loophole would leave one in the unattractive position that qualia are organizationally invariant when they are central enough in one's attention, but dependent on other features when they are not. (Presumably an inverted green experience on the fringe will flip back to red when one attends to it?) Such an asymmetric position would be theoretically unsatisfying in the extreme.

It should be noted that the Dancing Qualia argument works just as well against the possibility of absent qualia as against that of inverted qualia. If absent qualia are possible, then on the path to absent qualia we can find two slightly different systems whose experience differs significantly, and we can install a backup circuit in the same way. As before, the hypothesis implies that switching will cause my qualia to dance before my eyes, from vivid to tepid and back, without my ever noticing any change. This is
implausible for the same reasons as before, so we have good reason to believe that absent qualia are impossible.

Overall, the Dancing Qualia argument seems to make an even more convincing case against absent qualia than the Fading Qualia argument does, although both have a role to play. Where an opponent might bite the bullet and accept the possibility of Fading Qualia, Dancing Qualia are an order of magnitude more difficult to accept. The very immediacy of the switch makes a significant difference, as does the fact that the subject cannot notice something so striking and dynamic. The possibility of Fading Qualia would imply that some systems are out of touch with their conscious experience, but Dancing Qualia would establish a much stranger gap.

5 Nonreductive functionalism

To summarize: we have established that if absent qualia are possible, then Fading Qualia are possible; if inverted qualia are possible, then Dancing Qualia are possible; and if absent qualia are possible, then Dancing Qualia are possible. But it is implausible that Fading Qualia are possible, and it is extremely implausible that Dancing Qualia are possible. It is therefore extremely implausible that absent qualia and inverted qualia are possible. It follows that we have good reason to believe that the principle of organizational invariance is true, and that functional organization fully determines conscious experience.

It should be noted that these arguments do not establish functionalism in the strongest sense, as they establish at best that absent and inverted qualia are empirically (naturally, nomologically) impossible. There are two reasons why the arguments cannot be extended into an argument for logical or metaphysical impossibility. First, both Fading Qualia and Dancing Qualia seem to be intelligible hypotheses, even if they are very implausible. Some might dispute their logical possibility, perhaps holding that it is constitutive of qualia that subjects can notice differences between them. This conceptual intuition would be controversial, but in any case, even if we were to accept the logical impossibility of Fading and Dancing Qualia, there is a second reason why these arguments do not do not establish the logical or metaphysical determination of conscious experience by functional organization.

To see this second reason, note that the arguments take as an empirical premise certain facts about the distribution of functional organization in physical systems: that I have conscious experiences of a certain kind, or that some biological systems do. If we established the logical impossibility of Fading and Dancing Qualia, this might establish the logical necessity of the conditional: if one system with fine-grained functional organization $F$ has a certain sort of conscious experiences, then any system with organization $F$ has those experiences. But we cannot establish the logical necessity of the conclusion without establishing the logical necessity of the premise, and the premise is itself empirical. On the face of it, it is difficult to see why it should be logically necessary that brains with certain physical properties give rise to conscious experience. Perhaps the most tenable way to argue for this necessity is via a form of analytic functionalism; but in the context of using the Fading and Dancing Qualia arguments to establish this sort of functionalism, this strategy would be circular. It follows that the Fading and Dancing Qualia arguments are of little use in arguing for the logical and metaphysical impossibility of
absent and inverted qualia.

The arguments therefore fail to establish a strong form of functionalism upon which functional organization is *constitutive* of conscious experience; but they succeed in establishing a weaker form, on which functional organization *suffices* for conscious experience with natural necessity. We can call this view *nonreductive functionalism*, as it holds that conscious experience is determined by functional organization without necessarily being reducible to functional organization. As things stand, the view is just as compatible with certain forms of property dualism about experience as with certain forms of physicalism. Whether the view should be strengthened into a reductive version of functionalism is a matter that the Fading and Dancing Qualia arguments leave open.

In any case, the conclusion is a strong one. It tells us that systems that duplicate our functional organization will be conscious even if they are made of silicon, constructed out of water-pipes, or instantiated in an entire population. The arguments in this paper can thus be seen as offering support to some of the ambitions of artificial intelligence. The arguments also make progress in constraining the principles in virtue of which consciousness depends on the physical. If successful, they show that biochemical and other non-organizational properties are at best indirectly relevant to the instantiation of experience, relevant only insofar as they play a role in determining functional organization.

The principle of organizational invariance is not the last word in constructing a theory of conscious experience. There are many unanswered questions: we would like to know just what sort of organization gives rise to experience, and what sort of experience a given organization gives rise to. Further, the principle is not cast at the right level to be a truly *fundamental* theory of consciousness; eventually, we would like to construct a fundamental theory that has the principle as a consequence. In the meantime, the principle acts as a strong constraint on an ultimate theory.

What is the Unity of Consciousness?

1 Introduction

At any given time, a subject has a multiplicity of conscious experiences. A subject might simultaneously have visual experiences of a red book and a green tree, auditory experiences of birds singing, bodily sensations of a faint hunger and a sharp pain in the shoulder, the emotional experience of a certain melancholy, while having a stream of conscious thoughts about the nature of reality. These experiences are distinct from each other: a subject could experience the red book without the singing birds, and could experience the singing birds without the red book. But at the same time, the experiences seem to be tied together in a deep way. They seem to be unified, by being aspects of a single encompassing state of consciousness.

This is a rough characterization of the unity of consciousness. There is some intuitive appeal to the idea that consciousness is unified, and to the idea that it must be unified. But as soon as the issue is raised, a number of questions immediately arise.

(1) *What is the unity of consciousness?* What does it mean to say that different states of consciousness are unified with each other, or that they are part of a single encompassing state? The idea of unity is multifaceted, and has been understood in many different ways by different thinkers. In some senses of "unity", the claim that consciousness is unified may be obvious or trivial; in other senses, the claim may be obviously false. So the first project in this area is to distinguish between varieties of unity, and to isolate those varieties that pose the most important questions.

(2) *Is consciousness necessarily unified?* Some thinkers (Descartes and Kant, for example) have argued that some sort of unity is a deep and essential feature of consciousness. On this view, the conscious states of a subject are necessarily unified: it is impossible for there to be a subject whose conscious states are disunified. On the other side, some thinkers (e.g. Nagel 1971) have argued that the unity of consciousness can break down. On this view, there are cases (especially neuropsychological cases, such as those involving patients with split brains) in which a subject's states of consciousness are disunified. Some (e.g. Dennett 1992) hold more strongly that consciousness is often or usually disunified, and that much of the apparent unity of consciousness is an illusion.

(3) *How can the unity of consciousness be explained?* If consciousness really is unified, and especially if it is necessarily unified, then it is natural to look for an explanation of this fact. What is it about
What is the Unity of Consciousness?

consciousness that yields this unity? Is unity a primitive feature of consciousness, or is it explained by something deeper? Further, the unity of consciousness may put strong constraints on a theory of consciousness. If consciousness is necessarily unified, then a correct theory of consciousness should at least be compatible with this unity, and we can hope that it will explain this unity.

We can see these three questions as clustering around the status of what we can call the unity thesis (UT):

Unity Thesis: Necessarily, any set of conscious states of a subject at a time is unified.

The first question raises the issue of how the notion of unity in the unity thesis is to be understood: what is it for a set of conscious states to be unified? The second question raises the issue of whether the unity thesis is true. The third question raises the issue of how, if the unity thesis is true, its truth might be explained.

In this paper we will address all three of these questions. Our central project will be to isolate a notion of unity on which the unity thesis is both substantive and plausible. That is, we aim to find a more precise version of the unity thesis that is neither trivially true nor obviously false. With such a thesis in hand, we will look at certain arguments that have been made against the unity of consciousness, to determine whether they are good arguments against the unity thesis as we understand it. And finally, after fleshing out the unity thesis further, we will apply the thesis to certain currently popular philosophical theories of consciousness, arguing that the thesis is incompatible with these theories: if the Unity Thesis is true, then these theories are false.

We will not aim to conclusively prove the unity thesis in this paper, and indeed we are not certain that it is true. But we aim to suggest at least that the thesis is plausible, that it captures a strong intuition about the nature of consciousness, and that there are no knockdown arguments against it. If the thesis is true, it is likely to have strong consequences for a theory of consciousness.

2 Varieties of Unity

To start with, we need to distinguish different notions of unity. In particular, we will distinguish various different ways in which different states of consciousness might be said to be unified with each other.

(1) Objectual unity. We can say that two states of consciousness are objectually unified when they are directed at the same object. For example, when I look at a red book, I have an experience of redness, and an experience of rectangularity. The color experience and the shape experience here are unified in a particularly strong way. They are present in my consciousness as directed at a single entity: the book. The same goes for my experience of a blue car moving down the street. Here I experience color, shape, and motion, all of which are unified by being directed at the same object. I might even have an auditory experience of the car's engine, and also experience this as directed at the same object. So there can be objectual unity across different sensory domains.
For two experiences to be objectually unified, their object need not actually exist. If I hallucinate a red book, then my experiences of redness and of rectangularity will be objectually unified, despite the book's nonexistence. On the other side of the coin, two experiences can be experiences of the same object without being objectually unified. I might see a car's shape and hear its noise, without anything in my conscious state tying the noise to the car (perhaps I perceive the noise as behind me, due to an odd environmental effect). If so, the experiences are not objectually unified. For objectual unity, what matters is that two states are experienced as being directed at a common object.

The notion of objectual unity is closely tied to a central issue in cognitive psychology and neurophysiology. When I look at a red square, the color and the shape may be represented in different parts of my visual system. But somehow these separate pieces of information are brought together so that I experience a single red square, so that I can identity and report a red square, and so on. This phenomenon is often referred to as binding, and the question of how it is achieved is often referred to as the binding problem. The binding problem is in large part the problem of how objectual unity is possible. As we will see, this divides into two problems in turn.

Objectual unity is an important phenomenon, but it will not be central for our purposes. Where objectual unity is concerned, the unity thesis is almost certainly false. While some sets of experiences are objectually unified with each other, it seems that most sets are not. For example, my experience of the color of the book and of the shape of the car are not objectually unified: they are experienced as being directed at different objects. My experiences of a bird singing and of a sharp pain do not seem to be directed at the same object at all. If so, then objectual unity cannot unify all of a subject's conscious states. For such a notion of unity, we must look elsewhere.

(2) Spatial unity. A related notion of unity is that of spatial unity. We can say that two conscious states are spatially unified when they represent objects as being part of the same space. For example, my experiences of a book and of a car are not directed at a common object, but they represent both objects as part of the same visual space. More generally, all of my visual experiences seem to be spatially unified in this way: every visual experience represents something spatially, and everything that is represented is represented as part of a common space. Auditory experiences usually represent objects as part of the same space; such auditory experiences are spatially unified with visual experiences.

The notion of being "represented as part of the same space" can be fleshed out in various ways, but the crucial idea will be something like this: a set of experiences are spatially unified if (i) each has spatial representational content, and (ii) the representational content of each is comparable, in the sense that the objects represented are represented as being in spatial relations to each other. So visual experience might represent a car as being near a tree, or behind a truck, or to the left of a building. Auditory experience might represent exhaust noise as coming from the same area as the car, or it might represent a siren as being much further away. This sort of comparability is endemic to visual experience and to much perceptual experience, and makes for a deep spatial unity in perception.

Like objectual unity, however, spatial unity does not yield a plausible version of the unity thesis. Some experiences seem to have no spatial representational content at all. An emotional experience such as that...
What is the Unity of Consciousness?

of melancholy does not obviously represent anything as located within space. A conscious thought about philosophy might have no spatial content at all. If so, these conscious states are not spatially unified with other conscious states. As before, to find a notion of unity that unifies all of a subject's conscious states, we must look elsewhere.

(3) Subject unity. Let us say that two conscious states are subject unified when they are had by the same subject at the same time. So all of my current experiences — my perceptual experiences, my bodily sensations, my emotional experiences and conscious thoughts — are subject unified, simply because they are all my experiences.

If we construe the unity thesis as involving subject unity, it is certainly plausible. If a set of conscious states are had by a subject at a time, then they will be subject unified by definition. The trouble with this version of the unity thesis is that it is trivial. It is true by definition, and tells us nothing substantive about consciousness. As such, it cannot capture the intuition that there is some nontrivial way in which consciousness is unified. So subject unity will not be our central focus here.

Still, the notion of subject unity is at least useful in articulating the unity thesis. As it was characterized above, the unity thesis holds that if a set of experiences of a subject at a time is subject unified, then that set is unified. So in effect, the unity thesis states that subject unity entails unity. Now we simply need to find a notion of unity for which this entailment is both plausible and nontrivial.

(4) Subsumptive unity. We started the paper by invoking the intuition that there is some substantial sense in which all of a subject's experiences — including at least perceptual, bodily, emotional, and cognitive experiences — can all be unified. This sense is not object or spatial unity, since these notions do not apply to all of the relevant experiences. And this sense is not subject unity, since the resulting unity holds trivially. Rather, it is the sense that all of these experiences are somehow subsumed within a single state of consciousness.

We can say that two conscious states are subsumptively unified when they are both subsumed by a single state of consciousness. The notion of one state being subsumed by another should be taken as intuitive for now; we will spell it out more shortly. To take an example: it seems plausible that all of my visual experiences are subsumed by a single encompassing state of consciousness, corresponding to my visual field. More generally, my visual and auditory experiences might all be subsumed by a single encompassing state of perceptual consciousness. And it does not seem unreasonable to suppose that there is a single encompassing state of consciousness that subsumes all of my experiences: perceptual, bodily, emotional, cognitive, and any others.

We can think of this last encompassing state of consciousness, for a given subject, as the subject's total conscious state. When it exists, a subject's total conscious state might be thought of as the subject's conscious field. It can be thought of as involving at least a conjunction of each of many more specific conscious states: states of perceptual experience, bodily experience, emotional experience, and so on. But what is important, on the unity thesis, is that this total state is not just a conjunction of conscious states. It
is also a conscious state in its own right. If such a total conscious state exists, it can serve as the "singularity behind the multiplicity" — the single state of consciousness in which all of a subject's states of consciousness are subsumed.

It is worth pointing out certain sorts of unity with which subsumptive unity should not be confused. We are not talking about gestalt unity, where the conscious experiences of two different objects are deeply related in a way that transforms each of the experiences and produces a "gestalt" experience with a novel content. And we are not talking about normative unity, which requires some special coherence or consistency among multiple contents of consciousness. As we have characterized subsumptive unity, two conscious states might be subsumptively unified whether or not their contents stand in a special gestalt relation to each other, and whether or not they are especially consistent or coherent with one another. We are also not dealing with neurophysiological unity, which requires that conscious states involve a single area or mechanism in the brain. Finally, we are not dealing with diachronic unity, or the unity of consciousness across time. It might turn out that one or more of these notions is deeply related to the issues at hand, but none of them is our primary object of discussion.

To spell out the notion of subsumptive unity in more detail, we need to go into more detail about just what consciousness involves, and just what is involved in the idea of one conscious state being subsumed by another. This requires making some further distinctions.

3 Access unity and Phenomenal unity

What is it for a mental state to be a conscious state? There is no single answer to this question. As many have pointed out, the notion of "consciousness" is ambiguous, and is understood in different ways by different people. So to make progress we have to make distinctions. For our purposes, the most useful distinction is Ned Block's distinction between access consciousness and phenomenal consciousness (Block 1995).

A mental state is access conscious when a subject has a certain sort of access to the content of the state. More precisely, a state is access-conscious if by virtue of having the state, the content of the state is available for verbal report, for rational inference, and for the deliberate control of behavior. When I look at a red book, I can report the presence of the book ("there's a red book"), I can reason about it (e.g., concluding that I must have put it there when reading yesterday), and I can use its presence in deliberately directing by behavior (e.g., picking up the book and putting it back on the shelf). So my perception of the red book gives me the relevant sort of access to information about the red book. So my perceptual state here is access-conscious. One can also say that in such a case, the subject is access-conscious of the relevant object. So here, I am access-conscious of the red book.

In a similar way, many of my perceptual states are access-conscious, and so are many of my emotional and cognitive states. Not all mental states are access-conscious, however. In some cases, such as those involving subliminal perception, blindsight, or unconscious belief, a mental state represents information without that information being reportable or usable in rational control of reasoning and behavior. The
What is the Unity of Consciousness?

The exact definition of access consciousness is somewhat flexible, and can be varied for different purposes. The most important point is that a state's being access-conscious is defined in terms of the causal role that the state plays within the cognitive system, and in particular in terms of the role that the state plays in making information available to other parts of the system.

A mental state is *phenomenally conscious* when there is something it is like to be in that state. When a state is phenomenally conscious, being in that state involves some sort of subjective experience. There is something it is like for me to see the red book — I have a visual experience of the book — so my perception of the book is phenomenally conscious. There is something it is like to hear the bird singing, and to feel the pain in my shoulder, so these states are phenomenally conscious. There is something it is like to feel melancholy, and there is arguably something it is like when I think about philosophy. If so, then these states are phenomenally conscious. Phenomenal consciousness is often taken to be the most important sort of consciousness, and to be the sort of consciousness that poses the most difficulty for scientific explanation.

There is a close empirical connection between phenomenal consciousness and access consciousness. It is arguable that the two almost always go together empirically: when a state is phenomenally conscious, it is access-conscious, and vice versa. That is, when there is something it is like to be in a state, a subject can usually report the contents of the state and use it to directly guide reasoning and behavior. And when a subject can report the contents of a state and use it to directly guide reasoning and behavior, there is usually something it is like to be in that state. So when I am phenomenally conscious of the red book, I am access-conscious of it, and vice versa.

Despite this empirical connection, there is plausibly a *conceptual* distinction between access consciousness and phenomenal consciousness. Access consciousness is defined in terms of the causal role that a state plays, whereas phenomenal consciousness is defined in terms of the way the state feels. It is arguable that we can at least imagine states that are access-conscious without corresponding states of phenomenal consciousness (the philosophers' zombie, which is functionally like a normal human being but without any conscious experience, would be one such imaginary case). And it seems that we can know about another being's states of access consciousness without knowing about their states of phenomenal consciousness: one might know what information is available for report and for behavioral control in a cognitive system without being in a position to know what it is like to be that system.

When there is something it is like to have a mental state, we can say that the mental state has a phenomenology, or a phenomenal character. Slightly more formally, we can say that such mental states have *phenomenal properties*, or *qualia*, which characterize what it is like to be in them. We can also say that *subjects* have phenomenal properties, characterizing aspects of what it is like to be a subject at a given time. We can then say that a phenomenal state is an instantiation of such a property. For example, the state of experiencing a certain sort of reddish quality is a phenomenal state.

When a subject is in a phenomenally conscious mental state, the subject will thereby be in a phenomenal state that reflects the phenomenology of being in the mental state. For example, if there is something it is like for a given subject to believe that Paris is in France, the subject will be in a corresponding
What is the Unity of Consciousness?

phenomenal state. But the phenomenally conscious mental state and the phenomenal state may be distinct states. For example, it may be that there is now a certain phenomenology associated with my occurrent belief that P, while it is also possible for me to believe that P with a different phenomenology or no phenomenology at all. If so, the belief state (this instance of believing such-and-such) is a phenomenally conscious mental state, but it is not a phenomenal state. There is a special class of phenomenally conscious mental states such that the mental state and the corresponding phenomenal states are identical: phenomenal states themselves. Phenomenal states are at the core of phenomenal consciousness.

We can use the distinction between access consciousness and phenomenal consciousness to make a distinction between two corresponding notions of unity: access unity and phenomenal unity. Broadly speaking, two conscious states are access-unified when they are jointly accessible: that is, when the subject has access to the contents of both states at once. Two conscious states are phenomenally unified when they are jointly experienced: when there is something unified it is like to be in both states at once.

We can construct more precise versions of phenomenal and access unity by combining these distinctions with the distinctions outlined earlier between objectual unity, spatial unity, and field unity. These distinctions crossclassify each other, so that one can isolate notions of objectual phenomenal unity, objectual access unity, spatial access unity, subsomptive phenomenal unity, and so on. The distinction applies less clearly to the notion of subject unity, so we will set that notion aside here.

We can say that two conscious states are objectually access-unified when their contents involving attributing properties to a single object of representation, and when these contents are jointly accessible within the system. The contents will be jointly accessible when their conjunction is available for report and the rational control of reasoning and behavior. When I am conscious of a red square, I can report the presence of red, and the presence of a square, but I can also report the presence of a red square. Similarly, the presence of a red square can be used in guiding my reasoning and my behavior. So my perception of red and my perception of a square are not just individually access conscious: they are access-unified.

We can say that two conscious states are objectually phenomenally unified when they are experienced as representing a single object. When I am conscious of a red square, I experience the presence of red and I experience the presence of a square, but I also experience the presence of a red square. There is a distinctive sort of unity involved in what it is like to experience the redness and the squareness simultaneously here: the two states are unified by being experienced as aspects of a single object.

Objectual access unity and objectual phenomenal unity correspond to two distinct aspects of the binding problem. It has often been pointed out that there are actually two binding problems (see e.g. Revonsuo 1999). The first is that of how a system such as the brain manages to bring together two separately represented pieces of information (e.g., representations of color and shape in different areas of the visual cortex), so that these can play a joint role in the control of behavior (e.g. so that we can report the presence of a red square and a blue circle, rather than a red circle and a blue square). This is a sort of engineering problem concerning the design of the cognitive system; one can think of it as the neurophysiological or cognitive binding problem. This binding problem is the problem of explaining
objectual access unity. The second binding problem is that of explaining how it is that we perceptually experience separate pieces of information as bound together in pertaining to the same object. This is the problem of explaining objectual phenomenal unity. On the face of it, these two problems are distinct: one could solve the neurophysiological binding problem, giving an explanation of how two pieces of information are brought together in the brain to be jointly accessible, while still having no explanation of why the jointly accessible information should be experienced. So objectual phenomenal unity and objectual access unity are at least conceptually distinct.

One can make a similar distinction between spatial phenomenal unity and spatial access unity. We can say that two conscious states are spatially access-unified when they have spatial representational contents that can be jointly accessed by the cognitive system, so that they can be spatially compared and so that the results of the comparison can be made available for report, reasoning, and behavioral control. For example, when I see a car and a tree, I do not just have access to their spatial locations individually; I also have access to the spatial locations jointly, in that I can report that the car is to the left of the tree. So these two perceptual states are spatially access-unified. Two conscious states are spatially phenomenally unified when they involve experiencing entities as part of the same space; as part of the same phenomenal space, one might say. I experience the car as being in the same space as the tree, and to the left of it; so these two states are spatially phenomenally unified.

The most important distinction is that between subsumptive phenomenal unity and subsumptive access unity. These notions apply to two arbitrary conscious states, as long as they are phenomenally conscious in the first instance and access-conscious in the second. Because these are the most important versions of unity, we will henceforth usually speak simply of "phenomenal unity" and "access unity", where it is understood that we are referring to phenomenal field unity and access field unity respectively.

We can say that two conscious states are subsumptively access-unified (or simply access-unified) if the conjunction of their contents is available for verbal report, reasoning, and the deliberate control of behavior. So if mental state A has content P and mental state B has content Q, these states will be individually access-conscious if the information that P is available for report and for control, and if the information that Q is available for report and control. They will be jointly access-conscious, or they will be access-unified, if the information that P∧Q is available for report and control. More briefly: two states A and B are access-unified if and only if the subject is access-conscious of the conjunction of their contents. In this case, there is an access-conscious mental state with the conjunctive content: this conjunctive mental state can be seen as subsuming the original states A and B.

For example, when I see a book and feel a pain, I can report the presence of the book and of the pain individually, but I can do more than that: I can report them simultaneously. I can also reason about the book and the pain jointly, and use information about both to jointly control my behavior (e.g. looking in the book for a remedy for the pain, or ceasing to read the book to help alleviate the pain). Because of the accessibility of this conjunctive content, the two states are (subsumptively) access-unified. Similarly, I can often jointly report or reason about an emotion and a sound: if so, the emotional state and the auditory state are access-unified. And so on.
It is worth noting that for a state to be access-conscious, it is not required that the content of the state actually be *accessed*, in the sense that it is directly used for report or for control. What matters is that it be *accessible*, in a certain direct sense, or "poised" for use in access, as Block puts it. The same goes for access unity. For two states to be access-unified, they need not be simultaneously accessed at any given moment. What matters is that they are simultaneously accessible, in that it would be possible for a subject to jointly report them, and to use them jointly in reasoning and behavior control. Typically, our conscious states are not jointly accessed, but they are much more often jointly accessible. It is joint accessibility that matters for our notion of unity.

We can use the notion of access unity to put forward a version of the unity thesis:

**Access Unity Thesis**: Necessarily, any set of access-conscious states of a subject at a time is access-unified.

This thesis appeals to the notion of a set of states being access-unified. This is a natural generalization of the notion of two states being access-unified. We can say that a set of states is access-unified if the contents of all of the states are jointly accessible.

It might be objected that in requiring that *any* set of a subject's access-conscious states is access-unified, the thesis is highly implausible. A subject might have a large (possibly infinite) number of access-conscious states, and the conjunction of the contents of these states might be so complex that it is implausible that a subject could have access to this conjunction. The full conjunction would not be reportable or directly available to guide reasoning and behavior. To get around this, we could put forward a slightly weakened version of the thesis:

**Pairwise Access Unity Thesis**: Necessary, any two access-conscious states of a subject at a time are access-unified.

One might argue that the pairwise version is too weak to count as a full unity thesis (which requires unity of all states at a time), or that it suffers from the same problems as the full unity thesis (since it entails that conjunctions of conjunctions will be access-conscious, and so on). But none of this will matter for our purposes, since as we will argue shortly, even a weak version of the access unity thesis, limited to pairwise unity of relatively simple access-conscious states, is straightforwardly false.

We can say that two conscious states are *subsumptively phenomenally unified* (or simply *phenomenally unified*) if there is something it is like for a subject to be in both states simultaneously. That is, two states are phenomenally unified when they have a *conjoint phenomenology*: a phenomenology of having both states at once that subsumes the phenomenology of the individual states. When A and B are phenomenally conscious states, there is something it is like for a subject to have A, and there is something it is like for a subject to have B. When A and B are phenomenally unified, there is not just something it is like to have each state individually: there is something it is like to have A and B together. And the phenomenology of being in A and B together will carry with it the phenomenology of being in A...
What is the Unity of Consciousness?

and the phenomenology of being in B.

For example, when I look at the book while feeling a pain, there is something it is like to see the book (yielding a phenomenal state A), and there is something it is like to feel the pain (yielding a phenomenal state B). But there is more than this: there is something it is like to see the book while feeling the pain. Here there is a sort of conjoint phenomenology, that carries with it the phenomenology of seeing the book, and the phenomenology of feeling the pain. As in the discussion of field unity, we can think of the conjoint state here as involving at least the conjunction A&B of the original phenomenal states A and B. But importantly, the conjoint state is itself a phenomenal state: a single complex state of consciousness that subsumes the individual states of consciousness A and B. It is this encompassing state of consciousness that unifies A and B.

More generally, we can say that a set of conscious states is phenomenally unified if there is something it is like for a subject to have all the members of the set at once, and if this phenomenology subsumes the phenomenology of the individual states. As a special case, we can say that the set consisting of all of a subject's conscious states at a given time is phenomenally unified if there is something it is like for the subject to have all these states at once, where this phenomenology subsumes the phenomenology of the individual states. If so, then the subject has a total phenomenal state that encompasses all of the subject's phenomenal states. One can think of a total phenomenal state as capturing what it is like to be a subject at a time. If a subject has a total phenomenal state, there is a clear sense in which all of a subject's phenomenal states are unified within it.

We can put forward a phenomenal version of the unity thesis, as follows:

**Phenomenal Unity Thesis:** Necessarily, any set of phenomenal states of a subject at a time is phenomenally unified.

This is not quite the same as the unity thesis that falls out of our original definition. Such a thesis would hold that any set of phenomenally conscious mental states of a subject at a time will be phenomenally unified. But the two theses are clearly equivalent. The first version (regarding phenomenally conscious mental states) entails the second version (regarding phenomenal states) as a special case. In reverse, the second version entails that for any set of phenomenally conscious mental states, their associated phenomenal states will be phenomenally unified. So there will be a phenomenal state that subsumes each of the original phenomenal states. So there will be something it is like to be in all the original mental states simultaneously that subsumes what it is like to be in them individually. So the original mental states will be phenomenally unified, and the first version of the unity thesis holds.

One can also put forward slightly weaker versions of the phenomenal unity thesis:

**Pairwise Phenomenal Unity Thesis:** Necessarily, any two phenomenal states of a subject at a time are phenomenally unified.
What is the Unity of Consciousness?

**Total Phenomenal Unity Thesis:** Necessarily, the set of all phenomenal states of a subject at a time is phenomenally unified.

The original phenomenal unity thesis clearly entails the pairwise unity thesis and the total unity thesis. The pairwise thesis does not obviously entail the first version. It is plausible that subsumption is transitive, so that necessarily, if A subsumes B and B subsumes C, then A subsumes C. If so, the pairwise unity thesis will entail the phenomenal unity thesis for any finite set of phenomenal states, as any pair of these will be subsumed by a single phenomenal state, and any pair of those in turn will be subsumed by a single phenomenal state, and so on. But the pairwise thesis does not obviously entail the original thesis where infinite sets of phenomenal states are concerned. The total unity thesis entails the original phenomenal unity thesis, however: if there is a state that subsumes each phenomenal state of the subject, that state will also subsume each member of an arbitrary set of phenomenal states of the subject, so that set will be phenomenally unified. So the total unity thesis and the original phenomenal unity thesis are equivalent.

The total unity thesis arguably captures the central intuition behind the unity of consciousness. This thesis suggests that there is always a single phenomenal state that subsumes all of the phenomenal states of a subject at a time. That is, it suggests that any conscious subject at any time has a total phenomenal state. If a subject has a total phenomenal state, subsuming every specific phenomenal state of the subject, then the subject's consciousness will be unified in a deep way.

It might be objected that when a subject experiences a number of phenomenal states at once, the original phenomenal states will be transformed. For example, it might be phenomenally different to see a red book in the context of a moving car than to see a red book on its own, and the phenomenal state that was present when one saw the book on its own might not be present at all. This may be so, but it is no objection to the unity thesis. The unity thesis says that the phenomenal states had by a subject at a time are subsumed by a complex phenomenal state. So the experience of a red book and a moving car at a given time should subsume the experience of the red book at that time and the experience of the moving car at that time. It is not required that the complex experience should subsume the experience of a red book as the subject might have it at a different time, in a different context. If the experience of the book is itself transformed by the context of the car, then it is the transformed experience that will be subsumed by the complex state.

It might also be objected that these unity theses are trivial. If a subject has a set of phenomenal states, there will automatically be a phenomenal state that subsumes them: the conjunction of the original states. But this is not a trivial claim. It is trivial that if a subject is in a number of phenomenal states, the subject will be in the conjunction of those states. But it is nontrivial that this conjunction will itself be, or be subsumed by, a phenomenal state. That is, it is nontrivial that there will be *something it is like* to be in the conjunctive state. This can be seen from the fact that some philosophers deny the total unity thesis, or at least entertain its denial. For example, when Hurley (1998) discusses the possibility that the unity of consciousness could break down and that consciousness could be "partially unified" (so that two phenomenal states are each unified with a third state, but not with each other), she says:

What is the Unity of Consciousness?

Therefore, we cannot imagine what it is like for there to be partial unity. That doesn't show partial unity is unintelligible, because being partially unified isn't the sort of thing there could be anything it is like to be. We shouldn't expect to be able to imagine what it is like.

In general, it seems that a case in which the unity of consciousness breaks down would be precisely a case in which there is no total phenomenal state of the subject: that is, there is nothing it is like to be the subject at that time, or at least there is no single something-it-is-like that captures all the phenomenal states of the subject. Such a subject would have states with a local phenomenal character, but there would be no global phenomenal character involved in having these states. It is certainly very hard to see how this could be the case. Indeed, one might suspect (as we do) that such a scenario is impossible and perhaps incoherent. But to say this is not to say that the unity thesis is trivial: it is a substantive thesis about the nature of consciousness. This is reflected by the fact that (as we discuss later in the paper) certain theories of consciousness entail that the unity thesis is false. If so, then the thesis puts substantive constraints on a theory of consciousness.

4 When Access Unity Breaks Down

The access unity thesis holds that necessarily, any two access-conscious states are access-unified. This entails that whenever a subject is access-conscious of P and is access-conscious of Q, the subject will be access-conscious of P∧Q. This thesis is clearly false.

To see that the thesis is false, we need only note that it is possible for a subject to be access-conscious of P and access-conscious of Q, without being access-conscious of P∧Q. For this to happen, it should be the case that P is reportable and available for guiding reasoning and behavior, and that Q is reportable and available for guiding reasoning and behavior, but that P∧Q is not reportable and not available for guiding reasoning and behavior. This can happen in a quite straightforward way. All that is required is that there be an access bottleneck. This will be a pathway of information access through which only a limited amount of information can pass at one time. If P and Q are both accessible only through the bottleneck, and if each carry an amount of information that is near the capacity of the bottleneck, then P and Q will be individually accessible, but the conjunctive content P∧Q will not.

This is not merely a hypothetical description of an imaginary case. Such access bottlenecks can occur in real cognitive systems, and are revealed by a number of experiments in the psychological literature. Perhaps the clearest example of such a bottleneck is given by a famous experiment by George Sperling (1960).

In Sperling’s experiment, a subject is presented with a matrix consisting of three rows with four letters each. The matrix is flashed only briefly, for 250 milliseconds. After the matrix vanishes, a tone sounds, indicating whether the subject is to report the contents of the first, second, or third row. When subjects are required to report the contents of the top row, on average they correctly report 3.3 of the four letters in that row. The same goes when they are required to report the contents of the middle row, or of the bottom row. But when subjects are asked to report the contents of the entire matrix, on average they
correctly report 4.5 of the twelve letters. So, to simplify a little, it seems that the subject has access to the information in any single row, but the subject does not have joint access to the information in all three rows.

In this case, it is natural to hold that the subject (just after the matrix disappears, before the tone sounds) is access-conscious of the contents of any individual row. Recalling that access consciousness requires accessibility for report and for reasoning and behavior: the contents of each row are available for report (individually), and could presumably be used to guide reasoning about those contents and to guide behavior. But it also seems that the subject is not access-conscious of the conjunctive contents of the whole matrix, or of any two rows. The conjunctive contents of more than one row are not available for verbal report, and presumably are not available to guide reasoning and behavior. If so, then a subject can be access-conscious of P (one row) and of Q (another row), without being access-conscious of P∧Q (both rows). So two access-conscious states of a subject at a time can fail to be access-unified, and the access unity thesis is false.

We do not claim that the Sperling experiment alone proves that the access unity thesis is false. There are other possible interpretations of the experiment: for example, one could hold that the subject has some sort of internal access to the conjunctive content, but that the process of report destroys this access. But the interpretation we have suggested is a natural one: on the face of it, the conjunctive content does not seem to be available for any sort of reasoning or control, although the individual contents are available taken one at a time. And importantly, whether or not this interpretation is correct of the actual case, it seems to be a perfectly coherent interpretation, one that describes a perfectly reasonable way for a cognitive system to function.

Indeed, given a natural design for cognitive systems with limited resources, we would expect certain restrictions on the flow of information in access and control, and we would expect access bottlenecks to arise in some cases. It may be that most of the time, when a subject has access to P and to Q, the subject has access to P∧Q. But this sort of joint access clearly cannot hold necessarily. So even if there is a reasonably high degree of access unity in ordinary conscious states, this sort of access unity cannot hold across the board.

This breakdown of access unity does not entail a breakdown of phenomenal unity. This can be seen by examining the Sperling case. It is difficult to know exactly what is going on in the phenomenology of the subject who is undergoing the Sperling experiment, before being asked about the contents of a row. Perhaps the details of all nine letters are present in the subject's phenomenology (as some subjects report); perhaps these details are not present, and there is merely an indeterminate patch in each cell of the matrix; or perhaps there is something in between. But whatever the exact phenomenology here, there is little reason to suppose that phenomenal unity breaks down.

No matter what it is like for a subject to experience each individual cell of the matrix in the Sperling case, it is plausible that there will be something it is like for the subject to see the entire matrix. And it is plausible that the phenomenology of seeing the matrix will subsume the phenomenology of seeing the
individual cells. If the phenomenology of seeing a cell involves just a hazy patch, then the phenomenology of seeing the matrix will plausibly involve nine hazy patches. If the phenomenology of seeing a cell involves a detailed shape, then the phenomenology of seeing the matrix will plausibly involve nine detailed shapes. Either way, the individual phenomenal states are subsumed by the overall phenomenal state. So there is no reason to deny phenomenal unity here.

At most, this sort of case suggests that a subject does not always have simultaneous access to the contents of all of the subject's phenomenal states. If the subject is indeed experiencing the details of all nine letters, then the subject is in a position where the contents of these experiences can be accessed and reported only a few at a time, and not all at the same time. There is nothing paradoxical or contradictory about this. It simply suggests that a subject's access to a total phenomenal state is sometimes piecemeal. But this is just what we might expect.

One consequence of this is that access consciousness and phenomenal consciousness can come apart. We have seen that the subject is access-conscious of the individual letters but not of their conjunction. And it is natural to hold that either (i) the subject is phenomenally conscious of neither the individual letters nor their conjunctions, or (ii) the subject is phenomenally conscious of both the individual letters and their conjunction. In case (i), a subject is access-conscious of an individual letter but not phenomenally conscious of it. In case (ii), a subject is phenomenally conscious of the conjunction but not access-conscious of it. Either way, access consciousness and phenomenal consciousness of a given content can come apart. Our own view is that description (ii) is somewhat more plausible. If this is so, we can still hold that access consciousness and phenomenal consciousness are correlated with each other for simple contents. But access consciousness and phenomenal consciousness will not always be correlated for complex contents.

The moral of all this is that a breakdown of access unity does not entail a breakdown in phenomenal unity. There is a sense in which a breakdown of access unity is a "disunity" in consciousness, but it is a relatively shallow sense. Such a breakdown is quite compatible with an underlying phenomenal unity. Of course we have not demonstrated that no breakdowns of access unity involves a breakdown of phenomenal unity. But this discussion does strongly suggest that one cannot infer a breakdown of phenomenal unity from a breakdown in access unity. To accept a breakdown of phenomenal unity, one would need some quite distinct reason.

An opponent might try to argue that the Sperling case is a case where phenomenal unity breaks down. For example, the opponent might argue that the phenomenology of seeing each individual cell involves a detailed letter, but that the phenomenology of seeing the whole matrix does not, and that any "global" phenomenology here involves only hazy patches. Such a response would seem unmotivated and implausible, on the face of it, at least in the absence of much supporting argument. If the phenomenology of each letter is detailed, then there seems to be good reason to hold that this phenomenology is present in a global phenomenal state. And even if it is coherent for an opponent to hold this, it is equally coherent (and seemingly more plausible) to deny this, and to hold that the experience of the letters is phenomenally unified. The mere coherence of the denial is enough to show that one cannot infer a breakdown in phenomenal unity from a breakdown of access unity.
5 Can Phenomenal Unity Break Down?

We think that there is a strong prima facie case that the unity thesis is true. This prima facie case is brought out by the fact that there seems to be something inconceivable about phenomenal disunity. It is difficult or impossible to imagine a subject having two phenomenal states simultaneously, without there being a conjoint phenomenology for both states. And there is a sense that there is something incoherent about the suggestion. This prima facie inconceivability — whether it takes the form of unimaginability or apparent incoherence — gives at least some reason to believe that cases in which phenomenal unity break down are impossible, so that the unity thesis is true.

But this is only a prima facie case. There are some possible scenarios that humans cannot imagine, and there are arguably some possible scenarios that no being could imagine. And the judgment of incoherence in this case is not so strong that it could not be incorrect. So the prima facie case for the unity thesis needs to be balanced with the case against the unity thesis. A number of philosophers and scientists have argued that the unity of consciousness can break down. So to assess the unity thesis, one needs to examine these arguments in order to see what force they have against the unity thesis as we have understood it.

By far the most common reason for holding that the unity of consciousness can break down is grounded in neuropsychology. It is widely held that patients in various unusual neuropsychological states have a disunified consciousness. The paradigm case here is that of a split-brain patient, whose corpus callosum has been severed for medical purposes, preventing the left and right hemispheres of the cerebral cortex from communicating directly (although there is still some connection through lower areas of the brain). Such a patient behaves in a surprisingly normal fashion much of the time, but in certain circumstances they behave quite unusually. For example, when presented with different pictures in different halves of their visual field (e.g., a cat on the left and a dog on the right), and asked to report the contents, the patient will report seeing only a dog, since the left hemisphere, which dominates speech, receives input from the right visual field. When asked to write down what they see with their left hand (which is controlled by the right hemisphere), such a patient may slowly write "CAT"; with the right hand, the patient may write "DOG". If a patient writes with her left hand in her right visual field, a conflict may occur when the patient sees what is written, and in some cases the right hand scratches out what the left hand has written.

It is often held that in cases like this, consciousness is disunified. On one interpretation (e.g. Puccetti 1981), there are two distinct subjects of consciousness, corresponding to each hemisphere. Such an interpretation is actually compatible with the unity thesis, since the unity thesis requires only that every subject have a unified consciousness. More threatening to the unity thesis are interpretations on which there is a single subject with a disunified consciousness. Some (e.g. Marks 1980) hold that the subject has two separate streams of consciousness, at least under experimental conditions. Others (e.g. Lockwood 1989) hold that the subject has a fragmented consciousness with nontransitive unity between the states: for example, the experiences of "CAT" and of "DOG" might each be unified with some background
What is the Unity of Consciousness?

emotional state, but not with each other. Others (e.g. Nagel 1971) hold that our conceptual framework in speaking of subjects may simply break down in this area.

Adjudicating this question requires a very detailed examination of both the empirical details and the philosophical analysis of these phenomena, which we cannot provide here. Here, we will simply note that given what we have said so far in this paper, the advocate of a phenomenal unity thesis has a natural line of response.

It is plausible that in split-brain cases, there is some sort of breakdown of access unity. If we assume that there is a single subject, then it seems that the subject in the case above has at least a weak sort of access both to the presence of a cat and to the presence of a dog, and can use each in reasoning and in the control of behavior. But it seems that the subject has no access to a conjunctive content involving both the cat and the dog. The conjunctive content is not reported, and plays no apparent role in reasoning and in the control of behavior. So this may well be a case in which access unity fails. In this case, it seems that two accessed contents are not jointly accessible, because of a disconnection between the relevant access mechanisms.

But as we have seen, a breakdown of access unity does not entail a breakdown of phenomenal unity. So the possibility remains open that split-brain subjects have a unified phenomenal field, with some sort of conjoint phenomenology subsuming each of the separate contents. It is just that the subject has pathologies of access, so that the contents of the field are accessible only singly and not jointly. If so, the subject in the experiment described has a phenomenal field that includes experiences of both "CAT" and "DOG". The subject simply has no conjoint access to these contents. Of course this implies that the subject has highly imperfect knowledge of her conscious states: she will believe (in both "halves" of the brain) that she is experiencing only one word, when in fact she is experiencing two. But it is plausible for many other reasons that knowledge of consciousness is fallible, and it is not unreasonable to suppose that in cases of brain damage, this fallibility might be quite striking.

Of course nothing here proves that this interpretation is correct. It does suggest, however, that we should not be too quick to conclude that these cases involve a breakdown of phenomenal unity. Most of those who have discussed these cases have not carefully distinguished the relevant notions of unity and consciousness (an exception is Marcel 1994, who distinguishes "reflexive consciousness" from "phenomenal experience" and argues that the disunity concerns the former), and have often discussed things in terms of access and related functional notions. Once we distinguish access unity from phenomenal unity, it becomes clear that the direct evidence concerns access disunity, not phenomenal disunity. To establish phenomenal disunity requires substantial further argument. It may be that such arguments can be given, but the case is far from clear.

One might say something similar about other disorders of consciousness, such as dissociative identity disorder (multiple personality disorder). In this case, it seems that there are pathologies of access between different parts of a cognitive system. But it seems quite tenable to hold that nevertheless, there is a single field of consciousness at any given time, subsuming the conscious states of the subject, even if they are in certain respects mutually inaccessible. Of course as in the split-brain case, the subject may well have
various false beliefs about her own consciousness (e.g. that the various states belong to different subjects), but again this is not unexpected. Indeed, there are other cases involving "alien thoughts" in schizophrenic patients where it seems most plausible to hold that a subject incorrectly attributes some of her conscious states to a subject other than herself.

To completely assess this thesis requires much further analysis. But for now, we conclude that the empirical case against the phenomenal unity thesis is at best inconclusive. Given the strong prima facie positive case for accepting the phenomenal unity thesis, this suggests that the unity thesis remains quite plausible.

6 Formalizing the unity thesis

6.1 Subsumption and entailment

For further analysis, we need to clarify the phenomenal unity thesis, and the corresponding notion of phenomenal unity. We have said that a set of states is phenomenally unified when there is something it is like to be in all those states at once. When this is the case, the subject will have a phenomenal state (corresponding to the conjoint what-it-is-like) that subsumes each of the states in the original set. So phenomenal unity can be seen as a sort of subsumptive unity, and the phenomenal unity thesis on the table is a sort of subsumptive unity thesis.

**Subsumptive Unity Thesis:** For any set of phenomenal states of a subject at a time, the subject has a phenomenal state that subsumes each of the states in that set.

There are also closely related total and pairwise subsumptive unity theses, requiring subsumptive unity only for pairs of phenomenal states or only for the complete set of a subject's phenomenal states at a time, but we can focus on the thesis above for now.

As it stands, the notion of subsumption is something of an intuitive primitive. There are some things we can say about it. It is a relation among token phenomenal states. It is plausibly reflexive (a state subsumes itself), antisymmetric (if A subsumes B and B subsumes A, then A = B), and transitive (if A subsumes B and B subsumes C, then A subsumes C). Note that reflexivity eliminates any apparent problem of regress in the unity thesis (if A and B are subsumed by C, there is no need for a further state to subsume A and C, since C subsumes itself).

The paradigm case of subsumption is the relation between a complex phenomenal state and a simpler state that is intuitively one of its "components". One might think of subsumption as analogous to a sort of mereological part/whole relation among phenomenal states, although this should be taken as an aid to intuition rather than as a serious ontological proposal, at least at this point. It is also useful to stipulate that subsumption holds between a phenomenal state and less specific states that intuitively correspond to the same experience: for example, that the state of experiencing a sharp pain subsumes the corresponding...
state of experiencing a pain. This sort of subsumption is required in order for it to be possible that a highly specific total phenomenal state can subsume all of a subject's phenomenal states, including unspecific states.

It should be noted that there are alternatives to analyzing phenomenal unity in terms of subsumption. Often, phenomenal unity is analyzed in terms of an intuitive relation of co-consciousness, where this relation is taken as primitive. We think that the analysis in terms of subsumption runs deeper in certain respects than a primitive analysis in terms of co-consciousness, and offers the promise of further analytic tools, as discussed below. But the exact relation between these notions is an open question. (Dainton (2000) gives a thorough and insightful analysis of the unity of consciousness in terms of a primitive co-consciousness relation; Bayne (2001) discusses the relationship between the different accounts.)

The notion of subsumption is connected to the notion of "what it is like" in at least the following sense: when A subsumes B, what it is like to have B is an aspect of what it is like to have A. Of course this appeals to the unexplained notion of an "aspect". One might try to go further by defining subsumption wholly in terms of notion of "what it is like" as follows: A phenomenal state A subsumes phenomenal state B when what it is like to have A and B simultaneously is the same as what it is like to have A. This seems to capture the connection articulated above, and it also can ground the connection between subsumptive unity and the original definition of phenomenal unity. If there is something it is like to be in a set of states (as the original definition requires), then this phenomenology will correspond to a phenomenal state A of the subject, and it is clear that this state will subsume the states in the original set in the sense defined above. It is arguable that the defined notion if subsumption goes beyond the intuitive notion in certain respects (someone might hold that the "what it is like" locution can be read such that what it is like to have A and B differs from what it is like to have A, even when A subsumes B), and we will not rely on it in what follows, but nevertheless it can serve as a useful aid to the understanding.

(Extending this line of thought, one could say that a state A precisely subsumes a set of states S what what it is like to be in A is the same as what it is like to simultaneously be in the members of S. Then if A precisely subsumes S, A subsumes each of the members of S, but the reverse entailment does not hold. For example, a subject's total state of consciousness subsumes each of the subject's visual experiences, but it does not precisely subsume the set of them. One could then articulate a Correspondence Thesis holding that for any set of phenomenal states of a subject at a time, there is a corresponding phenomenal state that precisely subsumes that set. The correspondence thesis is formally stronger than the original subsumptive unity thesis: the existence of a total phenomenal state suffices for the truth of the original thesis, but it does not suffice for the truth of the correspondence thesis. The correspondence thesis nevertheless has some intuitive plausibility, and one could argue that this thesis, rather than the subsumptive unity thesis, best captures the idea articulated in the original phenomenal unity thesis. The difference between these theses will not be important for our purposes, however.)

There is a close relation between subsumption and entailment. Let us say that a state P entails a state Q when it is impossible (logically or metaphysically impossible) for a subject to instantiate P without instantiating Q. Then it seems clear that when a phenomenal state P subsumes a phenomenal state Q, P will entail Q. For example, if P involves the phenomenal character as of seeing a red book and hearing a
What is the Unity of Consciousness?

bird singing, and if Q involves the phenomenal character as of seeing a red book, then it is impossible to have P without having Q. The same goes with any case of subsumption: by its nature, the subsuming state carries with it the subsumed state.

Note that strictly speaking, entailment is a relation among state-types, while subsumption is a relation among state-tokens. For present purposes, we can regard entailment as derivatively a relation among state-tokens, so that one state-token entails another when there is entailment between the corresponding state-types (although see below). We will generally pass over this nicety in discussion, acknowledging it where it is relevant. Note also that a phenomenal state A entails a phenomenal state B if necessarily, a subject in A is also in B — *not* if the content of A entails the content of B.

The close relation between entailment and subsumption raises an interesting possibility: perhaps we can simply *define* subsumption in terms of entailment? That is, perhaps we can hold that phenomenal state A subsumes B when A entails B? If this were possible, instead of relying on a novel primitive relation, we could analyze unity in terms of a well-understood relation that allows the use of standard logical tools. To help assess this possibility, we can define a corresponding notion of unity and a corresponding unity thesis:

A set of phenomenal states of a subject at a time is *logically unified* when the subject has a phenomenal state that entails each of the phenomenal states in that set.

**Logical Unity Thesis:** For any set of phenomenal states of a subject at a time, the subject has a phenomenal state that entails each of the states in the set.

This gives an attractively simple formulation of the unity thesis, and one that has some intuitive force. Unfortunately there is an obstacle to replacing subsumption by entailment. We know that when A subsumes B, A entails B. But the reverse is not obviously the case. In fact, there are two ways in which it may seem that A could entail B without subsuming B.

First, A and B might correspond to intuitively distinct experiences that share a type. For example, a subject might have two pains at the same time, or two experiences of red, and so will have two distinct phenomenal states of the same type. In this case, one state-type will entail the other, so if entailment among tokens is derivative on entailment among types, one state-token will entail the other. In this case, it is not plausible to hold that one state subsumes the other. (What it is like to have A and B simultaneously is quite different from what it is like to have A.) One might instead refine the definition of entailment among state-tokens, requiring that it is impossible for one token to exist without the other, in addition to the requirement that one type cannot exist without the other. But one can also deal with this case by a strategy discussed below.

Second, A and B could be intuitively distinct phenomenal states that do not share any simple type, but that are nevertheless necessarily connected. This would involve a sort of *gestalt unity*, which involves constraints on the co-occurrence of distinct phenomenal states. For example, perhaps there are cases
What is the Unity of Consciousness?

where feeling a pain in one's shoulder while also experiencing a splitting headache produces a unique sort of pain that could not be experienced in the absence of the headache. Or perhaps seeing a certain person in the middle of a crowd produces a unique sort of visual experience of that person that could not be had in the absence of the experience of the crowd. Or perhaps (to use an example from Dainton 2000) the experience of the boundaries of a Kanisza triangle is of a special sort that could not be had in the absence of the circles in which the triangle is embedded. In this sort of case, we can say that the pain is gestalt unified with the headache; the experience of the person is gestalt unified with the experience of the rest of the crowd; and the experience of the boundaries is gestalt unified with the experience of the circles.

Whether there are really any cases of gestalt unity is arguable. One could argue that in the above cases, it would be possible to experience the pain without the headache, or have the visual experience of the person without that of the crowd, or to have that of the boundaries without that of the circles, perhaps in some very different context. But it is not implausible that at least some experiences put some constraints on concurrent experiences, and that one cannot mix and match experiences arbitrarily. If this is so, then there is at least a weak sort of gestalt unity, since the presence of one phenomenal state puts constraints on the nature of concurrent phenomenal states. In this case one can even say that the presence of one phenomenal state entails the existence of another phenomenal state, where the second is understood as an instantiation of a sufficiently unspecific phenomenal property.

If there is gestalt unity, then there will be cases in which one phenomenal state entails another phenomenal state without the first subsuming the second, at least in any intuitive sense. For example, the experience of the boundary of a Kanisza triangle might entail something about the experience of the nearby objects, but the experience of the nearby objects does not intuitively subsume that of the boundary of the triangle. Similarly, the experience of the shoulder pain might entail the experience of the headache, but it does not intuitively subsume the experience of the headache. (Intuitively, what it is like to have the pain and the headache goes beyond what it is like to have the pain, even if the former is entailed by the latter.)

So: If there is gestalt unity, then subsumption cannot be understood in terms of entailment. But this does not mean that we must give up on the logical unity thesis. Even if subsumption cannot be understood in terms of entailment, one can make a case that the logical unity thesis entails the subsumptive unity thesis.

To see this, we can first note that not all phenomenal states are gestalt unified. Even if some pairs of phenomenal states are gestalt unified, it seems very unlikely that all pairs are, and it seems much more plausible that most pairs are not. Given a typical pair of phenomenal states had by a subject such that neither subsumes the other, it usually seems to be straightforwardly possible that a subject could have an instance of the first state without the second. When I see the red book and hear the bird singing, there seems to be no good reason to deny that I could have a visually identical experience without hearing the bird singing, and so on. (Dainton 2000 gives a more extended argument for the conclusion that gestalt unity is not universal and is in fact rare.)

If there can be pairs of states that are not gestalt unified, it also seems that there can be subjects none of whose states are gestalt unified. One simply needs a subject all of whose basic phenomenal states are
What is the Unity of Consciousness?

independent in the above way: each of them could occur without any of the others. There seems to be no obstacle in principle to such a subject, and one could even argue that our own phenomenal states are often like this. Let us say that such a subject is gestalt-free. In gestalt-free subjects, the gestalt cases of entailment without subsumption will not arise. So (setting aside for a moment any other cases of entailment without subsumption), we can say that if the logical unity thesis holds, the subsumptive unity thesis holds at least when restricted to gestalt-free subjects.

Now let us assume that the subsumptive unity thesis holds for gestalt-free subjects: for any set of phenomenal states of a gestalt-free subject, there is a subsuming phenomenal state. If so, it is very plausible that the subsumptive unity thesis holds for all subjects. If there is always a subsuming state in gestalt-free cases, there will plausibly always be a subsuming state in gestalt cases. There is nothing about gestalt unity that makes the existence of a subsuming state in such cases less likely. If anything, the situation is the reverse. In a case of gestalt unity, the experiences will be connected in such a way that the existence of a subsuming state will be more likely, not less. So if there are cases in which gestalt unified states are not phenomenally unified, there should equally be cases in which gestalt-free states are not phenomenally unified. So the subsumptive unity thesis for gestalt-free subjects plausibly entails the subsumptive unity thesis for all subjects.

We are close to establishing a connection between the logical unity thesis and the subsumptive unity thesis in general. But we still need to deal with the other case of entailment without subsumption discussed above, in which a subject has distinct simultaneous experiences that share a type. We can deal with this in an analogous way. Let us say that a subject has duplicate experiences when the subject has two intuitively distinct experiences that share a maximally specific phenomenal type (two pains or two color experiences with exactly the same quality, say). It is not entirely obvious that duplicate experiences are possible; but in any case, let us say that a duplicate-free subject is a subject without duplicate experiences. It is plausible that if the subsumptive unity thesis is true when restricted to duplicate-free subjects, it is true also of subjects with duplication: if it is possible for duplicate experiences not to be subsumed by a common experience, it will be equally possible for non-duplicate experiences not to be so subsumed. As with gestalt phenomena, there is nothing about duplication per se that contributes to a breakdown of phenomenal unity. So the subsumptive unity thesis for duplication-free subjects plausibly entails the subsumptive unity thesis for all subjects.

Combining the last two cases, we can say that the subsumptive unity thesis restricted to gestalt-free, duplication-free subjects plausibly entails the subsumptive unity thesis for all subjects. But it is also clear that the logical unity thesis entails the subsumptive unity thesis for gestalt-free, duplication-free subjects. In such subjects, a phenomenal state T that entails all phenomenal states will also subsume all phenomenal states, since we have removed the relevant gaps between subsumption and entailment. One might worry that one gap remains: by ruling out duplication, we have ruled out the possibility of entailment without subsumption for maximally specific phenomenal states, but two sufficiently nonspecific states of the same type might entail each other without subsuming each other. Nevertheless, since T entails maximally specific versions of each of these nonspecific states, T will subsume these maximally specific states, and so T will subsume the nonspecific states. So T subsumes all the subject's phenomenal states.
What is the Unity of Consciousness?

We have established that the logical unity thesis entails the subsumptive unity thesis for gestalt-free subjects, duplication-free subjects; and we have established that the latter thesis plausibly entails the subsumptive unity thesis for all subjects. So the logical unity thesis plausibly entails the subsumptive unity thesis. In reverse, the subsumptive unity thesis clearly entails the logical unity thesis. So it is plausible that the subsumptive unity thesis holds if and only if the logical unity thesis holds. The only obstacle to this equivalence will arise if there are breakdowns of phenomenal unity that are solely due to gestalt unity or to duplication, but there seems to be little reason to take that possibility seriously.

If this is correct, we can assess the truth of the subsumptive unity thesis by assessing the truth of the logical unity thesis. This latter task is in some respects more straightforward, since we no longer have to deal directly with the primitive notion of subsumption. This also allows the possibility of using familiar logical tools to formulate and assess versions of the unity thesis. We will look more closely at some versions of the thesis in the following section.

### 6.2 Logical unity and conjunctive closure

There are three versions of the subsumptive unity thesis: the pairwise version, the general version, and the total version. There are correspondingly three versions of the logical unity thesis, holding either that there is logical unity among either any two states of a subject at a time, any set of states, or the complete set of states. Or more directly:

**Pairwise Logical Unity Thesis**: Necessarily, for any two phenomenal states had by a subject at a time, the subject has a phenomenal state that entails both original states.

**General Logical Unity Thesis**: Necessarily, for any set of phenomenal states of a subject at a time, the subject has a phenomenal state that entails each state in the set.

**Total Logical Unity Thesis**: Necessarily, for any conscious subject at a time, the subject has a phenomenal state T such that for any phenomenal state A of the subject at that time, T entails A.

As before, it is clear that the general thesis entails the pairwise thesis and the total thesis as special cases. The total thesis also entails the general thesis and the pairwise thesis, since a state that entails all phenomenal states of a subject will also entail any pair or any set of states. Arguably the pairwise thesis does not entail the other two theses, because of the formal possibility that there might be entailing states for any finite set of states, but not for infinite subsets.

We can start by focusing on the total logical unity thesis, since this corresponds most closely to the total phenomenal unity thesis, which arguably captures the central intuition behind the unity of consciousness. Intuitively, we can think of T, the entailing state in the thesis, as the subject's total phenomenal state, capturing what it is like to be the subject at that time. If such a state exists, it will fulfill the requirement...
What is the Unity of Consciousness?

of the total logical unity thesis.

One can also approach the matter in logical terms. Let us say that the conjunction of a set of states is a state $C$ such that necessary, a subject is in $C$ if and only the subject is in each of the states in that set. (Like entailment, conjunction is fundamentally a relation among state-types, and derivatively a relation among state-tokens. Note also that the conjunction of states is quite different from conjunction of the contents of states.) This identifies $C$ at least up to mutual entailment. For present purposes, it is useful to assume that when two states $A$ and $B$ mutually entail each other (i.e. when necessarily, a subject is in $A$ if and only if the subject is in $B$), then the two states are identical. If so, then $C$ is identified uniquely. Nothing that follows rests essentially on this assumption — one could rephrase things in terms of equivalence classes of states — but this makes the discussion easier.

We can then propose a natural candidate for $T$: the conjunction $C$ of all of a subject's phenomenal states at a time. It is clear that if $T$ exists, $T$ entails $C$ (since $T$ entails each of the conjuncts of $C$). And it is clear that if $T$ exists, $C$ entails $T$ (since $T$ is itself a phenomenal state). So if $T$ exists, then $T$ is identical to $C$ (and $C$ is therefore a phenomenal state), by the criterion for state identity above. It is also clear that if $C$ is a phenomenal state, then $C$ will satisfy the total logical unity thesis with $T=C$. We can therefore say that an appropriate $T$ exists if and only if $C$ is a phenomenal state.

Let us say that a set of states is conjunctively unified when the conjunction of the members of that set is itself a phenomenal state. Then from the discussion above, it follows that the total logical unity thesis is equivalent to the claim that the set of a subject's phenomenal states is conjunctively unified:

**Total Conjunctive Unity Thesis**: If $C$ is the conjunction of all of a subject's phenomenal states at a time, then $C$ is itself a phenomenal state.

As before, someone might think that a thesis of this sort is trivially true, but this would be incorrect. It is trivial that for any set of phenomenal states of a subject at a time, there will be a conjunctive state $C$ that entails each of the original states. But it is nontrivial that $C$ will itself be a phenomenal state. That is, it is nontrivial (although very plausible) that there will be something it is like to be in $C$: some global phenomenal character that a subject will have if and only if the subject is in $C$. Those who deny the original unity thesis will deny the existence of such a phenomenal character, and so will deny that $C$ is itself a phenomenal state.

In effect, we have seen that the original phenomenal unity thesis is equivalent to a thesis about the conjunctive closure of co-instantiated phenomenal states (where co-instantiated states are states had by the same subject at the same time): certain conjunctions of states in this class must also be states in this class. This is very useful, since conjunctive closure is amenable to relatively straightforward analysis.

One can also formulate conjunctive closure theses that are closely related to the other versions of the logical unity thesis. There is a pairwise version, and a general version:
**Pairwise Conjunctive Unity Thesis:** For any two phenomenal states of a subject at a time, their conjunction is a phenomenal state.

**General Conjunctive Unity Thesis:** For any set of phenomenal states of a subject at a time, their conjunction is a phenomenal state.

These theses are not quite formally equivalent to the corresponding versions of the logical unity thesis. To see this, note that it is at least a formal possibility that two states might be logically unified but not conjunctively unified. For example, it is at least formally possible that the conjunction of all of a subject’s phenomenal states might be a phenomenal state, but that the conjunctions of certain pairs and subsets might not be. If so, then these pairs and subsets will be logically unified but not conjunctively unified. In this case the pairwise and general conjunctive unity theses will be false, but the the pairwise and general logical unity theses will be true.

However, it is clear that these conjunctive unity theses entail the corresponding versions of the logical unity thesis. And they are interesting and plausible theses in their own right. The first says that for any two phenomenal states A and B of a subject at a time, there will be something distinctive it is like to be in A and B: that is, a distinctive conjoint phenomenal character that a subject will have if and only if the subject is in both A and B. The second says the same thing for arbitrary sets of co-instantiated phenomenal states. These theses are not formally trivial, but they are highly plausible theses about phenomenal consciousness. (These theses are closely related to the correspondence thesis discussed in the previous section.)

All three theses are simple and elegant. The pairwise conjunctive unity thesis says that the class of phenomenal states is closed under pairwise co-instantiated conjunction: the conjunction of two co-instantiated phenomenal states is a phenomenal state. The general conjunctive unity thesis says that the class of phenomenal states is closed under general co-instantiated conjunction: the conjunction of any set of co-instantiated phenomenal states is a phenomenal state. And the total conjunctive unity thesis says that the class of phenomenal states is closed under maximal co-instantiated conjunction: the conjunction of a maximal set of co-instantiated phenomenal states is a phenomenal state.

The total conjunctive unity thesis remains the core version of the unity thesis, but all of these theses are plausible and useful. Each of them can be used as a tool in assessing the status of the unity of consciousness, in assessing its consequences, and in assessing its compatibility with various theories of consciousness.

### 6.3 Hurley, Shoemaker, and what it is like

It should be noted all of these unity theses are stated simply in terms of the notions of phenomenal state, of co-instantiation, and of conjunction. And the notion of a phenomenal state is tied constitutively to the notion of there being something it is like to be a given subject, or to be in a given state. So we have an account of unity that requires little more than the existing "what it is like" conception of phenomenal
This stands in tension with a claim in a very interesting analysis by Hurley (1998; this volume). Hurley (1998, pp. 165-66) argues that the unity of consciousness cannot be characterized "subjectively", and that suppositions about the structure of consciousness are not captured by the "what it is like" test, so that we need to appeal to further "objective" properties to give an account of unity. This claim is grounded in the claim that in a case where unity breaks down, there is no "what-it-is-like" that captures the structure of a subject's consciousness. Hurley backs up this claim by considering two cases: (i) two subjects, one experiencing red and hot, the other experiencing red and dizzy; and (ii) a partially unified single subject, in whom red and hot are unified, red and dizzy are unified, but hot and dizzy are not. Hurley argues that no "what it is like" facts can distinguish these two cases.

But from the claim that there is no what-it-is-like that characterizes a disunified subject, it does not follow that one cannot characterize unity in what-it-is-like terms. Indeed, following Hurley's own claim, one can hold that unity breaks down precisely when there is nothing it is like to have all a subject's conscious states simultaneously. We can distinguish case (i) from case (ii) above by noting that in case (ii), both subjects have a phenomenal state that subsumes all their phenomenal states, whereas in case (i), the subject has no such phenomenal state. Hurley might extend her argument by suggesting case (iii): a bifurcated subject with two different (but indistinguishable) tokens of red in separate streams. In this subject, red1 is unified with hot, red2 is unified with dizzy, and no state in either pair is unified with a state in the other pair (Hurley 1998, p. 166, seems to point toward such a case). If (iii) is possible, one could argue that it could not be distinguished from (ii) by talk of subjects and their phenomenal states alone. We would need to appeal to the identity of phenomenal states: a single "red" experience is involved in both complex experiences in (ii), but not in (iii).

There are a number of things one could say in response. One might concede that "what it is like" talk cannot distinguish the two different cases of disunity (ii) and (iii), but hold that it can nevertheless distinguish unity from disunity, which is the most important work we need it to do. If the unity thesis is true, then cases of disunity will be impossible, and distinctions among impossible cases will not matter to characterizing the structure of consciousness. More deeply, one can suggest that Hurley's argument shows at best that one cannot distinguish the cases in terms of the distribution of phenomenal state-types. If we appeal to facts about the distribution of phenomenal state-tokens, things are straightforward: there is a token experience that is subsumed by two different complex experiences in (ii), but not in (iii). It may be that (ii) and (iii) will be introspectively indistinguishable, so that the structure of consciousness is not transparent to a subject. But nevertheless, a characterization of the structure of consciousness in terms of...
What is the Unity of Consciousness?

phenomenal relations among phenomenal state-tokens is still, in a deep sense, a characterization in subjective terms.

Our characterization of unity in phenomenal terms also stands in tension with a claim by Shoemaker (this volume). Shoemaker suggests that if a conscious state is understood as one with a phenomenal property (i.e. one such that there is something it is like to be in it), this leads to "consciousness atomism": the view that the factors that make a state conscious are independent of the factors that make two states unified. Our discussion here suggests that this is false. What it is for two conscious states to be unified can be understood in terms of the existence of a more complex conscious state, where both the simple state and the complex states are states characterized by what it is like to be in them. So the factors that enter into unifying conscious states are the same sort of factors as those that enter into those states being conscious in the first place.

At one point, Shoemaker characterizes "consciousness atomism" differently, as the view that "whether a state is conscious will be independent of whether there are other conscious states with which it is co-conscious". The account here is neutral on this claim. For all we have said here, it may be possible for there to be a subject with a single conscious state. This claim does not seem to us to be obviously objectionable, and it is compatible with the more important view that the factors that enter into consciousness are the same as those that enter into co-consciousness.

In fact, the definitions of unity that we have given here suggest that any account of what it is to be a phenomenal state will automatically yield a theory of what it is for two such states to be unified. We need simply to apply the theory to the relevant conjunctive states, in order to determine whether they are phenomenal states. In this way, it seems that any substantive theory of phenomenal consciousness can yield unified definitions of consciousness and of co-consciousness. It is precisely because of this that the unity thesis (if it is true) puts strong constraints on a theory of phenomenal consciousness, as we will see.

7 Applications of the Unity Thesis

We have already mentioned the objection that the conjunctive versions of the unity thesis are trivial: that is, that it is trivial that the the conjunction of a set of co-instantiated phenomenal states is itself a phenomenal state. It is clear that the thesis is not formally trivial, in that there are many classes of states that are not closed under co-instantiated conjunction: e.g., states of the sort "talking with X", where X is an individual. Closer to home: there are also many classes of mental states that are not closed under co-instantiated conjunction.

For example, the class of belief states does not seem to be closed under conjunction. Let us say that a belief state is the state of believing some proposition. Then it is not the case that the conjunction of any set of belief states is a belief state. For example, if A is the state of believing that P, and B is the state of believing that Q, there is plausibly no belief state that a subject will be in precisely when they are in A and B. The only tenable candidate for such a belief state is the state of believing P and Q. But there are well known reasons to believe that a subject can believe that P and believe that Q without believing the
What is the Unity of Consciousness?

conjunction $P \land Q$. For example, $P$ and $Q$ might be believed in different "compartments" of a compartmentalized mind. It may even be that for some $P$, a subject can believe that $P$ and separately believe that $\neg P$, without believing the contradiction $P \land \neg P$. And it seems quite possible that a subject can have many different beliefs without accepting the massive conjunction of the contents of all of those beliefs. If this is right, then the conjunction of co-instantiated belief states will not in general be a belief state. So the class of belief states is not closed under co-instantiated conjunction.

It may seem plausible or even obvious that the class of phenomenal states is closed under conjunction. But if so, this is a substantive thesis about the class of phenomenal states, and their difference with other classes of mental states. It may even be a conceptual truth, in some sense, that the class of phenomenal states is closed under co-instantiated conjunction. But if so, this is again a substantive thesis about the concept of a phenomenal state, and a way in which it differs from the concept of a belief state, and of other sorts of states.

The substantive nature of the thesis is revealed by the fact that the conjunctive unity theses put a strong constraint on potential theories of consciousness. We have seen that the unity thesis is prima facie plausible, and there there seem to be no strong arguments against it. If this is right, then the unity thesis puts a prima facie constraint on theories of consciousness: they must be compatible with the unity thesis. And in particular, any account of phenomenal states must be compatible with the total conjunctive unity thesis. Whatever phenomenal states are, according to a given account, the class of phenomenal states must be closed under total co-instantiated conjunction. A number of prominent theories of consciousness appear to be incompatible with this constraint.

One example is the higher-order thought theory of consciousness, put forward by David Rosenthal (1997) and others. Not all higher-order thought theorists intend the theory as an account of phenomenal consciousness (e.g. Lycan 2000 explicitly rejects the idea), but we are only concerned with versions of the theory that are aimed at phenomenal consciousness. The central idea of these theories is the following:

**Higher-Order Thought Thesis:** A mental state $M$ is phenomenally conscious if and only if a subject has a higher-order thought about $M$.

Here, a higher-order thought about $M$ should be understood as a thought by the subject with the content "I am in $M". The thesis will usually be modified and qualified in some ways. For example, Rosenthal holds that for $M$ to be conscious, the higher-order thought must be brought about in the right sort of way, and in particular must be a noninferential thought. Rosenthal also holds that only sensory states can be phenomenally conscious, so that we would have to insert a rider to that effect in the definition above. This is arguably a mere terminological difference, however, since Rosenthal holds that there will be something it is like to be in a state whenever it is the object of the right sort of higher-order thought, whether the state is sensory or not. In any case, for our purposes we will take the thesis in the simple form above. Our arguments should apply straightforwardly to most modified versions.
What is the Unity of Consciousness?

Is the higher-order thought thesis compatible with the unity thesis? It is easiest to approach this question by considering the conjunctive versions of the unity thesis. The conjunctive versions say that the class of phenomenal states are closed under conjunction. So we can ask: on the higher-order thought theory, is the class of phenomenal states closed under conjunction?

We can start by thinking about phenomenally conscious mental states. If A and B are phenomenally conscious mental states, is A&B necessarily a phenomenally conscious mental state? Assuming the higher-order thought thesis, this translates into the following: if a subject has a higher-order thought about A and a higher-order thought about B, does the subject necessarily have a higher-order thought about A&B? That is, if the subject has a thought "I am in A" and a thought "I am in B", does it follow necessarily that the subject has a thought "I am in A and B"?

It seems not. It is surely possible for a subject to think "I am in A" and "I am in B", without connecting these into a thought "I am in A and B". We can take a case like those discussed above, in which a subject has contradictory beliefs, knows that she has each belief, but never puts the two together. She might have the thought "I believe P" and the thought "I believe ~P" without ever putting these two together into a thought "I believe both P and ~P". This might be strange or unusual, but there is nothing contradictory about it. There would only be something contradictory here if the beliefs of a subject are necessarily closed under logical consequence; but of course no subject's beliefs are closed under logical consequence.

The same is even clearer where total conjunctivity is concerned. On the higher-order thought theory, if a subject has a number of phenomenally conscious mental states, is their conjunction a phenomenally conscious mental state? That is, if a subject is has mental states A_1, ..., A_n, and has the thoughts "I am in A_1",..., "I am in A_n", does the subject necessarily have the thought "I am in A_1&A_2&...A_n"? Again, it seems not. One might reasonably argue that this entailment does not even hold typically, let alone necessarily. That is, it is arguable a typical subject with these higher-order beliefs would not have the complex conjunctive belief. Whatever one says here, it is hard to dispute that it is possible for a subject to have the individual higher-order beliefs without the complex conjunctive belief.

So it appears that if the higher-order thought view is true, the class of phenomenally conscious mental states is not closed under co-instantiated conjunction. This already contradicts the central intuition behind the unity thesis: that necessarily, if there is something it is like to be in each of a set of states, there is something it is like to be in all the states at once. On the higher-order thought view, this thesis will clearly be false.

The official version of the unity thesis is stated in terms of phenomenal states, not phenomenally conscious mental states. The analysis of phenomenal states is slightly tricker, since advocates of the higher-order thought view have not usually talked about phenomenal states and phenomenal properties directly. But given that higher-order thought theorists hold that there is something it is like to be in a mental state when the subject has a higher-order thought about it, they presumably hold that what it is like to be in that state is determined by the content of the higher-order thought. If so, it seems that phenomenal properties will be the properties of having higher-order thoughts with certain contents, and
What is the Unity of Consciousness?

phenomenal states will be the states of having such higher-order thoughts.

Do phenomenal states, understood this way, satisfy the unity thesis? It seems not, for much the same reason as before. Here it is useful to take the entailment version of the unity thesis: that necessarily, when a subject has a set of phenomenal states, the subject has a phenomenal state that entails each of the individual states. When a subject has a set of higher-order thoughts H₁, ..., Hₙ, does the subject necessarily have a higher-order thought HH such that being in HH entails being in H₁, ..., Hₙ? It seems not, for the usual reasons. A subject might think "I am in A" and "I am in B", without any higher-order thought (e.g. "I am in A&B") such that having that thought entails having the original thoughts.

The problem is not that the higher-order thought theory provides no way to understand phenomenal unity. It can do so in a natural way. Two phenomenally conscious mental states A and B are unified when the subject has a higher-order thought about them not just singly but jointly. And two phenomenal states, the states of having higher-order thoughts "I am in A" and "I am in B", are phenomenally unified when there is a complex phenomenal state that entails them: that is, if there is a complex higher-order thought such that having the complex thought entails having the specific thoughts. This requirement will arguably be satisfied when the subject has a complex higher-order thought such as "I am in A&B".

The problem is rather that on this account, there is no reason to believe that phenomenal states, or phenomenally conscious mental states, will always be unified. Certainly it will not be necessary that they be unified, and it seems plausible that in a typical case, they will not be unified. So the higher-order thought thesis is incompatible with the unity thesis. It is clearly incompatible with the conjunctive and logical versions of the unity thesis. It is therefore also incompatible with the subsumptive versions, since any failure of logical unity automatically entails a failure of subsumptive unity. So if the higher-order thought thesis is true, the unity thesis is false. And if the unity thesis is true, the higher-order thought thesis is false.

Proponents of the higher-order thought thesis might reply in a number of ways. Most straightforwardly, they might reply by denying the unity thesis. This is a tenable response, since the truth of the unity thesis cannot be taken for granted. But still, there is a strong intuition that the unity thesis is true, so the incompatibility is at least a cost of the higher-order thought thesis. Proponents might also embrace a more limited version of the unity thesis, arguing for example that unity holds typically but not necessarily, or that it holds given contingent facts of human psychology, but not for all possible beings. Here there would still be the cost of denying the intuition of necessary unity, and there would be the added difficulty of defending the claim that unity holds in the relevant range of cases, when there seems to be no obvious reason why complex conjunctive thoughts about all the objects of our higher-order thoughts should typically exist.

A higher-order thought theorist might also respond by finding fault with the argument for incompatibility: they might hold, for example, that it is necessary that the class of mental states that are objects of higher-order thoughts is closed under conjunction. This would be a difficult case to make, in face of the apparent possibility of failure of this principle, and in face of the general phenomenon that
What is the Unity of Consciousness?

Beliefs are not closed under logical consequence.

Finally, a proponent might modify the higher-order thought thesis to make it compatible with the unity thesis. To do so, they must modify the definition of a phenomenally conscious mental state. It could be held, for example, that a mental state is phenomenally conscious when either (i) it is the object of a higher-order thought, or (ii) it is the conjunction of states that are the objects of higher-order thoughts. This sort of disjunctive account would be contrary to both the letter and the spirit of existing higher-order thought views (which hold that a conscious state is one that the subject is conscious of). One could also raise questions about whether this thesis delivers any substantive unity of consciousness, or merely a stipulated sort of unity of consciousness that holds trivially. And so far as the unity of consciousness seems to be a substantive fact about consciousness, one could argue that this modified version of the higher-order thesis does not really account for it.

Of course all of this is debatable and could lead to fruitful further discussion. But the prima facie incompatibility between the two theses is at least interesting. It is worth noting that the incompatibility extends straightforwardly to other "higher-order" views of consciousness, including views on which a conscious state is an object of a higher-order perceptual state, or the object of some other sort of higher-order representational state. The existence of a set of higher-order perceptual states does not entail the existence of a complex conjunctive higher-order perceptual state, and the same goes for other sorts of representational states. So if the unity thesis is true, these theses are false, and vice versa.

The unity thesis is also incompatible with many representationalist views of consciousness. According to representationalist views (e.g. Dretske 1995, Tye 1995), all phenomenally conscious mental states are representational states (that is, states with representational content). This is commonly allied with a further functional criterion to yield:

**Representationalist Thesis**: a mental state is phenomenally conscious if and only if it is a representational state that plays an appropriate functional role.

We will focus on this broadly functionalist variety of representationalism. The details of the relevant functional role different between representationalists, but it is typically held to involve some sort of access and control. One can then say that what it is like to be in a mental state is determined by the content of the representational state, on the condition that it plays the relevant functional role. On this sort of view, then, a phenomenal state is a state of having a certain sort of representational state play the appropriate functional role, where distinct phenomenal states are individuated by distinct representational contents.

Two phenomenal states P1 and P2 are conjunctively unified when there is a phenomenal state P that entails each of the original states. On the representationalist account, two phenomenal states P1 and P2, corresponding to representational states A1 and A2 (with contents C1 and C2) playing the relevant functional role, will be conjunctively unified when there is a phenomenal state P, corresponding to representational state A (with content C) playing the relevant functional role, such that P entails P1 and
P2. This will occur if and only if the existence of A playing the role entails the existence of both A1 and A2 playing the role. The only reasonable way to satisfy this is for the content of A to entail the content of A1 and the content of A2: that is, for C to entail both C1 and C2, or for C to entail C1&C2. For example, if A1 has content "red to the left", and A2 has content "green to the right", P1 and P2 will be conjunctively unified if there is a state A (playing the role) whose content entails "red to the left and green to the right". So two phenomenal states, corresponding to two representational states, will be conjunctively unified if and only if there is a conjunctive representational state (playing the appropriate role) whose content entails the conjunction of the contents of the original representational states.

The unity thesis is true if and only if necessarily, every set of phenomenal states is conjunctively unified. On the representationalist view, is this the case? It seems not. It seems at least possible to have a state with content C1 and a state with content C2, each playing a certain role, without having a state with content C1&C2 that plays the role. We saw this earlier in the case where the relevant role involves accessibility: it is possible that C1 is accessible and C2 is accessible with C1&C2 being accessible. Something similar will hold for any functional role involving access and control. If this is so, then representationalist thesis in the relevant class are incompatible with the unity thesis.

As before, representationalists could respond in a number of ways. They could deny the unity thesis, at cost of denying a strong intuition. They could modify it to apply to a more limited range of cases, at cost of some intuition and perhaps some empirical constraint. (For example, in the Sperling case, this representationalist may have to deny that the subject has a phenomenally unified visual field.) They could modify the representationalist thesis to allow a disjunctive definition on which is stipulated that conjunctions of phenomenal states are phenomenal states, at cost of endangering the substantive status of the unity thesis. Alternatively, they could move to a different sort of representationalism which is not so closely tied to functionalism: for example, it might be held that phenomenally conscious states are representational states whose content is represented phenomenally, or that they are representational states with some other property that is not functionally defined. The resulting version of representationalism might be compatible with the unity thesis (as well as being independently more plausible than the previous versions), at cost of giving up the reductive aspirations of many representationalist views.

One might also argue that other nonrepresentationalist forms of functionalism are incompatible with the unity thesis, on the general grounds that there will not be the relevant conjunctive property among states playing the functional role. The details will depend on the details of the functionalist theory, and in particular on the account that is given of phenomenal states and properties. These accounts can vary between functionalist theories, and are often not clearly articulated, so it is difficult to give a general analysis of such theories with respect to the unity thesis. But it is clear that it will be at least highly nontrivial for a functionalist account to satisfy the unity thesis.

If what has gone above is correct, then the unity thesis is incompatible with higher-order thought (and other higher-order representation) views of consciousness, with many representationalist views of consciousness, and with many functionalist views of consciousness. So the unity thesis is clearly nontrivial. Nevertheless, it has strong independent plausibility as a thesis about phenomenal states. So the incompatibility of the unity thesis with these views of consciousness should be seen as at least a prima
What is the Unity of Consciousness?

facie argument against these views.

8 Explaining the Unity Thesis

If the unity thesis is true, how is its truth to be explained? We do not know the answer to this question. But in this concluding section, we will explore some possibilities.

One common strategy is to try to explain unity in functional terms. For example, one might try to explain unity in terms of some sort of informational integration, or in terms of serial processing in the brain, or something along those lines. One obvious problem with this sort of strategy is that it is not clear why this sort of functioning should yield phenomenal unity, as opposed to something like access unity. But an equally deep problem is that for reasons similar to those discussed above, it seems inevitable that this sort of functioning will be present contingently, and that it will be possible for conscious states to exist that do not stand in the relevant functional relations. If so, unity (on these analyses) will obtain only contingently, and the unity thesis will be false. If unity is to obtain necessarily, as the unity thesis suggests, we must look elsewhere.

Much of the reason for accepting the truth of the unity thesis comes from the fact that its denial seems to be inconceivable, and perhaps incoherent. This suggests that the unity thesis may be at some level a conceptual truth, although perhaps a deep conceptual truth, whose roots are revealed only by a deep analysis of our concepts. The central concepts involved in the unity thesis are that of a phenomenal state and that of a subject, along with various additional notions such as subsumption, entailment, conjunction, and so on. So one might hope that some light could be shed by attention to the concept of a subject, or by attention to the concept of consciousness.

One natural suggestion is that our concept of a subject of experience is somehow premised on unity. For example, one could suggest that ascriptions of subject-hood require as a precondition that subjects correspond to unified phenomenal fields. In the spirit of a sort of bundle theory of the subject, one could argue that we have a prior notion of a phenomenal field, and that we then associate subjects with phenomenal fields. If this is the case, we would expect that every subject would have a unified consciousness. A subject with two distinct phenomenal fields, for example, would be ruled out as a conceptual impossibility: where there are two phenomenal fields, there will automatically be two subjects.

How might this work? Our articulation of the notion of a phenomenal field in this paper appeals to subjects and co-instantiation, but one might argue that these can be bypassed. For example, one might appeal to a primitive relation of subsumption (or of co-consciousness) among phenomenal states that makes no presuppositions about subjects of those states, and then define a phenomenal field as a maximal phenomenal state: a phenomenal state that is not subsumed by any other phenomenal state. But even if something like this works, there is a deeper problem. This strategy might explain why distinct phenomenal fields correspond to distinct subjects, but it cannot explain why states of consciousness come packaged into unified phenomenal fields in the first place. For example, nothing in this strategy explains...
why a phenomenal state cannot be subsumed by two different phenomenal states such that no further phenomenal state subsumes both of these in turn. More generally, nothing here explains why the subsumption relation does not hold in quite unsystematic and fragmented manner. It is possible that an analysis of subsumption itself could do some work: for example, one could argue that subsumption is conceptually akin to a mereological part-whole relation, and so must hold reflexively, antisymmetrically, and transitively, and perhaps in a way that allows no overlap. But this conceptual stipulation does not really make the problem go away. It simply raises the question of why conscious states come packaged as parts and wholes.

One might then take a different approach. Instead of focusing on the concept of a subject, one can focus on the concept of consciousness itself. It could be argued that our basic concept of consciousness is not the notion of a simple phenomenal state — what it is like to such-and-such at a time. Rather, our basic notion of consciousness is that of a total phenomenal state: what it is like to be a subject at a time. This yields a holistic rather than an atomistic view of consciousness. On this approach, we do not start with basic atomic states of consciousness, and somehow glue them together into complex states. Rather, we start with a basic total state of consciousness, and then differentiate it into simpler states, and ultimately into atomic states.

If this were truly our basic notion of consciousness, then it might explain why the unity thesis is true. On this view, any non-total phenomenal state is derivative on a total phenomenal state that subsumes it. On this view, it is to be expected that any phenomenal states of a subject at a time are all simply aspects of what it is like to be that subject at that time. As such, it is to be expected that for any set of co-instantiated phenomenal states, there will be a subsuming state. On this view, the most basic problem with the theories of consciousness discussed in the last section is that they are atomistic rather than holistic, starting with simple states rather than total states. If this view is right, then any such analysis of consciousness will be a misanalysis from the start.

It is not obvious that this sort of conceptual claim on its own yields a substantive unity thesis. But one might naturally tie this analysis to a corresponding view of the metaphysics of consciousness. In nature, it may be that the most basic sort of conscious state is the total phenomenal state, or the phenomenal field, or even the phenomenal world. These total states are basic, but they are not featureless: they come with a complex structure from which one can differentiate many aspects. (As an analogy, one can think of a quantum wavefunction, which is a basic state in physics but which nevertheless has a complex structure.) So metaphysically, simple conscious states might be derivative on total conscious states. If so, we would have a clean explanation of why a substantive unity thesis is true.

This sort of suggestion is highly speculative, and much needs to be worked out. For example, it is far from obvious that our basic concept of consciousness is that of a total state of consciousness, and one needs to make a direct case for this. And the corresponding metaphysics needs to be worked out in much more depth. But there is at least some plausibility in the idea that the concept of consciousness, and states of consciousness, are fundamentally holistic rather than atomistic. And this squares well with our intuition that consciousness is necessarily unified.
What is the Unity of Consciousness?

In any case, whether the substantive claims that we have made in this paper are correct or incorrect, we hope to have helped to pin down some of the crucial issues. It is clear that there is much need for further work in analyzing the notion of unity, in assessing the truth of the unity thesis, and in seeking an explanation of its truth. It is likely that such work will be philosophically fruitful.

Acknowledgments

Versions of this paper have been presented at the ASSC conference on the unity of consciousness in Brussels, at a Pew conference on the metaphysics of human beings in Syracuse, at a conference on neurophenomenology in Boulder, and in talks at Alabama, Arizona, Barcelona, University College London, and Wake Forest. We thank audience members on all those occasions for helpful comments. Special thanks to Barry Dainton, Bernie Kobes, Graham Macdonald, and Paul Studtmann.

What is the Unity of Consciousness?

Contemporary Philosophy of Mind: An Annotated Bibliography

Compiled by David Chalmers, Department of Philosophy, University of Arizona, Tucson, AZ 85721. E-mail: chalmers@arizona.edu. (c) 2001 David J. Chalmers. Last updated: July 15, 2001.

This is a bibliography of recent work in the philosophy of mind, philosophy of cognitive science, philosophy of artificial intelligence, and on consciousness in the sciences. It consists of 5702 entries, and is divided into six parts, each of which is further divided by topic and subtopic.

- **Part 1: Consciousness and Qualia** [1082 entries]
- **Part 2: Mental Content** [869 entries]
- **Part 3: Metaphysics of Mind** [1026 entries]
- **Part 4: Philosophy of Artificial Intelligence** [565 entries]
- **Part 5: Philosophy of Psychology** [561 entries]
- **Part 6: Consciousness in the Sciences** [1599 entries]

Many of the entries are annotated with a brief summary. (I don't necessarily take responsibility for these annotations, many of which I wrote in the distant past.) The bibliography consists mostly of papers and books from the last few decades, with density of coverage increasing with proximity to the present. Most of the core areas of contemporary philosophy of mind are covered, but some areas (e.g. (philosophy of perception, philosophy of action, propositional attitude semantics, moral psychology) receive less coverage than others. A fuller table of contents is below.

Part 6 is relatively new and is not annotated. It's not strictly "philosophy of mind", but I've put it here for convenience. Of course the division between parts is inexact. There is plenty of material by philosophers in part 6, and plenty of material by scientists in the other parts (especially parts 1, 4, and 5).

The six parts here are in HTML. You can also get ASCII versions of Part 1, Part 2, Part 3, Part 4, Part 5, Part 6, and the whole thing. These can be useful for systematic use when downloaded, in combination with standard search functions.

I can no longer spend as much time on this bibliography as I used to, but I try to make a fairly thorough update once a year. New entries are rarely annotated, however. The online versions of Current Contents, PsychInfo, and the Philosophers' Index are all invaluable in this process. Thanks to Brad Thompson for his help with the 1999 and 2001 updates. I am grateful for pointers to any relevant material that I have missed.

For links to other bibliographies, and for links to around 1000 online papers in many of these areas, see...

### Part 1: Consciousness and Qualia [1082]

- 1.1 **Consciousness** [85]
  - 1.1a **General** [47]
  - 1.1b **The Concept of Consciousness** [38]

- 1.2 **Explaining Consciousness?** [115]
  - 1.2a **Subjectivity and Objectivity** (Nagel) [46]
  - 1.2b **The Explanatory Gap** (Levine) [16]
  - 1.2c **`Hard' and `Easy' Problems** (Chalmers) [25]
  - 1.2d **Cognitive Closure** (McGinn) [16]
  - 1.2e **Miscellaneous** [12]

- 1.3 **Materialism and Dualism** [213]
  - 1.3a **The Knowledge Argument** (Jackson) [46]
  - 1.3b **Zombies & Modal Arguments** [38]
  - 1.3c **Essentialist Arguments** (Kripke) [31]
  - 1.3d **Arguments from Disembodiment** [17]
  - 1.3e **Consciousness and Physicalism, Misc** [14]
  - 1.3f **Consciousness and Dualism** [16]
  - 1.3g **Mind-Body Problem, Misc** [51]

- 1.4 **Specific Views on Consciousness** [227]
  - 1.4a **Higher-Order Thought Approaches** (Rosenthal, etc) [46]
  - 1.4b **Dennett on Consciousness** [60]
  - 1.4c **Functionalism** [8]
  - 1.4d **Eliminativism** [16]
  - 1.4e **Epiphenomenalism** [30]
  - 1.4f **Interactionism** [16]
  - 1.4g **Panpsychism** [24]
  - 1.4h **Intrinsic Monism** (Russell, Feigl, etc) [27]

- 1.5 **Consciousness and Content** [129]
  - 1.5a **Consciousness and Intentionality** (Searle, etc) [23]
1.5b The Content of Experience [48]
1.5c Representationalism [38]
1.5d Internalism and Externalism about Experience [12]
1.5e Miscellaneous [8]

1.6 Aspects of Consciousness [182]
   1.6a Self-Consciousness [54]
   1.6b Unity of Consciousness [45]
   1.6c Homogeneity of Consciousness (Sellars, etc) [11]
   1.6d Knowledge of Consciousness [50]
   1.6e The Function of Consciousness [22]

1.7 Qualia [131]
   1.7a Qualia, General [27]
   1.7b Qualia and Materialism [13]
   1.7c Eliminativism about Qualia [11]
   1.7d The Inverted Spectrum [31]
   1.7e Absent Qualia (Block, etc) [15]
   1.7f Introspection and Absent Qualia (Shoemaker) [10]
   1.7g Functionalism and Qualia, General [24]

Part 2: Mental Content [869]

2.1 Propositional Attitudes and Folk Psychology [285]
   2.1a The Language of Thought (Fodor) [54]
   2.1b The Intentional Stance (Dennett) [40]
   2.1c Eliminativism (Churchlands, etc) [57]
   2.1d Propositional Attitudes, General [42]
   2.1e The Nature of Folk Psychology [38]
   2.1f The Simulation Theory [54]

2.2 Internalism and Externalism [278]
   2.2a Is Content in the Head? (Putnam, Burge) [38]
   2.2b Externalism and Psychological Explanation [41]
   2.2c Externalism and Mental Causation [28]
   2.2d Externalism and the Theory of Vision [16]
   2.2e Externalism and Computation [11]
   2.2f Externalism and Self-Knowledge [72]
   2.2g The Status of Narrow Content [43]
   2.2h Miscellaneous [29]

2.3 Theories of Content [144]
2.3a Information-Based Accounts (Dretske, etc) [29]
2.3b Asymmetric Dependence (Fodor) [20]
2.3c Causal Accounts, General [17]
2.3d Teleological Approaches (Millikan, etc) [48]
2.3e Conceptual Role Approaches [19]
2.3f Theories of Content, Misc [11]

2.4 Representation, General [25]
2.5 The Explanatory Role of Content (Dretske, etc) [22]
2.6 Concepts [46]
2.7 Meaning Holism [26]
2.8 Mental Content, Misc [43]

Part 3: Metaphysics of Mind [1026]

3.1 Supervenience [94]
3.1a Psychophysical Supervenience (Kim, etc) [14]
3.1b Supervenience and Physicalism [25]
3.1c Technical Issues in Supervenience [27]
3.1d Supervenience, General [28]

3.2 Reduction [82]
3.2a Multiple Realizability and Reduction [25]
3.2b Nonreductive Materialism [28]
3.2c Reduction in Psychology [14]
3.2d Miscellaneous [15]

3.3 Other Psychophysical Relations [127]
3.3a Physicalism [29]
3.3b Token Identity [7]
3.3c Emergence [58]
3.3d Dualism [21]
3.3e Miscellaneous [12]

3.4 Functionalism [63]
3.4a Causal Role Functionalism (Armstrong/Lewis) [17]
3.4b Machine Functionalism (Putnam) [15]
3.4c Miscellaneous [31]

3.5 Other Psychophysical Theories [238]
3.5a Logical Behaviorism (Ryle, etc) [53]
3.5b Identity Theory (Smart, Place, etc) [98]
3.5c Eliminative Materialism (Rorty, Feyerabend) [30]

1.1 Consciousness

1.1a

Consciousness -- General

An anthology of central philosophical papers on consciousness.

Exploring the link between consciousness and judgments about consciousness. Coherence between these \( \Rightarrow \) consciousness depends on the functional but isn't reducible. Toward a dual-aspect theory based on pattern and information.

Argues against the reductive explanation of consciousness, and for a kind of naturalistic dualism. Moves toward a "fundamental theory" to bridge the gap, and draws out some consequences.

A collection of 5 psychological and 8 philosophical essays on consciousness.

Argues that consciousness can be accounted for in a naturalistic framework. With arguments against eliminativism and epiphenomenalism, evidence from neuroscience and psychology, and discussions of the stream and the self.

A history of the study of consciousness, especially in psychology.

A summary of recent philosophical debates over consciousness, focusing on the "what/where/who/why/how" questions, the explanatory gap, and the stalemate between "essentialist" and "causal" intuitions.

Separates computational mind from phenomenological mind, and studies the former, a third-person approach. The residue is the "Mind-Mind" problem. Consciousness supervenes on an intermediate level of representation. Elegant.

Physicalism can explain consciousness in all its glory. Argues against zombies and inverted-spectrum scenarios, and suggests that the explanatory gap can be bridged by an account of directly-active information-processing.

An excellent collection of 20 philosophical papers on consciousness.

Lawrence Erlbaum.

Argues that the first-person view has been ignored too much in the philosophy of mind. Even unconscious states are only mental by virtue of their potential consciousness.

On the centrality of consciousness to the mind. Consciousness is irreducible but biological. On the history of the field, the structure of consciousness, its role in constituting intentionality, and problems with computation.

On the notion of consciousness, its relation to the brain, and some features that need to be explained: its subjectivity, unity, intentionality, center and periphery, Gestalt structure, aspect of familiarity, and so on.

Value is only found within streams of consciousness. Three ways of studying it: phenomenology, anthropology, and by relation to the physical. With an analysis of the "self-transcending" nature of conscious intentionality.

A collection of philosophical articles on consciousness.

### 1.1b

#### The Concept of Consciousness

On minimal consciousness, perceptual consciousness, and introspective consciousness. Introspective consciousness seems so special because it gives inner awareness of self, and memory of other mental events.

Distinguishes C1 (phenomenal experience) from C2 (access of parts of a system to other parts). C2 is can be scientifically studied, and has a graspable, if fragmented, causal role. C1 is mysterious and perhaps beyond science.

Reportability is not phenomenology, as blindsight has reportability but no phenomenology.

Argues that the cognitive correlate of consciousness is direct availability for global control.

Analyzes consciousness in terms of the "presence" of information to the main decision-making processes of a system. No great conceptual capacities required, no higher-order thoughts. With application to blindsight.

Separates consciousness from the mental -- functionalist accounts work for the latter but not the former. With remarks on Zen "pure consciousness".

On the role of consciousness in psychology, and distinguishing various notions of consciousness: mutual knowledge, internal knowledge, awareness, direct awareness, personal unity, wakefulness, and double consciousness.

Ideas about consciousness from Locke, Brentano, Hebb, Dennett, Skinner, Sellars, Aristotle, Gibson. Theories: inner eye vs. verbal vs. outer eye.

Critiques three senses of consc: awareness, verbalization and phenomenology. Argues that none are sufficient for person-consciousness. Quite good.

On three senses of consciousness: phenomenality, intentionality, and introspectibility. Argues from empirical evidence (especially blindsight cases) that these three are all dissociable.

Argues that consciousness and sensory quality are independent properties: there can be unconscious sensations. Consciousness is a relational property.

On three kinds of consciousness -- sensed being, mental awareness, and reflection -- and their relationships.

Uses various puzzles cases to distinguish higher-order consciousness, discriminatory consciousness, responsive consciousness, and phenomenal consciousness.

1.2

Explaining Consciousness?

1.2a

Subjectivity and Objectivity (Nagel) [see also 1.3a]

Physicalist explanations leave out consciousness, i.e. what it is like to be an organism. Objective accounts omit points of view (could there be an objective phenomenology?). Physicalism may be true, but we can't
see how.

Subjective and objective views clash e.g. on meaning of life, free will, personal identity, mind-body problem, ethics. How to reconcile: reduction, elimination, annexation? Maybe just let multiple viewpoints coexist.

Seeing philosophy as a clash between the subjective and objective views of various phenomena (mental states, self, knowledge, freedom, value, ethics). Eliminating the subjective is impossible.

Akins, K. 1993. What is it like to be boring and myopic? In (B. Dahlbom, ed) *Dennett and his Critics*. Blackwell.

Gives a detailed account of perceptual processing in bats, and suggests that we can know what bat-experience is like: it's like nerd experience. But then is there an unexplained residue?

On what science tells us about the experience of bats, birds, and others. Why a movie of bat-experience isn't good enough -- because of the inseparability of intentionality and experience. Science can do OK.

No real problems are posed by subjectivity and points of view, no matter how they are construed (fixed, portable, tokens, types). It's either a confusion or a triviality about the logic of indexicality.

On what is required for consciousness of agency (rather than qualia): belief, intention, and most importantly desire, enabling a capacity to care. A robot could have all this, and it would be like something to be it.

Naturalism can do autophenomenology just fine.

A Super Neuroscientist will know how we describe and think about experience, so will know as much as a Super Sympathist. One doesn't have to imagine to know what it's like. With remarks on bat experience.

Nagel conflates metaphysical and epistemological versions of the subjective/objective distinction. Consciousness is metaphysically subjective, and science is epistemically objective, so there is incompatibility.

Being graspable from only one point of view does not define the class of facts about conscious experience. Various ways of cashing this out fail.

The objective and subjective don't conflict, but complement each other.

Nagel conflates questions about sensory qualities with those about a unique point of view. The truth of physicalism is irrelevant to uniqueness.

The subjective/objective distinction is ill-drawn. Objective descriptions aren't species-independent, but in terms of the space-time causal network. Science can explain the experience this way, but not provide the experience.

Knowing what it's like consists in an ability, not possession of information.

Various anti-Nagel points.

Lycan, W. G. 1990. What is the "subjectivity" of the mental? Philosophical Perspectives.

The subjectivity of the mental is no more special than usual propositional subjectivity. It can be handled by a self-scanner model of introspection.

A critique of Nagel's idea of a "point of view" that is occupied by a "subject". There aren't any peculiar facts about given viewpoints.

There are no fact about what an experience is like. Knowing what it's like is an ability to imagine, recognize, and recall; this explains ineffability, etc. With remarks on the experience of imagining an experience.

Phenomenological properties cannot be picked out in physical or computational terms; argues against Lycan's criticism of Nagel. But all this is compatible with materialism. With comments on the phenomenological tradition.

Criticizes absent/inverted qualia arguments for a special "what it is like", but argues that the possibility of "what it is like" differences relative to semantic states shows that something's not conveyed by functional accounts.

The Nagel/Jackson argument is analogous to the Perry indexical argument, and can be treated the same way.

Nagel's dilemma: separating feeling from process. Moral consequences?

Nagel-consciousness exists, but isn't so important. It's essential for sensations, but not for thoughts. Beings without it could still be persons.

Understanding does not consist only in facts; we can understand via sympathy.

Knowing what it's like is really knowing how to imagine. We should reduce Nagel's question to a question about possession of a certain ability.

Subjectivity is not something we have knowledge of, as we lack comparisons.

On the Nagel/Dennett debate: Nagel holds out for unexplained intrinsic properties once the relational is all accounted for; Dennett can renounce the transcendental ambition. Remarks on realism, holism, and metaphilosophy.

Divides Nagel's problem: qualitative differences, special access, mineness.

Simoni-Wastila, H. 2000. Particularity and consciousness: Wittgenstein and Nagel on privacy, beetles and
Nagel's "View from Nowhere" doesn't take subjectivity seriously enough.

Rebutting various intuitions for the non-physical nature of experience. The Nagel/Jackson argument commits an intensional fallacy; experiences are physical states known from a different perspective.

A Wittgensteinian critique of Nagel. Nagel's question is confused: "what it's like" is a matter of behavior, sociality, etc, not inner experience.

Reducing doesn't imply understanding. Two different kinds of reduction.

Nagel is an epistemological solipsist, whether he likes it or not.

### 1.2b The Explanatory Gap (Levine)

Reflections on the explanatory gap between physical processes and conscious experience. With remarks on different sorts of consciousness, and on why we need an intelligible necessary connection.

On the physiological bases of phenomenal states, particularly color. Inverted spectrum isn't really coherent, as coolness/warmth would have to be inverted too. So the contingency of qualia is diminished.

Argues in detail that psychophysics can provide a structural map to close the explanatory gap. If there is an explanatory residue, perhaps panpsychism can help.

Argues for a distinction between reduction and reductive explanation, and argues that reductive explanations generally involves conceptual connections via "functionalization". With comments on Block and Stalnaker.

Contra Kripkean arguments, a good enough functional theory may help close the conceivability/explanatory gap between the physical and qualia. Contra Nagel/Jackson, such a theory could provide us with recognitional abilities.

How do we explain the apparent contingency of the qualia-matter reduction? Even if it's not metaphysically contingent, it's conceptually contingent, so there's a gap in any physical explanation of qualia. Excellent.

Physical accounts leave out qualia epistemologically but not metaphysically. So physicalism holds, but there is an explanatory gap. Discusses Kripke's and Jackson's arguments in detail; also explanation and

Argues that the explanatory gap between brain and consciousness is just the same as that found with causal relations everywhere; it's just that we usually overlook it in the latter case.

Qualia can't be explained in more basic terms, as that sort of explanation works by accounting for a property's canonical evidence, but the canonical evidence for qualia are qualia themselves. But they still may be physical.

1.2c `Hard' and `Easy' Problems (Chalmers) [see also 3.1]

Divides the problems of consciousness into easy and hard problems; the hard problem eludes reductive explanation as it isn't about explaining functions. Argues instead for a nonreductive theory with psychophysical laws.

Like the JCS article, but shorter, more accessible, and with pretty pictures.

There is no a priori entailment from the physical to phenomenal facts (arguments from conceivability, epistemology, analysis), so reductive explanation fails. With a critique of existing empirical proposals.

A reply to the 25 "hard problem" articles in JCS.

Argues that the "hard problem" in effect invokes an argument from ignorance, and that there's no deep difference between consciousness and other domains.

Argues contra Chalmers that experience is identical to certain functions, rather than emerging from them.

Divides the hard problem into three parts, and argues that neuroscience can make progress on at least one part (incommunicability); and maybe "meaning" holds the key to the rest.

Argues contra Chalmers 1995 that functions are all we need to explain.

Argues that consciousness plays a vital role in performing mental functions, so the easy problems won't be solved until the hard problem is solved.

Endorses the idea of consciousness as fundamental, but criticizes Chalmers' psychophysical laws. Advocates a theory with a "conscious mental field".

Argues that the "easy problems" -- reportability, attention, etc -- all involve concepts and therefore experience itself, for Kantian reasons, and therefore are not mechanistically explainable.

Argues that the truly hard problem is that of giving a constitutive account of consciousness, and Chalmers doesn't solve that (laws aren't good enough); in fact it's unsolvable.

Argue that we should work on the easy problems for now, as nobody has any good ideas about the hard problem; maybe it will gradually fade away.

On the epistemology of the hard problem. Argues that a scientific study of phenomenology is possible, drawing on work in developmental psychology and Eastern thought. "Pure consciousness" may be relevant to a resolution.

A collection of essays consisting of Chalmers' keynote paper, 26 replies from many perspectives, and Chalmers' response to the replies.

Part 1: Consciousness and Qualia [1082]

Advocates a careful phenomenological study of consciousness in its own right, systematically linked with a neurophysiological investigation.

Agrees with Chalmers on nonreductionism, but disagrees on "awareness", organizational invariance, and thermostats. Advocates a kind of dual-aspect theory, where the physical world is present within consciousness,

1.2d Cognitive Closure (McGinn)

McGinn asks too much of a solution to the M-B problem. We might understand consciousness without understanding specific experiences; we could get at it by studying brain and consciousness not separately but simultaneously.

Argues that the mind-body problem might be solvable in principle, but beyond human capacities. Neither perception of the brain nor introspection of consciousness can uncover the property by which consciousness arises.

A collection of articles on the problem of consciousness, advocating a view on which the phenomenon is natural but permanently mysterious to us.

Argues that a naturalistic account of the intentionality of conscious states requires an account of their embodiment; and that embodiment may depend on the hidden structure of conscious states, not accessible to introspection.

Suggests that consciousness may have a hidden structure, analogous to the deep structure of language, that relates its surface properties to physical properties. We may not be able to understand this hidden structure, however.

**1.2e Miscellaneous**

Parodies arguments by Searle, Jackson, and Chalmers for the irreducibility of consciousness with analogous arguments for the irreducibility of "luminescence". The consciousness arguments are no better.

Argues that consciousness can be handled within a scientific framework. We can translate first-person accounts into third-person accounts. Replies to skeptical objections using analogies from elsewhere in science.

A "committed materialist" will not see any explanatory gap, or any "brute fact". The entrenched differences lie in one's choice of initial framework.

Qualia pose no insurmountable problems for materialism: knowledge argument can be answered, explanatory gap can be closed, and absent qualia arguments beg the question. With speculations on their functional role.

Distinguishes six explananda, four explanatory restrictions, and four sorts of relations between them, making 96 possible problems. With a discussion of whether and how the central problems might be answered.

1.3

Materialism and Dualism

1.3a
The Knowledge Argument (Jackson) [see also 1.2a]

Knowing a completed neuroscience does not imply knowing about qualia. Mary, the colorblind neuroscientist, gains color vision and learns about red. So physicalism is false, as there are facts over and above the physical facts.

Reply to Churchland 1985: Mary learns, Churchland misstates the argument.

Contra Pereboom 1994: The way a color sensation appears is a fact about it.

Argues that Churchland's neuroscientific descriptions must leave at least some qualia behind: they might account for what we know (e.g. brain states) in qualia-knowledge, but can't handle distinctions in how we know.

Mary gains knowledge of old facts, in a new way: she gains a new mode of acquaintance with those facts. Analogies with indexical knowledge: her new knowledge eliminates no possible worlds.

Qualia can undergo a normal reduction to the neurophysiological. Jackson commits an intensional fallacy; in any case, perhaps Mary can understand red. When we apprehend qualia, we are directly introspecting our brain state.

Rejoinder to Jackson 1986. The key lies in knowing-how vs. knowing-that.

Contra Lewis, Nemirow, and Horgan on the knowledge argument. But qualia may still be physical (though outside vocab of science) due to their causal role.

Mary knew all the facts about qualia beforehand, she just wasn't acquainted with them. Knowledge by acquaintance isn't factual knowledge.

Speculation on how consciousness might be left out by a physical account.

Argues that most people don't really imagine Mary's situation. In fact, Mary would be able to identify blue objects from the way they make her react.

Defends Jackson's argument against criticisms by Nemirow, Smith & Jones, Warner, Horgan, & Connee. The argument forces physicalism into a quandary: either deny qualia, or make the confused claim that qualia are physical.

On Dilthey's "Verstehen", or "understanding from within". Mostly about meaning, but with application to the knowledge Mary gains.

Mary didn't know all the physical facts: she knew all the explicitly physical information, but not all the ontologically physical information.

A new version of the knowledge argument: given all the physical facts, one can't know when two experiences are indistinguishable. This avoids various objections to the standard version.

Contra Nagel/Jackson: Understand qualia through relational properties, and separate the mental concept from the recognitional capacity.

Against the hypothesis that phenomenology carries information. If it does, then qualia are epiphenomenal. Better to analyze the "new information" as acquiring an ability instead. In-depth and entertaining.

Phenomenal and functional concepts are distinct, but the relevant properties may be identical. We directly refer to phenomenal properties by recognition. Remarks on other minds, transparency, incorrigibility & more. A meaty paper.

Gives nine arguments against the Lewis/Nemirow ability analysis, and proposes instead that the same fact is learned a new way, like water and H2O facts. This sort of phenomenal information is no danger to materialism.

Defends against objections from Dennett, Churchland, etc. Horgan's objection (same fact different ways) has a certain force, but the argument can be reformulated to avoid them and imply property dualism. With remarks on Loar.

Contra Churchland 1985: we couldn't introspect sensations as brain states, although we could interpret them as such.

Reconstructing the Mary case as a Marianna case, and introducing a distinction between phenomenal and nonphenomenal beliefs, to support the knowledge argument. A very nice and sophisticated paper.

Mary goes from a third-person concept of experience to a first-person concept, but they co-refer; we can refer to an experience without having the experience. Physical and phenomenal properties are brutely identical.

Mary learns an old fact under a new mode of presentation, and doesn't even learn a new fact about a mode of presentation. Her access to internal states is always mediated by representation, so we can always ascend to a new mode.

A thorough discussion of Lewis 1990. Phenomenal information implies epiphenomenalism, even at the intra-psychic level. Remarks on ineffability, and on whether properties should be individuated by nomic role or by essence.

Contra Dennett, Mary can't tell an object's color unless she already knows about experience. The knowledge argument bears on thought, not just qualia.

Introspection reveals functional properties, not physical, so qualia should be reduced to the functional, not to the physical.

Physicalism explains all the relevant evidence, hence all facts, and needn't admit mental entities; belief in mental entities is based on physical facts.

Interesting remarks on what it would be for someone to see colors that we cannot, combining philosophical considerations with empirical findings about color space. Argues that science could tell us what such colors are like.

A Jackson-like argument that physical knowledge can't give you the knowledge of what pain feels like. With detailed consideration of objections and replies. Argues from limited incorrigibility to factualism about pains.

Epiphenomenalism => qualia don't cause beliefs => we don't know about qualia.

**1.3b Zombies & Modal Arguments [see also 1.2c, 1.3a, 1.3c, 1.3d]**

Argues from the lack of logical supervenience to the falsity of physicalism. A two-dimensional analysis shows that objections from a posteriori necessity fail. Argues for a naturalistic variety of property dualism.

Argues that the conceivability of zombies and the like can be explained away, in terms of the cognitive separability of perceptual imagination and sympathetic imagination of the same states.

Describing a situation where we would be justified in believing in zombies. Argues that zombies are
logically possible, which seems incompatible with most or all varieties of materialism.

Materialism requires that physical states logically entail all non-relational states; but zombies are logically possible, so materialism fails. With a description of a zombie, and replies to a verificationist. All very true.

Reply to Locke 1976: materialism needs zombies to be logically impossible.

If Campbell's imitation man is possible, then the causal relation between the physical and phenomenal is unreliable.

Contra Kirk: the logical possibility of zombies is compatible with empirical materialism. With some comments on Kirk's thought-experiment.

Argues that behavioral differences in zombies would show up, in their discourse about consciousness.

On the possibility of an Insentient Perceiver, who perceives the world without sensation. Sensation is inessential to perception and understanding, except understanding in the "whatlike" manner.

Argues for the conceivability of insentient perception of colors (in "Insent", a kind of blindsighter or zombie), in order to argue for a realistic account of colors.

A discussion of materialism and its difficulties. The conceivability of zombies poses special problems. Criticism of Smart's & Armstrong's analyses.

1.3c Essentialist Arguments (Kripke) [see also 1.3b, 1.3d]

An identity between mental and physical states can't be contingent, as it relates rigid designators. But nevertheless the co-occurrence of certain mental and physical states is contingent, so the identity theory is false.

Both "pain" and "C-fibres firing" are rigid designators, so if they are identical, this must be necessary. But their co-occurrence is contingent, and this can't be explained away epistemically, so the identity theory fails.

Argues that pain and the associated epistemic situation are inequivalent. Beliefs about pain are simply produced by mechanisms, and could come about without any sensation.

Trying to turn Kripke's argument against him: it's possible that pains and C-fibre stimulations are identical, so it's necessary that they're identical.

On four arguments against the identity theory: multiple-realizability, modal, knowledge, and certainty arguments. All face difficulties due to scientific essentialism, but the latter two can be reformulated to avoid them.

Kripke's argument doesn't refute token identity. Pains can have other essential properties besides painfulness, so psychophysical token identities can be necessary.

Materialism doesn't need rigid identities, due to the compositional plasticity of mental states. So the possibility of disembodiment is compatible with materialism. The possibility of zombies is illusory.

A materialist must deny essentialism to meet Kripke's argument.

Comments on Feldman 1974: Feldman's view requires rejection of Kripke's views on necessity, or a problematic mixed view on rigid designators.

Kripke's premise that pains are essentially mental either begs the question (by assuming pains don't have physical properties) or weakens the premise that physical events aren't essentially mental.

Painfulness need not be an essential feature of pains.

Kripke's arguments against person-body and mind-brain identity rely on the essentialness of aliveness to persons and painfulness to pains. There's no reason to grant this. If we do, rigidity is irrelevant to the argument.

Defending a contingent event identity thesis against Kripke. Mental properties (which are distinct from physical properties) may not be essential properties of an event.

Uses Kripke's 1979 direct-reference theory against him. When rigid designators don't have associated reference-fixing descriptions, we can't expect the "explaining away" strategy to work.

The apparent contingency of identity is due to the fact that one can be aware of pain without being aware of C-fibers and vice versa, as well as to the fact that "C-fibers" may be picked out by a contingent description.

Defending Kripkean arguments against various objections. Analysis in terms of manifest properties and their role in fixing reference to the subjective and objective.

A Kripkean argument against non-analytic physicalism. Even if pain rigidly designates a brain state, the physicalist still has problems explaining the property of "pain-presents".

Kripke's argument doesn't refute contingent identity between minds and nonrigidly designated bodies, which is all materialism needs.

Some theoretical identification are analogous to mental-physical identifications -- entities are introduced by properties considered essential within a theory, but this doesn't preclude identification.

The reference of "pain" is fixed not by essential features but by contingent topic-neutral descriptions; this is the real moral of Wittgenstein's private language argument. So Kripke's apparent contingency can be explained away?

Reply to Bealer 1994. Tries to clarify the dialactic, and argues that the materialist can explain "possibility" of straw thought as thought conjoined with mere appearance of straw.

Kripke equivocates on "pain-sensation": pains aren't the same as impressions of pain. Argues that imaginability arguments aren't decisive, and that functionalism may be less vulnerable than the identity theory.

Painfulness needn't be essential to pains: pains are events, not objects, and events don't have essences; and the reference of "pain" is fixed by topic-neutral descriptions. With remarks on pains vs. pain-sensations.

"Brain state" reference is fixed by topic-neutral description; picks out pain but mightn't have, explaining
the illusion of contingency. "Nonphysicalist materialism" results, with mind the essence of matter. An important paper.

Token identity theories aren't vulnerable to Kripke's argument: it may be essential to this pain that it is a C-fibre firing, although not to pain as a type.

We can explain away the apparent contingency of identity in terms of possible differences in *evidence* for the physical state. With a discussion on identities between something perceived and something described.

"Pain" need not be a rigid designator, but instead may pick out a state by its causal role. If it is a rigid designator, then the apparent contingency of identity comes from imagining something else filling the causal role.

The reference of "C-fibre stimulation" might be fixed contingently, allowing the intuitive contingency of identity to be explained away.

Contra McGinn 1977, the counterpart strategy fails as any pain that occurred here now would have been this pain. A counterpart strategy on brain states may work. With a reply by McGinn and a later rejoinder by Woodfield.

**1.3d Arguments from Disembodiment [see also 1.3b, 1.3c]**

Argues that materialism is only contingently true, as it's conceptually possible that we could become immaterial by gradual replacement.

Physicalism is compatible with the possibility of disembodiment: one can hold that mind and body are identical, that the body is physical, but that it is not essentially physical.

There's no reason to believe that disembodied existence is possible: lack of logical contradiction doesn't imply possibility, conceivability is too weak a criterion, and it's not obvious that the situation is imaginable.

1.3e Consciousness and Physicalism, Misc [see also 1.2, 1.3, 1.7b, 3.5b]

Defending type materialism, by way of criticism of dualism and functionalism. With treatments of introspection, sensory concepts, and other minds.

On why materialism requires conceptual analysis to locate mental properties in the natural world. Even a posteriori necessary connections have to be backed by a priori links. With remarks on supervenience. A nice paper.

If every physical events has a physical explanation, and the mental is causally efficacious, then mental facts are strictly implied by physical facts. A nice argument.

Physicalism requires that all mental facts be strictly implied by the physical facts. Once this is recognized, questions about necessary or contingent identity are beside the point, and indeed identity is irrelevant.

On the problems posed for materialism by intentionality, autonomy, awareness, and indexicality. Tentatively advocates a Cartesian position.

A collection of arguments against physicalism, mostly based on worries about consciousness and qualia.

Consciousness could be physical even if not explicable; but supervenience worries make it hard to see how it *could* be physical, though causal role suggests that it must be. We need a new conception. A stimulating book.

On the place of "occurrent pink" and the "sensorium" in the physical world. It may turn out that the physics of the brain differs from other physics, in order to accommodate the causal role of sensations.

A careful discussion of how to characterize physicalism, in terms of identity or supervenience, and argues that physicalism must reduce (bowdlerize) qualia to something they are not, as physicalism requires topic-neutral analyses.

### 1.3f Consciousness and Dualism [see also 1.2c, 1.3, 3.4d]

Argues that all forms of materialism fail, and that dualism is the only option. Defends dualism against objections, and argues for interactionism over epiphenomenalism. A very clear and interesting paper.

Argues that the hypothesis of consciousness as an irreducible global property of the brain is compatible with what we know of both neuroscience and physics. With interesting remarks on quantum mechanics.

A dialogue with a "hyperdualist". On the pros and cons of materialist vs. dualist ontology and cosmology. Dualism avoids the "magic" of emergence at the cost of an inflated and bizarre ontology.

On the non-physical nature of consciousness, and the threat of a merely contingent connection to behavior; suggests a denial of "Hume's principle". Perhaps consciousness is the noumenal essence of the physical. A nice paper.

1.3g Mind-Body Problem, General

An overview: behaviorism, identity theory, functionalism, etc.

Yes it is. Empirical evidence bears on materialism, property dualism, emergentism, functionalism, interactive dualism, idealism, etc.

The core of the mind-body problem is the first/third-person asymmetry. It's like a periscope trying to place itself between its crosshairs. But this doesn't imply any strong ontological consequences.

Against "neural functionalism", and on how Searle's view reduces to either neural functionalism or property dualism.

On the mind-body problem and physical theory. Against reductive physicalism; instead, experience is the intrinsic nature of the physical. Discusses the interpretation of quantum mechanics and much else. A very enjoyable book.

Minnesota Press.

On ways in which we might locate consciousness within the natural world via scientific study. Perhaps we need a wider conception of objective reality.

An in-depth analysis of Sperry's views on consciousness. Sperry is not a dualist; he simply believes in "structural causation" based on emergent properties. Thorough and interesting.

A collection of essays from the 1960s on the identity theory, functionalism, eliminative materialism.

Part 1: Consciousness and Qualia

Consciousness is an emergent property of brain dynamics that itself governs low-level flow of excitation. Midway between mentalism and materialism.

A summary of the position whereupon mental properties are emergent and have independent causal powers. With a contrast to Popper and Eccles' dualism.

An account of the "new mentalist paradigm". Clarifies earlier work, comments on others' interpretations. The view is monist and functionalist, but consciousness is a distinct emergent quality with a "downward" causal role.

A collection of 27 (mostly original) papers on the mind-body problem.

Specific Views on Consciousness [see also 1.2, 1.3, 1.5c]

1.4a Higher-Order Thought Approaches (Rosenthal, etc) [see also 6.2i]

Higher-order thought theories have two unacceptable consequences: one can notice one's hearing a sound without noticing one's consciousness of the sound; and one can unconsciously perceive one's surroundings as gloomy.

Argues for a distinction between conscious and non-conscious experiences, depending on whether one is conscious of the experience. Animal experiences are of the second kind, and therefore are not morally significant.

Advocates the "reflexive thinking" account of consciousness over Kirk's "presence" account. Availability for reflexive thinking is naturally necessary and sufficient for qualia. Interesting paper.

Against higher-order thought accounts: one can have a conscious experience without being aware that one is having it. With remarks on thing-awareness vs. fact-awareness and on "inner-sense" accounts.

We're not conscious of our experience in general, but conscious with it. Criticizes HOP theories (not conceptualized enough) and HOT theories (rules out animals; there's more in experience than thought).

Argues that a higher-order thought is insufficient for consciousness, even with Rosenthal's constraint. A causal constraint is required, but the only strong enough such constraint doesn't work.

Carruthers 1989 misanalyzes higher-order thought theory. There's no need for conscious HOTs, and not too much conceptual sophistication is required, so animals might have HOTs and therefore conscious pains.

A critique of higher-order-perception theories of consciousness. They're either committed to a "representational divide" fallacy or collapse into higher-order-thought or first-order theories.

Various points against Carruthers 1989. His examples of nonconscious experience are likely conscious, and the higher-order account is circular.

Argues for a Lockean quasi-perceptual view of consciousness as internal monitoring via second-order states. Contra objections, e.g. Rey's point that it makes consciousness too prevalent -- consciousness isn't
an on-off affair.

Conscious belief (or assent) is believing that one believes. Addresses various objections, from self-deception and from consciousness of assent. Communication needs conscious belief, not just belief.

On various pros and cons of HOT theories, to do with reflexivity, objects of HOTs, introspection, and so on. With comparisons to "intrinsic" theories.

On three theories of our direct awareness of conscious states: mental-eye theories, self-intimational theories, and appendage theory. Appendage theory (i.e. HOT theory) is promising, but how does an HOT determine its object?

On the differences between first-order and second-order consciousness. Second-order consciousness is essential for communication and locomotion. With remarks on "nonconscious consciousness".

Separates CN (phenomenological) from C1 (info-processing) and C2 (higher order beliefs). CN is a subset of CS (image-representation state). We are always C2 of CN states, but not of other CS states: unconscious sensations!

Argues that we need not be apperceptively aware of phenomenal states. Introspection leaves the matter open, but some empirical results (e.g. hue blindsight) and theoretical arguments support dissociability.

Consciousness should be construed neither as sensation nor intentionality, but as the existence of higher-order thoughts.

A conscious mental state is a state that is the subject of a higher-order thought. Consciousness is not essential to mentality, should be separated from sensory quality, and is not an intrinsic property of conscious states.

Because verbally expressing and reporting are easily and immediately connected for 1st-order thoughts. But not for 2nd-order thoughts. Hmmm.

Conscious states are states that are the contents of higher-order thoughts. Express/report distinction: we report them, and express the HOT (which may be unconscious). Defense against dispositional and collapsing objections.

Distinguishes the sense in which we are aware of conscious states; argues for the separation of consciousness and sensation; and outlines how higher-order thoughts might explain the what-it's-like of conscious states.

In response to Natsoulas, HOT theory needn't answer the general question of how intentional states determine their objects. With remarks on the other alternatives and the dangers of self-intimation.

### 1.4b Dennett on Consciousness [see also 1.7c]

Criticizing Dennett's accounts of pains, dreams, and images: in no case do his arguments earn their

Reportability is no good for capturing consciousness: it completely leaves out the qualitative content of conscious states.

Argues that Dennett's account of the blindspot and scotomas are wrong. Neurophysiological data suggests that blind areas are represented explicitly; psychological data shows that it's not just "more of the same".

On various notions of awareness: contents of the speech center, contents directing behavior, and contents of attention. We have privileged access to one sort, but it is a different sort that plays the main role in control.

Conscious contents are contents of a buffer memory to which a public report module has access. We only have conscious access to propositional judgments, not to underlying processes. With a cute functional diagram.

There is no real phenomenology. There are only judgments about phenomenology, and nothing more is going on. We don't have privileged access to anything, except perhaps certain propositional episodes.

We can study consciousness by the method of heterophenomenology: studying the things we say about conscious states, which we can interpret as we interpret texts. Autophenomenology gives nothing extra. With comments by Rorty.

Consciousness is a virtual machine which evolved.

Argues against the "Cartesian Theatre", advocating a "multiple drafts" model of consciousness. Presents a detailed model of processes underlying verbal report, and argues that there is nothing else (e.g. qualia) to explain.

Using temporal anomalies in consciousness to support a "Multiple Drafts" theory of consciousness rather than a "Cartesian Theater". Contents of consciousness are wholly determined by effects on action/memory.

A discussion of *Consciousness Explained*, with comments by Tye, Jackson, Shoemaker, and Rosenthal, and a reply by Dennett.

A reply to Clark, Fellows & O'Hear, Foster, Lockwood, Seager, Siewert, and Sprigge.

A reply to Baars & McGovern, Mangan, Toribio.

Dennett, D. C. 1995. Is perception the "leading edge" of memory. In (A. Spafadora, ed) *Memory and Oblivion*.

There is no "leading edge" of consciousness, separating perception and memory. With an analysis of metacontrast cases, etc.

Criticizes Dennett's first-person operationalism as Cartesian. There can be awareness without judgment -- e.g. non-epistemic perception. This comes from information or "micro-judgments", and is not conceptual.

Presses Dennett on the "truth-maker" question for materialists: what sort of physical fact makes it true that people are conscious?

Joycean machines and multiple drafts turn out to shed no light on the question of what features make a conscious system conscious.

Argues for a suitably sophisticated Cartesian Theatre, and against the identification of phenomenology with judgments.

Brings empirical evidence to bear against Dennett's "filling-in" account of the blindspot, and argues that blindsight and the blind spot aren't analogous.

Dennett's Orwell/Stalin argument doesn't establish its conclusion, as "brain smear" is quite compatible with determinate qualia.

We can subtract first-person operationalism from Dennett's multiple-drafts account, giving a higher-order thought theory.
An elucidation of Dennett's fundamental eliminativism about phenomenology, resting on verificationist arguments. Like many sceptical arguments, it ends up too powerful to be convincing.

Argues that zombies are conceivable, via partial zombiehood in blindsight patients who respond unprompted. Dennett's arguments rely on a question-begging third-person absolutism.

Criticizes behavioral, localist, and "intransitive" approaches to consciousness, and recommends a "transitive" metacognitive approach. But criticizes Dennett for not explaining subjective experience.

Argues that Dennett's verificationism begs the question, and that "seeming" cannot be identified with believing or judging.

**1.4c Functionalism [see also 1.4a, 1.4b, 1.5c, 1.8, 3.4]**

Contra Kripkean arguments, a good enough functional theory may help close the conceivability/explanatory gap between the physical and qualia. Contra Nagel/Jackson, such a theory could provide us with recognitional abilities.

Argues that introspective access is essential to many sorts of mental state, due to constitutive rationality requirements. Against a perceptual model of introspection; introspecting and introspected states are closer than that.

How functionalism can handle consciousness: Self-consciousness is the possession of reflexive metapsychological information. This helps understand learning, representation, and belief. Phenomenal experience is still tricky.

1.4d Eliminativism [see also 1.7c, 2.1c, 3.5c]

Experimental evidence against consciousness/introspection/transparency.

Argues that dreams might not be experienced, but rather be stored directly into memory (the "cassette-tape" theory of dreaming).
Consciousness is an indispensable concept in anesthesiology, and therefore (contra Churchland and Wilkes) is a scientifically legitimate kind. With empirical details and anesthesiological theory on levels of consciousness.

One could make a machine, duplicating the usual abilities that go along with consciousness, but surely it wouldn't be conscious. So what are the conditions for consciousness? Maybe there are none.

A rerun of Rey 1982: An unconscious machine could duplicate all the obvious criteria for consciousness, so maybe even we aren't conscious. With remarks on the relation between our belief in consciousness and consciousness itself.

We "project" consciousness into ourselves and others. There are no explanation-transcendent phenomena for which there is non-question-begging evidence. With remarks on self-attribution and Wittgenstein.

Commentary on Rey 1986: we are directly aware of our consciousness. It's not a theoretical entity, but rather something to be explained.

A skeptical argument: single neurons are not conscious, and adding a neuron won't produce consciousness, so finite brains are not conscious.

No, and it's not very coherent either. It divides into awakening, sensation, sensory experience, and
propositional attitudes. Also a history of the term.

Consciousness is not a tenable notion in either commonsense or scientific psychology; we should return instead to the "psuche".

**1.4e Epiphenomenalism [see also 1.3a, 1.3f, 1.6e, 3.6]**

Considers major arguments against the causal or explanatory irrelevance of consciousness -- arguments from self-knowledge, memory, reference, etc -- and argues that none pose fatal flaws.

Discusses two senses of "epiphenomenalism" -- "Huxley's" and "philosophical" varieties -- and argues that the philosophical sort is crazy. (N.B. Huxley actually subscribed to the "philosophical" variety.)

http://www.u.arizona.edu/~chalmers/biblio/1.html (54 of 100) [4/7/2002 1:48:08 PM]

Part 1: Consciousness and Qualia

Argues that phenomenal information implies epiphenomenalism, even at the intra-psychic level. With remarks on ineffability and on whether properties should be individuated by nomic role or by essence.

Argues that we can have non-inferential knowledge of sensations even if they don't make a causal difference to our beliefs, so epiphenomenalism is OK. All theories have a similar problems.

Epiphenomenalism => qualia don't cause beliefs => we don't know about qualia.

1.4f Interactionism [see also 1.3f, 3.3d]

Argues from the fact that we talk about consciousness to the conclusion that consciousness plays an active role, so physical laws must be incomplete.

Argues with Elitzur on quantum mechanics and consciousness. With response.

**1.4g Panpsychism [see also 1.4h]**

There are no strong arguments against panpsychism, and good reason to take it seriously. Extrapolating the processing properties crucial for standard complex experience suggests that simple process may yield simple experience.

An analysis of a debate between Griffin and McGinn on panexperientialism, arguing for new forms of understanding.

An excellent review article on panpsychism; highly recommended.

An interesting paper arguing for an experiential aspect in all matter, explicating a Whiteheadian position.

Argues for a new fundamental feature ("X") which stands to consciousness as time stands to motion, thus making consciousness possible and ubiquitous.

Material composition, nonreductionism, realism, non-emergence => panpsychism.

On why consciousness extends beyond the cognitive. Argues that fundamental laws for consciousness must connect at a basic level, and argues that panpsychism is not as implausible as often thought.

Examines a position on which experience is fundamental to the world, and suggests that this ought to lead to panpsychism. With some connections to information and quantum mechanics.

On Nagel 1979: emergence is more plausible than panpsychism. A construal of emergence as nomological supervenience without logical supervenience.

1.4h Intrinsic Monism (Russell, etc) [see also 1.4h]

Physics is dispositional, but if there are only bare dispositions, then the world has no nature of its own.
And if there are categorical grounds, we have no idea what they could be, except maybe subjective qualia.

An "it from bit" view fits the Russellian metaphysics (described earlier): physics is info from the outside, (proto)experience is info from the inside. The problem is constituting macrophenomenal from microphenomenal; some ideas.

A nice account of Russell's (and Schlick's and Carnap's) structuralism and Newman's objection, with analysis. (N.B. no philosophy of mind.)

A long and very interesting essay on the mind-body problem. Ultimately advocates a "structural" view of the physical and identifies experience with the underlying reality, at least for some neurophysiological states.

Argues that Russell's and Schlick's views on the structural nature of physics and the possible identification of the "content" with experience are quite close to each other. With interesting historical remarks.

Argues that the Russellian view is implausible, as the structure of the underlying physical processes does not correspond to the structure and quality of consciousness.

On the mind-body problem and physical theory. Against reductive physicalism; instead, experience is the intrinsic nature of the physical. Explores some potential links with quantum mechanics.

On the "grain problem" for the intrinsic-nature view: how do lots of microphysical qualities add up into a smooth experience? Appeals to quantum mechanics and a preferred set of observables.

"Brain state" reference is fixed by topic-neutral description; picks out pain but mightn't have, explaining the illusion of contingency. "Nonphysicalist materialism" results, with mind the essence of matter. An important paper.

Argues against Russell's structuralism: any collection can be arranged to have a given structure, under some relation, so if physics tells us only about structure, it tells us at most the cardinality of the world.

Argues that physics characterizes the external world only structurally, and leaves intrinsic qualities
unspecified. Only experience acquaints us with anything intrinsic. Perhaps the intrinsic nature of physics is experiential?

1.5 Consciousness and Content

1.5a

**Consciousness and Intentionality (Searle, etc)**

Crane, T. 1998. Intentionality as the mark of the mental. Philosophy.

Searle's formulation of the connection principle is unclear, and there is no formulation is both plausible and interesting.

About conscious beliefs. We are not "conscious of" beliefs, merely "conscious that" -- i.e. belief is not phenomenological.

Against Searle: some intentional states aren't even potentially conscious (blindsight, etc) and intentional content doesn't require a particular phenomenal feel. So there's no essential link. With remarks on McGinn.

(Subjective) intentionality sure is real. It causes and is caused.

Advocates a "connection principle": intentional states must be potentially conscious. If not, they're brutally neurophysiological. So cog-sci talk of "intentional" cognitive mechanisms below the conscious level isn't justified.

Clarifying the connection principle -- it's necessary in order to see how certain nonconscious neural states qualify as unconscious mental states.

Argues that belief requires consciousness, as we can't make sense of the personal/subpersonal content distinction without appealing to consciousness.

1.5b The Content of Experience

Contra Peacocke, we don't need sensational properties to understand the content of musical experience. Fine-grained representational properties can do the job, with the help of some Schenkerian analysis.

Lots of reasons why experiences have propositional content (i.e., their content is truth-evaluable, etc). A nice paper.

1.5c

Representationalism

Uses Inverted Earth case, colors and lenses inverted, to argue vs Harman that qualitative states aren't intentional states. Also, less convincingly, to argue that qualitative states aren't functional states.

http://www.u.arizona.edu/~chalmers/biblio/1.html (67 of 100) [4/7/2002 1:48:08 PM]

There are no real qualia problems, just Intentional confusions.

Suggests that conscious states are identical to representational states, and that unconscious representation is impossible; transition between conscious states is non-representational. Appeals to connectionist models in support.

Argues that consciousness and representation are distinct, as e.g. the latter depends on context but the former does not.

The phenomenological can be reduced to the intentional. Intentional states have a what-it-is-like, and there is no special phenomenal object of introspection.

avoid it. Philosophical Psychology 10:269-86.

Qualia can't be reduced to standard intentional properties (due to certain inversion cases). Projectivist and sense-reference accounts don't work either. Perhaps qualia are necessarily-illusory intentional properties.

On the relationship between phenomenal and intentional aspects of qualia, and in particular on the accessibility of qualia to conscious awareness. Phenomenal & intentional similarity are connected but must be distinguished.

Argues that pain is representational, and that its phenomenal character is narrow nonconceptual content. They have a complex representational structure, with map-like arrays of sentential contents.

Tye, M. 1995. What "what it is like" is like. Analysis.

1.5d

Internalism and Externalism about Experience [see also 2.2]

Argues that perceptual content does not supervene on internal state, even though it is non-conceptual. Constructs an Twin scenario to that effect. With remarks on the relation between perceptual content and phenomenology.

Distinguishes modal and constitutive externalism, characterizes perceptual content and its relation to sensational content, and argues for externalism about perceptual content by examples.
Part 1: Consciousness and Qualia [1082]

Argues that a swampthing isn't intelligent or intentional, with different physiological processes and no sensations, as these are functional kinds.

Dretske, F. 1996. Phenomenal externalism, or if meanings ain't in the head, where are qualia? In (E. Villanueva, ed) Perception. Ridgeview.

We only have access to qualia through our concepts, which are external; so internal qualia would be inaccessible. So if qualia are knowable, they're external; and if not, why posit them? With comments by Kim, Horwich, Biro.

Argues against McGinn that one should embrace a form of "strong externalism" about experience. Experience can be laden with externally-grounded concepts.

There is no epistemically available aspect of experience that is determined internally; experiences are "fused" with the environment.

1.5e Miscellaneous

On conceptual influences on experience, and aspectual seeing, focusing on bodily and dynamic elements. Self-awareness is not of phenomenal states but *in* them. With commentary by S. Mulhall.

Sensations don't have intentional objects, they are intentional objects.

Comparing the problems of consciousness and content, and reconciling optimism on content with pessimism on consciousness. The phenomenological nature of content may be mysterious, but the individuation of contents is not.

Arguing against the view that phenomenal properties are "read off" in making perceptual judgments. Experiences do not literally have color or shape.

On a propositional conception of experience, and making sense of awareness of experience and various problems for sense-data monadicism.

1.6

Aspects of Consciousness

1.6a

Self-Consciousness [see also 6.2o]

Part 1: Consciousness and Qualia

Argues that consciousness entails having episodic memory, which entails self-consciousness. So consciousness entails self-consciousness.

James, W. 1890. The consciousness of self. In The Principles of Psychology.

How functionalism can handle consciousness: Self-consciousness is the possession of reflexive metapsychological information. This helps understand learning, representation, and belief. Phenomenal experience is still tricky.

Weird examples of homunculi that are conscious but not self-conscious. Self-consciousness, not consciousness, is what really counts.

1.6b The Unity of Consciousness [see also 5.12d, 6.1e, 6.1g]

http://www.u.arizona.edu/~chalmers/biblio/1.html (78 of 100) [4/7/2002 1:48:08 PM]

1.6c Homogeneity of Consciousness (Sellars, etc)

Explains homogeneity in terms of nontransitive matching among pixelized parts of vision. Experience of continuity, not continuous experience. Experiences may have subphenomenal parts (e.g. invisible pixels).

**1.6d Knowledge of Consciousness [see also 1.3a, 1.8a, 5.13, 6.2i]**

Mary knew all the facts about qualia beforehand, she just wasn't acquainted with them. Knowledge by acquaintance isn't factual knowledge.

Qualitative beliefs can supervene on behavioral dispositions even if absent/inverted qualia are possible. We just individuate belief contents and behavior widely, with wide content fixed to the qualia.

A discussion of in what sense we are aware of qualia, and how we can have beliefs about them, with reference to Sellars. Ends up reducing qualia to phenomenal beliefs in a language of thought. A rich and subtle paper.

Reconstructing the Mary case as a Marianna case, and introducing a distinction between phenomenal and nonphenomenal beliefs, to support the knowledge argument. A very nice and sophisticated paper.

Argues that we can have non-inferential knowledge of sensations even if they don't make a causal difference to our beliefs, so epiphenomenalism is OK. All theories have a similar problems.

Contra Sellars, Rorty, and Churchland: knowledge of qualitative content is an important aspect of our understanding of mental concepts, although it is not everything.

We have a limited special authority about the contents of our mental states. This follows from the link between a state and beliefs about it in the functional definition of that kind of state.

Reply to Baier 1962: epistemological authority is compatible with materialism. Mental state reports are not completely incorrigible, though.

von Eckardt, B. 1975. Some consequences of knowing everything (essential) there is to know about one's mental states. Review of Metaphysics 29:3-18.

1.6e The Function of Consciousness [see also 1.4e, 6.4a]

Argues for nine major functions of consciousness: in defining inputs, adaptation, debugging, recruiting & control, prioritizing, decision-making, analogy-forming, self-monitoring, and self-maintenance.

Contra Popper, evolution doesn't provide an argument against physicalism or epiphenomenalism.
Speculation on what the function of consciousness might be, and how it might be realized: e.g. selecting information.

Separates phenomenal consciousness from access consciousness, and argues that cases like blindsight only suggest a function for access consciousness, not phenomenal consciousness. The latter remains a mystery. With commentaries.

Argues for the possibility of zombies (contra Moody), then notes that any function could be performed by an unconscious zombie, it seems, so there's no function of consciousness in sight.

Suggests that qualia serve to distinguish hypotheses about present from past.

Contra Mott 1982: Function needn't be exclusive, and brain processes and consciousness may share a function, due to their close relationship.

Function always underdetermines intrinsic nature, so absent/inverted qualia cases aren't incompatible with consciousness having a function.

Consciousness doesn't have a function, as any function it might have is a function of brain processes.

Argues that the function of consciousness is not obvious, but that once one accepts a representational view of consciousness, it becomes obvious.

Trying to counter absent qualia arguments by finding a role for consciousness e.g. in metacognition, or as a way to achieve semantic transparency. But consciousness doesn't seem necessary for these, so it's still a mystery.

Uses experimental evidence to argue that consciousness is functionally inessential: the tasks associated with consciousness can be performed without consciousness. Only focal-attentive processing is required.

### 1.7 Qualia

### 1.7a

### General

One can give an information-theoretic explanation of color perception, which leaves nothing out. Rebuts various qualia objections, e.g. from the possibility of inversion. Qualia are codes for external properties.

Argues that psychology is in the business of explaining sensory qualities, and does a perfectly good job using discriminability as a basis. With detailed argument and many interesting examples.

Searching for a theory of qualia: rejects epiphenomenalism, separation of the form and quality of experience, and immediate perception of phenomenal objects. Experience consists in represented (inexistent) objects of thought.

Against an account of phenomenal content as given by inner discrimination. Argues that the character of experience consists in its reason-giving role.

Qualia problems stem from assuming direct awareness of perceptual states. Instead, we should acknowledge only an ability to detect and label these states. Also argues for the possibility of unconscious

A discussion of in what sense we are aware of qualia, and how we can have beliefs about them, with reference to Sellars. Ends up reducing qualia to phenomenal beliefs in a language of thought. A rich and subtle paper.

Lormand, E. 1995. Qualia! (Now showing at a theater near you.) Philosophical Topics 22:127-156.

Sensations are an inessential element of experiences. Experiences are typed by their cognitive component, and the naming of sensations is derivative on this. With examples and empirical evidence about pain, color, perception.

Considers qualia, inverted and absent, and various other stuff. Wishy-washy.

Explicating sensory experience in terms of an appropriate computational relation to a sentence in the language of thought. Argues that this handles many features of qualia (privacy, ineffability, grainlessness, unity, etc).

Where does similarity come from? From belief therein? Similarity of experience = experience of similarity. Also relation to projectibility.

Phenomenal character is bestowed by representation of certain relational properties, defined by relation to experience. With a discussion of possible candidates, and argument against other views such as projectivism.

1.7b

**Qualia and Materialism [see also 1.2, 1.3]**

A Goodman-like theory of qualia discrimination.

A somewhat vague defense of materialism against objections from phenomenal properties. The only problems are epistemological.

On the unique nature of color expanses, which are laid bare to perception as they are in themselves. These are incompatible with functionalist accounts of mind, but might still be physical, on a broader conception thereof.

Arguing from the causal efficacy of qualia and the closedness of physical causation to the conclusion that qualia conceptually supervene on the physical. A very thorough paper.

A reply to Raffman 1995. Maybe our experiences are no more fine-grained than our concepts. Even our experiences of unique hues may be coarse.

Materialists can believe in qualia, qua occupier of the folk psychological role. But they cannot accept the Identification Thesis, that having qualia allows us to know exactly what they are.

Argues that qualia, if viewed as simple properties of phenomenal individuals, are problematic for materialism. Considers the case for phenomenal individuals, and argues that they are intentional inexistent.

Qualia aren't reducible to physical properties, but they are supervenient (and ontologically dependent) on microfunctional properties. With remarks on the knowledge argument, Kripke, absent qualia, epiphenomenalism, etc.

Argues that our inability to reidentify qualia is a problem for materialism. How are they represented? Empty demonstrative would be vacuous, predicate would be reidentified, so maybe a plain presentation? Very interesting.

Absent/inverted qualia aren't really imaginable. The Knowledge Argument fails, as discovering new experiences doesn't imply learning new facts, but only coming to know old facts in a new way.

1.7c Eliminativism about Qualia [see also 1.4d]

The concept of pain is incoherent, as it's asked to do too many things at once. With a discussion of drugs, flowcharts, reportability, etc.

A response to Sellars. All there is to seeing occurrent yellow is the judgment that one is seeing occurrent yellow.

Argues against the existence of ineffable, intrinsic, private, directly accessible properties. With lots of meaty-thought experiments, and arguments that there is no fact of the matter about inversion cases.

There are no qualia: qualia would have to be vague (for Sorites reasons), but there can be no vague properties in nature. The usual Sorites defenses don't work here, as there's no appearance/reality distinction for qualia.

Arguing against eliminativism for qualia. Even if nothing satisfies all the common-sense properties of qualia, reference of qualia terms is still fixed under a Putnam-style theory of meaning. Argues for scientific functionalism.

There are no irreducible phenomenal properties. Materialism can handle our direct awareness of inner states by the right sort of causal connection. Gives a materialism account of discrimination and learning mental concepts.

On bold vs. modest qualophilia, and against various qualophobic strategies. With remarks on scientific objectivity, qualia as an explanandum, and on how our knowledge of qualia is consistent with the conceivability of zombies.

Dennett's 1988 argument against ineffability, etc., doesn't nearly make the case against qualia, and largely relies on verificationist assumptions.

1.7d The Inverted Spectrum

Uses Inverted Earth case, colors and lenses inverted, to argue vs Harman that qualitative states aren't intentional states. Also, less convincingly, to argue that qualitative states aren't functional states.

Functional role counts more than qualitative content in determining what e.g. "redness" is.

Argues that there could be inverted spectra even without a symmetrical color space. Qualia must be distinguished from their place in color space.

Acquired spectrum inversions do not refute functionalism, if qualia revert after behavioral adaptation (as they do with inverting lenses).

Describes some "inverted spectrum" scenario in computer registers, and argues that in the absence of a "central clearing house", the inversion of qualia is indeterminate. There's no reason to believe in non-dispositional qualia.

Inverted spectra with constant behavior is a meaningful hypothesis even under verificationism. Switching nerve endings, tinting contact lenses, etc.

On the physiological bases of phenomenal states, particularly color. Inverted spectrum isn't really coherent, as coolness/warmth would have to be inverted too. So the contingency of qualia is diminished.

Distinguishes various functionally distinct inverted spectrum cases.

Reply to Levine 1991. "Green residue" and "red residue" may be identical. Physiology might put more constraints on qualia, eventually ruling out all other possibilities. But there may still be absent/alien qualia problems.

The inverted spectrum is impossible, due to asymmetries in color space.

The inverted spectrum can be detected, if a single person experiences both.

Against Shoemaker: physical realizations do not give empirical conditions for qualia inversion. Nice.

The possibility of an inverted spectrum w.r.t. dispositions implies the falsity of physicalism. But this rests on an implausible "slide-viewer" model of seeing, and is incoherent otherwise.

Inverted qualia, with respect to a functional account, are no more plausible than absent qualia (by analysis of thought experiments). Both lead to first-person skepticism about qualia.

Contra Hardin 1988: there's a "green residue" after coolness is subtracted, so inverted spectrum could still be possible. In any case, the impossibility of IS doesn't affect the explanatory gap for qualia, which is epistemic.

Inverted spectrum holding behavior constant is at least a coherent idea. Hook up brain in different ways, etc.

Argues that qualia are intentional properties, and that inverted spectra, though conceivable, are metaphysically impossible, due to considerations about society and normality. Argues against Block's "inverted earth".

A fascinating note on the possibility of people with doubled colorblindness genes, thus inverting color processing; such people may actually exist.

Argues for a computational/sentential theory under which qualia are fixed by functional organization. Argues against Block's 1990 inversion: qualia might slowly change back as associations fade. Memory isn't 100% reliable.

Maybe IS is ongoing, with memory changes. What is the logic of "appears"?

All about the coherence and otherwise thereof. Uses switch in state for IS IS wrt behavior. Also claims that IS wrt function is possible as qualia are fixed by realizing state, not functional state. Bad assumption.

Inverted spectra thought-experiments show that experiential content is incommunicable. Accounts for the fact that attempts to describe such cases lead to contradiction (I'm seeing green & not seeing green).

Argues that qualia are intentional properties, along the lines of "looks F to P". Handles inverted earth and related cases by taking the narrow intentional content. With remarks on the semantics of color terms.

1.7e

**Absent Qualia (Block, etc) [see also 1.3b]**

As a criticism of functionalism. raises the possibility that realizations of any given functional account of mental states may lack qualia.

All kinds of absent qualia cases: homunculi-headed robots, the population of China, and so on. There is a prima facie doubt that such cases lack qualia, so there is a prima facie case against functionalism.

It's OK for bizarre realizations to lack pain, as functionalism requires teleology as well as organization. With remarks on the relation between pain and "introspectible noxiousness".

Taking the personal stance, we should regard the Chinese nation as having qualia. A lack of qualia would make a functional difference.

Churchland, P. M. & Churchland, P. S. 1981. Functionalism, qualia and intentionality. Philosophical
Absent qualia are impossible. Also, qualia aren't essential to mental state, functional role is.

Replace neurons one by one with homunculi: what happens? Beliefs don't change, does consciousness fade? Very nice.

If absent qualia are possible, then either qualia are inexplicable or species chauvinism is true. Homunculi-heads could make similar arguments about us.

Conceivability arguments are only a problem for empirical functionalism insofar as they are a problem for materialism in general. Very true.

Argues that metaphysical conclusions can be drawn from conceivability arguments, but that absent qualia cases have not been clearly and distinctly conceived. The functionalist is better off than the identity theorist here.

IQ are no more plausible than AQ (by analysis of thought experiments and skepticism). So there's no reason to choose physicalist-functionalism over pure functionalism, as Shoemaker does. Nice.

The Chinese Nation would require less people than Churchland & Churchland 1981 suggest, as we'd only
need to handle a subset of all possible inputs.

Gives a thorough neurophysiological analysis of blindsight and related pathologies, and argues that these cannot be used to support the possibility of absent qualia. With remarks on the mystery of consciousness.

### 1.7f Introspection and Absent Qualia (Shoemaker) [see also 1.6d]

Absent qualia possible => qualia make no causal difference => no knowledge of qualia, therefore absent qualia are impossible. If qualia are introspectively accessible, they must be functional. An important argument.

Reply to Block 1980. Distinguishes two AQ theses, and argues that if AQ are possible, then the problem for functionalism isn't due solely to qualia.

Defending Shoemaker's argument against Conee: immediate awareness and qualitative beliefs are the same. But maybe people *can't* tell whether they're having genuine or ersatz pain. Eliminativism is the best option.

Reply to Shoemaker 1975. The possibility of absent qualia is compatible with a functional role for qualia, as qualia can make a causal difference that is independent of a given functional account.

Contra Shoemaker: qualia cause qualitative beliefs, which are affected by the absence of qualia, so we know about qualia even if AQ are possible.

Elucidating Shoemaker's argument: if absent qualia are possible, then the difference between real and ersatz pain makes no difference to belief, so qualia aren't introspectively accessible. A nice analysis.

Qualia and qualitative beliefs are the same, so Shoemaker's argument fails. A numbness/pain inversion argument shows that pain isn't a functional state; it yields an introspectible difference without a functional difference.

Qualitative beliefs can supervene on behavioral dispositions even if absent/inverted qualia are possible. We just individuate belief contents and behavior widely, with wide content fixed to the qualia.

Argues that the possibility of absent qualia is compatible with introspective knowledge. The fact that we have evidence of qualia isn't altered by the fact that we'd still think we had that evidence if we didn't have qualia.

Shoemaker's account leaves out experienced relations, such as experienced similarity. Experienced similarity is not the same as similarity between experiences. Being experienced is not an experienced feature.

**1.7g Functionalism and Qualia, General**

Various comments on functionalism's troubles with qualia, including absent and inverted qualia. Analogis with biology and information theory.

Argues that absent qualia and inverted qualia are empirically impossible (though logically possible), using neural-replacement thought-experiments. So functional organization fully determines conscious experience.

Acquired spectrum inversion doesn't refute functionalism, if qualia revert after behavioral adaptation. With empirical evidence.

Pain-qualia are in the body, not the mind, and so aren't part of psychology.

Gives a number of arguments against both analytic functionalism and psychofunctionalism: arguments from absent qualia, absent functional role, epistemology, semantics, and heterogeneity of functional roles.

Argues that non-phenomenal mental events are functional, while qualia are low-level physiological.

Accuses Block of a perspective error. Functionalism can handle a lot, if it's multi-levelled.

Various stuff, mostly against absent qualia arguments.

Behavioral evidence for qualia is always indirect. And you can't check by replacing own neurons by chips, as you'll still believe you have qualia if you're functionally identical. Posit robot qualia as explanatory construct?

Computational functionalism about qualia is compatible with Wittgenstein's views. It makes sense of the points about "dividing through" my private objects, for example. With remarks on spectrum inversions.

Functionalism can't explain the causal role of qualia by identifying them with functional states (circularity) or physical realizations (chauvinism). Which leaves property dualism, epiphenomenalism, or eliminativism for qualia.

Against drawing strong conclusions from first-person imaginings. Considers Searle's silicon-replacement scenario: we might infer that perception isn't veridical, that there's another mind about, or even another body.

Commentary on Moor 1988. Systems that differ in qualitative properties will likely differ in functional organization.

Criticism of "physicalist-functionalism", where functional organization doesn't completely determine qualia (e.g. Shoemaker/Block). The only tenable options are pure functionalism or transcendental dualism. Nice.

Taking transcendental dualism seriously. Privileged access provides strong arguments against objective theories, but it turns out that transcendentalism can't explain it any better, so maybe embrace objective theories after all.

Replacing a brain chunk while preserving causal role must preserve experience;

Subject: Philosophy 596B: Mind and Modality
Status: RO

To participants in Philosophy 596B (Mind and Modality):

As you probably know, I won't be in Tucson for the start of this course. Due to a bureaucratic mix-up, I wasn't granted a US visa in time for the start of term, and I'm currently in Australia (at ANU in Canberra) waiting for the visa to come through. I'm told that that should happen before February 15, and could happen as soon as the next few days, but there is no way to know. I hope that we won't miss more than two or three meetings of the seminar; in the worst case, we'll miss perhaps five.

Until I'm present in Tucson, the course will be conducted as an online seminar. The first meeting was scheduled for Tuesday Jan 19 (tomorrow Arizona time), so this can be considered a kick-off announcement. My plan is to make the first couple of weeks reading-intensive, with the opportunity for online questions and discussion. I'm currently trying to set up a listserv mailing list for the course and a web site; I'll let you know as soon as those things are operational. If it's possible, I'll try to arrange extra meetings once I make it to Tucson to get everything up to speed.

In the next message, I'll send a syllabus for the course, giving topics and readings and an approximate schedule. Note that the first part of the schedule will slightly be revised to accommodate the electronic format, to a degree that depends on the date of my return. In a third message (coming shortly) I'll detail initial topics, readings, and methodology.

Here's a list of participants in this seminar (the recipients of this mailing). If you know of someone else who should be on this list, please let me know. And if you shouldn't be on this list, let me know.

Enrolled students

Angela Burnette       aburnette@u.arizona.edu
Josh Cowley           cowley@u.arizona.edu
Anthony Lane          atlane@u.arizona.edu

Subject: Initial readings and discussion
Status: RO

READING MATERIAL:

The reading material for the first bit of the course is:

_The Conscious Mind_, Chapters 2-4.
Jackson, Epiphenomenal Qualia [web].
_Naming and Necessity_.

You can also read Chapter 1 of TCM as background. But the course will very much be concentrating on the modal issues, so you might not want to become too distracted by general issues about consciousness.

Here's a suggested order of reading, corresponding roughly to the order in the syllabus. Because of the reading orientation, things will proceed a little differently from the way they would in person; for example, I'll leave some of the material intended for the first seminar until I get back. And you shouldn't think of the numbers below as corresponding to weeks, exactly. It might make sense to try to give most of this material a quick reading in the first week or so (assuming you haven't read it already, as some will have), before going back for a more detailed and careful reading to go along with a sequential discussion of these topics.

(1) Start with TCM sections 2.1-2.4 (pp. 32-55), for a general introduction to some issues about modality, ontology, and explanation. You might read the rest of 2.4 (pp. 55-71) and 2.5 lightly; we'll return to them later.

(2) Next read TCM Chapter 3 and section 4.1, as well as the Jackson piece, for an introduction to epistemic arguments against materialism.

(3) Next we come to a posteriori necessity. The relevant material here is _Naming and Necessity_, the rest of TCM section 2.4 (pp. 55-71, on the two-dimensional analysis of a posteriori necessity), and perhaps "The Components of Content" if you want more on the 2-D framework. The order of reading here depends to some extent on familiarity. If you're already familiar with the contents of N&N (as I assume many or most are), it would make sense to first read TCM 2.4, before going back to reread N&N in light of that analysis. If you haven't read N&N, you might want to read it first,
perhaps going back and forth with TCM 2.4 to gain a feeling for the 2-D analysis along the way.

Either way, the two-dimensional framework will be central to many topics in the course, so it's very important to gain a good understanding of it (I hope that before long you'll be living and breathing it). You'll want to go over that material very carefully to be sure that you understand it. "The Components of Content" has some further material (though applied to the semantics of thought rather than language) that may help you if you're not sure about things. After gaining a familiarity, try to translate all the central examples and arguments of N&N into the 2-D framework; that should prove to be a useful exercise in gaining an understanding. (I will probably make something like this an official assignment at some point.)

(4) Next (if we are still online) will be material on the application of the 2-D framework to the argument against materialism: the rest of TCM Chapter 4 (especially 4.2), and Jackson's "Finding the Mind in the Natural World". But I'll leave the details on that until later. If the seminar is in the flesh by this point, we'll have some material on subjunctive and indicative conditionals vis-a-vis the 2-D framework first.

ONLINE DISCUSSION:

We will start with a discussion of the material in (1) above, especially TCM 2.1. This is the closest thing easily available to an introduction to foundational issues concerning modality, ontology, and explanation. Try to get clear especially on the notions of logical and natural necessity, the various notions of supervenience, and the definition of materialism. The material on reductive explanation is secondary for our purposes, but you should still look at it. Post any questions and comments you might have to the list. Ideally, I'd like to see everyone (i.e. everyone officially enrolled in the course; participation by others is encouraged but optional) post some initial comments or questions in the next week (the sooner the better), so we can get an initial discussion going.

(N.B. I wouldn't now lay things out exactly as I do in those parts of TCM, but it should work as a first approximation. Hopefully a lot of things will be clarified and elaborated in discussion.)

I hope to have a listserv mailing list and/or web site for discussion up and running soon, but in the meantime, send all public messages to the list of recipients at the top of this message. N.B. My previous two messages had a couple of e-mail addresses wrong, so this is the one to use.

BACKGROUND:

It would be useful to get a sense of the class's familiarity with relevant issues. I'd appreciate it if everyone officially enrolled in the course could send me a note indicating their background in metaphysics, the philosophy of language, and the philosophy of mind: courses taken, relevant works read, and so on. It would be particularly useful to know whether and to what extent you're familiar with the ideas in and around (1) _Naming and Necessity_ (2) _The Conscious Mind_ (3) Lewis's _On the Plurality of Worlds_ and (4) two-dimensional semantics. You might also mention your areas of main philosophical interest, your year, and any other relevant information, to help me get a sense of things. And you should feel free to take the opportunity to ask any questions that you might have. People who
aren't officially enrolled in the course should also feel free to send such a note.

(I was going to suggest sending such notes to the whole list, but don't want to clog people's mailboxes too badly, and some relevant information about background is probably best regarded as private. But people should feel free to send messages to the whole list to kick off discussion and to start building our little online community.)

--Dave.

Hi folks,

I guess I will get the ball rolling. I would like to note that I'm not really committed to anything I'm about to say.

I have some concerns about the use of "facts" and properties in the various definitions surrounding supervenience. My worry is pretty general, but I'll draw it out by focussing on the definition of a possitive fact or property. "A possitive fact in W is one that holds in every world that contains W as a proper part; a positive property is one that if instantiated in a world W, is also instantiated by the corresponding individual in all worlds that contain W as a proper part." "(pg 40) In footnote 14 it is suggested that we ought to take the containment relation between worlds as primitive.

Here's my problem. Possible worlds are complicated and unnatural entities. Facts and properties are less complicated and more natural things. My inclination is to define possible worlds in terms of properties or facts. Something like, 'Two possible worlds, A and B, are identical just in case all the facts that hold in A hold in B and vice-versa. Two worlds differ in so far as the facts in A are not in B.'

Now there is nothing inherently wrong with defining possible worlds with facts and still saying that containment is a primitive notion. But it does seem to add some tension. I would be inclined to define containment by making reference to facts (or maybe properties) rather than using containment to define certain types of facts. What do people think?

Josh
Here's a reply to Josh's note. I'll hold off replying to Brad's note for a day or so to give other people a chance. I may not have said explicitly enough that everyone enrolled in the class should have posted some initial questions and comments by now. They don't have to be deep and profound; even simple clarifications or dumb questions are fine. But it's only through posting this sort of thing that we can get a good discussion going (hopefully on multiple fronts at once). We need to move on to the next material fairly soon. So I hope to see something from everyone within the next day or so.

Re Josh's point on the appeal to facts in the definition of containment. The worry is that if worlds are defined in terms of facts, then it may be troublesome to define positive facts in terms of worlds. Personally I'm neutral on whether possible worlds should be defined in terms of facts/properties or vice versa, but I'd like to think that even in the former case, the definition of positive fact is OK.

I guess the order of priority would be: (1) take the notion of a property (or a fact) as primitive; (2) build up the notion of a possible world out of these; (3) use the notion of a possible world so defined to characterize the class of positive facts. Of course one still needs to appeal an unreduced notion of containment relations between worlds; but it seems that we have clear intuitions about the application of this notion, and it doesn't seem especially problematic as unreduced notions go. Maybe Josh's idea is that it is less natural to apply an unreduced notion (containment) to an reduced ontology (worlds as facts) than to an unreduced ontology (worlds as basic), but it isn't clear to me that the former is problematic. Again, as long as we have clear judgments about its application.

I suppose the alternative would be to have a "fact-based" definition of a positive fact, or just to take the notion as primitive. I wouldn't wholly object to the latter, but personally I find the world-based definition (with containment as primitive) much more intuitive, and I think one ends up at least informally appealing to such a notion in explaining even a primitive notion of positive fact.

--Dave.

P.S. We are going to be particularly concerned with questions about the nature of and relationships between notions such as logical possibility and necessity, metaphysical possibility and necessity, a priori, a posteriori, natural possibility and necessity, etc. So any questions (including simple clarificatory questions) or comments there would be particularly welcome.
Hi all!

Here's a question about the reading for last week. As I wrote this, I answered this question to my own satisfaction (the error I was making was obvious later)! But, in the interest of contributing to discussion and in the hopes that my own error will be illuminating to others, I will send the message anyways. No jeers or hate mail, please!  :)

I find it difficult to conceive of 2 worlds that are identical with respect to their chemical facts but different with respect to their physical facts. In general, I'm worried that for all cases in which B-properties supervene on A-properties, it will turn out that A-properties supervene on B-properties. This would be odd, because it would entail that, for example, physical properties supervene on biological properties (since biological properties supervene on physical properties).

I think that the way that Dave specifies what it is for 2 worlds to be identical with respect to a set of properties is supposed to rule out this problem (see footnote 4). What we want is to be able to say that there are two possible worlds that are identical with respect to their biological properties but different with respect to their physical properties--this would rule out physical properties supervening on biological properties.

So, let's imagine a biological duplicate of our world which, by stipulation, has a different physics. Wouldn't the structure and dynamics of that world's physics have to be the same as ours in order for it to have the same biological properties? But if so, it isn't clear that we've really imagined a world with a different physics.

Note: I don't think we can solve this problem simply by saying that there are possible worlds which are biologically identical and physically identical to our world except that there is extra physical stuff in that world. This would be analogous to arguing that biological facts don't supervene on the physical facts because of the possibility of a world with extra biological facts (like ectoplasmic angels).

* Here is where I went wrong. There *are* possible worlds with the same biological properties but with fewer or just different physical properties (as long as those absent or different physical properties belong to individuals which do not possess any biological properties). So, for example, there are possible worlds with the same biological properties as this one but in which my shirt is red rather than blue, or in which there simply is no Statue of Liberty.

Perhaps, despite this obvious blockade to the objection about supervenience above, my worry that a biologically identical world to this one would really have to have the same physical laws as this one is of independent interest. For example, if it makes sense at all to speak of a supervenience relation among types of properties rather than token instantiations of properties, the above consideration would suggest (maybe) that we would need to modify our definition of supervenience in a way that rules out physics supervening on biology. I'm not entirely sure this would be a consequence, since one would first need to figure out how we are to individuate or specify biological and physical property types.

All:

I have a question about supervenience...Brad suggested that we may have to modify our definition of supervenience to rule out the possibility of the physical supervening on the biological...On a related note, can someone please explain to me how the direction of a supervenience relation is built into the concept of supervenience? Or is this just a contingency that, once established, allows us to use the term when the appropriate relation is discovered? It just seems to me that there is nothing about the concept of supervenience that makes it move in one direction, and not both...so, my question is, what is it about supervenience that allows us to say that B supervenes on A without necessarily saying that A must also therefore supervene on B?

Status: RO

Hi,

I'll try to reply to Brad and Angela on the question of the supervenience relation. The worry is that, if B-properties supervene on A-properties, then equally A-properties should supervene on B-properties. This seems, at best, odd--one doesn't want to say that physical facts supervene on biological facts or be committed to that view given that biological facts supervene on physical facts. I think the problem is that the notion of one set of facts "fixing" another set is left unaalyzed in the concept of a supervenience relation. It is not literally true that biological facts fix physical facts, because the physical facts have already fixed the biological facts, so there is no more work left to be done. But the notion of "fixed" seems a contingency left out of the strict definition of supervenience--at least insofar as we have encountered it in the readings thus far.

The other position is that, while physical facts MAY supervene on biological facts given the concept, such a statement is uninformative. But again, whether or not something is "informative" or not seems another
contingency that is left out of the concept of the supervenience relation.

What do you think?

Erik L.

all,

regarding Erik's take on supervenience, that sounds good but, given that
the mentioned aspects are left out of the concept of supervenience then we
are just using the word as a convenient label?  I think that I was
categorizing supervenience alongside words like entailment, for example.
Establishing that an entailment holds between A and B allows you to do all
sorts of things in virtue of the entailment, but if supervenience is just
a label, then it won't be helpful in establishing new facts or conclusions
about anything in the way that a concept like entailment does, right?

Some very interesting points re supervenience. Angela asks about
whether directionality is built into the supervenience concept.  I
would say that it is built in, as the definition is asymmetrical.
Take the first definition: B supervenes on A if all A-indiscernible
worlds are B-indiscernible.  One can see that the definition is
asymmetrical by noting that if the A-indiscernible worlds are a proper
subset of the B-indiscernible worlds, B will supervene on A but not
vice versa.  Something similar applies to the modified definitions
given later on.

So there's at least conceptual room for B to supervene on A but not
vice versa.  And it's not too hard to find examples.  Let A be exact
height, and let B be the property of being over six feet tall.  Then B
supervenes on A but not vice versa.
Brad raises the concern that in the case where the A-properties are
the physical properties (the usual case for our purposes), it may be
hard to find asymmetries. I think one can find at least a few
straightforwardly asymmetrical cases by taking e.g. B = the total mass
of the universe, or B = the property of having mass, or even B =
position. It wouldn't be too hard (I think) to construct a world that
is physically different from ours, but has the same total mass, or has
the same distribution of massive objects (but e.g. with different
precise masses), or has the same distribution of positions (but maybe
different particles at some positions).

The physics/chemistry and physics/biology cases are at least somewhat
tricker, though. Of course things depend on just what we take to be
the chemical and biological properties. But there are at least two
natural places to look for asymmetry.

(i) Entities in our world that have physical properties but no
biological (chemical) properties, and which make no contribution to
biological (chemical) properties of other entities. Maybe isolated
photons, for example. Then there's presumably a possible world a lot
like ours but where that entity is absent. That world will be
biologically but not physically identical to ours. Brad gives some
cases like this.

(ii) Entities with biological properties and some
"biologically irrelevant" physical properties. E.g. one *could* claim
that one could change the position of one particle in my big toenail
an iota without changing any of my biological properties. Of course
that depends on just what we are counting as a biological property.

Anthony also gives the example of switching physical properties
wholesale (e.g. matter to anti-matter) while preserving biological
properties.

[Anthony also asks whether natural supervenience can be similarly
asymmetrical. I think the answer is that it is a bit harder to find
asymmetries, because we have fewer possible worlds to play with, but
we should still be able to find them. E.g. the world without the
photon, or with the moved particle in my toenail, are presumably
naturally possible. And clearly for examples such as the height case,
one has asymmetrical natural supervenience. Finally, someone like me
might argue that the psychophysical case is an example of asymmetric
natural supervenience, if e.g. a silicon duplicate of me might have
the same phenomenal properties -- abstracting away from certain
worries posed by panpsychism and the like.]

This being said, presumably there are certain liberal ways of
construing biological properties that may lead to asymmetry. For
example, if one includes things like "being exactly 2.3 light years
from something that is alive", and similar properties, then even the
photon case might come out symmetrical. I recall there was a paper
in the Journal of Philosophy a few years back:

Miller, R.B. 1990. Supervenience is a two-way street. Journal of Philosophy
87:695-701.

that made something like this point to argue that most interesting
cases of supervenience are symmetrical.

Personally I think it makes sense to go with a narrower notion of
biological property. But this sort of example does at least make the
useful point that the mere fact that B supervenes on A doesn't show that B is ontologically dependent on A. In the case above, the physical properties might supervene on fine-grained and relational biological properties, presumably without ontologically depending on them. Some people react by insisting that we need a further clause of "ontological dependence" for the supervenience relation to be useful. I think Grimes made a point like this in

arguing that supervenience isn't at all useful in understanding ontological dependence. Some similarly argue that at least an asymmetry clause should be built into the definition.

Personally I think we should leave the definition of supervenience as it is, allow the conceptual possibility that A and B can supervene on each other in some cases, and consider the question of ontological dependence case by case. I think one can at least say that when (logical/metaphysical) supervenience fails, ontological dependence fails, so supervenience can be considered a necessary condition here. Just what further is required to give a sufficient condition is an interesting question. Any ideas are welcome! (One might presumably also want to deal with questions about e.g. mathematical facts supervening on anything (as they're necessarily true) without being ontologically dependent on those things, etc.)

I think Erik L.'s point about fixing and informativeness is related to this point. I think Erik is pointing toward the sense of "fixes" in which A "fixes" B when B ontologically depends (and is determined by) A. So in the cases above, physics might supervene on fine-grained biology without being "fixed" by it in the ontological sense (though I think one could say that it is "fixed" at least in a modal sense). Again, this points to the fact that supervenience doesn't give a complete accounting of ontological dependence. Similarly, one can argue that it doesn't give a complete account of reductive explanation (I think Erik's point about "informativeness" is tied to this). So again people could think about what we need to add to supervenience to get ontological dependence and reductive explanation.

I think in most cases of supervenience on the physical, it's plausible that this goes hand in hand with ontological dependence on the physical, though there may be a tricky case or two we'll encounter later on. (E.g., what if a strong sort of panpsychism is true, and every physical particle is constituted by an inner phenomenal essence?) In any case the central application of supervenience will be in its guise as a necessary condition for ontological dependence; e.g. in the mind-body case where a failure of supervenience would imply the falsity of materialism. The idea that supervenience is a necessary condition for ontological dependence is relatively uncontroversial, I think, at least among those who buy into modal talk about these things.

All this ties into Angela's second point about supervenience as a convenient label. It's certainly the case that supervenience won't solve all our problems for us; it may not give an exhaustive analysis of ontological dependence or reductive explanation, for example. On the other hand, it may be able to do a good amount of work in clarifying those notions (e.g. at least as a necessary conditions, and perhaps as part of a sufficient condition); and it certainly has roles in other philosophical areas. I guess the moral is that a technical notion such as supervenience should be seen as our servant, not as our
master. (I think more or less the same goes for notions such as "entailment", actually.) It doesn't solve major philosophical problems for us on its own, but we can hope that it at least plays a useful role in clarifying them, and we can judge its application and usefulness on a case-by-case basis as we go.

That's enough for one note. All thoughts are welcome!

--Dave.

P.S. I've used Thony's idea of putting the mailing list in the Bcc label. The only trouble is that it means one can't reply directly to the list. That isn't a problem as long as one has kept a copy of the list around the place. If anyone needs a copy, let me know. Hopefully a listserv will be set up soon.

Subject: Laws, angels, etc.
Status: RO

A few other issues that came up.

(1) Is there a strict boundary between logical and natural possibility, or a gray zone? (Erik H.)

Hmm. I suppose I'd say there's a gray zone for logical possibility at least of statement, because of vagueness in the meaning of words. E.g., it might be vague whether it is logically possible to have a heap with four grains of sand. But that's not a vagueness in the boundary between logical and natural possibility per se. A vagueness in that boundary would require something that is clearly logically possible, such that it's vague whether it is naturally possible. I suppose one could again find examples due to vagueness in language (say it were vague whether photons counted as "particles"; then it might be vague as to whether massless particles are naturally possible). But those aren't very interesting. Leaving such cases aside, a gray zone for natural possibility would presumably involve a gray zone in the laws of nature themselves. I suppose one could try to find such areas of grayness -- e.g. sometimes it's not clear how much variation in initial conditions should be counted as naturally possible, and how much should be seen as built into the laws of nature. But I think for most of our purposes it won't hurt to see the bounds of natural possibility as fairly strict.

(2) What if there are nonphysical angels (etc.) in our world? (Erik H.)

If that's the case, then materialism is certainly false in our world. Here the supervenience definition in 2.1 seems to give the right result. There's a world physically identical to ours but without the angels (presumably), so angels won't logically supervene on the physical by the account on p. 39 (and p. 40). And the angel facts will be positive facts about our world that don't supervene, so materialism will be false by the account on p. 41.

Of course, we don't need to make assumptions about whether or not there are angels in our world for the purposes of defining materialism, as long as our definition gives the right results either way. The particular difficulty is raised by the case in which (1)
there are no angels (etc.) in our actual world, but (2) there's a physically identical possible world (not actual) with angels. In this case, the intuition is that materialism should be true in our world, despite the existence of a physically identical world where things differ. Hence the modifications to the definition. In the case where the actual world has angels, the original definition was already OK.

Re angels traveling across worlds: I guess I'd say (with Lewis) that if a being can move from one world to another, then those worlds are causally connected, and so aren't really different worlds in the first place. Just one big world with two parts. Of course the same being might arguably be present in two worlds (e.g. a possible world where I'm a mathematician, not a philosopher), but that's not the same as traveling between worlds.

(3) Are laws of nature captured in the physical properties of the world, or are they additional? (Anthony.)

This comes down to the question of Humean vs non-Humean views of laws. Personally I lean toward a non-Humean view, holding that laws involve more than any kind of regularity. It seems to me that two physically identical worlds (at least identical in their distribution of physical properties) could have different laws (e.g., Tooley's example of worlds that differ in the laws governing the behavior of a pair of particles that never actually meet), and maybe that there could be a world physically identical to ours but with no real laws at all (the Hume world where it's a giant cosmic coincidence). If so, laws (and causation, etc.) involve something ontologically significant in the world over and above distribution of particular physical properties. I discuss this a little on p. 86 of TCM.

I think a commitment on this view isn't essential to most of the core issues we'll be discussing, though. I avoid the issue for the most part in the book by stipulating that physically identical worlds have the same physical laws (i.e., physical laws are built into the physical supervenience base). The issue is interesting, though, as another example of the way in which ontology and modality interact, and as another domain in which there are modal arguments with ontological consequences. We'll see later on that there are interesting parallels between the law case and the phenomenal case.

One complication is that a smallish minority of philosophers hold that laws of nature are metaphysically necessary and hold in all possible worlds. If that's so, then metaphysical and natural necessity arguably collapse (and so will metaphysical and natural supervenience, etc). On my preferred usage, such laws still won't be logically necessary, as it is still conceivable that they are false, there are conceivable scenarios with different laws, etc; so we'll still have a distinct notion of logical necessity and logical supervenience. (The necessity of laws will be an example of what I call in the book "strong metaphysical necessities".) But this is a tricky matter that we'll be discussing later on. (Again, any clarifying questions on logical vs. metaphysical necessity, etc, are welcome.)

(4) Thony's (interesting) question re Kripke and the 2-D framework. Maybe I'll save that one until we're focusing on those issues in a little while.

Looking forward to people jumping in and continuing the discussion...

--Dave.

OK, here goes,

First is a question: by definition, is there a strict boundary between logical and natural possibility, or is there a gray zone?

Comment: The idea that there is a world physically identical to ours but has extra nonphysical stuff: Can we postulate anything about that world when we don't know about our own worlds non-physical stuff--if it is bound by logical entailments, etc? (if that makes any sense) Assuming our world has no angels is a strong assumption perhaps. And maybe these angels can travel across worlds? Is that allowed?

-Erik

Subject: Re: Initial discussion
Status: RO

Erik points out that if B-properties supervene on A-properties, it seems that A-properties must also supervene on B-properties. It seems that this possibility depends on the type of supervenience being discussed. If we are talking about logical supervenience, this does not seem to be true. At the global level, given that the world has certain physical properties and natural laws that constitute its A-properties, there is no possible way in which it could have different biological properties. However, the reverse of this does not seem to be true-- one can imagine a world that is biologically identical to this one, but in which there are slightly different physical properties. For instance, one can imagine a world composed of anti-matter, but which has suitably different laws than we have in our own world such that it is biologically indistinguishable from our own world.

I am not sure whether this is also true in the case of natural supervenience. Is it possible that, given the natural laws that hold in our world, a world could be biologically identical to ours and yet be physically different? I would hazard a guess that it might be. We can imagine a world identical to our own biologically, except that organisms
are based on Silicon instead of Carbon. Of course, it might be impossible that such a world could be biologically identical to this one-- it would have to be a world in which there is a great abundance of Silicon and it must somehow behave chemically just like Carbon does in this world. Perhaps tis is ruled out by the laws of nature.

A question about laws of nature: are they somehow captured in an exhaustive list of the physical properties of the world, or are they additional facts that are added on? I expect you (Dave) do not need to say much about them beyond the fact they may be different in logically possible worlds, but not in naturally possible worlds.

Anthony

Subject: Re: Supervenience and symmetry
Status: RO

David has suggested that global-logical supervenience is necessary but not sufficient for reductive explanation. It seems clear that supervenience is a necessary condition for reductive explanation- but it is not so so clear that a good explanation of a phenomenon can be cached out merely in terms of the lower-level facts. Searle implies this when he suggests that it is inadequate to explain a cocktail party or a football game merely in terms of the physical facts, though logical supervenience implies that this is possible. If a reductive explanation is to be illuminating, perhaps what is necessary beyond supervenience is what David suggested on page 51. He suggests that the project of reductive explanation requires both explication and explanation. Thus we can explicate a football game in terms of the rules, the players, the plays, etc. and explain it in terms of the lower-level physical facts, eliminating any mystery surrounding the high-level phenomena.

My question: can some one expand on why local logical supervenience is too stringent a requirement for reductive explanation?(51)I'm not disputing the claim- I would just like to understand it better.

Rachel, the key is "local" logical supervenience. Dave gave the example of two physically identical organisms (ie meeting the condition of local...
supervenience) with non-supervenient high-level properties (their biological "fitness" say) because of differences in the match of the physical characteristics of the organisms to their environment. So if physical facts are not considered globally, certain facts about individuals may fail to supervene, even though they are entirely physical. I want to say that certain properties about individuals are context-dependent in a way that requires global fixing of facts to cache out the supervenience relation. Searle's quip about the football game is consistent with this.

Erik L.

Subject: Re: Supervenience and symmetry
Status: RO

Rachel is right that logical supervenience alone doesn't capture everything that is relevant about explanation. I do think that it's captures what's going on with reductive explanation, especially when one thinks of this as a two-stage process of explication plus empirical satisfaction. But it's also true that reductive explanation is far from the be-all and end-all of explanation. Obviously a reductive explanation of a football game or a cocktail party may not provide the most illuminating explanation of what is going on there. It will be a "mystery-removing" explanation in that it will explain how football games and cocktail parties are possible, but even after the process of explication plus empirical satisfaction is complete, there will presumably be a major role for high-level explanations in helping us to understand the high-level phenomena in a comprehensible way.

There is still the point which came up last time, concerning cases (e.g. symmetrical cases) where B supervenes on A while not being intuitively ontologically dependent on A, or reductively explanable in terms of A. The supervenience of the physical upon sufficiently
fine-grained biological properties might be an example. Maybe to handle this sort of case one needs to build in some further clause about the autonomy of the domain of the supervenience base. It's not entirely obvious how to cash this out, though, and all ideas are welcome.

Re local supervenience, I think we often want to say that phenomena are reductively explainable even when they aren't locally supervenient. Fitness is an example, as Erik suggests. Perhaps my being a brother is another one. These things don't supervene locally, as they depend constitutively on environmental factors. But it still seems reasonable to say that we can give reductive explanations of them. In such a case, a reductive explanation will advert to lower-level properties of both me (locally) and of my environment.

--Dave.
Hi all,

I have a sort of ill-defined, amorphous worry about epistemic arguments against materialism. But, be warned, the worry seems to come and go as it pleases, and I may not have it by the time I get to the end of this message.

In general epistemic arguments against materialism have the form:
1. Imagine someone (typically someone named 'Mary') who knows all there is to know about X (color vision, etc.)
2. But, imagine Mary has cognitive deficiency Y (color blind, raised in a black and white room, etc.)
3. One day she's released (or her color vision miraculously is restored, or ...) and sees *green* grass for the very first time.
4. She's learned something new; ergo materialism is false.

Here's my worry (I think). (Incidentally, it probably rests on another amorphous, ill-defined worry about conceivability.) How can we be sure we're getting our inferences about Mary's inferences right? The argument needs it to be that Mary learns nothing new, but as far as I can tell this requires us to track Mary's inferencing. But this is hard for us since *we don't know* all there is to know about X. And how much someone knows about X has an obvious impact on the conclusions one can draw, no?

Here's an example of what I have in mind. The Churchland's have a pretty cool parody of a thought experiment called (I think) the "Dark Room Argument". I'll change their example to make it an epistemic argument.
1. Imagine Mary knows all there is to know about light.
2. But Mary is in a completely dark room.
3. Suppose Mary is swinging a bar magnetic abover her head in the dark room. Nothing happens. Then someone turns on a light.
4. She's learned something new: light isn't electromagnetic wave propagation after all.

Now, since we know more about light and how it works, the argument is uncompelling. But we can imagine that it may have been compelling to (say) folks in the middle ages.

Like I said, the worry comes and goes. But at the moment I am a bit worried about this sort of thing.

Cc: chalmers@ling.ucsc.edu, aburnett@U.Arizona.EDU, agillies@U.Arizona.EDU, akolers@U.Arizona.EDU, atlane@U.Arizona.EDU, bayne@U.Arizona.EDU,
I have some concerns about the epistemic and analysis arguments. In particular it seems that the two epistemic arguments and part of the analysis argument ultimately come back to conceivability arguments. If one is still hesitant about conceivability arguments, then it isn't so clear that the other arguments will take its place. I'll take each in turn.

1) The Argument from Epistemic Asymmetry

The argument is that my knowledge that conscious experience exists derives primarily from my own case. External evidence doesn't play a role in it. (pg 102). This is unlike how we know about other things. From this we can conclude that consciousness can't logically supervene because, "If it were logically supervenient, there would be no such epistemic asymmetry; a logically supervenient property can be detected straightforwardly on the basis of external evidence." (pg 102)

My problem is with the word "straightforwardly." On one interpretation electrons cannot be detected straightforwardly from external evidence. In order to detect electrons you first have to postulate their existence and build a partial theory describing some of their observable properties. Then you have to build some elaborate tools to see one. Why shouldn't I think that we just don't have a partial theory are the right tools to detect consciousness from external evidence. Most of the rest of the mind is an unsolved problem, why not this one?

It seems that my only reason for thinking this can't be done is the conceivability arguments.

2) The Knowledge Argument:

Mary knows everything about the physics/functionality of the mind, but there is something she still doesn't know until she actually sees red.

I have no idea what it would be like to have a complete theory of the physics and functionality of the mind. So my intuitions about Mary are not coming from an understanding that *the* theory of mind doesn't explain consciousness. Rather, it is that I cannot imagine a completed physical/functional theory of mind explaining consciousness. Again it comes to a conceivability argument.

3) From the absence of analysis.

In order for a reductive explanation to work there needs to be an analysis of consciousness whose satisfaction physical facts could imply. But there is no such analysis. Functionalism gives the best hope, but then to explain consciousness is just to explain our ability to manifest some capacity. "But on the face of it, it is entirely conceivable that one could explain all these things without explaining the experience that accompanies the report or the discrimination." (pg 105)

The first part of the absence of analysis argument pretty clearly rests on a conceivability argument. The remainder of the argument is quite interesting and I don't think it is subject to the line I'm running here.

Even if you don't agree with what I've said, there is one point I've used in this argument that I think is important. The mind (even without consciousness) is possibly the most complex thing human's
have ever studied. Vision is probably the most well developed area in
the theory of mind and there are still many ongoing debates and just
plain holes in that theory. When we imagine a completed functional
or physical theory of the mind, I would suggest that we are not even
coming close to imagining what such a theory will actually look
like. That isn't to say that such imaginings are pointless, but we
need to keep the limitations of our imagination in mind.

Subject: Epistemic arguments
Status: RO

Thanks to Thony and Josh for their messages. I'm looking forward to
more comments and to others' reactions, but in the meantime here are
some thoughts (I hope they'll be helpful in the discussion Tuesday).
I'll begin with some background and stage-setting, putting the
discussion here within the context of the more general metaphysical
issues in the seminar.

Modal arguments against materialism, and against other ontological
doctrines, take off from the central point that ontological views have
modal consequences. For example, if materialism is true, so that in
some sense the fundamental constituents of the world are physical,
then the physical facts must necessitate all the facts. So one can
argue against materialism by arguing that the physical facts don't
necessitate all the facts. One can similarly argue for and against
other ontological views, by considering the question of whether facts
in the (putative) reductive domain (call it the A domain) necessitate
facts in the to-be-reduced domain (the B domain).

How does one argue for such a modal claim? This comes down to some
deep issues about the epistemology of modality, issues which we'll be
concentrating on in this seminar. But the most common way to argue
for such a claim is to make an *epistemic* argument. Such an argument
tries to establish that there is an epistemic gap between the A domain
and the B domain. The thrust of such an argument is usually that
there is no a priori entailment from A truths to B truths. From here,
it is inferred that there is no necessary entailment from A truths to
B truths, so the ontological reduction of B to A can't succeed.

Perhaps the central questions we'll be concentrating on in this
seminar is whether the move from an epistemic gap to an ontological
gap (from failure of a priori entailment to failure of necessary
entailment, for example) is valid, and if so, when and why. But in
this section, we're looking at what's involved in the antecedent of
such a move -- i.e. the argument for an epistemic gap, which will
always be the first step in such an argument. There are a number of
ways such arguments can be run. One can use epistemological
arguments, arguing directly that knowledge of A truths isn't
sufficient to yield knowledge of B truths (even when combined with
arbitrary a priori reflection). One can use conceivability arguments,
arguing that there is no incoherence in the suppositions that the A
truths hold but certain B truths do not. And one can use arguments
from conceptual analysis, arguing that B concepts are not of the right
type to support a priori entailment from A to B.

The case of consciousness provides some paradigm examples. The
question at issue is whether there is an epistemic gap between
physical and phenomenal, and in particular whether there is an a
priori entailment from physical to phenomenal. Here arguments from conceivability, epistemology, and conceptual analysis can all be invoked. All of these arguments involve an appeal to some sort of epistemic or conceptual intuition at some point (as do most modal arguments, and indeed most arguments anywhere in philosophy).

I'm not going to try too hard to convince you that there is indeed an epistemic gap in these cases, as we'll mostly be interested in the independent question of whether the epistemic-to-ontic move is valid (a question that remains of general interest for all sorts of issues even if one rejects the epistemic gap in this particular case). But it's good to get a sense of what's involved in supporting such a claim.

Thony and Josh both raise the question: how can we know that there is an epistemic gap between A and B when we don't yet know all the A facts. An anti-materialist will surely concede that we don't yet know all the physical facts, so presumably he or she will have to be making a general claim about what can follow from physical facts, a claim independent of the specifics. I think Jackson intends to make it plausible, for example, that no matter what physical facts Mary knows (even future physical facts), that can't be enough to teach her what red experiences are like. I take it there is at least a strong intuition here (i.e., to the effect that Mary's epistemic gap isn't merely due to her not having the right specific physical knowledge).

And I think an opponent would be fighting an uphill battle if they were to argue that with the right specific physical knowledge, Mary really could know what red experiences (and the rest) feel like from within her room. So, we seem to have an intuition of a general epistemic gap here, not just a specific epistemic gap. But it is interesting to think about what might be grounding such an intuition.

One possible general way of grounding the Mary intuition would be: (1) Physical knowledge is all descriptive knowledge; (2) No amount of descriptive knowledge could on its own enable Mary to know what it's like to see red; so (3) No amount of physical knowledge could enable Mary to know what it's like to see red. Of course there are questions about just what "descriptive knowledge" comes to here. One might try to cash it out as "knowledge acquirable in a black-and-white room", or "knowledge acquirable without relevant experiences", or "knowledge about the objective structure of causal systems". For any such reading one could then of course at least argue about whether premise (2) is compelling. My own view is that the general Mary claim has a force which doesn't need to be grounded in such an argument, but such arguments can certainly be used to lend force (and often are, by proponents of epistemic arguments).

Something similar goes for conceivability arguments. When it's claimed that zombies are conceivable, for example, an opponent might respond by saying that we don't know all the relevant physical facts, and therefore don't know just what to conceive of when conceiving of a zombie. In response, the conceivability-arguer might make a general claim such as: for any physical P, it's conceivable that P could be true in the absence of experience. And it might be claimed that this has some strong intuitive plausibility. It seems to many, for example, that the conceivability of zombie scenarios is more or less independent of the specific physical facts in question, and that varying those facts in the conception makes no difference at all to the presence or absence of experience in the conception.

I have some sympathy for this myself, but it's true that such a point
is more compelling if accompanied by some sort of general argument, or
some sort of analysis of the underlying relation between physical and
phenomenal concepts. For my part, I'd support the claim roughly as
follows:

(1) Physical concepts are all structural-dispositional concepts;

(2) If B truths are to be entailed a priori by structural-dispositional
truths, there must be some analysis of B concepts in
structural-dispositional terms;

(3) There is no analysis of phenomenal concepts in
structural-dispositional terms; so

(4) Phenomenal truths are not entailed a priori by physical truths.

In a way, this corresponds to the point stressed in the book that the
argument from the absence of analysis is what lies at the root of the
epistemic arguments; and premise 2 in particular corresponds to the
point that "structure and function only ever adds up to more structure
and function".

Of course, an opponent could question premise 3. (They might also
question premises 1 or 2, but I think this would probably not be
fruitful in the end.) I take it that a dispositional (functional)
analysis would be the only candidate of any promise, and that
ultimately there are only a few promising dispositions in the
vicinity. Here, though, note that the epistemic arguer can mount a
case against such analyses without needing to worry about the precise
nature of specific physical facts. The claim will just be that for
any disposition in the vicinity, there is an epistemic gap between
that disposition and experience. For example, for any such
disposition, it's conceivable that it be present without
consciousness; or one could know all the facts about such dispositions
without knowing all the facts about consciousness. Someone might
still question this, but at least we have narrowed down the scope of
the discussion from worries about future physical facts.

All this bears directly on Josh's question about priority between
arguments from conceivability, epistemology, and analysis. To my
mind, the question of priority is subtle. I think that each of the
claims have a certain prima facie force that needn't be grounded in
the others, but that underneath there is something of a relation of
mutual support going on. It would be surprising to me if the
conceivability argument were seen to ultimately carry the burden, as
there are a number of people who have the Mary intuition and the
analysis intuition while being unsure about or even denying the full
conceivability intuition. But no doubt there is something of a circle
of mutual support here, and it is interesting to uncover its
structure.

If I were to try to articulate the substratum underneath the
intuitions, I guess I would hold as above that the full conceivability
claim is grounded in the deeper point about absence of the relevant
sort of analysis, i.e. in a claim about the nature of phenomenal
concepts, and it may be that the epistemological arguments are too
(though I think that both of these arguments can have prima facie
force to one who is uncommitted on the abstract underlying point).
It's arguable in turn that the point about analysis is itself grounded
to some extent in intuitions about conceivability and epistemology,
but note that these are now much more limited claims than the
full-blown claims (concerning arbitrary physical facts) which we
started with.

I also think, though, that the argument from absence of analysis has independent support, e.g. in the sort of reasoning which holds that "for any function, we can always raise the question, why is the performance of this function accompanied by experience, and this will always be a nontrivial further question?". This sort of further-question reasoning (which I rely on most in my paper "Facing Up the the Problem of Consciousness") can arguably be supported by conceivability and epistemological considerations, but I'd argue that it has intuitive support which is more or less independent of and prior to such considerations. So if I were to rest on any point as supporting the central burden, it might be on points like this concerning the conceptual distance (at least in a priori space) between functional and phenomenal concepts. But I think it is most accurate to see things in terms of a complex web of support among a number of related considerations.

A few specific points re Thony and Josh.

Re the "Dark Room":

>1. Imagine Mary knows all there is to know about light.
>2. But Mary is in a completely dark room.
>3. Suppose Mary is swinging a bar magnetic abover her head in the dark room. Nothing happens. Then someone turns on a light.
>4. She's learned something new: light isn't electromagnetic wave propagation after all.

I presume that premise 1 is meant to say that Mary knows everything *physical* about light (in order to engage appropriately with 4, and to provide an appropriate analogy). Here I'd want to know in what intuitive sense "Mary has learned something new". It seems to me that intuitively, the only new thing Mary has learned is what it is like to see light; i.e. some facts about light *experience*. From here, one might well infer that facts about light experience are not reducible to facts about EM wave propagation. But it's hard to see a more general argument about non-experiential aspects of light getting off the ground; so it's hard to see that we have any analogous plausible but fallacious argument in the vicinity. At least, I'd need to see a lot more spelling out of just what is supposed to be going on in this scenario, and what is supposed to be learned, from the point of view even of the 18th century scientist.

Re: the epistemic asymmetry argument, and "a logically supervenient property can be detected straightforwardly on the basis of external evidence."

This was probably too quick on my part. Properties such has "had meat for breakfast in 10,000 BC" are presumably logically supervenient but not straightforwardly detectable. On the other hand, *given* relevant physical and microphysical knowledge, such properties are fairly straightforwardly detectable. I guess something similar would apply to electrons. They're detectable only nonstraightforwardly from external evidence, but determinable pretty straightforwardly from complete microphysical knowledge. Whereas even complete microphysical knowledge leaves a gap in the consciousness case. Of course an opponent might deny the epistemic intuition here, and say that with the right physical knowledge, one's knowledge of consciousness would be fairly straightforwardly derivable. I agree that this epistemic asymmetry argument is pretty close to both the conceivability and direct epistemological arguments, which is why I don't rely on it
much.

Re the knowledge argument: I think I'd want to deny that this is a conceivability argument. The argument isn't that one can't conceive of Mary knowing what it's like to see red, it's that we have good reason to believe that she won't know what it's like to see red. See above.

Re the analysis argument: I've tried to spell out the extent to which this does and doesn't rely on conceivability considerations.

Re the brain being complex: Of course this is so. But still, a physical theory of the brain's functioning has a certain shape, irrespective of the details, and it may be that there are things we can know about what theories of such a shape can and can't explain, by virtue of certain very general principles that are independent of the details. (Think about someone arguing that no theory of pure statics [without a temporal element] could explain dynamics, for example.) E.g., if it were the case that (1) a physical theory can only explain structure and function, and (2) to explain structure and function is not to explain experience, then one could draw conclusions about the limitations of physical theory in explaining experience. Of course work is being done by general premises such as (1) and (2), which can be questioned, but the point is that we can do a good amount of work in assessing such premises even in advance of knowing the specific details of physical theories of the brain.

I certainly don't want to say that empirical knowledge of the brain is completely irrelevant in these matters; and it's certainly vital for understanding all sorts of philosophically important things about the mind. But there is a lot of philosophy we can do in advance of understanding all the details. One had better be sure that the philosophy one does is compatible with any details that emerge, of course. My own view is that attention to the details of neurophysiology and other empirical areas tend to give the epistemic considerations in question fairly strong support. One might reasonably disagree about that, or hold that some future neurophysiology will show us something pretty different, but I suspect that for such a view to have much weight, it's going to have to be supported by a good amount of relatively a priori argument on the conceptual and epistemic matters in the vicinity.

These are all deep issues that deserve attention, and I'd be interested to hear any thoughts.

Subject: minutes from seminar meeting
Status: RO

Hi all:

Here is a summary of our discussion Tuesday--feel free to add anything that I may have left out.

First, questions about the unidirectionality of the supervenience relation were addressed, relating to some of our earlier online
discussion.

We also briefly touched on the definition of materialism and how it is that the logical possibility of zombies would entail the falsity of materialism. This lead us into a discussion of the relationship between conceivability and possibility. It was pointed out that the relevant notion of conceivability has to be stated carefully, so as to rule-out the conceivability of Goldbach's conjecture being false if in fact it is true, for example. Some other remarks were made to the effect that the close relationship between conceivability and possibility is (perhaps pragmatically?) desirable, since any gap between conceivability and possibility might lead to mysteriously inaccessible possibilities or impossibilities.

Everyone seemed to be clear about supervenience, possibility, and necessity. We spent most of our time discussing epistemic arguments against materialism, especially the case of what Mary didn't know. Thony was asked to restate the issues he had raised in online discussion. We then debated some of the points raised there. In particular, we discussed whether or not epistemic arguments were weakened by the fact that the physical facts which are claimed to be insufficient for knowledge of phenomenal facts are left unspecified. Some claimed that this did make epistemic arguments weak. Others were essentially in agreement with Dave that it was sufficient to notice that the relevant physical facts would merely provide more information about structure and dynamics, and that such information would always fall short of providing knowledge of the phenomenal facts.

We also ended up discussing subjectivity and objectivity, as well as concepts (and whether or not they had both subjective and objective aspects to them). Somehow (!) this also lead us into discussing Wittgenstein on private language and on the beetle in the box, and Dennett with regard to purported differences that "don't make a difference" (such as Orwellian vs. Stalinesque revisions).

Brad

To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

Thanks to Brad for the minutes. I would be interested to see more on these points.

I'm a little perplexed that so little is being posted to the mailing list. Only a couple of messages in the last 6 or 7 days, even though I asked that everybody post something about the current round of readings by now. If this goes on, we are going to fall a long way behind. Is there a problem? If so, please let me know (private e-mail is fine). Any suggestions as to methodology are welcome.

As things stand, I think I have to be more explicit. There is a weekly writing assignment, which involves posting at least a page or so of questions and/or comments on the current round of readings (and feel free to post more). Students are also expected to engage in a good amount of mutual discussion of each others' contributions, in
addition to this (N.B. "in addition", i.e., the initial writing assignment shouldn't be primarily reactive). These writing assignments are a core part of the seminar.

I know the online seminar is an unusual arrangement and is not ideal, and I hope we'll be meeting as a normal seminar soon (no news on the visa yet, alas). In the meantime, though, I think some effort at participation on everyone's part can make this a fruitful and productive arrangement. Again, any suggestions are welcome.

I'll look forward to seeing everyone's questions and comments on the second set of readings in the next day or so, followed by a good round of discussion. You should also be reading over _Naming and Necessity_ for the third round; your thoughts on that will be due early next week. Although we won't be focusing on the 2-D material until the fourth round, I suggest that those of you who have read N&N already read over the 2-D material first (esp. in TCM and The Components of Content), and then read over N&N with that material in mind, trying to understand it in those terms. I'll give advance notice that at some point fairly soon there will be an assignment asking you to translate all or most of the central examples in N&N into the 2-D framework. That should help you get a working understand of what the 2-D framework is all about and of how to use it, which will be important for the rest of the seminar.

--Dave.

P.S. We're now ready to switch to the listserv, so all future contributions should go to modality@listserv.arizona.edu.

All, In reply to Dave's request for more info on Tuesday's discussion, let me attempt to elaborate the line that Thony and I were attempting to develop. (Though don't hold Thony accountable for what follows!) I don't think that the argument would convince anyone not already convinced that Mary can know what it's like to see red, but perhaps it focuses the argument on the issues on which it should be focused: the nature of *concepts* about the phenomenal.

(1) Assume that Mary is not only an expert neuroscientist, but an expert developmental psychologist as well. She knows how infants develop all the concepts that they do on the basis of their innate mental structure and the sensory input that they receive. Not a contentious assumption, I hold.

(2) Assume that infants develop all concepts on the basis of phenomenal states and their innately given structure. This is controversial. The idea is that sensory input leads to phenomenal states in infants, and they form their concepts on the basis of those phenomenal states (probably together with the feedback they get from action - which we could regard as simply more sensory input). Note: I don't claim that this is the only way in which one could develop concepts. Surely you could (logically) build a machine that develops concepts on the basis of input without going via the sensory states that that input generates, but it does not *seem* as though...
this is how we do it.

(3) Mary has the innate mental structure that infants do.

(4) Mary has the concepts that, say, the normal adult human being has. In particular, she has the concept red. After all, she knows everything that there is to know about colors, and to do this she must have all the color concepts.

(5) So, Mary will be able to subtract from her concept of red the innate structure that went into it, and come up with the phenomenal experience on the basis of which it was constructed. In other words, she can simply reverse-engineer her concept of red, and do in reverse what the infant does in forward. Thus, Mary-the-developmentalist does know what it's like to see red.

Here's the predicted reply from Jackson and friends: (4) is false. Mary does not have the concept of red. Or, perhaps more accurately, she does not have the concept of red that is important for this discussion. She may have *a* concept of red in the sense that a blind person can have a concept of red (its a color, people see it, tomatoes are red, as are fire engines, etc.) but she does not have the phenomenal concept of red, of which red qualia is a *constituent.* You cannot have the phenomenal concept of red without qualia because the red quale is a (proper?) part of it. Knowing—that can include phenomenal states, because it includes phenomenal concepts, and phenomenal states are part of (some) phenomenal concepts. And the only way you can generate these concept is by having certain selective types of input from the environment. Mary is in her dark room (or is color blind), and thus cannot get (or operate on) this type of input. (And she cannot provide this input endogenously either – she cannot visualize in red.) Hence she could never concept of red from which to sift out or distill the phenomenal experience of red.

As I say, this is a fair reply on the part of Jackson. (And actually, there are other problems with the argument too.) It seems to me that the essential issue is now the nature of phenomenal concepts. If we accept the claim that qualia are constituents of phenomenal concepts, then we can say that there are two ways one can come to know a phenomenal property: via the experience itself, or via the phenomenal concept. Indeed, we might even be so bold as to suggest that qualia simply *are* phenomenal concepts. Perhaps qualia can have inferential roles, enter into reasons, and do some of the other nifty things that concepts do. Actually, it occurs to me that this is Lycan's line on qualia (I think): they are concepts that are only intra-subjectively potent; they are, so to speak, words in the experiencers language of experience, that can't make the leap into public discourse. (But perhaps I have Lycan wrong.)

What got me thinking along these lines was the attempt to bridge the gap between the objective (concepts - available for intersubjective discourse, the box a la Wittgenstein) and the subjective (qualia - not available for intersubjective discourse - the beetle). Now: if infants can build up from the subjective to the objective, then why can't Mary go in the other direction. Of course, Fodor's reply is that infants don't build up from the subjective to the objective: all concepts are innate. But as long as you're with Auntie on this one and think that Fodor's wrong, maybe there is something to the thought that Mary can do in reverse what we - as infants - do forward.

Tim
Here's the predicted reply from Jackson and friends: (4) is false. Mary
does not have the concept of red. Or, perhaps more accurately, she does
not have the concept of red that is important for this discussion. She may
have *a* concept of red in the sense that a blind person can have a
concept of red (its a color, people see it, tomatoes are red, as are fire
engines, etc.) but she does not have the phenomenal concept of red, of
which red qualia is a *constituent.* You cannot have the phenomenal
concept of red without qualia because the red quale is a (proper?) part of
it. Knowing-that can include phenomenal states, because it includes
phenomenal concepts, and phenomenal states are part of (some) phenomenal
concepts. And the only way you can generate these concepts is by having
certain selective types of input from the environment. Mary is in her dark
room (or is color blind), and thus cannot get (or operate on) this type
of input. (And she cannot provide this input endogenously either - she
cannot visualize in red.) Hence she could never concept of red from which
to sift out or distill the phenomenal experience of red.

I think Tim is right in predicting this reply. One worry: if we say (in
the premises) that Mary doesn't have the full concept of red but just the
non-phenomenal component, then aren't we begging the question against the
materialist? After all, the *conclusion* is supposed to be something
along those lines. On the other hand, the materialist's use of premise
(4) (i.e., that Mary has the full concept of red) seems to beg things the
other way; so this might be an indication not that this Tim's argument is
an argument *for* materialism, but rather an argument that the
Mary-the-neuroscientist-case isn't a good argument *against* materialism.

Thony

"Curious green ideas sleep furiously."

I have a question regarding Thony's example of the government or
"body-politic" (I can't remember the precise phrase now). Did you mean that, even in principle, there are no illuminating accounts of a political process in terms of basic physics. If you meant in principle, I guess I'm confused. In practice, explaining a high-level phenomenon like a political process might be very cumbersome using physics, but it seems like, if that political organization you spoke of is entirely physical, there is nothing precluding such an explanation in principle. "not very illuminating" is perplexing in it's own right. What makes something "illuminating"? That's a strange notion once you've conceded that the process referred to is nothing over and above physics. I guess what I'm asking is, what is the role--ontologically, functionally, explanatorily or whatever--of concepts in explanations and why should they be NECESSARY if a supervenience relation holds between the phenomenon and a set of entirely physical facts? For that matter, WHAT IS A CONCEPT in this sense that we keep using it?

Erik L.

Dave suggests that conceivability arguments are distinct from knowledge arguments. The Mary argument is a knowledge argument: Mary knows all the physical facts (A facts) but she doesn't know all the facts about experience (B facts), therefore . . . . Zombie arguments are conceivability arguments: I can conceive of my zombie, i.e. of a being with all my physical properties but none of my phenomenal properties, therefore . . .

I'm not so sure that these arguments are really distinct at any deep level of analysis (although there's a caveat below). First, note that one has to conceive of Mary and locate her in the distant future of neurosience. What does this involve? Well, it's hard to say. It might involve visualizing a certain scene (say, Mary wearing a white lab coat), and labelling it *Mary the expert neuroscientist who knows everything about the brain*. What does conceiving of my zombie involve? Well, perhaps something similar. I have a picture of someone just like me, but there's nothing it's like to be him - nobody's home and the lights aren't on - and I stick a label on him: *My zombie twin.*

But in fact, I doubt that we do anything *like* this in either case. Conceivability does *not* seem to involve the imagination - at least that's what it seems like to me in *these* cases. It's *not* like trying to work out in your head whether you can fit a ball of diameter two inches inside a triangle of sides 3, 4 and 4 inches which has an outer perimeter of 1/2 an inch thick.

So what is going on in these cases? Well, it seems to me that in both cases you have the following intuitions or you don't.

(a) Necessarily, all physical properties are functional or structural properties, and phenomenal properties aren't functional/structural properties; OR, the very similar intuition: (b) Nec., all physical facts (or, perhaps, propositions) are exclusively composed out of functional/structural concepts, and phenomenal concepts are not structural/functional concepts.
(a) is at work in the zombie cases, (b) is at work in the knowledge cases. If there is a one-one correspondence between facts and properties as is commonly supposed in setting these cases up, then it is hard to see why one should have (a) and not (b), or vice-versa. (Caveat: Of course, some do reject the claim that if you've got two facts you've also got two properties, but then you can accept that Mary does learn something new without rejecting physicalism.)

But imagination does seem to play some role in conceivability. Consider the following problems: (1) is logically it possible to be an agent without, being a perceiver (or vice-versa)? (2) Is it possible for one subject of experience to have two distinct (spatially separated) bodies at the same time, so that, e.g., one of my bodies might be in Tucson, and the other one in Texas at the same time, and they are simultaneously conscious? Well, people seem to have very different intuitions about both of these cases? Why? Are they: (1) actually imagining different scenarios? or (2) imagining the same sorts of scenarios, but putting different labels on them because of the differing structure of their concepts? I dunno, but I'm tempted towards (2).

Perhaps conceivability and knowledge arguments are different types of arguments because they are different ways of pumping the same intuitions (i.e. the same concepts), but I'm not even sure that this is true.

Tim's and Thony's line of argument is interesting. Speaking as someone sympathetic with Jackson, I'd be tempted to endorse the predicted reply to Tim's argument, contesting (4). Actually, I'd be tempted by a somewhat fuller two-part reply.

(1) There are certain concepts of "red" that Mary has in the black-and-white room, but these are not concepts that require the experience of red for their possession. They might be concepts analyzable as "experiences of the sort caused is normal observers by certain paradigm objects (the objects which normal observers label 'red')" (for her concept "red experience") or "objects of the sort that produce red experiences (i.e. the same sort of experiences as are produced by the paradigm objects) in normal observers under normal conditions" (for her concept "red object"). It's plausible that the "red" concepts that Mary possesses have this sort of nature, but I think it's clear that neither of these concepts requires Mary to have
ever had a red experience, and there's no reason to believe that possession of either concept will allow her to know what a red experience is like.

(2) There are other concepts of "red" that Mary doesn't have in the room, but acquires later on having her first red experience. Such a concept might include the concept R corresponding to her new belief, tomatoes look R. (Of course she already knew they look red, in the above senses.) Mary doesn't have this concept in the room, so she won't be able to use it to figure out what red experiences are like.

I think that (1) alone is a sufficient reply to the argument, so the anti-materialist doesn't need to put special weight on (2). But I think that (2) is plausible all the same. I think it's more or less common sense to say that a blind person can have only an "indirect" concept of red experiences, as opposed to the "direct" concept that is possessed by someone who has actually had the experiences.

Is this question-begging? I hope not. (1) seems more or less like common sense to me, and (2) isn't really going out on a limb. It seems to me that both of these are claims that even many materialists might endorse. One needn't even rely on claims about what Mary could and couldn't figure out in principle; one can just think about the ordinary concepts possessed by a non-omniscient colorblind Mary, and the concepts possessed by an ordinary person who can see colors.

(Incidentally, "begging the question" is a very interesting phenomenon in its own right. Almost any philosophical argument can be accused of begging the question. Say it is a valid argument from premise P to conclusion not-C, arguing against a C-ist. Then it's obviously equally the case that if C is true, then P is false. So clearly on the C-ist position, not-P. So a C-ist can accuse the original arguer of begging the question against them by asserting P. Obviously this can't be quite right. I think the most important distinction between question-begging and non-question-begging arguments is whether the premises have plausible independent support antecedently to considering the conclusion.)

In any case Tim is right that these issues about phenomenal concepts are very important. I try to develop an account of phenomenal concepts of the sort discussed in (2), on which the concept R is partly constituted by the red experiential quality itself, in my "The Content and Epistemology of Phenomenal Belief" (online as the third Princeton talk).

--Dave.
"all the physical facts", so that what we *succeed* in imagining when we try to imagine Mary's situation (or similarly being a bat, or a physical duplicate of me without consciousness) is not what the thought experiment *asks* us to imagine. The materialist assumption that goes with this reply is that *if* we did know all the relevant physical facts, zombies would be inconceivable (and we'd know what it is like to be a bat, and we'd be able to imagine being in Mary's situation and wouldn't conclude that she didn't know what seeing red was like).

Dave's response to this objection appears to be that even though we do not know the specific physical facts needed, we know what *types* of facts that additional knowledge would be--more structure and dynamics. And adding more structure and dynamics would still not give us a reductive explanation. Look at functionalist theories of qualia. They radically fail to give an account of why a red experience has the particular quale that it does, or any quale at all. The inverted spectrum argument shows this, but the shortcomings of functionalist accounts doesn't really require argument--they simply fail to provide any explanation for why there are qualia or for why mental states have the particular qualia that they do. But in the case of functionalism, I think it is pretty easy to see that adding extra functional information could not possibly remedy the situation.

But what about some yet unknown neurophysiological information--could this close the epistemic gap (is this what Mary knows, that we don't)? Well, it is difficult to imagine how such a view could resist positing what Dennett would call "wonder tissue". What non-functional property does the brain possess which makes it conscious?

Though I think that the above considerations help against the materialist response I've been discussing, I think we have to concede that the anti materialist arguments are weaker than they would be if we did in fact have total physical knowledge. The materialist might insist that this concession entails that the anti materialist arguments simply fail. But it seems to me that they should not be too comfortable in resting their own view on a check which, prima facie, they probably cannot cash. One can view the anti materialist thought experiments as providing the prima facie evidence that that check won't be cashed. Perhaps we are left then with the question of where the burden of proof lies--on the materialist or on those who deny materialism.

PS-- On another note, there is a wonderful example of what Dave was talking about with regard to begging the question. In _Philosophical Naturalism_, David Papineau gives an argument for materialism which has the falsity of epiphenomenalism as one of its premises. Jackson, on the other hand, argued against materialism and then uses that to argue for epiphenomenalism.

In response to Brad.

> Dave's response to this objection appears to be that even though we do
> not know the specific physical facts needed, we know what *types* of
> facts that additional knowledge would be--more structure and dynamics.
> And adding more structure and dynamics would still not give us a
> reductive explanation.

What is it that 'structural' means here? Does it mean physical
structure or is it more general? If it is more general, then I'm not
sure why consciousness isn't structured.

One note on the materialist insufficient-info rebuttal. We have been
discussing the rebuttal as if it has the following form.

1. We don't know all the physical facts.
2. You can't have a good conception of Mary (zombies etc.) unless you
   know all the physical facts.
3. Therefore the arguments fail.

I think an important step is being left out of the real argument
though.

3. Everything other than consciousness seems to be explainable in
terms of physics
4. It would be weird if there were only a single phenomena that
   couldn't be explained by physics.
C. Therefore I have better reason for thinking I'm missing something
   than for thinking physics can't explain qualia.

You can, of course, argue whether you actually have better reason for
this. But its important to see that the materialist is comparing
possibilities and judging one to be more plausible.

I'm heading out of town for a couple of days, but a quick reply to
Brad and Josh.

Brad says:

>It seems to me that the most defensible materialist response to the anti
>materialist arguments we've been discussing and reading about is the one
>that the Churchlands and Dennett have given (I think all 3 philosophers
>have given this basic response to Jackson's argument, Nagel's argument,
>and the conceivability of zombies). The response is that we don't know
>"all the physical facts", so that what we *succeed* in imagining when
>we try to imagine Mary's situation (or similarly being a bat, or a
>physical duplicate of me without consciousness) is not what the thought
>experiment *asks* us to imagine. The materialist assumption that goes
>with this reply is that *if* we did know all the relevant physical
>facts, zombies would be inconceivable (and we'd know what it is like to
>be a bat, and we'd be able to imagine being in Mary's situation and
>wouldn't conclude that she didn't know what seeing red was like).

Actually, I don't think this is really Dennett's main line of response
(though I know he says something like this somewherte), and for good
reason. Dennett holds that there is nothing more to qualia than
certain reactive dispositions -- i.e. he holds that qualia are
functionally definable, and/or that any sense in which qualia aren't functional concepts is a sense in which qualia don't exist. In follows from this that on Dennett's view, once we know the appropriate facts about which functions are performed -- the facts about discrimination, integration, higher-order monitoring, control of behavior, and verbal report -- we know everything. So Mary knows everything as soon as she knows that much (the apparent residue is just an illusion), and it's not really coherent to suppose that something could have that functional profile without having qualia (or: any sense of "qualia" in which this is coherent is a sense in which we don't have qualia). So relying on further unknown physical facts is more or less irrelevant to Dennett's position.

I respect this position, as I think it is the most coherent line for a materialist to take. If qualia are to be conceptually entailed by physical facts, it will be by virtue of functional analysis of phenomenal concepts, so what matters are the functions, not the underlying physical facts. And the relevant work in seeing how the entailment can go through is in a sense conceptual (an a priori entailment will be grounded in an a priori (if deep) conceptual analysis, so one doesn't need to wave one's hands to future physical discoveries). Someone like Lewis is also admirably clear about this.

Something like this comes out in what Brad notes:

>But what about some yet unknown neurophysiological information--could this close the epistemic gap (is this what Mary knows, that we don't)?
>Well, it is difficult to imagine how such a view could resist positing what Dennett would call "wonder tissue". What non-functional property does the brain possess which makes it conscious?

The obvious trouble is that the explanatory relevance of neurophysiology is always by virtue of the functions that the neurophysiology performs. So it's not the neurophysiology itself which is crucial to crossing the gap, it's the function, and we're back to the previous sort of position. To suppose that there's some other way that the neurophysiology might be relevant seems to lead to "wonder tissue" -- perhaps conceptual entailment by virtue of intrinsic properties rather than by virtue of functional role? -- and doesn't seem to hold up to a close analysis of what neurophysiology is all about. (Actually, I'm not completely hostile to the idea that there could be some sort of intrinsic entailment, but taken seriously the idea leads straight to "panprotopsychism").

Of course the "we don't know all the physical facts yet" position is very tempting at first blush, but it's not clear to me that this temptation should survive a careful analysis, and whether one can make coherent sense of the hopeful gesture. Entailment by virtue of a functional analysis I can understand, but then the real burden will be carried by analysis, not by the empirical details. And it's not at all clear how any other sort of entailment from physical to phenomenal could work, given the nature of physical concepts (and in any case, the central work will still be done by an analysis, which is conceptual).

Of course a materialist might say that future physical discovery will lead to something utterly unlike the kind of physical knowledge we currently have, and which won't be subject to the same constraints. I think of this as more of a "new physics" than a "new neurophysiology" approach, and certainly not the sort of thing a Churchland or Dennett would be tempted by (it would require the sort of "real humdinger"
than Churchland derides). Even here, I think that close analysis reveals that the options are pretty limited.

All this being said, if someone wants to try and develop the "future physical knowledge" line into some sort of coherent position that evades the obvious objections, I think that would be a very useful service indeed, and I'd be very interested to see it.

Josh writes:

>What is it that `structural' means here? Does it mean physical structure or is it more general? If it is more general, then I'm not sure why consciousness isn't structured.

Well, consciousness certainly has structure but (a) it's structural properties don't seem to exhaust the explananda (which most centrally involve intrinsic non-structural features), and (b) the structure it has doesn't seem to be the right sort to hook into entailment by physical facts. As you suggest here, the structure isn't physical structure. Physical structure seems to involve (a) spatiotemporal relations and (b) relations in certain underlying physical spaces, such as Hilbert spaces and the like. But this sort of structure is clearly conceptually compatible with the absence of consciousness. Even if one could get some sort of structural match-up (e.g. one might suppose that *given* that we have experience, one will have some sort of structural coherence), it's even less clear how one could exhaustively analyze the concept of experience in terms of static physical-structural concepts than in terms of functional concepts.

(But still some interesting conceptual space to play with, so one might like to try!)

>One note on the materialist insufficient-info rebuttal. We have been discussing the rebuttal as if it has the following form.

>1. We don't know all the physical facts.
>2. You can't have a good conception of Mary (zombies etc.) unless you know all the physical facts.
>C. Therefore the arguments fail.

I think an important step is being left out of the real argument though.

>3. Everything other than consciousness seems to be explainable in terms of physics
>4. It would be weird if there were only a single phenomena that couldn't be explained by physics.
>C. Therefore I have better reason for thinking I'm missing something than for thinking physics can't explain qualia.

>You can, of course, argue whether you actually have better reason for this. But it's important to see that the materialist is comparing possibilities and judging one to be more plausible.

Well, of course there are lots of good reasons to be a materialist. That's more or less taken for granted in these discussions, by virtue of the fact that materialism is always regarded as the plausible default position which has to be dislodged, rather than vice versa. But of course the materialist still has to answer counterarguments. And as a counterargument, "maybe we're missing something" is not the strongest. Of course things would be different if one could provide some sort of faint gesture to just what we might be missing (not
asking for an explanation, just for the conceptual room for an explanation).

The anti-materialist can also try to "explain away" the force of (3) by noting that all those "everything else"s that have been explained seem to come down to the explanation of physical structures and of functions, and quite obviously so, whereas experience is prima facie not a matter of explaining either. So one has grounds right there for not giving the inductive argument too much force.

I'm not really trying to convert anyone to anti-materialism here, and there are all sorts of reasons why materialism is an attractive position. But I do think the materialist has to face up to bullets that need to be bitten. As I said, I think the most coherent sort of materialism is the sort that just denies the epistemic intuitions, and is either functional or eliminative about the concept of qualia. Of course what the position gains in coherence it may lose in plausibility. There are other intuitively "more plausible" positions out there at least at first blush, but the question is whether they are philosophically coherent. Hopefully the rest of the course will provide us with some of the tools to examine such positions in some depth.

--Dave.

P.S. Kripke questions and comments are due by Tuesday. In the meantime this discussion is interesting, so please go ahead with any further thoughts in this vicinity or elsewhere re the second set of readings. A number of people still owe comments re this week -- soon, please!

I agree with Jackson but I don't find his examples very compelling. Learning from feeling and learning from being told/reading it are two totally different ways to experience something. They are different in kind and so can't really be compared. It's like telling someone blue feels cold-- you aren't gonna get it unless there's a one to one correspondence between blue and cold or sight categories and olfactory categories in general. If there WERE this correspondence then I would say that it's fair to translate visual information into verbal information in which case I think we WOULD be able to know red2.

The situation with Mary: Again, I think she certainly will learn something when she sees the color TV. But what won't be immediately obvious to her is how the colors correspond to her prior interpretation of all the black and white things, other than there just being differences.

As for the Modality Argument, I am concerned that there are inherent lawlike connections among physical things, and perhaps consciousness is one of these-- that by virtue of having a brain physically identical to mine, a duplicate must be conscious and in the same conscious state.

Oh, not to jump around but back to Fred, does it ruin everything if qualia is unique to each individual? Could it be that what you feel is your
relation to that thing (so it involves both parties to the interaction)?

Also, I can't help but think that Mary would dream in color-- does this count as a qualia?

Subject: Re: Perplexity
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

Here are a few general questions about last week's material. A bit of a regression in the discussion. I'm afraid, but here goes...

In section IV of *Epiphenomenal Qualia* Jackson discusses three arguments that might be presented to show that qualia might have some role in determining brain states. I suppose that his commitment to the impossibility of qualia having any causal efficacy stems from the rest of his argument. If Mary were to know everything about physics, neurophysiology and so forth, but had not had the experience of seeing red, and seeing red had some causal role in determining brain states, then, presumably, she would not have all of the physical knowledge there is to have. There are two points I am not clear about here:

First, I am a bit confused about the phenomenal/psychological division. It seems to me that the phenomenal quality of our experiences does play a causal role in determining behavior. Isn't it the feeling of pleasure that one has when one sees a particularly beautiful sunset that leads one to try to have such experiences? I think this is probably a misunderstanding on my part, but it does seem that when I want to eat a pint of Ben and Jerry's, it is the phenomenal quality of the experience that I find particularly appealing. How does this work if we speak in purely psychological terms?

This also gave me a worry in regard to the zombie argument. We are asked to admit the logical possibility of a world in which there are beings physically and functionally identical to us, but without consciousness. But why would these beings look at sunsets or eat ice cream? I don't know how behavior such as we exhibit is to be explained in terms of only functional states.

Secondly, is it a fact that prior to having a particular kind of sensory experience we are incapable of having experiences of that sort? Could Mary, having read about the experience of seeing red and having examined various MRIs and what not of people as they experience red, devise some sort of device to stimulate her brain in such a way as to have the phenomenal experience of red?

Sorry to be rambling somewhat. A somewhat unrelated question... In the first part of chapter you talk about the form of dualism you are advancing. You suggest that phenomenal properties are basic and that there must be fundamental psychophysical laws relating these phenomenal properties to physical properties. Will these laws relate particular physical (brain) states to certain conscious experiences? Is the point of this that it is a contingent matter what psychophysical laws actually exist?
Nobody needs to worry about "retarding discussion". It's important to be clear about things, and we can easily have numerous discussion topics open at the same time, so it's OK for a discussion of one's week's topics to drag over into the next week. As long as the next week's discussion goes ahead just the same, things should be fine (N.B. everyone should make their initial contribution near the beginning of the week, though, to maximize discussion potential).

Here are some random notes on comments, mostly about qualia, by Erik H. and Anthony.

Erik writes:

>I agree with Jackson but I don't find his examples very compelling.  
>Learning from feeling and learning from being told/reading it are two 
>totally different ways to experience something. They are different in 
>kind and so can't really be compared. It's like telling someone blue

>correspondence between blue and cold or sight categories and olfactory 
>categories in general. If there WERE this correspondence then I would say 
>that it's fair to translate visual information into verbal information in 
>which case I think we WOULDN'T be able to know red2.

Well, for our purposes, Jackson is just trying to argue that the phenomenal facts are not entailed a priori by the physical facts. As far I can tell, you're agreeing with this here (e.g. you agree that Mary gains new knowledge that complete knowledge of physics and physiology can't give her). Of course it's then a further question whether this epistemic gap leads to an ontological gap, and that's one of the things we'll be looking at a lot more deeply.

>The situation with Mary: Again, I think she certainly will learn 
something when she sees the color TV. But what won't be immediately 
obvious to her is how the colors correspond to her prior interpretation of 
all the black and white things, other than there just being differences.

Right, that may not be obvious from introspection. On the other hand, Dennett has a nice passage where he suggests that Mary might be able to figure out which color is which, etc, because she might know that different colors will cause slightly different reactions (e.g. emotions, twinges, flickers, etc) in her which she can identify. So when the scientist's try to trick her by presenting her with a blue banana, she isn't fooled into thinking it's yellow. I think that's entirely possible (it's an empirically open question), though I don't think it impacts the materialism debate.

>As for the Modality Argument, I am concerned that there are inherent 
>lawlike connections among physical things, and perhaps consciousness is 
one of these-- that by virtue of having a brain physically identical to 
>mine, a duplicate must be conscious and in the same conscious state.
Well, even a non-materialist like me thinks there are inherent lawlike connections between brain processes and consciousness. But for materialism to be true there has to be more than a lawlike connection -- witness the distinction between natural supervenience and logical supervenience.

Oh, not to jump around but back to Fred, does it ruin everything if qualia is unique to each individual? Could it be that what you feel is your relation to that thing (so it involves both parties to the interaction)?

Also, I can't help but think that Mary would dream in color-- does this count as a qualia?

I think for the purposes of the issues re materialism, it doesn't matter whether individual's qualia are unique or not. It may well be that our qualia are at least "colored" by individual factors.

Re Mary's dreams, you're right that this could well happen in practice (similarly she could presumably experience color patches when rubbing her eyes, and she'd see reddish qualities in her skin, etc). We just have to abstract away from those things for the purposes of the thought-experiment (or make Mary cortically colorblind, which would presumably do the job).

----------------------------------------------

Anthony writes:

In section IV of *Epiphenomenal Qualia* Jackson discusses three arguments that might be presented to show that qualia might have some role in determining brain states. I suppose that his commitment to the impossibility of qualia having any causal efficacy stems from the rest of his argument. If Mary were to know everything about physics, neurophysiology and so forth, but had not had the experience of seeing red, and seeing red had some causal role in determining brain states, then, presumably, she would not have all of the physical knowledge there is to have. There are two points I am not clear about here:

Well, I think Jackson is assuming that physics is causally closed. It's an interesting question what to say if interactionist dualism is true, i.e. if qualia are nonphysical and play a causal role with respect to a non-causally-closed physics. Maybe here one could still make a case that Mary could know (at least in principle) the physical facts about a system; she just wouldn't know about the nonphysical causes of some of the physical events.

Anyway, if interactionist dualism is true, materialism is already false, so for the purposes of the argument one can take it as a concession to the materialist to rule that view out. Of course it then becomes a further question whether, upon rejecting materialism, one should accept epiphenomenalism or interactionism. (Actually, I think of the choice as a three-way disjunction between epiphenomenalism, interactionism, and "panprotopsychism").

First, I am a bit confused about the phenomenal/ psychological division. It seems to me that the phenomenal quality of our experiences does play a causal role in determining behavior. Isn't it the feeling of pleasure that one has when one sees a particularly beautiful sunset that leads one to try to have such experiences? I think this is probably a misunderstanding on my part, but it does seem that when I want to eat a pint of Ben and Jerry's, it is the phenomenal quality of the experience that I find particularly appealing. How does this work if we speak in purely
psychological terms?

To say that phenomenal concepts aren't functional concepts (or even to say that phenomenal states aren't functional states) doesn't automatically imply that phenomenal states don't play a causal role. It merely says, in effect, that they aren't *defined* by their causal roles. A concept such as "poison" is arguably a functional concept: to be a poison is roughly to be the sort of thing that has certain sickening effects on certain biological systems. So there's nothing more to the idea of a poison than the idea of something which plays a certain functional role. (Once Mary knows that something is the sort of thing that plays the role, she knows it's poison; one can't conceive of something being the sort of thing that plays the role without it being poison; etc, etc.) That's how it is arguably for very many concepts. But (according to the epistemic arguments) not so for qualia. Maybe these play a causal role, but that causal role doesn't define them.

The point can be put somewhat controversially by saying that qualia are intrinsic properties rather than functional properties. Functional properties are defined by their causal role. Intrinsic properties are defined by their intrinsic nature. Of course intrinsic properties can still play a causal role. Indeed, presumably any causal role will ultimately be played by some intrinsic state or property. E.g. the "poison" role in any given case will be played by such-and-such a chemical structure. It's plausible that the chemical properties in question are intrinsic properties. (N.B. There is a case that these may be functional properties at a lower-level of analysis, but I leave that aside for now.)

This also gave me a worry in regard to the zombie argument. We are asked to admit the logical possibility of a world in which there are beings physically and functionally identical to us, but without consciousness. But why would these beings look at sunsets or eat ice cream? I don't know how behavior such as we exhibit is to be explained in terms of only functional states.

Well, the first thing to note is that it's not obvious that the same strictures of "explanation" hold in logically possible worlds as hold in the actual world. E.g. there are presumably possible worlds where monkeys coincidentally type "Hamlet", where the world explodes for no reason at all, etc. But anyway: presuming that actual physics is causally closed, I suppose the zombie's behavior might be explained simply in terms of its physical states. When it eats ice creams, certain receptors are triggered which leads to a state which it "likes", i.e. which leads it to attempt to return to the state again. It's not obvious that there's a problem in principle with explaining the behavioral part in physical terms. Of course one may find it counterintuitive that qualia don't play a causal role in our actual behavior, in which case there may be at least some reason for the nonmaterialist to consider alternatives on which they play such a role (such as interactionism or panprotopsychism).

Secondly, is it a fact that prior to having a particular kind of sensory experience we are incapable of having experiences of that sort? Could Mary, having read about the experience of seeing red and having examined various MRIs and what not of people as they experience red, devise some sort of device to stimulate her brain in such a way as to have the phenomenal experience of red?

It's very likely that she could. But I don't think this affects the central dialectic, which concerns what Mary can know merely by virtue
of knowing the physical facts and reasoning about them. Direct brain stimulation in the production of experience is obviously a further "empirical" sort of knowledge. Crucially, the fact that Mary can do this in no way suggests that the phenomenal facts are entailed a priori by the physical facts. At best this relies on some sort of contingent a posteriori connection between them, the sort that even a non-materialist might embrace. (E.g., if there are contingent psychophysical laws connecting brain states to experiences, this method ought to work.)

>Sorry to be rambling somewhat. A somewhat unrelated question... In the first part of chapter you talk about the form of dualism you are advancing. You suggest that phenomenal properties are basic and that there must be fundamental psychophysical laws relating these phenomenal properties to physical properties. Will these laws relate particular physical (brain) states to certain conscious experiences? Is the point of this that it is a contingent matter what psychophysical laws actually exist?

Well, I think there will be psychophysical laws relating brain states to experiences; e.g., it will be a law that when you have such-and-such a brain state, you have an experience of red. But those laws probably won't be fundamental. It's unlikely that universal laws of nature will make reference to brains, etc. So one would expect there to be some much simpler underlying principles (e.g. principles linking information and experience?), from which the specific high-level laws are consequences. I take it that their nature is very much an open question, though.

Hello All-
Like Anthony, I hope I am not holding discussion back here...
In 3.3 of TCM, Chalmers criticizes attempts at reductive explanations of consciousness. In his critique of Baars cognitive model he argues, "But there is no reductive explanation of *experience* to be found here. The question of why these processes should give rise to experience is simply not addressed."(112) I take it that this is because the explanation of lower-level facts does not (and cannot) explain the higher-level phenomena of consciousness.

I am curious as to how this is different from the problem of reductive explanation in the case of the football game or the cocktail party. It does not seem that in giving a complete description of the lower level facts of a football game, I am really explaining how the lower level facts give rise to a football game. What is necessary for a complete explanation is not only a description of the lower level facts but also a description of the higher level phenomena (in terms of plays, players, touchdowns, etc.)

>From this, we may propose that what is necessary to supplement a cognitive or neurobiological model is a complete description of the higher level phenomena in question, specifically, consciousness. I assume that a
description of this sort would rely heavily on psychology. It seems that combining a reliable cognitive or neurobiological model with a comprehensive psychology should be able to play the same sort of explanatory role as describing a football game in terms of both the lower and higher level facts.

It is tempting to conclude that this sort of explanation of consciousness, in terms of lower level and higher level facts is satisfactory. However, objections to explanations of this type are given by Chalmers in this chapter. To take just one, we can conceive of something physically identical to ourselves not having consciousness (a zombie). But can we conceive of something physically identical to a football game not being a football game? Although it is conceivable that such a thing not be *called* a football game, it is safe to say that the higher level phenomena of a football game will be in place once all of the lower level facts are fixed.

My question is one which arises from Chalmers objection to cognitive models. Chalmers says, "The question of why these processes should give rise to experience is simply not addressed."(112) I am curious as to why and how these processes *should* give rise to experience, but as I have not read all of TCM, I take it the answer will surface at some point in my reading.

-Rachael

Some thoughts in responses to Rachael's and Erik L's notes on reductive explanation:

Rachael writes:

> does not seem that in giving a complete description of the lower level
> facts of a football game, I am really explaining how the lower level facts
> give rise to a football game. What is necessary for a complete
> explanation is not only a description of the lower level facts but also a
> description of the higher level phenomena (in terms of plays, players,
> touchowns, etc.)

Well, giving the low-level facts alone will never be enough for a reductive explanation, since you have to connect them to the high-level story. That's the part which is played by explication of the high-level concepts (e.g. as functional concepts), and by showing how the low-level properties can entail the high-level properties.

For functional concepts such as "poison", "life", and the like, this is fairly straightforward. Things are more complex for football games and cocktail parties, mostly because a complete explanation of these things centrally involves various *intentional* properties, characterizing people's attitudes, beliefs, desires, etc. And it's not at all obvious how these intentional properties are to be reductively explained. But leaving aside these worries stemming from
the "mental" aspects of the games and parties, it seems pretty clear that the residual high-level phenomena in question (the movement of people and balls and drinks, the production of utterances, etc) can be accounted for in physical terms. As before, it may not be the most illuminating explanation of all time, but we'll remove any ontological mystery.

The intentional aspects pose special worries, but here of course we're back to the mind-body problem itself. Personally I am hopeful that the intentional can be explained in terms of the functional and the phenomenal, but I don't say this is completely obvious. (N.B. The book is officially neutral about whether intentionality can be functionally explained, but I was probably more sympathetic to the idea then than I am now. I now tend to think that phenomenology may be central to a full understanding of intentionality.)

> From this, we may propose that what is necessary to supplement a cognitive
> or neurobiological model is a complete description of the higher level

> and higher level facts.

Well, it's not just a matter of giving the low-level facts and the high-level facts at the same time. One needs to have the right sort of relationship of entailment between them. And as you point out below, it's this epistemic relationship that seems to be missing in the case of consciousness.

> My question is one which arises from Chalmers objection to cognitive
> models. Chalmers says, "The question of why these processes should give
> rise to experience is simply not addressed." (112) I am curious as to why
> and how these processes *should* give rise to experience, but as I have
> not read all of TCM, I take it the answer will surface at some point in my
> reading.

I'm not certain what the question is here. If it's about why and how the processes give rise to experience on my view, it's because there are fundamental psychophysical laws linking the physical and the phenomenal. At some point it's like "why do apples fall? Because of the law of gravity". The apple and the earth stand in the right sort of relation for the law to apply; and the brain is presumably in the right sort of state for psychophysical laws to apply. As to why the law exists, at some point one has to take that as a brute fact, just as in physics. Of course one wants the residual "brute" part to be as simple as possible.

Actually, we won't be talking much about these issues in the rest of the seminar, as we'll be focusing more on modality than on mind, but I'm sure some of these things will come up.

-------------

Erik writes:

> "not very
> "illuminating" is perplexing in it's own right. What makes something
> "illuminating"? That's a strange notion once you've conceded that the
> process referred to is nothing over and above physics. I guess what I'm
> asking is, what is the role--ontologically, functionally, explanatorily or
Re "illuminating", presumably this is an epistemic notion, and (unlike "a priori") not an idealized one, so relative to human psychology. So A can a priori entail B, but the entailment may not be terribly illuminating to us, because we're not in a position to easily grasp the deep structure in what is entailed, or something like that, at least not without a lot of further work (and that further work is what one might call "high-level explanation"). Whereas perhaps a more cognitively skilled race of beings might see these things much more easily.

Re the role of concepts: If the physical facts entail the B facts a priori, then one who merely possesses the B concepts ought to be able to figure out the B facts from the A facts. If this person can do this merely in virtue of concept possession (plus reasoning) it seems clear that the concept has to be of the right sort to enable the entailment. In particular, there ought to be some sort of analysis of the concept's conditions of application so we can see why they are satisfied automatically whenever the A facts are satisfied.

The main point is that a priori entailment is an epistemic relation, and epistemic relations seem to be grounded in relations between concepts. The question of how these concepts (in our mind) correspond to properties (in the world) and what this means about the bridge between epistemology and ontology is one we'll be thinking about.

What's a concept? That's a hard one. We've been more or less helping ourselves to the notion at an intuitive level, requiring only that there is a concept corresponding to (most) words, that concepts have conditions of application, and that these conditions of application when composed yield the conditions of application of corresponding sentences. Or something like that. The underlying metaphysics of concepts is far from clear (though maybe the 2-D framework helps a little in clarifying their structure). But I hope even the intuitive level, thinking of concepts in terms of their pattern of application to possibilities, is helpful for our purposes.

From: David Chalmers <chalmers@LING.UCSC.EDU>
Subject: Re: Conceivability and Knowledge arguments
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

Sorry to the slow reply to Tim's very interesting message about conceivability.

First, Tim suggests that the knowledge argument may be a conceivability argument, since one has to conceive of Mary in her lab coat, etc. Personally, I think this act of conceiving is pretty inessential (certainly I make not the slightest effort to really conceive of Mary herself when thinking about this). What's more central is the claim that conceivability or no, it's extremely plausible that someone with full physical knowledge of the brain is
not thereby in a position to know what it's like to see red, and will learn something new when they see red for the first time. I don't think one needs to engage in detailed acts of conceiving to find this plausible.

The zombie case, on the other hand, at least involves a token attempt at conceiving the details of the case. I try to conceive of someone functioning just like me, behaving like me, with mechanisms of perceptual discrimination, attention and integration, higher-order monitoring, control of behavior, verbal report, etc, but no consciousness. Of course one's attention to detail is highly imperfect here, but as before there may be reasons to believe that the details can't make the crucial difference.

>But in fact, I doubt that we do anything *like* this in either case.
>Conceivability does *not* seem to involve the imagination - at least that's what it seems like to me in *these* cases. It's *not* like trying to work out in your head whether you can fit a ball of diameter two inches inside a triangle of sides 3, 4 and 4 inches which has an outer perimeter of 1/2 an inch thick.

I'm not surely exactly why you say this. Certainly there are some senses in which conceivability needn't involve imagination -- e.g. if one acquaints imagination with visual or sensory imagery. But it seems plausible to me that conceivability involves *something like* imagination -- e.g. a sort of "conceptual imagination", involving considering a lot of details about a case, and seeing if they are coherent and composable.

>So what is going on in these cases? Well, it seems to me that in both cases you have the following intuitions or you don't.
>
>(a) Necessarily, all physical properties are functional or structural properties, and phenomenal properties aren't functional/structural properties; OR, the very similar intuition: (b) Nec., all physical facts (or, perhaps, propositions) are exclusively composed out of functional /structural concepts, and phenomenal concepts are not structural/functional concepts.
>
>(a) is at work in the zombie cases, (b) is at work in the knowledge cases.
>If there is a one-one correspondence between facts and properties as is commonly supposed in setting these cases up, then it is hard to see why one should have (a) and not (b), or vice-versa. (Caveat: Of course, some do reject the claim that if you've got two facts you've also got two properties, but then you can accept that Mary does learn something new without rejecting physicalism.)

Hmm, this is interesting. It may well be the case that a tacit acceptance of something like your principles (a) and (b) underlies our acceptance of the conceivability and knowledge intuitions. But I think it would at least be highly tacit. Plenty of people would be unsure whether to accept the abstract principle, but quite confident about the conceivability or knowledge intuition. And it's certainly the case that a good number of people accept the Mary intuition while being uncertain about the zombie intuition, at least in its full-blown form. So I think there's reason to believe that something is going on in our evaluation of the conceivability and knowledge intuition that is at least somewhat different from each other and somewhat different from our evaluation of the abstract principles, though it may be the case that the three are a priori connectable and that someone who...
Incidentally I don't quite accept your diagnosis of (a) going with zombie intuitions and (b) with knowledge intuitions. It seems to me that (b) is weaker than (a), as it's a claim about concepts, not properties. The type-B materialist who holds that there is an epistemic gap but not an ontological gap may well accept (b) but not (a), for example. But this type-B materialist may well still have the zombie intuition, i.e. will find zombies conceivable; they'll just deny that conceivability implies possibility. So that suggests that (b), not (a), may underlie the zombie intuition, if anything does.

(Of course, one may call the "zombie intuition" the claim that zombies are metaphysically possible; then accepting the intuition may well go along with accepting (a). But then the zombie intuition isn't the pure epistemic intuition. I prefer to reserve the term "intuition" for the epistemic part, as the residual part is a matter of straight philosophy, not really intuition.)

Another slight difference between zombie and knowledge intuitions. Take someone who holds the epistemic theory of vagueness, according to which there is a sharp line in the application of vague predicates, although we can't know where that line is. So e.g. someone 5'10" is either tall or not tall (abstracting away from issues about context), but we can't know which through any amount of reasoning. Such a theorist will hold that complete physical knowledge won't enable someone (e.g. Mary) to know whether the person is tall. But it's not clear that such a person will hold that a 5'10" tall person and a 5'10" short person are both conceivable in the way that me and my zombie twin are both conceivable. Maybe they are "negatively conceivable" in that we can't rule them out a priori, but they don't seem to be "positively conceivable" in the sense that we can clearly and distinctly conceive of both scenarios. Rather there seems to be just one scenario that we conceive of, such that we can interpret it in two different ways.

So it seems that zombie intuitions involve a slightly stronger claim than knowledge intuitions. The former requires "positive conceivability", the latter mere "negative conceivability" or absence of contradiction. So maybe that is more evidence that the two are slightly distinct. The distinction between these two sorts of conceivability is something we'll be discussing quite a bit in a few weeks.

>But imagination does seem to play some role in conceivability. Consider
>the following problems: (1) is logically it possible to be an agent
>without, being a perceiver (or vice-versa)? (2) Is it possible for one
>subject of experience to have two distinct (spatially separated) bodies at
>the same time, so that, e.g., one of my bodies might be in Tucson, and the
>other one in Texas at the same time, and they are simultaneously
>conscious? Well, people seem to have very different intuitions about both
>of these cases? Why? Are they: (1) actually imagining different scenarios?
or (2) imagining the same sorts of scenarios, but putting different labels
>on them because of the differing structure of their concepts? I dunno, but
>I'm tempted towards (2).

I'm tempted to agree with you here. It seems that at least in (1), the scenario one conceives of is pretty clear; the question is then how to describe and interpret it. One positively conceives a being who can't see/hear/etc, but who seems to move around, etc, and one considers whether that being is an agent. So we have a core conceived scenario and an issue of how to describe it. A little like the
epistemic vagueness case, actually, in that there's just one positively conceivable scenario in the vicinity. Contrast the zombie case, where there seem to be two (at least to some people -- at least here the issue is about whether there is one or two, rather than about how to interpret the obvious one). Maybe something similar goes in (2).

>Perhaps conceivability and knowledge arguments are different types of arguments because they are different ways of pumping the same intuitions (i.e. the same concepts), but I'm not even sure that this is true.

I tend to think they are ways of pumping similar intuitions, though perhaps not exactly the same intuitions. They certainly play separable roles as argument and a rhetorical devices, though of course that's often the case with "intuition pumps". As often in philosophy, there can be two closely related ways to reach the same conclusion,

I agree, though, that the key underlying point in both cases concerns the gap between our concepts. And the central questions are then (a) is there an a priori gap between the concepts and (b) if som does it lead to a gap in properties. The type-A materialist denies the gap in concepts. The type-B materialist accepts the gap in concepts but denies that it leads to a gap in properties. This type-B materialist will typically lean on a posteriori necessities ("water" and "H2O" are arguably different concepts picking out the same properties) and on Kripke's discussion thereof. Which leads nicely into this week's topic.

From: Anthony S Gillies <agillies@U.ARIZONA.EDU>
Subject:      twins and such
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

All,

Here's a puzzle I have. My trouble is in imagining my zombie twin.

(1) I think it's pretty clear that for purposes of the materialism debate it won't do for me to imagine (say) your zombie twin. You might *be* a zombie for all I know. Since I don't have any immediate access to your subjective states, a case where you don't consciousness isn't any different (from my vantage point) than a case where you do. So I have to imagine my own zombie twin.

(2) OK, now how do I do that? I imagine zombie twin earth. The problem is that there are lots of (zombie) folks there. How do I pick out my zombie twin? Since it's crucial that I pick out *my* zombie twin, I figure that I tag him *Zombie Thony*, and use the name to identify him. Imagining my zombie twin comes down to evaluating the truth of

(*) Necessarily, Thony is conscious

Materialism is false if (*) is false according to the 1-intensions.

(3) The trouble with this is (as I think you say in TCM) consciousness is at the core of our epistemic universe--we can't help but think we're conscious. But then the 1-intension of 'Thony' (when thought by me) will
include 'is conscious'. And so (*) is true after all.

Apparently something has gone wrong: my zombie twin *seems* possible, but in fact isn't when I try to imagine him. Conceivability and possibility seem to come apart. But I don't think things are really that simple. My guess is that one might be tempted to say that what I need to imagine is not really *my twin*, just any old thing that is physically identical to me. I'm probably missing something in this would-be reply. I thought that what's at stake is the truth of modal statements like (*), and imagining something physically identical to me doesn't decide that.

Thony

"Curious green ideas sleep furiously."

Thony

I think the false move (if there is one here) is the first move. Why won't it do to imagine somebody else's zombie twin? As far as I can see, it will do. I take it that the argument from zombiehood is meant to show that you can (logically) have all the functional/physical properties that we have, without having conscious experience. The reason why the zombie arguments ask you to imagine your own zombie, is that they hope that in this way they *guarentee* that you've got the sort of physical/functional properties on which consciousness naturally supervenes (since one supposes that one is oneself consciousness).

I read Thony's worry re imaging his zombie twin in the following way: if consciousness is one of my essential properties, then I don't have a zombie twin - there is no world in which there I exist and am not conscious (or, perhaps, capable of having conscious experience). I think Thony reads Dave is endorsing this premise or something like it. Whether or not Dave does, it's not an unreasonable assumption.

Suppose that we grant this point. I take is that the zombie argument can make do with *qualitative* identity rather than *numerical* identity. Suppose there is an organism just like you, twin Thony. Twin Thony is physically and functionally identical to you. That is, for every physical property that you instantiate, he also instantiates, and vice-versa. But we can conceive that twin Thony is not conscious, and if conceivability=logical possibility, consciousness does not (logically) supervene on the physical.

As I say, I think that you can probably run the argument without getting into worries about trans-world identity and individuation (which is good!): what matters is that isolate the sort of physical facts that the reductive materialist insists that consciousness is logically supervenient (and then you go to work with the zombie intuitions. . Talking about *My* zombie twin is just used (perhaps wrongly) as a
convenient way to isolate those facts.

Tim

I'm not sure that the first step of

Some further thoughts on Thony and Tim's comments re "twins and such"

I admit it is puzzling to imagine imagining a physical replica of yourself without conscious experience. The gut feeling is something like, What would it mean to imagine MYSELF without my consciousness? I suppose in so far as one is trying to imagine one's twin "from within", there is no way to get the physical-replica-without-consciousness conception off the ground. So I suppose the conception of a zombie-twin or a physical replica of oneself sans consciousness when you want to construct it from the first-person point of view—that is the very perspective that is supposed to be excluded. So I suppose the job is to determine whether this perspective—the "from within" perspective—can be detached from the rest of the picture in imagining a replica of oneself. I can imagine myself without an arm—all else being equal. And so on for all sorts of physical alterations. So the problem is not one of simply subtracting physical constituents—we can do that. Personality is trickier. Can one imagine ONESELF without certain memories, or dispositions, etc? Now I suppose that's a question of personal identity, and I think it is more puzzling than the case at hand. That is because, imagining yourself without conscious experience is tantamount to imagining yourself qua physical THING, or, imagining yourself as someone else would see you—from the third-person so to speak. And what is so tricky about that? We do it all the time, or can do it all the time, as even a moments reflection should convince one of. I personally do not have any trouble imagining myself qua physical thing—looking exactly the same, moving the same, behaving and reacting the same—only without any conscious experience whatever. Now I can't imagine ME in any strong sense this way, since I think that part of my personal identity is my consciousness, or that my consciousness is a precondition of having a personal identity, perhaps. So that is not a possiblity. But, I think it is also not at issue here. What is at issue is whether we might conceive of ourselves qua physical thing, identical in all physical (and behavioral) aspects but lacking conscious experience. Would this be you in any strong sense? No. But would it be you in precisely the sense required—having the physical properties en mass but without conscious experience.

So, replying to Thony's point directly, I think he is conflating questions of personal identity with questions of purely physical conceivabley, where the latter is less troublesome.

Erik L.
we have, without having conscious experience. The reason why the zombie arguments ask you to imagine your own zombie, is that they hope that in this way they *guarantee* that you've got the sort of physical/functional properties on which consciousness naturally supervenes (since one supposes that one is oneself consciousness).

I read Thony's worry re imaging his zombie twin in the following way: if consciousness is one of my essential properties, then I don't have a zombie twin - there is no world in which there I exist and am not conscious (or, perhaps, capable of having conscious experience). I think Thony reads Dave is endorsing this premise or something like it. Whether or not Dave does, it's not an unreasonable assumption.

Suppose that we grant this point. I take is that the zombie argument can make do with *qualitative* identity rather than *numerical* identity. Suppose there is an organism just like you, twin Thony. Twin Thony is physically and functionally identical to you. That is, for every physical property that you instantiate, he also instantiates, and vice-versa. But we can conceive that twin Thony is not conscious, and if conceivability=logical possibility, consciousness does not (logically) supervene on the physical.

As I say, I think that you can probably run the argument without getting into worries about trans-world identity and individuation (which is good!): what matters is that isolate the sort of physical facts that the reductive materialist insists that consciousness is logically supervenient (and then you go to work with the zombie intuitions. . Talking about *My* zombie twin is just used (perhaps wrongly) as a convenient way to isolate those facts.

Apparently something has gone wrong: my zombie twin *seems* possible, but in fact isn't when I try to imagine him. Conceivability and possibility seem to come apart. But I don't think things are really that simple. My guess is that one might be tempted to say that what I need to imagine is not really *my twin*, just any old thing that is physically identical to me. I'm probably missing something in this would-be reply. I thought that what's at stake is the truth of modal statements like (*), and imagining something physically identical to me doesn't decide that.

I'm sympathetic with what Tim and Erik say in reply to Thony's question, and I don't have a whole lot to add to their reply on the central point. But there are a number of very interesting issues in the vicinity, some of which tie in with current and forthcoming issues on Kripke and 2-D semantics, so here are a few thoughts.

In the conceivability argument, I don't think too much turns on whether the conceived being is one's own zombie twin. It can just as well be the zombie twin of any conscious being. Of course in one's own case there is the advantage that one is certain the actual being in question is conscious. But on the plausible assumption that other beings are conscious, the argument will work just as well for them.

Thony suggests a problem: imagining someone else to be a zombie won't be any different from imagining them to be conscious, because both will seem the same from my point of view. I think I disagree with this. There seem to be two pretty distinct epistemic possibilities that I can entertain re that being: that they are conscious or that they are not. It's true that both would "look" the same to me, but this just means that we not should individuate epistemic possibilities according to the way they look, or the way they seem, or according to the evidence one would have. I take it that to suppose that conceivability or epistemic possibility is determined by appearances or evidence involves a sort of verificationism; and I take it that verificationism is usually taken to be implausible precisely because...
there seem to be distinct epistemic possibilities that would yield exactly the same evidence. E.g., empirically equivalent theories in science, or possibilities involving entities that leave no trace, or indeed possibilities involving consciousness.

So I think doing the thought-experiment on others is OK. Still, I suppose one doesn't want to be *forced* to do the thought-experiment only for others, as if one did, then presumably someone could evade the argument by accepting solipsism (i.e. denying that any other beings are conscious), and the conclusion of the argument would be "materialism is false or solipsism is true". Solipsism isn't exactly attractive, but this would be messy, so it would be best if the argument works for one's own twin.

Thony raises the worry: if it has to be *me* that is a zombie, maybe this can't happen, because consciousness may be part of the primary intension of our concept of ourselves, or some such. Here I would endorse what Tim and Erik say in reply. The epistemic argument against materialism merely involves the claim that "P -> Q" is not a priori, or that P-and-not-Q is conceivable, where P is the complete physical truth about the world and Q is a phenomenal truth. Nothing here requires that the zombie world contains me, or that the zombie twin be me; it merely has to be a physical duplicate of our world, and he merely has to be a physical duplicate of me. And here, Thony's worry doesn't arise.

Still, it's an interesting question: could my zombie twin be me? Speaking for myself, I don't usually think of my zombie twin as being me; I think of him perhaps as some sort of close relative. But could I be a zombie? Matters depend here on whether one is thinking of standard "subjunctive possibility" (secondary-intension possibility) or "epistemic possibility" (primary-intension possibility).

In the subjunctive case, we're considering the standard sort of possibility that Kripke and others discuss. Here, I can imagine someone arguing that it is essential to sentient human beings (like me) that they be at least potentially sentient, so that the hypothesis that I could be a zombie is like the hypothesis (discussed by Kripke) that I could have descended from a different sperm and egg, etc. If so, the 2-intension of "me" and "DC", etc, can only pick out potentially conscious beings, and it's (secondarily) impossible that I be a zombie; counterfactual possibilities concerning a zombie should not be described as possibilities concerning me. (I say "potentially conscious" as it's quite possible that I be temporarily unconscious, and perhaps that I died before becoming conscious.) I'm not sure whether this essentialist claim is right, but it has a certain possibility.

The epistemic possibility (primary intension) case is closer to what matters in the epistemic arguments, though, since we're dealing with a priori connections, and in such epistemic matters, primary intensions are central. Is it epistemically possible that I'm a zombie? By this, we're in effect asking (modulo a few small frills): is there a conceivable scenario satisfying the primary intension of "I am a zombie"?

(Note that this isn't quite the standard sense of "epistemic possibility", where P is epistemically possible if it's true for all I know. Obviously, I know I'm not a zombie, so it isn't epistemically possible in that sense. Rather, I'm invoking the Kripke-esque sense in which it's epistemically possible that water is XYZ, even though we know that it isn't, and so on. We could call this "broad epistemic
possibility" -- it is broadly epistemically possible that P when P isn't ruled out a priori. If you don't like calling this "epistemic possibility", just think of it as "1-possibility" instead, though I think it is epistemic in some deep sense. We'll come back to this.)

On my view, it is 1-possible that I'm a zombie. There is a centered world centered on a zombie, and the primary intension of my term "I" picks out the zombie in that world, and the primary intension of my term "consciousness" doesn't apply to that being. Thony may not like this, on the grounds that the primary intensions of our conceptions of ourselves include consciousness. But on my view, that isn't quite right: the primary intension of my "I" concept just picks out the person at the center of a centered world. Of course I very strongly believe (even know) that I am conscious, but this isn't part of the semantics of "I". Similarly (but more so) for concepts such as "DC", "Thony", etc. So in a centered world centered on an unconscious being, the primary intension of "I" picks out that being.

One can come at this slightly differently, by forgetting the 2-D details for a moment, and asking directly whether it is broadly epistemically possible that I am a zombie, i.e. whether it is a priori that I am not a zombie, i.e. whether it is a priori that I am conscious. On my view, this isn't a priori. This is something we know, and know directly and in some sense "non-empirically", but we don't know it through reason alone; we know it in virtue of having certain experiences. I can't know that I am conscious independently of experience, so it isn't a priori. So I can still consider the broad epistemic possibility that I am not conscious (even though it is a possibility easily ruled out by things that I know), and I can use my concepts to describe that epistemic possibility, etc. The broad epistemic possibility in question (in effect, the hypothesis that my world is centered on a zombie) is describable as an instance of the epistemic possibility that I am a zombie, an instance of the possibility that I am not conscious, etc. So this is a 1-possibility, and is a broad epistemic possibility, even though I know it doesn't obtain, so it isn't an epistemic possibility in the standard sense.

So, on my view, it probably isn't 2-possible that I'm a zombie, but it is 1-possible that I'm a zombie. None of this matters much for the argument against materialism (for which the semantics of "I" is mostly tangential), but it's independently interesting, especially for the illustration it gives of the way 2-D semantics and modality works.Obviously this hooks up nicely with the Kripke discussion, and some of it turns out to be important later. What I say above certainly isn't trivial or obvious or uncontestable, so feel free to fire away with questions and reactions.

--Dave.

P.S. A few of these issues come up very briefly around p. 133 of the book (middle paragraph), where I suggest that (in effect to avoid the technicalities above which arise from considering epistemic possibilities in which I'm not conscious), it's easiest to consider conceivable scenarios in which I'm at the center, conscious, and in which some other people are zombies. So I suppose my official version runs with third-person zombies (and so officially has the solipsism loophole). In principle, I think things work even with zombies at the center, though I don't talk about that much in the book. The above gets at the beginning of how this works, though there are some more subtleties I haven't mentioned yet about whether concepts are required at the center of centered worlds. That turns out to be important for
various purposes, too.

P.P.S. More on the Kripke messages shortly. It would be good to get something from everybody soon (I have Thony's and Tim's contributions posted a couple of weeks ago already). I also look forward to getting a detailed summary of Tuesday's discussion (the more detailed the better).
Regarding Kripke's arguments for a priori contingencies and a posteriori necessities, I am assuming that the basis for the arguments is the fact that a prioricity is an epistemic notion while necessity is a metaphysical notion. Given this, there is the possibility that necessary truths be known only a posteriori and contingent truths (if true) can be known a priori. Identity statements such as Hesperus is Phosphorus are supposed to be examples of the former because, while the identity (which is between rigid designators?) is necessarily true, we could only find this out through empirical means. This sounds plausible, but I have a problem with Kripke's example of an a priori contingent truth...

He argues that the length of S at time 0 is used to fix the referent of the rigid designator 'one metre' by way of definition, which is not to say that the meaning of 'one metre' is 'the length of S at time 0'; so, even though we can know that 'the length of S at time 0 is one metre' a priori (because that's how we defined it?) this is a contingent truth because the length of S at time 0 could have been different (if it were heated or whatever). Now, 'one metre' is a rigid designator, while 'the length of S at time 0' is not; so the meaning of 'one meter' is not the same as the meaning of 'the length of S at time 0'. But, given this, what exactly is the meaning of 'one metre' if, as Kripke stipulates, the length of S at time 0 could be the only standard being used? In other words, given that there is no standard for 'one metre' besides 'the length of S at time 0' how can 'one metre' be a rigid designator? How could someone reapply the term without reference to the description which is only supposed to fix its reference, not provide its meaning? I don't see why this isn't a problem. If someone can tell me where I've gone wrong in describing Kripke's account, such that I'm asking this question, I'd appreciate it.

Kripke's example of an a priori contingent truth...
He argues that the length of S at time 0 is used to fix the referent of 'one metre' by way of definition, which is not to say that the MEANING of 'one metre' is 'the length of S at time 0'; so, even though we can know that 'the length of S at time 0 is one metre' a priori (because that's how we defined it?) this is a contingent truth because the length of S at time 0 could have been different (if it were heated or whatever). Now, 'one metre' is a rigid designator, while 'the length of S at time 0' is not; so the meaning of 'one meter' is not the same as the meaning of 'the length of S at time 0'. But, given this, what exactly is the meaning of 'one metre' if, as Kripke stipulates, the length of S at time 0 could be the only standard being used? In other words, given that there is no standard for 'one metre' besides 'the length of S at time 0' how can 'one metre' be a rigid designator? How could someone reapply the term without reference to the description which is only supposed to fix its reference, not provide its meaning? I don't see why this isn't a problem. If someone can tell me where I've gone wrong in describing Kripke's account, such that I'm asking this question, I'd appreciate it.

The crucial part of Kripke's account is that when a term is a rigid designator, once one has fixed its reference to a particular object (e.g. "Hesperus" refers to the planet Venus) or to a particular property (e.g. "hot" refers to a certain energy property) or to a certain length (e.g. "one meter" refers to length L, about 39.37 inches), one can then consider modal questions about what the term picks out in alternative possible worlds just by considering what is "that object" or "that property" or "that length" in other possible worlds, and by forgetting about the factors that were involved in fixing reference. So "Hesperus" picks out Venus in all worlds, irrespective of whether Venus is the evening star there. Similarly, one meter picks out length L in all worlds, irrespective whether the stick in Paris has that length there. The reference-fixer serves as a sort of bootstrap, or as a ladder we can kick away once it has done the job of giving the reference.

The reference of "one meter" is fixed by looking at what is the length of stick S, but once we have accepted that this is a given length L, then we can consider what is length L in other worlds quite independently of what is the length of S there. And according to Kripke, the modal application conditions of "one meter" go with the former (length L), not with the latter (the length of S). As Kripke notes, it seems that we can quite coherently consider counterfactual possibilities in which the length of stick S was less that one meter (just say it broke, or that it had never grown that long in the first place); so the application of "one meter" to these possibilities can't merely involve the length of stick S.

(Incidentally, if you accept that it's necessary that Hesperus is Venus, then presumably you don't think it's necessary that Hesperus is the evening star (as it certainly isn't necessary that Venus is the evening star). But arguably it's a priori that Hesperus is the evening star (by analogy with the meter case). So you'll then be committed to something like a contingent a priori statement there, i.e. "Hesperus is the evening star".)

(One difference between the meter case and the Hesperus case is that one might argue that there are deeper problems with reidentifying lengths across worlds than with reidentifying planets across worlds. What counts as length L in a given world? In reply, I think Kripke would make his suggestion here that we can "stipulate" lengths in our possibilities (e.g. considering the possibility that something is two meters long) rather than have to "find" the length through a distant
What's the "meaning" of one meter? Kripke manages to stay away from that sort of question for the most part. Many people take the moral of Kripke's discussion to be that the "meaning" of the term is distinct from what "fixes reference" to the term. The reference of "one meter" is fixed as "whatever is the length of stick S"; but the "meaning" of the term involves its condition of application to possible worlds, which is different. The term "one meter" picks out length L in all worlds, so the "meaning" of the term involves that every length. Analogously, one might think of the reference-fixation of "Hesperus" as going via whatever is the evening star, but the "meaning" as involving the planet Venus. This is the sort of thing a "direct reference" theorist might say, for example, and there are a couple of passages in Kripke that suggest sympathy (e.g. where he distinguishes "fixing reference" from "giving the meaning").

For my part, I think both reference-fixing conditions and counterfactual application-conditions are in some sense part of the "meaning" of a term. I think of the former as the epistemic application-conditions (primary intension) and the latter as the subjunctive application-conditions (secondary intension). The former can be thought of as the a priori part of meaning; the latter as the (often) a posteriori part. In the 2-D framework, we'll say (roughly) that the primary intension of "one meter" picks out whatever is the length of a certain stick in all centered worlds, and that the secondary intension picks out a specific length L in all worlds. It doesn't matter much which of these we call the "meaning", but I think one can make a case that both are crucial.

If one likes, one can think of the a priori conceptual analysis of "one meter" as something like "the actual length of stick S" or "that(the length of stick S)". Then we can make sense of most of the phenomena. E.g., we can make sense of Kripke's counterfactual possibility that stick S could be less than one meter by noting that stick S could have been shorter than its actual length (i.e., than its length in the actual world). i.e., there are worlds in which the secondary intension of "one meter" and the secondary intension of "the length of stick S" come apart. But it isn't epistemically possible that stick S is less than one meter, as the primary intensions of "one meter" and "the length of stick S" are the same.

Hi all,

I was wondering about applying the two-dimensional framework to the arguments that Kripke gives in _N & N_, particularly those against the cluster concept view of names in the first lecture. Does it seem fair to say that the cluster concept view (a la Searle) is a theory about the primary intensions of names, and Kripke's examples point to the secondary intensions of names?

For example: the primary intension of 'Aristotle' can be cashed out as the guy who has some chunk of the properties: pupil of Plato, teacher of
Alexander the Great, and so on. This function won't pick out the same
guy in all possible worlds, and so "Aristotle was a pupil of Plato" will
be contingently true (according to the 1-intensions).

Kripke's examples, though, go like this: OK, imagine a counterfactual
world where Aristotle was not a pupil of Plato (or any old property we
think picks out Aristotle in this world). It is still a counterfactual
situation about *Aristotle*. So, the name 'Aristotle' picks out the guy
Aristotle in all possible worlds (according to the 2-intensions). So
names are rigid designators.

What this suggests, I think, is that assuming the two-dimensional picture
of reference, Kripke's arguments about how names work is missing a
premise: namely, that in natural language we mostly care about the
2-intension of names. So: (1) does this seem like an accurate
description of the landscape when we apply two-dimensional semantics to
_N & N_?; and (2) do we ever care about the primary intensions of names?

--Thony

What this suggests, I think, is that assuming the two-dimensional picture
of reference, Kripke's arguments about how names work is missing a
premise: namely, that in natural language we mostly care about the
2-intension of names. So: (1) does this seem like an accurate
description of the landscape when we apply two-dimensional semantics to
_N & N_?; and (2) do we ever care about the primary intensions of names?
First a bit of background, which may already be clear to some people,
but which is very important and makes some of these issues clearer.

There are actually two very distinct strands in Kripke's argument
against the traditional view of names.

The first, centered on Lecture 1, is what we can call the "modal
argument". This makes the point that names are rigid designators, so
that there counterfactual conditions of application are different from
those of the various descriptions in the vicinity. E.g., for any
description D, there's a counterfactual possibility that Aristotle
wasn't D.

The second, centered on Lecture 2, is what we can call the "epistemic
argument". Here, he argues that it's not even the case that the
reference of names is fixed via description. This is where he brings
in the cases of Feynman, Godel, Jonah, etc, and argues that for any
description D in the vicinity, it is not a priori that Feynman (etc.)
satisfies D. That's because it's always epistemically possible that
Feynman didn't satisfy D; we could imagine finding that out. So not
only can't we be descriptivists about modal application conditions, we
can't even be descriptivists about reference-fixing.

To see that the two points are quite distinct, note that the modal
argument alone is compatible with the idea that names are "descriptive
names": their reference is fixed via some description, but then they
pick out the referent in question in all possible worlds. Some names,
are arguably like this: e.g. "Jack the Ripper" arguably has its
reference fixed to whoever committed the murders, in effect via
description, but then picks out that very person (person X) in all
possible worlds. Note that for a name such a "Jack the Ripper", one
could run the modal argument, but not the epistemic argument: it's not
necessary that Jack the Ripper committed the murders (there are worlds
where someone stopped him), but it's a priori that Jack the Ripper (if
he exists) committed those murders. But Kripke argues that most names
are not like this. This is why (in Chapter 2) he argues that the
descriptive theory of reference has to be supplanted by a causal
theory (or picture) of reference.

The modal point, in effect, is a point about secondary intensions. It
concerns the application conditions of our concepts to counterfactual
scenarios, given that the actual world is fixed. And we can express
Kripke's insight by saying that the secondary intensions of names pick
out the same object in all worlds. E.g. the secondary intension of
"Jack the Ripper" picks out the same person in all worlds,
irrespective of whether that person committed any murders there.

The epistemic point, in effect, is a point about primary intensions.
It concerns the application of our concepts to epistemic
possibilities, and concerns matters of reference-fixation. Even
though the secondary intension of "Jack the Ripper" goes with a specific person, not the description, the primary intension goes with the description: the primary intension of "Jack the Ripper" picks out (roughly) whoever committed the murders in question in a given centered world. But Kripke's point is that most names are not like this. We can express it by saying that the primary intensions of most names are not captured by any description. Rather, the primary intension involves picking out whatever is at the other end of a long causal chain.

Kripke's epistemic argument is somewhat more controversial than his modal argument, and one might argue that there are certain resources available to a description theorist to resist his conclusion. E.g., one might invoke descriptions such as "the entity at the other end of an appropriate causal chain" (causal descriptivism), or "the person called such-and-such around here" (metalinguistic descriptivism). And arguably the 2-D framework can give support to a certain sort of attenuated descriptivism. But that's a complex issue (feel free to raise issues in the area). Kripke's epistemic point re names is widely but not universally accepted in contemporary philosophy; I think it's fair to say that the modal point is fairly close to being universally accepted these days (or as close to universal acceptance as anything gets).

Now to Thony's points (some of which are in effect addressed already). Re the cluster theory: pre-Kripke, the modal and epistemic issues weren't carefully distinguished. It may be that in effect, Searle intended this as a theory of both, and in effect was concerned with both primary and secondary intensions. But I think it's arguable that it was most centrally intended as a theory of what fixes actual reference, and so was implicitly concerned with primary intensions. Certainly, the modal argument seems fairly decisive against it as a theory of secondary intensions; one might think it has more promise as a theory of primary intensions. But Kripke in lecture 2 is concerned to argue against it even as a theory of primary intensions (via the epistemic arguments). Someone like Searle might resist by accepting the modal point but not the epistemic point, and arguing that one can still give some sort of modified cluster theory at least as a theory of reference-fixation, if not as a theory of counterfactual application. That sort of debate is to some extent still going today.

But anyway, I don't think it's quite right to say that Kripke isn't concerned with the primary intensions of names, given all the discussion in lecture 2. And I think that one could argue that the "missing premise" of his argument against description theories is supplied by the argument in lecture 2. It's true, though, that the modal discussion in lecture 1, which is arguably the central point, is largely concerned with secondary intensions.

I think you're right that in some sense, Kripke thinks we are most concerned with secondary intensions of names rather than primary intensions. As noted before, he seems to implicitly see SIs as more closely tied to "meaning", whereas the "reference fixation" involved in PIs isn't really a matter of meaning. Of course matters are complicated by the fact that Kripke doesn't put things in terms of the 2-D framework at all (I'm told he isn't all that keen on it). Still, it's easy to translate much of his discussion into those terms.

One further reason for his preference for SIs over PIs may be what we might call the "semantic argument". Arguably, different users of the same name can have quite different primary intensions for it, though
the same secondary intensions. E.g., maybe my PI for "Bill Clinton" is different from Hillary's PI for "Bill Clinton", though we have the same SI. And more generally, maybe the PI of a name can vary throughout a community, whereas the SI is constant. If so, and if one adds the premise that the meaning of a term should be something that is shared between users of that term, one can see the case for thinking of the SI, not the PI, as part of a term's "meaning".

I think this is one of the reasons why contemporary philosophers of language tend to focus more on names' SIs, not PIs. (Another reason may be that some are skeptical of the very idea of a PI, or haven't thought much about it.) For my part, I think that even if one accepts that the PI of a term may not be the same for all users, there's still a sense in which it is part of the meaning of a term at least for a specific user (and arguably, it corresponds much more closely than the SI to what we can think of as the "cognitive content" of the term for the user). Or one can distinguish between "sentence meaning" and "utterance meaning" (as Marga Reimer does in some of her work) and argue that PIs are at least part of the latter, perhaps. But again, what truly gets to count as "meaning" is to some extent a terminological issue.

Subject: Comment on Thony; thoughts on primary intensions
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

Some thoughts. . .first, a comment on Thony's message, then a thought or two on primary intensions. It's pretty long - sorry.

(1) Some comments about Thony's point re the 2 level framework and Kripke's ruminations on proper names. (a) First, an exegetical point. I find it very difficult to nail down the distinction between Searle and Kripke. When you read them very closely (i.e. footnotes and all), you see that Kripke allows for description to play a role in fixing reference, and Searle allows for causal chains to play a role in transmitting reference, and it becomes harder to see where they really disagree. (b) Assuming that a 2 level approach to proper names might work, Thony asks whether we ever care about the primary intension of proper names (i.e. the Searlian descriptive part). Note that Chalmers seems to think that we care about primary intensions *more* than secondary intensions - they are 'cognitive content' of thought (p. 65). I'm tempted to say that our use of a proper name (drawing inferences from it, etc.) involves its primary intension - and thus, at the very least, we do care about the primary intension a lot. But there may be another sense in which we also care about secondary intensions (i.e. the referent itself). (c) A disanalogy between natural kind terms and proper names is that the primary intension of the former is presumably shared by all members of the linguistic community who have the term (even if only by relations of deference, e.g. "elm"), while the descriptive content that I associate with, say, "Bill Clinton" may not be that which others, say ex-interns, associate with that same proper name. I'm not sure whether or not this difference is a difference that makes a difference.

(2) (a) Chalmers says that primary intensions may not always be easy to
uncover, but they are in principle open to reflection (to the degree that they are determinate). Here's a couple of cases that people have wildly different intuitions about and reflection really doesn't seem to help all that much. (i) I could have been a builder; (ii) I could have been born a century earlier than I was. (iii) I could have been a poached egg. (That last one is meant to be read literally - and it is in fact false in case you are wondering). (iv) I could have been the number 2. Some think that only (i) is true. Some think that (i) and (ii) alone are true. Some think that only (i), (ii) and (iii) are true. Perhaps you think that all four are true. (In which case you are a poached egg.) Is this just a particularly difficult case for the notion of the in principle transparency of primary intension, or does it suggest deeper and more pervasive problems with it?

This example also raises another question. Some want to say that it shows that some of my properties are essential to me (perhaps, say, being human), while other properties are not. How do we cash out the difference between these two types of properties in the 2D framework? Perhaps it goes like this. For any possible world P and any property x, if I have x essentially, then it is logically true that I have x in every world in which I exist, and if I have y only contingently, then it is logically true that there are some world in which I exist and have y, and other worlds in which I exist and don't have y, and which worlds are which depends on the natural laws and boundary conditions therein. In this way, perhaps, we can cash out the difference between essential and non-essential properties, without bringing in metaphysical necessity.

(b) Chalmers responds to the Quinean point about revisability by saying that his arguments are not affected, because they turn on supervenience conditionals (p. 55). I'm not sure why the fact that the propositions in question are supervenient conditionals should ipso facto bestow on them a certain kind of immunity to revision. First, note that our judgments about laws of nature (i.e. conditionals) are revisable. Second, note that we can distinguish two types of supervenience conditionals. First, there are those conditionals that state that B facts merely are supervenient on some other range of facts, without specifying which range of facts forms the supervenience base. (Actually, this is not really a supervenience conditional, but rather the claim that there is such a conditional.) Second, there are those conditionals which go on to say that B facts are supervenient on A facts. Now, presumably we can be wrong about the latter type of supervenience conditional. It is harder to see how we could be wrong in thinking that a certain type of fact is supervenient. We might go wrong in thinking that, say, aesthetic facts supervene on F facts, but could we err in thinking that aesthetic facts are supervenient in the first place? Chalmers, I take it, claims that we can't go wrong in such have an argument here, but it seems to me that we could mistakenly assume that a certain type of fact is supervenient although it is fact not, and vice-versa (its the vice-versa that DC needs, I think).

(c) I think that Chalmers wants to tie in the claim about supervenience conditionals being unrevisable, with the claim that we have transparent access to the primary intensions of our concepts, but I'm not sure that I see the connection. It seems to me that primary intensions are something like application conditions - this is what "watery stuff" seems to come to. But need application conditions involve a conception of whether or not a property is supervenient or not? I don't see it. One's general conception of what is or is not supervenient, and what may be supervenient on what, seems to be a fairly sophisticated thing. But perhaps that's okay. Perhaps all Chalmers needs to say is that if you have the (note: not "my") concept of consciousness, then you have the ability to reflect on it, and to see that it could not be logically supervenient on any other
types of properties. So: one can have a perfectly good concept of consciousness without having grasp of the supervenience conditionals that is contained within it and are putatively immune to Quine's worries. Is this the connection?

Sorry to be so long-winded.

>difference.
Re (a), I think you're right that Searle's and Kripke's views of reference-fixing (i.e. primary intensions) are closer than they may seem. I think the crucial difference at that while Kripke allows descriptions a role, you can't do everything with descriptions, whereas Searle thinks you can. Of course, as you note, some of Searle's descriptions may involve "the thing at the other end of a causal chain", or something like that. This leads to what is sometimes called "causal descriptivism" (a sort of hybrid); but I think it's a view that is more congenial to the descriptivist in some ways (after all, why should they object to having some descriptions involve causation). Kripke's response (e.g. around p. 162, and footnote 38) is to suggest that this is a pretty trivial sort of descriptivism (incorporating the whole causal theory as a part!), but the issue isn't entirely clear. Certainly someone like David Lewis is happy to take this on board as enough descriptivism for the descriptivist's central purposes (though it may be somewhat unlike a traditional descriptivism).

Re (b), yes, my own view is that primary intensions are in many ways more important than secondary intensions. I think they are more central to thought, to rational inference, and to capturing the way that language describes the world. On my view secondary intensions are mostly crucial to making sense of counterfactual thought and language; that's an important role but somewhat in the background. (Just why contemporary philosophy has then focused so much on SIs becomes something of a question; we'll talk about that a bit in the upcoming discussion of "the tyranny of the subjunctive"). Of course reference is important, but I think it is important qua reference, not qua its role in constituting an SI (to see this, note that reference is just as important for descriptions, like "the inventor of the zip", even though in these cases the SI doesn't involve the actual referent). But all this is just my view and of course is arguable.

Re (c), I discussed this in the reply to Thony. I think it is plausible that PIs of names, but not SIs, vary in a community. It's actually not entirely obvious whether or not the same goes for natural kind terms. I think someone might argue that different people could have different PIs for "water" or "gold" or whatever. For example, maybe there could be an isolated chemist who only associated "water" with the "H2O" description, and doesn't know about its appearance. His PI would be different from ours, but arguably he would still be using the term "water". Someone might suggest in reply that he doesn't really have our word, as the "watery" mode of presentation is somehow essential to the word; the resolution of that debate isn't entirely clear. But in any case it seems that at least mild variations in PIs may be possible even in the natural kind case.

>(2) (a) Chalmers says that primary intensions may not always be easy to uncover, but they are in principle open to reflection (to the degree that they are determinate). Here's a couple of cases that people have wildly different intuitions about and reflection really doesn't seem to help all that much. (i) I could have been a builder; (ii) I could have been born a century earlier than I was. (iii) I could have been a poached egg. (That last one is meant to be read literally - and it is in fact false in case you are wondering). (iv) I could have been the number 2. Some think that only (i) is true. Some think that (i) and (ii) alone are true. Some think that only (i), (ii) and (iii) are true. Perhaps you think that all four are true. (In which case you are a poached egg.) Is this just a particularly difficult case for the notion of the in principle transparency of primary intension, or does it suggest deeper and more...
pervasive problems with it?

Hmm, I think you're concerned here not with primary intensions but
with secondary intensions. You're considering subjunctive
counterfactual possibilities about what could have been; i.e., the
sort of modal possibilities Kripke is concerned with in N&N
(epecially lecture 1). That is, I take it that people who are
concerned with these questions are worrying about the same sort of
modality as in Kripke's questions about whether I could have descended
from a different sperm and egg (given that I descended from these
ones). These are matters of secondary intension.

Personally, I don't have really strong intuitions about what I (DC)
could and couldn't have been in various counterfactual possibilities.
Maybe I could have been born earlier; probably not a poached egg or
the number 2, but I'm not certain. This goes along with the idea that
the secondary intensions of many of our concepts are not all that
determinate; on my view, it is often almost a terminological issue
which way to go. (There are even times when I'm tempted by the
contra-Kripkean thought that water could have been XYZ.) Of course
other claim to have much more determinate intuitions about these
things, and even when they don't, they think that at least the SI is
fairly determinate.

(Of course it's not required that we have a priori access to SIs. But
one does hope that one has a priori access to SIs conditional on
knowing the nonmodal facts (e.g. about actual reference). So insofar
as SIs still seem a bit loose even given the nonmodal facts, it ought
to be the case that either (a) one hasn't analyzed the case well
enough, or (b) the SI is in fact indeterminate, or (c) disagreeing
people actually have slightly different concepts.)

As to primary intensions, I think these are generally a lot more
determinate and accessible, though of course even these can be fuzzy
around the edges. When one is considering not subjunctive
possibilities but epistemic possibilities about the way the world is,
I think our terms often seem to have a pretty determinate application.
There may be variation still in borderline cases and in very way-out
cases, but there's at least a fairly determinate core; and much of the
variation in wild cases can be dismissed as somewhat terminological
and so not really important metaphysically. Again, I'll want to make
the claim of a priori access, and argue that disagreement involves
either (a) inadequate reflection, (b) indeterminacy in PI, or (c)
terminological differences.

This example also raises another question. Some want to say that it shows
that some of my properties are essential to me (perhaps, say, being
human), while other properties are not. How do we cash out the difference
between these two types of properties in the 2D framework? Perhaps it goes
like this. For any possible world P and any property x, if I have x
essentially, then it is logically true that I have x in every world in
which I exist, and if I have y only contingently, then it is logically
true that there are some world in which I exist and have y, and other
worlds in which I exist and don't have y, and which worlds are which
depends on the natural laws and boundary conditions therein. In this way,
perhaps, we can cash out the difference between essential and
non-essential properties, without bringing in metaphysical necessity.

I think the difference between essential and inessential properties
will show up in the SI of a term. We'll say that Fred has property P
essentially if "Fred is P" is necessary, i.e. 2-necessary (necessary
in the subjunctive sense that Kripke considers). This will hold if
the SI of "Fred" picks out a being with P in all worlds. Fred has P inessentially if the SI of "Fred" picks out a being without P in some worlds.

In a certain sense, this is cashing out the difference between essential and inessential properties without bringing in any really heavy notion of metaphysical necessity. One still needs the basic space of worlds, but these can just be the conceivable worlds, more or less. Once one has worlds plus SIs, one has enough to understand the distinction. To get SIs, one needs (a) a good enough a priori grasp of the concept in question, and (b) nonmodal facts about the actual world. (E.g., say water is essentially H2O. Then if one has a full a priori competence with the term "water" and knows the nonmodal facts about the composition of actual water being H2O, one can know that the SI picks out H2O in all worlds. Etc.)

Indeed, it seems pretty clear that Kripke's methodology for thinking about what's essential is more or less like this. The only empirical knowledge he needs are some nonmodal facts, e.g. that he's descended from sperm S and egg E, or that water is made of H2O, and so on. The rest seems to follow by a priori analysis: arguably, by the method of conceivability plus a priori analysis of the way our concepts apply to worlds.

If this works, we can cash out essentialism relying only on (a) an a priori accessible space of worlds, (b) a full enough a priori grasp of the concepts in question, and (c) some nonmodal facts about the actual world. Sounds promising for modal rationalism!

More on Tim's other points later.

--Dave.
run along lines which would require using one's own proper name. If so, there are two options. (1) If we evaluate the scenario under PI's, then consciousness is (or arguably is) included in our PI of ourselves. (2) If we evaluate the scenario under SI's, then the name picks out the same thing in all possible worlds—and it's secondarily impossible that I could be a zombie. Either case looks problematic. Now, I don't know if any materialist would *want* (or bother) to try to come up with a way of forcing the thought experiment to make essential use of one's own proper name, but that's the sort of situation I had in mind.

Thony

I'm not sure just what you have in mind by "forcing the thought-experiment to use one's proper name", but it seems to me that that couldn't really be done, since proper names are strictly speaking irrelevant to the argument. The anti-materialist needs to argue that "P \rightarrow Q" is not a priori and not necessary, where P is the complete microphysical truth about the world and Q is a phenomenal truth. They can make that case quite independently of considerations about proper names. Maybe a materialist could try to argue that "P' \rightarrow Q" is a priori or necessary, where P' is some variant on P that includes proper names, but even if that conclusion were established, it wouldn't have much bearing on the question of whether materialism is true or false.

At best, what would be going on is the same as what might go on in the case where P'' includes facts about love (say), where we take the view that love requires consciousness. Then P'' will entail some facts about consciousness, but that implies nothing at all about materialism. As long as P doesn't entail Q, then materialism is false. The entailment from P'' just tells us that materialism is false about love, too, as one would expect. Similarly, if P doesn't entail Q but P' does entail Q, where P' includes facts about DC, all that will follow is that materialism is false about DC. Which is just what one would expect if being DC essentially involves being conscious.
Folks,

What follows are some impressionistic "minutes" regarding today's meeting, compiled by Tim, Thony and Brad, and loosely stitched together.

Our discussion seemed to focus on two issues, broadly conceived.

(1) What are primary intensions? We spent a lot of time trying to work out whether proper names, such as London, have primary intensions, and if so, what are they. There was some discussion of whether 'London' and 'Londres' have different primary intensions, if they have primary intensions at all.

Thony argued that primary intensions aren't epistemic in this sense, they are simply functions from possible worlds to individuals or properties. There seems to be some tension between the cognitive/epistemic role primary intensions are meant to play, and their metaphysical role.

It sounds odd to say that a PI is a function from worlds to referents, and then say that different people can have different primary intensions for the same terms. 'Water' is supposed to pick out the watery stuff in any world in which it is uttered, quite irrespective (I take it) of what folks know about water (though, presumably, most folks would know which stuff was the watery stuff--but this needn't be the case).

Perhaps related to this, there was some argument about whether even natural kind terms (our example was "water") have primary intensions. Brad claimed that it made sense to say "Water might not have been H2O", but Thony argued that this only made sense to him when the modality was construed epistemically rather than metaphysically. I (Brad) was claiming that it was true on a metaphysical reading. If it were true, that would motivate the notion that "water" has a primary intension (since it is certainly *not* true that H20 might not have been H20).

I guess the question that I (Thony) wanted to raise (though not at all clearly) was whether the semantically salient thing that names (natural kind terms, etc.) contribute to sentences/discourses in which they occur is anything like a primary intension. I'm (Thony) not at all sure, but my intuition seems to favor SI's in this respect.

This got us on to a discussion of whether it is words that are the (primary) bearers of primary intensions, or concepts. I (Tim) think we concluded...
that both words and concepts are meant to have primary intensions. There was some discussion of whether a word has a single primary intension associated with it. I (Tim) suggested that it is not obvious that this is the case: Imagine that I know that ice, liquid water and steam are the same stuff. I call all three kinds of stuff "water" and its part of my primary intension that all three kinds of stuff are the same stuff. Imagine that my kids are only exposed to liquid water, and I don't teach them that water can boil or freeze. Two questions: (A) When I talk with my kids about water (liquid water), are we using the same word (I guess I want to say yes, tentatively); (B) do we attach the same primary intension to it (I want to say no, tentatively).

{It also seems hard to draw a hard and fast distinction between primary and secondary intensions, given the way kids learn words/concepts. If content really has this dual structure, wouldn't one expect it to be reflected more clearly?}

But most of our discussion on this point concerned whether "London" has a primary intension, and if so, what is it? We also spent some time talking about the primary intensions of proper names, like 'Brad", and indexicals, like "me".

(2) Next, we talked about the debate that Thony and I (Tim) have had regarding the issue of trans-world individuation: does Thony have to be able to pick out his zombie twin, rather than just a zombie who is physical/functional type identical to him, to get the zombie argument going. This got us on to the topic of why it is important for the zombie argument that I know that I am conscious. Here is how I see the argument as running:

(A) I know I am conscious
(B) We assume that consciousness is logically supervenient (for reductio).
(Thus,
(C) Any being that is physically-functionally type identical to me will, in any possible world, also be conscious.
(D) I can conceive of an individual that is physically-functionally type identical to me, but is not conscious.
(Such an individual is my zombie "twin" in the sense that we are type identical, but note that it need not be *me* in any deep sense.)
(E) Conceivability entails logical possibility.
(F) from D and E, it follows that there is a world in which there is an individual that is physically-functionally type identical to me, but lacks consciousness.

But (F) is inconsistent with (C), so (B) is false.

I think you can run the zombie argument without making any claims about the trans-world identity of individuals. **Although** you might have to make commitments to the trans-world identity of properties, such as the property of consciousness, and this might be problematic.
was that in
> order to avoid someone concluding that (A) is false (and (B) true),
> imagining one's zombie twin becomes an exercise in considering
> counterfactual possibilities--and these require the 2-intensions.

Subject:      Do names have primary intensions
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

Some thoughts on the "minutes".

>Our discussion seemed to focus on two issues, broadly conceived.
>(1) What are primary intensions? We spent a lot of time trying to
>work out whether proper names, such as London, have primary
>intensions, and if so, >> what are they. There was some discussion of
>whether 'London' and 'Londres' have different primary intensions, if
>they have primary intensions at all.

Actually, I discuss the 'London'/Londres' case a bit in "The
Components of Content". Everyone should read that paper, since it
gives a lot more detail on the 2-D framework, though it is primarily
cast in terms of concepts, not words.

Do proper names have primary intensions? As I said yesterday, they
arguably don't have PIs that are universal to all users of a name. It
may be that two different users have different PIs for "London", just
as for "Bill Clinton", etc. So this might lead one to say that names
don't have PIs as a matter of "semantics", where the semantics of a
term is supposed to be universal to all users of the term.

Still, I think that it is plausible at least that any name has a PI
for any user on any occasion of use. We might put this by saying that
"name tokens" have PIs (or are associated with PIs), even though "name
types" may not. If so, we can arguably see PIs at least as part of
the semantics of an "utterance" (cf. Reimer's distinction), and
certainly as part of the semantics of an underlying thought.

Why think that name tokens have primary intensions? Basically, because like any referring word, a name (token) must have some pattern of application across epistemic possibilities. Just say I use the name "Godel". Then I can consider all sorts of epistemic possibilities about the way the actual world might be, and I can see how the name will refer with each of them.

Think of Kripke's own methodology in Lecture 2 -- we consider e.g. the epistemic possibility that the incompleteness of arithmetic was proved by a guy called "Schmidt" and stolen by a guy called "Godel" who published it, moved to Princeton, etc. Kripke notes, in effect, that if that epistemic possibility is actual, our term "Godel" refers to the Princeton guy. That's to say that the primary intension of "Godel" picks out the Princeton guy in the relevant centered world. One can do the same thing for a very wide range of worlds considered as actual (i.e. considered as epistemic possibilities): for a large numbers of such worlds, there seem to be clear facts about what our words will pick out if those worlds are actual.

We can think of the primary intension as the "reference-fixing" conditions of our terms, if we like, though actually I prefer to think of it as giving the epistemic application-conditions of our terms, or the "epistemic profile" (as opposed to the "modal profile" of the secondary intension). It's central to the way language works that any referring term has an epistemic profile (at least for a given user on a given occasion): there are facts about how it applies to different epistemic possibilities, and about how it will refer if those possibilities turn out to be actual.

How does one evaluate the primary intensions of names that one uses? Basically, take a name, e.g. "London", take a given centered world, and ask oneself "to what does the name refer if that world is actual"? Here, one considers the world as actual, i.e. considers it as an epistemic possibility: "what if the world actually turns out to be that way?". And for a very wide range of such worlds, we have clear intuitions about how the name refers. E.g., if the actual world turns out to contain XYZ in the oceans etc, then we'll say that "water" refers to XYZ. If the actual world turns out to have the Princeton guy stealing the proof from Schmidt, we'll say that "Godel" refers to the Princeton guy. If the actual world turns out to have a non-whale-eaten guy at the other end of a causal chain from our use of "Jonah", we'll say that "Jonah" refers to that guy. Etc, etc.

Summing up a primary intension in language is often difficult, and the same goes for these cases; what really matters is the function from worlds to referents, not any capsule summary. But if I were to try to get at some of the things that are involved e.g. in the PI of my name "Godel", we might try: "the guy called 'Godel' who's at the other end of a causal chain from my use of the name", or something like that. That's imperfect, as Kripke argues -- e.g. one can consider epistemic possibilities in which the guy my term refers to wasn't called "Godel" at all (I've got his name wrong, or some such). But that just means that we have to refine our view of the PI. Importantly, Kripke's own methodology here relies precisely on evaluating how the term will refer if a given epistemic possibility turns out to be actual, i.e., on evaluating the PI of the term at a world.

As for "London" and "Londres": think of Pierre's situation. For him, there are lots of epistemic possibilities. The world he thinks he is in is one with a beautiful faraway city by the name of "Londres", and
an ugly one close at hand called "London". Pierre quite reasonably says that if that epistemic possibility is actual (as he believes it is), then his terms "London" and "Londres" name two different cities: "London" picks out the faraway city and "Londres" the city close at hand. So in that centered world, the PIs of "London" and "Londres" give different results.

On the other hand, another epistemic possibility for Pierre (at least a broad epistemic possibility in the sense articulated earlier) is the actual possibility: i.e., that the people he got the term "London" from were actually referring to the same city he's living in now, and that it has both beautiful and ugly parts, etc. If Pierre were confronted with the hypothesis that this epistemic possibility is actual, he should rationally conclude that under that hypothesis, his terms "London" and "Londres" pick out the same city. So that's to say that in this centered world (Pierre's actual world!), the PIs of "London" and "Londres" give the same results.

So, Pierre's "London" PI and his "Londres" PI give the same result on some centered worlds (including the actual world), but different results on other worlds (e.g. the one he thinks is the case). So they are at least slightly different intensions overall.

How to summarize these intensions in language? Again, it's difficult and imperfect, but we might make a first attempt by saying that his "London" PI picks out "the beautiful city I've heard of under the name 'London'", and his "Londres" PI picks out "the ugly city I'm living in", or perhaps "the city I've heard of under the name 'Londres'".

Getting the details right will depend on careful consideration of cases, and will depend on just how Pierre's conceptual system is set up, etc. But this gives us enough to see how the PIs might pick out the same extension in one world (the actual world) but different extensions in some other worlds.

The fact that Pierre's PIs are different precisely reflects the fact that it is epistemically possible for him that London isn't Londres. This suggests a general principle: when "A=B" is a posteriori (for a user), A and B have different PIs. To see this, one can go through the following reasoning.

(1) "A=B" is a posteriori;

so (2) it is (broadly) epistemically possible that A is not B,

so (3) there is some epistemic possibility in which my terms "A" and "B"
    pick out different things (when that possibility is considered as actual)

so (4) there is some world in which the PI of "A" and the PI of "B"
    yield different extensions

so (5) A and B have different PIs.

I hope all the steps here make sense. You can illustrate it by thinking of the London/Londres case, or the Hesperus/Phosphorus case.

Note that the principle here is equivalent to: when "A=B" is a posteriori, "A=B" has a contingent primary intension. (N.B. the primary intension of a statement is just the obvious generalization of the primary intension of a term -- in the book I call this a "primary proposition", but I now tend to use the unified terminology.) If A and B have different PIs, there's a centered world where they pick out different extensions, and in which the PI of "A=B" is false. And to
say that "A=B" has a contingent PI is just to say that there's a world in which the PI is false.

This is an instance of a very important general principle:

if a statement S is a posteriori, S has a contingent primary intension.

It's fair to say that this is at the heart of the two-dimensional account of a posteriori necessity. The central claim of this account is

if a statement S is necessary a posteriori, S has a contingent primary intension and a necessary secondary intension.

That's not too hard to illustrate by working through the standard Kripke cases. I note that there are just possibly some counterexamples to this principle which someone might put forward, though they probably won't be the standard Kripke cases. We'll be discussing potential counterexamples later in the course, but feel free to suggest any now.

But anyway, one can see how all this hooks in with the need for names to have PIs. Presumably a lot of statements involving names will be a posteriori for many or all users, e.g. "London = Londres", "Cicero = Tully", etc. That's just to say that for a given user, there is the epistemic possibility that the statement is false, i.e., there are some scenarios such that if they turn out to be actual, the statement turns out false. So the very a posteriority of the statement indicates that the names in question have distinctive patterns of applications to epistemic possibilities, i.e. that they have (distinct) PIs.

That's enough for one message. Hopefully it gives useful background for thinking about issues in the rest of the minutes. More on the rest later.

--Dave.

More on the minutes.

>> >> Thony argued that primary
>> >> intensions aren't epistemic in this sense, they are simply functions from
>> >> possible worlds to individuals or properties. There seems to be some
>> >> tension between the cognitive/epistemic role primary intensions are meant
>> >> to play, and their metaphysical role.

Hmm, I'm not sure exactly what the tension is here. Say more? On my own view, primary intensions are in a sense "epistemic", in that they involve the way our terms apply to worlds considered as epistemic possibilities, but at the same time they are perfectly respectable functions for worlds to extensions. And the worlds in question may be perfectly respectable metaphysical possibilities at the same time. E.g., the XYZ-world, with XYZ in the oceans etc, is presumably a perfectly respectable world. Considering the world as counterfactual,
our term "water" picks out H2O in that world; considering the world as actual (as an epistemic possibility), "water" picks out XYZ.

At least, nothing in Kripke's discussion suggests that the worlds we are considering as epistemic possibilities can't all by metaphysically possible worlds in their own right. That's the centerpiece of the 2-D framework -- one space of worlds, two sorts of semantic evaluation. Somebody might want to argue that some of these epistemic possibilities don't correspond to metaphysical possibilities even in the 2-D way, but such a claim would have to rest on considerations quite distinct from Kripke's. That's something we'll be talking about later on.

>> It sounds odd to say that a PI is a function from worlds to >> referents, and then say that different people can have different primary >> intensions for the same terms. 'Water' is supposed to pick out the >> watery stuff in any world in which it is uttered, quite irrespective (I >> take it) of what folks know about water (though, presumably, most folks >> would know which stuff was the watery stuff--but this needn't be the >> case).

What exactly is odd here? I talked yesterday about some ways in which the PI of a term such as "water" might vary between individuals. Take the chemist who associates "water" only with certain chemical properties (and let's say, intends to use the term entirely without semantic deference). For him, if the XYZ-world turns out to be actual, "water" will still refer to H2O, not XYZ. So his PI for "water" is quite different from ours. He'd be a very unusual user, of course, but it's not obvious that the story is incoherent. One might resist by suggesting that his word "water" is not really our word, and part of me would have some sympathy, but that would be a tricky row to hoe.

And without going to this sort of extreme, one can arguably find everyday cases in which two different users of a natural kind terms have slightly different PIs (as witnessed by the fact that they would react to certain epistemic possibilities in different ways). E.g. a miner who is an expert on "chromium" and an airplane worker (I don't know anything about chromium, so let's pretend that it is found in mines and used in airplanes). Arguably the miner could pick out chromium as "the stuff with such-and-such superficial properties that I mine", and the airplane worker could pick it out as "the stuff with such-and-such chemical properties that I work on", or some such. Or at least, the miner might give a little more weight than the airplane worker does to superficial properties. All this is complicated by issues about semantic deference (where users intend to refer to what the community around them calls "chromium", as one gets in e.g. Burge's "arthritis" cases) but I'm taking it here that it's at least possible to use such terms without semantic deference.

I take it that Kripke's view is that natural kind terms are like names in this regard as well as in the "rigid designator" modal regard -- i.e., he thinks they don't have any canonical "mode of presentation" under which they are picked out. I.e., no universal PIs for natural kind terms. I don't think this matter is cut-and-dried, and the issues of to what extent natural kind terms are like names here is at least somewhat debatable; certainly, there is an intuition that they have some sort of descriptive "feel". It's a tricky issue.

It's true that when thinking about natural kind terms, it's easy to slip into a picture on which every user has the same PI, and I don't
think there's much harm in doing that (and it doesn't do huge violence to situation that most of us find ourselves in), as long as we recognize that it may turn out to be an idealization.

In any case, even if Kripke is right, it's not obvious that serious problems arise for us if different users have different PIs for the same terms. For most purposes that will matter for us, it might as well just be a single user's PI that we're interested in. The effect will be that what counts as (say) an explanation of "water" for us may differ from what counts for the chemist, but that won't indicate any major metaphysical difference, just a difference in the way we use the term. The general picture of metaphysical and explanation (abstracting away from surface terminology) will stay the same.

>Perhaps related to this, there was some argument about whether
even natural kind terms (our example was "water") have primary
intensions. Brad claimed that it made sense to say "Water might not have
been H2O", but Thony argued that this only made sense to him when the
modality was construed epistemically rather than metaphysically. I (Brad)
was claiming that it was true on a metaphysical reading. If it were true,
that would motivate the notion that "water" has a primary intension (since
it is certainly *not* true that H2O might not have been H2O).

Hmm. I guess I'd argue that natural kind terms (or term tokens) have PIs in just the same way as I argued that names have PIs: they have a distinctive pattern of application to epistemic possibilities.

Re "water might not have been H2O": personally, I find this ambiguous between what I'd call an epistemic and a "subjunctive" reading (I prefer not to use "metaphysical" here since I think both are metaphysical in a way). Given the way the actual world is, I think Kripke's makes a pretty strong case (though not an unarguable case) that there is no counterfactual world in which water is not H2O. If so, the subjunctive reading comes out false. But it's still the case that it's broadly epistemically possible that water isn't H2O, i.e. there a possible world such that when that world is considered as actual, "water is H2O" comes out false. So I think one can argue that the epistemic reading comes out true. One might argue over whether the sentence in question actually has the epistemic reading (one could argue it is intrinsically subjunctive). I personally think language is pretty flexible here, but if one has doubts, one can substitute something more clearly compatible, such as "water might not be H2O".

I'm not sure whether I'm agreeing with Brad or Thony here. I guess I agree with Thony that it's true on an epistemic reading, and the question of the "metaphysical" depends on just what one means by that. If one means a Kripkean subjunctive reading, then I suppose I'm inclined to agree with Kripke that the sentence is false, though I don't think the issue is entirely cut-and-dried. But as I said, I'm inclined to think that even the epistemic reading is "metaphysical", in that it involves evaluating perfectly respectable metaphysically possible worlds.

Anyway, I think that whatever one says about this, water comes out having a PI either way. All one needs for a PI is a distinctive pattern of application across epistemic possibilities (considered as actual), and that's just what we seem to find. E.g., it's epistemically possible that water isn't H2O, i.e., there a scenario (the XYZ-world) just that when it's considered as an epistemic possibility, "water is H2O" comes out false, i.e., the PI of "water = H2O" is false in that scenario, i.e., "water" and "H2O" have different PIs.
> I guess the question that I (Thony) wanted to raise (though not at all
> clearly) was
> whether the semantically salient thing that names (natural kind terms,
> etc.) contribute to sentences/discourses in which they occur is anything
> like a primary intension. I'm (Thony) not at all sure, but my intuition
> seems to favor SI's in this respect.

That's an interesting question that depends a lot on what we mean by
"semantically salient". It's true that given that PIs can vary
between users and that SIs don't, one might argue that SIs are most
central to semantics. On the other hand, when one looks at what goes
on in communication and understanding (e.g., what I learn when
someone tells me that there's water in the sink), I think it's
arguable that PIs are more central. It's a tricky issue.

>This got us on to a discussion of whether it is words that are the
>(primary) bearers of primary intensions, or concepts. I (Tim) think
>we concluded that both words and concepts are meant to have primary
>intensions.

Right. On my view, both words (or word tokens) and concepts have PIs.
The treatment in the book is largely directed at words; the treatment
in "The Components of Content" is largely directed at concepts. I
think one can argue that there is a certain sense on which the PIs of
concepts are "primary", in that the PI of a user's token of a word is
derivative on the PI of the user's corresponding concept. But that
matter isn't entirely obvious.

>There was some discussion of whether a word has a single
>primary intension associated with it. I (Tim) suggested that it is
>not obvious
>that this is the case: Imagine that I know that ice, liquid water and
>steam are the same stuff. I call all three kinds of stufff "water" and its
>part of my primary intension that all three kinds of stuff are the same
>stuff. Imagine that my kids are only exposed to liquid water, and I don't
>teach them that water can boil or freeze. Two questions: (A) When I talk
>with my kids
>about water (liquid water), are we using the same word (I guess I want to
>say yes, tentatively); (B) do we attach the same primary intension to it
>(I want to say no, tentatively).

Ah, excellent. That's a nice example of the sort of thing I was
talking about before. I think it clearly seems intuitive to say that
we're using the same word. Do we have the same PI? Actually, that's
a bit tricky. We may have different beliefs, but it certainly isn't
the case that every difference in beliefs is reflected in a difference
in PIs. What matters intuitively for a PI are the beliefs that a user
implicitly takes to be "constitutive", or a priori. It's not obvious
to me that your belief that water has three forms is one of those
beliefs. E.g., just say it turns out that the liquid around you only
has one form, and that the stuff in freezers and that comes out of
kettles is actually some entirely different chemical compounds. I
think then you'd say that "water" refers to the liquid but not to the
other things. If so, the "epistemic profile" of your "water" concept
doesn't require that water have the three forms. Arguably your PI for
"water" is more centered on the liquid stuff, just like the kids'. So
it's not completely obvious that this is a case of different PIs.
Still, it might not be too hard to turn it into such a case, or to
find other such cases in the vicinity.

>{It also seems hard to draw a hard and fast distinction between primary

http://www.u.arizona.edu/~chalmers/class/596b/week3.txt (22 of 45) [4/7/2002 1:48:25 PM]
I'm not sure exactly what the concept-learning considerations are here. On my view, the central structure of our concepts involves PIs, as these give the conditions whereby our concepts apply to the actual world, are most associated with "core beliefs", determine the epistemic possibilities that we take to be live options, etc. SIs have a secondary role, giving the application-conditions of our concepts to counterfactual worlds, and mostly are revealed in counterfactual thinking and in subjunctive contexts. So I suppose that SIs may be revealed in kids' thinking about counterfactual scenarios ("just say I had a twin brother"), and how they describe them, etc. But probably PIs are more central, as these are what are centrally involved in the kids beliefs about the way the actual world is, about the epistemic possibilities they're prepped to entertain, etc. So I think one would probably find it easier to "read off" a PI from a kid's surface conceptual structure than an SI; and indeed, firm SIs may take longer to develop than firm PIs (given that thinking about counterfactual scenarios can be very loose). But this all brings up some very complex and arguable issues (I don't think anything I just said is obvious or uncontestable, and don't worry if it's hard to follow).

I hope this all helps to clarify some issues about the way the 2-D framework works. Please go ahead and fire away with follow-up questions, other thoughts, etc.

--Dave.

Hi,

My main issue is Kripke's discussion of water, heat, and light (pg. 128). He says, and I agree, that "we identified water originally by its characteristic feel, appearance and perhaps taste...". But he goes on, and this is where I don't agree, to say that "if there were a substance...which had a completely different atomic structure from that of water, but resembled water in these respects, would we say that some water wasn't H20? I think not." He goes on to make an analogy to fools gold (fools water). My difficulty is in the amount of weight he/we are putting on physics. The reason fools gold isn't gold isn't because it is molecularly different but because the feel/appearance/(taste) part doesn't correspond to gold. My contention is that if everything were the same gold/fools gold, water/fools water than we WOULD say when we finally discovered the difference under the microscope that there are two kinds of water and two kinds of gold-- for one thing it would be impossible to determine which was the *right* one. As it turns out we understand these things in terms of the feel/appearance/taste rather than as the molecular descriptions they happen to have. Likewise, I feel the same way about heat and light. I do not think heat IS the motion of molecules or that light IS a stream of photons, rather they are the phenomenal qualities...
that happen to be stimulated by molecule motion and photon streams. I realize the importance of separating phenomenal effects from physical events but we shouldn't use the same word to describe both.

Am I running into a typical problem? Is there a name for the position I take?

More importantly, is there something big that I'm overlooking (I always feel like there is.)

Do I have it right that, in this case the primary intension would be the feel/appearance/taste? i.e. the essential qualities?

This stuff can get a little confusing.

:)

Erik H.

P.S. I don't see how consciousness could be a priori OR a posteriori -- could we make another category for it?!

Also, I can't see, especially in light of everything, how Chalmers could possibly think he's a zombie. Or any of us for that matter.
One relevant data point involves different rare-ish metals with the same surface structure, or very similar structure (titanium and chromium, say, though I have no idea). Here, it seems that finding a metal with the same surface structure as titanium isn't enough for us to call it titanium. Titanium goes with a particular atomic structure, and that seems to be that. So one might argue that the same goes for gold.

does, too.

And what would we say if a time of astronauts find a planet with the superficially identical XYZ? Water or not? Putnam and Kripke bet that we'd say it isn't water -- see "The Meaning of Meaning" for a much more extended argument for this sort of claim. I recall that I was sort of skeptical when I first heard the claim myself, but I've gradually come around. I can still see the intuition, though, and part of me can still go both ways.

Likewise, I feel the same way about heat and light. I do not think heat IS the motion of molecules or that light IS a stream of photons, rather they are the phenomenal qualities that happen to be stimulated by molecule motion and photon streams. I realize the importance of separating phenomenal effects from physical events but we shouldn't use the same word to describe both.

That's another tricky one. It raises the specter of the old riddle, "if a tree falls in the forest with no-one around, does it make a sound?". To which one standard answer is to say, it makes a sound in one sense but not another. We might say it makes an "objective sound" (the air movement) but not a "phenomenal sound" (the subjective experience). And one could argue that the term "sound" is ambiguous between these. One might make the same ambiguity claim for light and heat: objective light vs phenomenal light, objective heat vs. phenomenal heat.

You want to go further and say that terms such as "heat" refer to phenomenal heat, not objective heat. One reason for questioning this might lie in the fact that we sometimes say "it's really hot in there" even though there's no-one who's actually feeling the heat (e.g. inside a furnace). Similarly we can talk about the light sent from Alpha Centauri to others star (which maybe no-one sees, etc). So it seems that objective heat and objective light are at least sometimes called "heat" and "light".

Do we sometimes use the terms for phenomenal heat and for phenomenal light. I think maybe so, though it isn't so clear. Kripke seems convinced that in a world where someone feels our "heatish" sensations but caused by something very different in the external world, we'd say there's no heat. But it doesn't seem completely unreasonable to say that there is heat in that world, that the external things are hot, etc. It's a little less clear for "light", but maybe.

If you really insist that we shouldn't use the same word for both, my own feeling is that there is slightly more of a case for using the term for the objective kind than for the phenomenal kind. But of course it is ultimately a terminological issue. One of my fundamental principles in philosophy is that nothing of vast importance ever really turns on a terminological issue. But of course the way the terminology of natural language works is of some interest in its own right.

Am I running into a typical problem?

Is there a name for the position I take?
More importantly, is there something big that I'm overlooking (I always feel like there is.)

Do I have it right that, in this case the primary intension would be the feel/appearance/taste? i.e. the essential qualities?

I can't think of a name, offhand, but I think your view isn't entirely unusual. Some people have argued that the reference of our terms such as "heat" has gradually shifted from the phenomenal kind to the objective kind as science has progressed: i.e., we have gradually "objectified" the term. So when Goethe argued that light couldn't be explained by science, it wasn't so much that he was proved wrong as that the subject was changed.

Either way, the PI of "heat" etc will involve the appearance. If we think "heat" refers to phenomenal heat, the PI will just pick out that particular sort of sensation in all worlds, as will the SI. If (like Kripke) we think it refers to objective heat, the PI in a given world will pick out the external property that causes those sensations around the center of the world. The SI will pick out the *actual* external property (the motion of molecules, given the way the actual world turned out) in all worlds. (So the PI can be roughly summarized as "the cause of heat sensations", and the SI as "the motion of molecules".)

P.S. I don't see how consciousness could be a priori OR a posteriori -- could we make another category for it?!

I take it you mean knowledge of consciousness. I'm sympathetic with your point here -- there's certainly some sense in which we know about our consciousness non-empirically and certainly, so it can seem a priori. And some philosophers have argued that it is a priori. But I think for a number of reasons it is best to see it as a posteriori. One's knowledge of consciousness is knowledge in virtue of experience, which is just what a posteriori knowledge involves. It isn't a "truth of reason" in any clear sense. One can argue that phenomenology and introspection are just as "empirical" as external observation: one measures the first-person data, the other the third person data. And finally, a lot of philosophical issues make more sense if we see this as a posteriori. So I think there's a good case for putting it in this category, even if it has a somewhat different feel from the paradigm cases of a posteriori knowledge.

Also, I can't see, especially in light of everything, how Chalmers could possibly think he's a zombie. Or any of us for that matter.

I don't think I'm a zombie! All I said is that it's not a priori that I'm not a zombie, and that it's 1-possible that I'm a zombie. That's entirely compatible with the claim that I am certain that I'm not a zombie. It just turns out that I am certain of something that is a posteriori. That seems OK to me, but if there's a problem, I'm interested to hear it. As for you, I'm not certain you're not a zombie, but I think you're not, and arguably I know you're not. But still, it is certainly a broad epistemic possibility that you're a zombie; i.e., it isn't ruled out a priori.

--Dave.
A thought on proper names...

There is an interesting tension between two aspects of the proper names that we use. On the one hand, we want a proper name to be unique to the individual whose names it is. (This fact, or rather the absence of this fact, is the basis for Monty Python's Australian Philosophers sketch, in which everyone is called Bruce.) On the other hand, individuals do share proper names, lots of people are called Bruce. It is interesting to note that there is anecdotal evidence that kids resist calling another individual by a proper name that they have already attached to an individual: If my sister is called Jane, then it's wrong to call this other person Jane as well. They seem to over-extend the principle that proper names aren't like nouns and adjectives, they are meant to apply to unique individuals.

How does this relate to the "meaning" of proper names? Consider a conversation in which I am talking about my sister Jane, and not my friend Jane. Or, better, a conversation in which I'm talking about my sister Jane, and someone interrupts to tell me that "Jane wants to talk to me", and I interpret the second "Jane" to be about my friend. In order to keep the references of the various tokens of Jane straight, I presumably have to bind some kind of descriptive content to them. At some level, don't I have to be thinking "Jane-my-sister" or "Jane-my-friend", or something with *some* descriptive content?

The precise nature of the descriptive content needed here is not obvious, but it is clear that a traditional descriptivist suggestions won't work: "The person that everyone around here calls *Jane* won't work", because there are lots of people around here called Jane.

In other words: in general, the meaning of a proper name can't just be its referent, 'cos most proper names have a number of referents. One could respond to that by saying that *Jane* in one context means something different from *Jane* in another context, because it is used to refer to a different person. Thus, Jane/Jane would be just like bank(financial)/bank (river). But the analogy with "bank" seems to me to play into the descriptivist's hands. When I say "I saw you at the bank yesterday" I know that I either mean river bank or financial bank 'cos of the descriptive content I associate with the token. Unless I also associate descriptive content with 'Jane', how do I (or my interlocuters) know which Jane I am talking about?

With respect to my previous comment about proper names. . . (Re)reading the preface to *Naming and Necessity* tonight I was reminded that Kripke discusses just this point, and seems to think that it's of no real relevance. I'm not persuaded that he's justified in dismissing it in the way he does. He seems to think that you just bring in pragmatics or something to work out which Aristotle you're talking about, i.e. to work out which proposition you mean to express, and then plug his rigid designation account into the proposition that one has isolated. Well, maybe, but maybe not. But it's not obvious to me that we can simply dismiss the issue of homonymous names to speaker meaning or pragmatics or something. I don't have an argument here, but Kripke's discussion seems to me to be a little underwhelming.

Lots of interesting issues about multiple uses of the "same" name in Tim's message. Starting from the end of the message:

> In other words: in general, the meaning of a proper name can't just be its referent, 'cos most proper names have a number of referents. One could respond to that by saying that *Jane* in one context means something different from *Jane* in another context, because it is used to refer to a different person. Thus, Jane/Jane would be just like bank(financial)/bank (river). But the analogy with "bank" seems to me to play into the descriptivist's hands. When I say "I saw you at the bank yesterday" I know that I either mean river bank or financial bank 'cos of the descriptive content I associate with the token. Unless I also associate descriptive content with 'Jane', how do I (or my interlocutors) know which Jane I am talking about?

Hm. The view that the meaning of a proper name is just its referent is very popular in contemporary philosophy (held e.g. by direct reference theorists), perhaps even so popular as to be conventional wisdom. I think those who hold this view will respond by saying that the two instances of "Jane" here are simply two different names. One name means X, and one name means Y. It's just that somewhat
coincidentally, the two names are spelled and sound the same, or something like that. See for example Kripke's discussion on pp. 7-8, where he suggests that "uses of phonetically the same sounds to name distinct objects count as distinct names".

Of course one might object by saying there's an intuitive sense in we say that Jane 1 and Jane 2 "have the same name". Here a direct reference theorist (and others) might respond e.g. by saying that there are two ways of individuating names, either by their phonetics (etc.) or by their meaning; and that while phonetic individuation sometimes plays a role in ordinary practice, it is meaning-individuated name types that correspond best to the deep structure of language, or that matter most in philosophy, or something like that. As usual the issue isn't cut-and-dried, but I think the direct reference theorist has some resources here.

Your objection in turn raises a really central issue in the debate over the semantics of names: how do I know the referent of my name? The direct reference theorist might say, well, you know that the referent of "X" is X, but it might be objected that this is trivial and unhelpful. In practice something more seems to be involved in the way in which we identify the referent of our names, i.e. the way in which we come to know who or what the referent is. This seems closely tied to what we might call the "mode of presentation" of the name. The direct reference theorist may well accept that any use of a name has a mode of presentation associated with it by the speaker, or at least some way of identifying the referent, but they will deny that the mode of presentation is part of the "meaning" of the name. It might merely be something in the psychology of the speaker, for example, rather than a truly semantic phenomenon. (Often, a direct reference theorists will sharply separate "semantic" and "cognitive" issues.) Others (especially description theorists) prefer to think of the mode of presentation of a name as something in the realm of meaning and semantics.

One consideration in favor of the direct reference theorist is the point (which we've already noted a couple of times) that different users of the same names may well have different associated modes of presentation. E.g., Hillary's and my use of "Bill Clinton". One might then say it follows automatically that the mode of presentation can't be part of semantics, if the semantic features of a term are common to all users of a term, as it is often thought they must be. In response, it might be argued that the mode of presentation is at least part of "utterance meaning" rather than "sentence meaning", or something like that, where the former can be specific to a single use or user of a term, where the latter is required to be universal. Here again Marga Reimer's work on distinctions like these is relevant; I don't have the relevant papers with me (and may be misremembering them a bit), but fortunately Marga has just joined the mailing list -- any contribution is welcome!

At some point these debates about what truly counts as "meaning" and "semantics" become somewhat terminological (that's another of Marga's themes, I think), but the substantive issue remains of whether there are modes of presentation associated with names (whether or not they are part of semantics), and if so what they are. Tim in effect argues that there must be something like this, in order that we can know what we're talking about, and I'm sympathetic. One possibility is that these modes are descriptions; that would make things easy, as we could know that the referent is whoever satisfies the descriptions. But maybe there are other possibilities, e.g. that the modes of
presentation are causal chains linked to our tokens, and to identify a referent we follow down the causal chain associated with the tokens (given that we somehow know which causal chain to start following).

My own view, you won't be surprised to hear, is that these modes of presentation are precisely primary intensions. It's the case that any name (as used by a user) has its own epistemic application conditions, i.e. conditions under which it applies to epistemic possibilities, under the hypothesis that those possibilities turn out to be actual. The fact that users know what they're talking about corresponds to the fact that users have the conditional ability to identify the referent of a name given sufficient empirical information about the actual world -- that is, they have the ability to evaluate a name's primary intension at a world. So they have "cognitive access" to their names' primary intensions, and in a sense the primary intension represents the "cognitive content" of the name as used by them. And at the same times, the primary intension determines reference.

The primary intension needn't be a description in any obvious sense, but as we've seen its plausible that it will always have some associated descriptive content (core beliefs, etc).

How does all this relate to the dual-name case? I think the issue Tim raises (about knowing what we're talking about) applies even to cases without ambiguity, but it comes up in a sharp form here. When I use the names "Jane 1" and "Jane 2" (so to speak), I know (or believe) that these refer to different people. This reflects itself in my ability to identify the referent of each, given relevant information about the external world. So in many/most/all epistemic possibilities considered as actual, I can determine the separate referent of the names. This is just to say that I have cognitive access to quite different primary intensions for each name.

The question then arises about just what these primary intensions involve at the psychological/cognitive level; i.e., what is it that grounds my cognitive ability to identify the referents? The description theorist will say that it is the descriptions I associate with the name: in effect, the primary intension is given by some core or cluster descriptions. Someone else might say it is given by a reactive disposition of some kind, not necessarily mediated by descriptions. My own view is that a primary intensions needn't be represented as a description per se, but that nevertheless it will correspond to what we might think of as "tacit descriptive knowledge" about the referent. E.g., even if we identify the referent (with Kripke) by following a causal chain from a token, our very ability to do this suggests a tacit knowledge that the referent is at the other end of the causal chain, which one might think of as tacit descriptive knowledge about the referent in some sense. So on this view, there will at least be some sort of loose link between primary intensions and tacit descriptive content and the cognitive level.

Applying all this back to the Jane cases, the distinct cognitively accessible primary intensions for the two names suggests that there must at least be some sort of different descriptions tacitly associated with each name, that will emerge in the way reference is identified. Just what sort of descriptions they are will depend on the details of the case. I think one is likely to say something quite different depending on whether one is acquainted with the referent in question or has merely heard about them and picked up the name. In the case of acquaintance (e.g. the sister/friend case), I take it one will have tacit descriptive "immediate" knowledge of the people in
question and that some of this will be crucial to reference fixation
(e.g., knowledge of their roles vis-a-vis you).

In the case of non-acquaintance (say I have names for David Hilbert
the mathematician and David Hilbert the philosopher, though I haven't
met either), we'll have deference to a community of prior users of the
name, and things get a bit subtler. One might try using surface
descriptive knowledge (e.g. of career) to disambiguate, but I'm not
sure this gets to the heart of things, as arguably one could be wrong
about those things, and there are cases where one has little such
knowledge. I think it's better to note that one knows (at least
tacitly) that there are two names here (or one knows that there are at
least potentially two people), and one knows that one picked up each
name from the community in a slightly different manner. So in each
case, one fixes reference by deferring to the community, but in
different ways. Maybe for one I defer to the mathematical community
(where I heard the name) and the other to the philosophical community.
Or maybe I don't remember much at all about which community or users I
got the names from, but still, I implicitly defer in each case to
"whatever users I picked up *this* name from", as opposed to "whatever
users I picked up *this* name from" for the other (in effect
demonstrating the different name tokens). That arguably does enough
to get started on the different causal chains by which reference
through deference is fixed.

Anyway, I think you're right that the ability to refer differently
with the two names (or name tokens) suggests that we have some sort of
tacit descriptive knowledge associated with each that reflects our
ability to do so (though in the last case above, the difference in the
knowledge is pretty thin). Just whether this difference in associated
descriptive content (and difference in primary intension, etc) is
enough to refute the direct reference theorist isn't quite clear, as
they still have the option of saying that it's a matter of psychology
(say), not semantics, and that the true semantics of the name still
just involves the referent. But in any case it suggests that there is
something important going on in the vicinity.

This is already too long, and I think we've covered most of the bases
now, but a few quick notes on the other bits.

>How does this relate to the "meaning" of proper names? Consider a
>conversation in which I am talking about my sister Jane, and not my friend
>Jane. Or, better, a conversation in which I'm talking about my sister
>Jane, and someone interrupts to tell me that "Jane wants to
talk to me", and I interpret the second "Jane" to be about my friend. In
>order to keep the references of the various tokens of Jane straight, I
>presumably have to bind some kind of descriptive content to them. At some
>level, don't I have to be thinking "Jane-my-sister" or "Jane-my-friend",
or something with *some* descriptive content?
>
>The precise nature of the descriptive content needed here is not obvious,
>but it is clear that a traditional descriptivist suggestions won't work:
>"The person that everyone around here calls *Jane* won't work", because
>there are lots of people around here called Jane.

I hope I've mostly covered this above. One might argue that the mere
existence of the two names just suggests that you have two different
mental tokens (say) "Jane 1" and "Jane 2", and some sort of tacit rule
for figuring out when someone's "Jane" talk corresponds to one or
other symbol (e.g., your family speaking -> Jane 1, your friends
speaking -> Jane 2). But the fact that you have the ability to know
who you're talking about in a deeper sense, i.e. the ability to identify the referent of each in the world, suggests as above (at least to me) that you must at least have some sort of deeper tacit descriptive content associated with each.

You're right that the nature of the descriptive content isn't obvious. It's a nice example to refute one description (the one you give) that description theorists sometimes offer. It seems that one would need to appeal to either (a) different bits of "first-order" descriptive knowledge (e.g. in the acquaintance case), or (b) different bits of "metalinguistic" descriptive knowledge (in the deference case). And as you say (in effect), the metalinguistic knowledge can't be specified just by using the word "Jane". One will either have to use knowledge of the different communities or users that one picked up the name from, or at least, the knowledge that each token is part of a separate chain of uses, and that each token is causally connected to a point where you picked it up from somewhere. The last case is an example of the very thin "tacit indexical causal descriptive knowledge" that we talked about above, but I guess it is enough to enable one to pick out the different referents, in the case where one has very thin knowledge associated with the name.

The general question of what descriptions a description theorist should appeal to to handle the Kripke cases (e.g. the Feynman, Godel, Jonah cases) and others is a really interesting one that I hope we get a chance to spend some time on at some point. Arguably there are resources that Kripke doesn't consider. His discussion on pp. 160-162 is worth looking at. He concedes (as in footnote 38) the possibility of a relatively trivial "causal descriptivism" that encapsulates the whole causal theory of reference into a description -- not exactly a strong form of descriptivism, but maybe enough for some descriptivist purposes. There are also metalinguistic options to think about, of which he considers some but arguably not the best.

Interestingly he alludes (on p.162) to one of the better of these, "Let 'Glumph' denote the man called 'Glumph' by the people from whom I got it (whoever they are)" but only in conjunction with the "trivial" causal description above. One could argue that this is better than any of the metalinguistic options he considers explicitly, although it is still imperfect -- e.g. it might turn out that you misheard the name, so that you're the only one who uses 'Glumph' but you still refer. But then one might try "the person I heard of under the name 'Glumph'", or "the person referred to by the people from whom I got the name 'Glumph', under the name causally responsible for my use of 'Glumph'". And maybe bring in "this very name 'Glumph'" to get around the ambiguity problems Tim raises above.

It gets tricky, of course, but then the description theorist never said there has to be a universal description formula for all names. Arguably, going for a "cluster" description with one of the metalinguistic descriptions just mentioned as one of the components of the cluster (probably the central component) can handle almost all of the Kripke-style cases and other cases of deference, and can go along way to grounding something like a causal theory of reference in something like a description theory. But that's a long story. Personally one of the reasons I like the primary-intension framework is that it bypasses this need to come up with specific descriptions, which can obviously get very complex quite quickly. Nevertheless I think there are ways in which one can use the framework to lend support to an attenuated version of the description theory.
P.S. I just got this.

>With respect to my previous comment about proper names. . . (Re)reading

>something. I don't have an argument here, but Kripke's discussion seems to
>me to be a little underwhelming.

I think you're right that Kripke doesn't get at all the central
issues. He mostly says that this issue is irrelevant to issues
concerning rigidity, and I think he's more or less right about that.
But arguably it is important for issues about the fixation of
reference, e.g. for issues about causal theories and descriptive
theories of reference-fixing, of the sort he describes in Chapter 2.
There has to be some story about how the different tokens get their
distinct referents, and as we've seen, this isn't entirely trivial.

Incidentally I heard someone a while back give a paper with the
thesis, contra received wisdom but in sympathy with your view, that
all uses of name tokens such as "Jane" are in fact tokens of the same
name. So there is just one name "Jane", one name "Paul", one name
"David Hilbert", etc. She addressed the problem of how the name gets
to refer differently in different cases by arguing that names are
implicit demonstratives -- in effect one is saying "that Jane", "that
David Hilbert", etc, with different intentions to demonstrate in each
case. A demonstrative like "that" can have different referents in
different contexts and with different intentions, but it's still one
word. Same on this view for "Jane". I'm not sure the view is
completely unproblematic, but it's interesting.

---

I have some questions about the Kripke reading- specifically on pages
123-133.

On page 123 Kripke acknowledges that we could be mistaken about gold
having the atomic number 79. But he argues that given that gold does have
the atomic number 79, something could not be gold without having the
atomic number 79. Kripke makes light of Kant's mistaken assertion that
gold is a yellow metal- but it seems that it is *possible* that just as we
found out that all gold isn't yellow, we may find out that we are mistaken
about gold having the atomic number 79. Kripke argues that we can pick
gold out in all possible worlds by its atomic number. But if he was
arguing 300 years ago, perhaps he might have made a similar argument- that
gold is a yellow metal in all possible worlds.

This brings up the question of what properties are essential. I
think the answer is more difficult to pinpoint in cases like 'what makes a
tiger a 'tiger' then for 'what makes gold, gold?' On page 121, Kripke seems to suggest that the external appearance of a tiger is not essential— we must look at its internal structure to determine whether it is a true tiger. My question is two-fold. First, if we were to discover a microscopic virus that happened to have the same internal structure as a tiger—would we recognize it as a tiger? Second, Kripke asserts that certain properties like quadrepedal, tawny yellow, and carnivorous are not essential to tigers, we might find that all these properties are optical illusions, but couldn't we discover the same of the internal structure of tigers?

I guess I have a problem with how to identify natural kinds, particularly in recognizing which properties are essential and which are not. In light of past mistakes (like gold is a yellow metal) I am not sure that we can ever know that we have actually discovered the essence of a natural kind, or what picks it out in all possible worlds. Perhaps you could say, given *our* concept of gold, what picks it out for us is the atomic number 79. But if it seems logically possible to be wrong about gold always having the atomic number 79 in this world, then why couldn't we be wrong about it in other worlds?

As our science develops we discover that our original theories about light and heat were mistaken. I'm not sure how this works— but it seems like if enough of the data (what we recognize as heat and light) don't match up with the theory— then we find a new one. It is still possible to discover that heat is not just the motion of molecules— I suppose that to accomplish such a discovery we would have to be using our primitive notion of heat by which we identify it as a characteristic effect produced on our nerve endings. If heat just *is* motion of molecules then it looks like instead of reformulating the theory— we would have to call that other kind of thing that produces a hot sensation in us— something other than heat. It just doesn't seem that "heat is motions of molecules" or "water is H2O" are as necessary as "a bachelor is an unmarried man." What do you think?

-Rachael

Hi,
I would like to respond to some of Rachael's questions. First, you mention that Kripke doesn't deem properties such as quadrepepedal and tawny yellow essential to tigers. I think the reason for this, is not so much that he is worried about optical illusions, but rather more about cases where a tiger is missing a leg (or about one of those white tigers for instance). Both of these types of tigers are still tigers regardless of their minor physical defects. Secondly you mentioned the possibility of finding a virus that might have the same internal structure as a tiger, and asked whether or not this should be a tiger too? However, I think Kripke was being a little more direct when he mentioned internal structure. I think he was referring to something like the tiger's DNA structure. And, as far as I understand genetics, it will be quite unlikely that a virus would have the same genetic structure (i.e., DNA) as a tiger.

As for Gold having atomic number 79. This is an essential property of Gold. Gold and only gold has this atomic number. Now, we might find something that looks similar to gold, infact almost identical, but I don't see the reason why we would have to call it gold. I think that Kripke...
makes a strong claim here - that for something to be Gold, no matter whether in this world or a possible one, it must have the atomic number 79. Similar looking things with different atomic numbers will not be Gold. Perhaps as an illustrative example, consider Platinum and White Gold. I assume that there is a common distinction between these two. We all agree that they are different, but Platinum and white Gold share many of the same properties. They are both pliable and malleable, they both have a silvery color, etc..

One last thing you mentioned was that it did not seem like "a bachelor is an unmarried man" and "water is H2O" have equal degrees of necessity. You had remarked that it seems in fact that water is H2O does not seem to be as necessary as being a bachelor and unmarried. Perhaps, this comes from the fact that bachelor, simply entails unmarried man, but it doesn't seem to be the same for water (and H2O). However consider the following: Water, white Vinegar, and Parafin. All three look the same. They are all liquid, they all evaporate, they can all make you wet, etc. Now it is clear that these three are different. I think we can see Kripke's point here. When water was found and initially dubbed Water, the liquid took that name necessarily (given a correct dubbing ceremony by competent speakers). Given that the liquid H2O took the name water necessarily, and that that liquid was H2O, water is now necessarily H2O, just like Gold has atomic number 79. So, as I think Kripke would say, both the bachelor and example have the same degrees of necessity. One further thing to think about, and perhaps an issue that makes this a little unclear, is that the statement "water is H2O" is necessary a posteriori, while that of a "bachelor being an unmarried man" is necessary a priori. This might be why it does not seem like the two statements have the same degree of necessity, but, I think that Kripke argues for these two modes of 'coming' to the necessary (a posteriori and a priori) quite forcefully.

Anyways, I hope these comments have helped a little.

-Larry
point generally argues that for a name or natural kind term N and a description D, it is not *necessary* that N is D (there is a possible world in which N is not D). The epistemic point usually argues that it is not *a priori* that N is D (we could find out that N is not D). As we've seen, the points are quite separable, e.g. by considering cases such as "Jack the Ripper" or "Hesperus" where arguably the modal point holds but the epistemic point doesn't.

In Kripke, the modal point is tied to the thesis that names and natural kind terms are rigid designators, picking out the same thing or stuff in all possible worlds. The epistemic point is tied to the causal theory of reference, holding that our names pick out their referent in the actual world not by description but by a causal chain. These two main themes in Kripke -- rigid designation and the causal theory of reference -- are easy to run together but should be kept well apart.

How is all this reflected in the structure of Kripke's book? He goes back and forth a bit, but in essence, the central parts of Lecture 1 are devoted to modal issues and rigid designation, the central parts of Lecture 2 are devoted to epistemic issues and the causal theory, and Lecture 3 has some of each. In more detail (though still imperfectly), I'd divide things up as follows:

Lecture 1

- pp. 22-39: preliminaries (names and descriptions, apriority, necessity)
- pp. 64-70: general issues re description theory (mostly epistemic)

Lecture 2:

- pp. 71-73: general issues re description theory (mostly epistemic)
- pp. 74-78: modal issues (recap: Aristotle, Hitler)
- pp. 79-97: epistemic issues (non-descriptive reference: Feynman, Gödel, etc)
- pp. 97-105: modal issues (necessity of identity, Hesperus=Phosphorus, etc)

Lecture 3:

- pp. 106-116: modal issues (necessity of identity and of origins, essences)
- pp. 116-123: epistemic issues (natural kinds: gold, tigers)
- pp. 122-133: modal issues (natural kinds: gold, water, heat, etc)
- pp. 134-143: general considerations (both epistemic and modal)
- pp. 144-155: mind/body problem

OK, now what about his discussion of gold, in particular. As suggested above, the first part of the discussion (esp. pp. 116-119) focuses on epistemic issues, and the second part (esp. pp. 123-125) focuses on modal issues.

In the first part, he argues epistemically (contra Kant) that it is not a priori that gold is a yellow metal. Here he argues that we could find out (much to our surprise) that gold isn't a yellow metal, e.g. because there was a massive optical illusion. In the second part, he argues that given that gold has atomic number 79 in the actual world, it is necessary that gold has atomic number 79. Here he argues that in a counterfactual situation in which the ubiquitous yellow metal didn't have atomic number 79 (e.g. because it was all a yellow pyrite), it wouldn't be gold.

Note that both these methods of argument consider hypothetical scenarios, but that we think about the scenarios in very different
ways. In the first (epistemic) argument, we take a scenario (the optical illusion scenario) and consider what we would say if we found out that it was actual. In the second (modal) argument, we take a scenario (the ubiquitous pyrite scenario) that is explicitly counterfactual, and we consider how to describe that counterfactual scenario. Here there is no thought of "what to say if this is actual"; rather, we say "given that the actual world is as it is (with gold = element 79), how do we describe the counterfactual scenario".

This difference can be naturally translated into the 2-D framework, so I'll spend a few paragraphs doing that, to help get a feel for that framework.

To put things in the 2-D terminology, the first argument just mentioned requires us to *consider a scenario as actual*, and the second argument requires us to *consider a scenario as counterfactual*. Considering a scenario as actual involves considering it as a broadly epistemic possibility (a way the actual world may turn out to be); considering a scenario as counterfactual involves considering it as a "subjunctive" possibility (a way a world could be, given that the actual world is fixed).

Kripke's epistemic arguments generally involve considering a scenario (e.g. the optical illusion scenario) as actual and thinking about how to describe it. Kripke's modal arguments generally involve considering a scenario (e.g. the ubiquitous pyrite situation) as counterfactual and thinking about how to describe it. It's the former that's relevant to what is a priori, and the second that is relevant to what is necessary, in Kripke's sense.

Taking epistemic arguments first:

Kripke often wants to argue that some statement ("N is D", "Godel proved the incompleteness of arithmetic", "gold is a yellow metal") is not a priori. To do this, he finds a scenario that he considers as actual (considers as an epistemic possibility), and argues that the statement is false when that scenario is considered as actual (he puts this by saying that if the scenario turned out to be actual, we'd say that the statement is false). So he argues that "gold is a yellow metal" is not a priori by arguing that it comes out false when the optical illusion scenario is considered as actual.

This illustrates the general principle: if a statement is a priori, it is true in all scenarios considered as actual. Or to go all the way into 2-D terminology: if a statement is a priori, it has a necessary primary intension.

The primary intension of a statement is defined as the function that takes a possible world and returns the truth-value of the statement in that world when the world is considered as actual. When we think about an epistemic possibility and think about what to say if it is actual, we are just evaluating the primary intension of a statement there. So when Kripke is arguing that a statement would come out false if a given scenario (e.g. the proof stealing scenario, or the optical illusion scenario) is actual, he is in effect establishing that the primary intension of the statement is false in that scenario. So the statement has a contingent primary intension, which corresponds to the fact that it is a posteriori.

Doing this over again with modal arguments:

Kripke often wants to argue that some statement ("N is D", "Hesperus
is the evening star", "stick S is a meter long") is not necessary. To
do this, he finds a scenario that he considers as counterfactual, and
argues that the statement is false when that scenario is considered
that way. So he argues that "Hesperus is the evening star" is not
necessary by arguing that it comes out false when a given scenario
(e.g. Venus was hit by a comet thousands of years ago) is considered
as counterfactual.

This illustrates the general principle: if a statement is necessary,
it is true in all scenarios considered as counterfactual. Or to go
all the way into 2-D terminology: if a statement is necessary, it has
a necessary secondary intension.

The secondary intension of a statement is defined as the function that
takes a possible world and returns the truth-value of the statement in
that world when the world is considered as counterfactual. When we
think about a possibility "subjunctively" and think about how to
describe it (given that the actual world is fixed), we are precisely
evaluating the secondary intension of a statement there. So when
Kripke is arguing that a statement is false of a given counterfactual
scenario (e.g. the Venus-comet scenario, or the pyrite scenario), he
is in effect establishing that the secondary intension of the
statement is false in that scenario. So the statement has a
contingent secondary intension, which corresponds to the fact that it
is necessary.

>From all this, we can see the crucial point that Kripke's epistemic
points always (in effect) concern the primary intensions of our
statements and terms, and that his modal points always (in effect)
concern the secondary intensions of our statements and terms. For
example, the modal thesis that names are rigid designators is in
effect the thesis that names' secondary intensions don't correspond to
descriptions, but pick out the same individual in all worlds. The
epistemic argument against the descriptive theory of reference and for
the causal theory in effect corresponds to the thesis that names'
primary intensions aren't given by descriptions, but by picking out
whatever lies at the other end of certain causal chains.

OK, now back to the gold discussion. In effect, his epistemic point
re gold (that it isn't a priori that gold is a yellow metal, e.g.
because of the optical illusion scenario) is intended to count against
any descriptive theory of reference-fixing for gold, and for some sort
of causal account instead. His modal point re gold (that it
necessarily has atomic number 79, e.g. by considering the pyrite
scenario) is in effect intended to establish that a term like gold is
in some sense a rigid designator (picking out the same stuff across
counterfactual worlds).

The theses are separable, as usual. In effect, the first concerns the
primary intension of "gold" (it picks out what's at the end of a
causal chain, not what satisfies a description), and the second
concerns its secondary intension (it picks out a constant atomic kind,
not what satisfies a description). In this way, he aims to show that
natural kind terms are in *both* respects like names. Causal
reference-fixing, and rigid designation.

Corresponding to these distinct theses, we get somewhat different
results for the primary and secondary intensions of "gold", as
suggested above. To illustrate the difference explicitly, consider a
possible world where there are superficially goldy pyrites everywhere
in the mines and such, and nothing with atomic number 79 there. As
Kripke notes in effect, when we consider that as a counterfactual
scenario (with the actual world fixed), "there's gold in the mines" comes out false there, and "gold has atomic number 79" comes out true. (The pyrites aren't gold, element 79 is.) So, the secondary intension of "there's gold in the mines" is false in this world, and the secondary intension of "gold has atomic number 79" is true there.

But when we consider that world as actual, we get different results. If our actual world turned out that way (with all the stuff in the mines around us being pyrite), then we'd say that gold turns out to be a pyrite, and that it turns out not to have atomic number 79. i.e., when we consider that world as actual, "there's gold in the mines" comes out true, and that "gold has atomic number 79" comes out false. i.e., the primary intension of "there's gold in the mines" is true in this world, and the primary intension of "gold has atomic number 79" is false there.

So for each of these statements, their primary intensions and secondary intensions give quite different results when evaluated in this world. This reflects the fact that the secondary intension picks out atomic number 79 in all worlds, but the primary intension certainly doesn't. Rather, the primary intension picks out something like the substance at the other end of a causal chain from the center. As far as this example is concerned we might be tempted by something like "the yellowish substance in the mines around us" as approximating the primary intension, but Kripke's illusion scenario suggests that that may need to be modified a bit (whether there is any modified description that can do the job is still controversial). In any case, despite the anti-descriptive intention of both the epistemic and modal arguments, we can see that their upshots for the primary and secondary intensions of terms like "gold" is quite different.

--Dave.

P.S. I hope this, and my other messages re the 2-D framework, help to flesh out the discussion in the book and the paper. You can consider these messages part of the "readings" for next week's discussion of 2-D issues. Sorry if I've belabored some of these points, but they're really crucial to what comes later, so I'm hoping all this will soon be second nature, if it's not already.

Rachael writes:

> I have some questions about the Kripke reading- specifically on pages 123-133.
> On page 123 Kripke acknowledges that we could be mistaken about gold having the atomic number 79. But he argues that given that gold does have the atomic number 79, something could not be gold without having the atomic number 79. Kripke makes light of Kant's mistaken assertion that gold is a yellow metal- but it seems that it is *possible* that just as we found out that gold isn't yellow, we may find out that we are mistaken about gold having the atomic number 79. Kripke argues that we can pick gold out in all possible worlds by its atomic number. But if he was
arguing 300 years ago, perhaps he might have made a similar argument—
that gold is a yellow metal in all possible worlds.

OK, there are both epistemic and modal points here. I'll take the
above sentence by sentence. Kripke's initial acknowledgment is the
epistemic point that it isn't a priori that gold has atomic number 79.
His following argument is the modal point that it's necessary that
gold has atomic number 79 (given that it has that atomic number in the
actual world). Kant's "mistake" is the epistemic claim that it's a
priori that gold is a yellow metal. Kripke argues that this is not a
priori, e.g. by raising the epistemic possibility of an optical
illusion. You respond by in effect making the epistemic point that it
isn't a priori that gold has atomic number 79, either. That seems
right, and Kripke would agree. He thinks (modally) that gold's atomic
number is necessary, but he doesn't think (epistemically) that it is a
priori.

Note that Kripke's central point contra Kant isn't that we've found
out that gold isn't a yellow metal (I don't think we've found this
out!), but that we *might* find it out (witness the epistemic
possibility of an optical illusion). Correspondingly, his modal claim
that gold is necessary element 79 and not necessarily a yellow metal
isn't based on the fact that gold has turned out to be element 79 and
hasn't turned out to be a yellow metal -- as far as I know, it's
turned out to be both. The point is that given the way things have
turned out (in which gold is a yellow metal with atomic number 79,
etc), it is necessary that gold has atomic number 79.

Your last sentence raises an interesting issue. 300 years ago, might
Kripke have said that it was necessary that gold is a yellow metal?
Well, presumably if he'd lived 300 years ago he'd have had very
different philosophical views, but let's set that aside by thinking of
old-Kripke as having developed a similar abstract philosophy, but as
having different empirical knowledge (he thinks that gold is a yellow
metal, but doesn't know about atomic number). Certainly the mere fact
that he thought gold is a yellow metal wouldn't make him think its
yellowness was necessary: as above, the inference isn't from "gold has
property X" to "gold necessarily has property X". Rather, it's from
"gold has deep property X" to "gold necessarily has property X",m
where the "deep" properties are some special class. Kripke-1970
thinks that gold's deep properties involve atomic number, not surface
qualities.

The residual question, then, is whether Kripke-1670 might have thought
that gold's deep properties involved its yellowness. I suppose he
might have thought that gold was a homogeneous stuff with not many
further properties than its surface properties. If he'd thought that,
he might well have thought that it was necessarily yellow. If on the
other hand, he thought it had some unified deep microstructure, maybe
he'd have thought it had that microstructure essentially, even though
he didn't know what that microstructure was. Things are complicated
by the fact that the whole idea of microstructure as the unified basis
of surface properties hadn't really developed then. So it's hard to
know what to say. But in any case, it does seem that if Kripke-1670
had said something different about gold, it would have been grounded
in some ignorance about the empirical facts.

Bringing the analogy back, Kripke-1970 probably should acknowledge
that *if* he is wrong about the empirical facts about actual gold,
then he could be wrong in his modal claims. For example, if it turns
out that gold is a compound, then we might say it's that compound
necessarily, not element 79. Or if it turns out that gold has some
even deeper structure, "quark structure XY", then maybe we'll end up
saying that gold has quark structure XY necessarily, and perhaps not
atomic number 79. But all that depends on the empirical facts, which
Kripke is happy to take at face value from the scientists. If the
empirical facts turn out differently, the specific modal claims may
change, but the general philosophical claims will stay pretty similar
(the inference from "gold has deep underlying structure X" to "gold
necessarily has X").

Could even more radical empirical revision make us change even the
abstract philosophical framework? Maybe that's not impossible, but
it's not easy to see exactly how it would go.

> This brings up the question of what properties are essential. I
> think the answer is more difficult to pinpoint in cases like 'what makes a
tiger a tiger' then for 'what makes gold, gold'? On page 121, Kripke
> seems to suggest that the external appearance of a tiger is not essential
>- we must look at its internal structure to determine whether it is a true
tiger. My question is two-fold. First, if we were to discover a
> microscopic virus that happened to have the same internal structure as a
tiger- would we recognize it as a tiger? Second, Kripke asserts that
> certain properties like quadrapedal, tawny yellow, and carnivorous are not
> essential to tigers, we might find that all these properties are optical
> illusions, but couldn't we discover the same of the internal structure of
tigers?

The question of what properties are essential is a modal point.
Kripke thinks that tigers have their DNA structure (or some such)
especially, i.e. that it is necessary that they have this structure.
Your second point here brings together both modal and epistemic
points. The claim that quadrapedal/yellow/carnivorous aren't
essential to tigers is a modal point: it's not necessary that tigers
have these properties, since there are possible worlds where they
don't. The idea that we might find out that these are optical
illusions is an epistemic point: it's not a priori that tigers have
these properties, since we might find out that they don't.

I think you're right that we could find out that tigers don't have the
DNA structure, but that's an epistemic point (it's not a priori that
tigers have this structure) rather than a modal point, so it doesn't
threaten Kripke's claim that tigers have the DNA structure essentially
(given that they have it in the actual world).

What if a microscopic virus turns out to have the same DNA structure
as a tiger? That's an interesting one. Of course, as Larry points
out, we're unlikely to find this out, and if we did discover it, it
would cause our whole biological theory to be revised. My guess is
that if we discovered this, we'd probably give up on the claim that
DNA structure is the relevant deep structure, and so we'd give up on
the claim that tigers have their DNA structure essentially: we'd have
to find some other deep property that's responsible for the
macroscopic differences. Whatever happened, it seems unlikely to say
that we'd say that the virus is a tiger (though just possibly, there's
some outlandish scenario where we would say they were members of the
same natural kind, like carbon and diamonds?).

There's also the question, what should we say about a possible world
where there is something with the DNA structure of a tiger but looks
and behaves like a virus. That's a purely modal issue now (we're
assuming in the actual world, the DNA and tiger-ish properties go
together). Presumably there are weird possible worlds like this. Do
we call them worlds where tigers look like viruses, or not? My guess is that we wouldn't, and that we'd say the virus-ish things aren't tigers. If that's so, that means the property of being a tiger isn't identical to the property of having the DNA structure in question. It may still be that the DNA structure is necessary for being a tiger across possible worlds, but it isn't sufficient: perhaps one needs some sort of organic properties as well. E.g., one might argue that tigers are essentially animals, or essentially mammals, or some such, as well as being essentially that DNA structure (something can have more than one essentially property).

This raises more general questions about just what the essential properties of natural kinds are, and it's hard to give a complete answer easily. Personally, I find there are many cases about which I don't have firm intuitions, and it may be that beyond a certain point the facts about which properties are essential become indeterminate, or terminological, or some such.

> I guess I have a problem with how to identify natural kinds, particularly in recognizing which properties are essential and which are not. In light of past mistakes (like gold is a yellow metal) I am not sure that we can ever know that we have actually discovered the essence of a natural kind, or what picks it out in all possible worlds. Perhaps you could say, given *our* concept of gold, what picks it out for us is the atomic number 79. But if it seems logically possible to be wrong about gold always having the atomic number 79 in this world, then why couldn't we be wrong about it in other worlds?

That's a good point. Kripke will agree that insofar as we can be wrong about what gold is made of in the actual world, we can also be wrong about what's gold in other possible worlds. All he really wants to commit to is the claim that *if* gold has atomic number 79 as its deep structure in the actual world, then it has atomic number 79 across all worlds (or something like that). Presumably, he does actually believe that gold has that atomic number, so he also believes that gold has that atomic number essentially, but he needn't claim that he is certain of either (and they certainly aren't a priori). What matters here is more the abstract philosophical structure, and the conditional connection between gold's structure in the actual world and its structure across possible worlds.

(One might well argue that it's not a priori that gold has atomic number 79 as its deep structure, and its not a priori that gold necessarily has atomic number 79, but it *is* a priori that if gold has atomic number 79 as its deep structure in the actual world, then gold necessarily has atomic number 79. At least, Kripke's philosophical methodology seems to suggest that he regards that conditional connection between nonmodal facts about the actual world and modal facts about possible worlds as a priori.

This is an instance of a general pattern that one might discern in Kripke's claims about a posteriori necessity. The necessary modal truths in question may not be a priori, but they are entailed a priori by certain nonmodal facts about the actual world. E.g., it isn't a priori that Hesperus is Phosphorus or that Hesperus is necessarily Phosphorus, but it is a priori that if Hesperus is Phosphorus (in the actual world), then Hesperus is necessarily Phosphorus. Similarly for other cases.)

> As our science develops we discover that our original theories about light and heat were mistaken. I'm not sure how this works- but it
seems like if enough of the data (what we recognize as heat and light)
don't match up with the theory- then we find a new one. It is still
possible to discover that heat is not just the motion of molecules- I
suppose that to accomplish such a discovery we would have to be using our
primitive notion of heat by which we identify it as a characteristic
effect produced on our nerve endings. If heat just *is* motion of
molecules then it looks like instead of reformulating the theory- we would
have to call that other kind of thing that produces a hot sensation in us-
something other than heat. It just doesn't seem that "heat is motions of
molecules" or "water is H2O" are as necessary as "a bachelor is an
unmarried man." What do you think?

-Rachael

Here again, I think Kripke would agree that it's not a priori that heat is the motion of molecules, though it is necessary that heat is the motion of molecules (given that the motion of molecules causes heat sensations in the actual world). So we could find out that heat isn't the motion of molecules. If the scenario you describe turned out to be actual, I think Kripke would agree that we'd reformulate our theory, and say that the new thing that really causes the sensations is heat.

Kripke would insist, I think that "water is H2O" and "heat is the motions of molecules" are as necessary as "a bachelor is an unmarried man". He'd say that the difference is just that the latter necessity is a priori, while the first two are a posteriori.

I think there is a way of accommodating your idea that the first two are "less necessary" than the third, though. The third is both necessary and a priori. So in this case, the sentence has a necessary primary intension and a necessary secondary intension (it's true across all epistemic possibilities and across all counterfactual possibilities). Or in the terms of the book, it is both 1-necessary and 2-necessary. The first two, on the other hand, are necessary but posteriori. So each of them has a necessary secondary intension but a contingent primary intension (they're not true across all epistemic possibilities). That's to say, they are 2-necessary but 1-contingent. (Or in the terms Evans uses, they are "superficially necessary" but "deeply contingent"). In effect, Kripke always identifies "necessity" with 2-necessity (necessity of secondary intension), so all these come out "necessary" by his lights. Still, the 2-D framework seems to isolate a reasonable sense in which the first two are "less necessary" than the third.

--Dave.
to refer differently in different cases by arguing that names are
implicit demonstratives -- in effect one is saying "that Jane", "that
David Hilbert", etc, with different intentions to demonstrate in each
case. A demonstrative like "that" can have different referents in
different contexts and with different intentions, but it's still one
word. Same on this view for "Jane". I'm not sure the view is
completely unproblematic, but it's interesting.

Burge seems to have advanced something like this view. According to a
secondary source, Burge argued in a 1973 JP piece that proper names don't
refer to unique individuals, but to a kind of individual, namely the kind
with individuals of that name in its extension. The idea, I take it, is
that "Alfred" is a kind name that refers to all the individuals called
Alfred. Does this mean that *Alfred* changes its meaning when another
person gets called Alfred? I.e., Alfred did mean \([x, y]\) when they only
things called Alfred were \(x\) and \(y\), but now it means \([x, y, \text{and } z]\)? That
can't be right. Perhaps the theory is that Alfred refers to the property
(universal) of being such that Alfred is one's name -- in which case (on
most theories of universals), *Alfred's* meaning would not depend on the
objects it was true of. *Alfred* would be a bit like *chair*, on this
account. Being an Alfred would be a rather extreme nominalistic property.

Burge also brings in a demonstrative element to single out which Alfred
one is talking about it a particular situation.

Anyway, apparently Burge used the fact that such sentences as 'there are
lots of Alfreds in this department' to support his claim. Not having read
Burge's paper I don't have a settled opinion of his account.

Some thoughts on the "minutes".

> Our discussion seemed to focus on two issues, broadly conceived.
> (1) What are primary intensions? We spent a lot of time trying to
> work out whether proper names, such as London, have primary
> intensions, and if so, what are they. There was some discussion of
> whether 'London' and 'Londres' have different primary intensions, if
> they have primary intensions at all.

Actually, I discuss the 'London'/-'Londres' case a bit in "The
Components of Content". Everyone should read that paper, since it
gives a lot more detail on the 2-D framework, though it is primarily
cast in terms of concepts, not words.

Do proper names have primary intensions? As I said yesterday, they
arguably don't have PIs that are universal to all users of a name. It
may be that two different users have different PIs for "London", just
as for "Bill Clinton", etc. So this might lead one to say that names
don't have PIs as a matter of "semantics", where the semantics of a
term is supposed to be universal to all users of the term.

Still, I think that it is plausible at least that any name has a PI
for any user on any occasion of use. We might put this by saying that
"name tokens" have PIs (or are associated with PIs), even though "name
types" may not. If so, we can arguably see PIs at least as part of
the semantics of an "utterance" (cf. Reimer's distinction), and
certainly as part of the semantics of an underlying thought.

Why think that name tokens have primary intensions? Basically,
because like any referring word, a name (token) must have some pattern
of application across epistemic possibilities. Just say I use the
name "Godel". Then I can consider all sorts of epistemic
possibilities about the way the actual world might be, and I can see
how the name will refer with each of them.

Think of Kripke's own methodology in Lecture 2 -- we consider e.g. the
epistemic possibility that the incompleteness of arithmetic was proved
by a guy called "Schmidt" and stolen by a guy called "Godel" who
published it, moved to Princeton, etc. Kripke notes, in effect, that
if that epistemic possibility is actual, our term "Godel" refers to
the Princeton guy. That's to say that the primary intension of
"Godel" picks out the Princeton guy in the relevant centered world.
One can do the same thing for a very wide range of worlds considered
as actual (i.e. considered as epistemic possibilities): for a large
numbers of such worlds, there seem to be clear facts about what our
words will pick out if those worlds are actual.

We can think of the primary intension as the "reference-fixing"
conditions of our terms, if we like, though actually I prefer to think
of it as giving the epistemic application-conditions of our terms, or
the "epistemic profile" (as opposed to the "modal profile" of the
secondary intension). It's central to the way language works that any
referring term has an epistemic profile (at least for a given user on
a given occasion): there are facts about how it applies to different epistemic possibilities, and about how it will refer if those possibilities turn out to be actual.

How does one evaluate the primary intensions of names that one uses? Basically, take a name, e.g. "London", take a given centered world, and ask oneself "to what does the name refer if that world is actual"? Here, one considers the world as actual, i.e. considers it as an epistemic possibility: "what if the world actually turns out to be that way?". And for a very wide range of such worlds, we have clear intuitions about how the name refers. E.g., if the actual world turns out to contain XYZ in the oceans etc, then we'll say that "water" refers to XYZ. If the actual world turns out to have the Princeton guy stealing the proof from Schmidt, we'll say that "Godel" refers to the Princeton guy. If the actual world turns out to have a non-whale-eaten guy at the other end of a causal chain from our use of "Jonah", we'll say that "Jonah" refers to that guy. Etc, etc.

Summing up a primary intension in language is often difficult, and the same goes for these cases; what really matters is the function from worlds to referents, not any capsule summary. But if I were to try to get at some of the things that are involved e.g. in the PI of my name "Godel", we might try: "the guy called 'Godel' who's at the other end of a causal chain from my use of the name", or something like that. That's imperfect, as Kripke argues -- e.g. one can consider epistemic possibilities in which the guy my term refers to wasn't called "Godel" at all (I've got his name wrong, or some such). But that just means that we have to refine our view of the PI. Importantly, Kripke's own methodology here relies precisely on evaluating how the term will refer if a given epistemic possibility turns out to be actual, i.e., on evaluating the PI of the term at a world.

As for "London" and "Londres": think of Pierre's situation. For him, there are lots of epistemic possibilities. The world he thinks he is in is one with a beautiful faraway city by the name of "Londres", and an ugly one close at hand called "London". Pierre quite reasonably says that if that epistemic possibility is actual (as he believes it is), then his terms "London" and "Londres" name two different cities: "London" picks out the faraway city and "Londres" the city close at hand. So in that centered world, the PIs of "London" and "Londres" give different results.

On the other hand, another epistemic possibility for Pierre (at least a broad epistemic possibility in the sense articulated earlier) is the actual possibility: i.e., that the people he got the term "London" from were actually referring to the same city he's living in now, and that it has both beautiful and ugly parts, etc. If Pierre were confronted with the hypothesis that this epistemic possibility is actual, he should rationally conclude that under that hypothesis, his terms "London" and "Londres" pick out the same city. So that's to say that in this centered world (Pierre's actual world!), the PIs of "London" and "Londres" give the same results.

So, Pierre's "London" PI and his "Londres" PI give the same result on some centered worlds (including the actual world), but different results on other worlds (e.g. the one he thinks is the case). So they are at least slightly different intensions overall.

How to summarize these intensions in language? Again, it's difficult and imperfect, but we might make a first attempt by saying that his "London" PI picks out "the beautiful city I've heard of under the name 'London'", and his "Londres" PI picks out "the ugly city I'm living
in", or perhaps "the city I've heard of under the name 'Londres'."

Getting the details right will depend on careful consideration of cases, and will depend on just how Pierre's conceptual system is set up, etc. But this gives us enough to see how the PIs might pick out the same extension in one world (the actual world) but different extensions in some other worlds.

The fact that Pierre's PIs are different precisely reflects the fact that it is epistemically possible for him that London isn't Londres. This suggests a general principle: when "A=B" is a posteriori (for a user), A and B have different PIs. To see this, one can go through the following reasoning.

(1) "A=B" is a posteriori;
so (2) it is (broadly) epistemically possible that A is not B,
so (3) there is some epistemic possibility in which my terms "A" and "B"
pick out different things (when that possibility is considered as actual)
so (4) there is some world in which the PI of "A" and the PI of "B"
yield different extensions
so (5) A and B have different PIs.

I hope all the steps here make sense. You can illustrate it by thinking of the London/Londres case, or the Hesperus/Phosphorus case.

Note that the principle here is equivalent to: when "A=B" is a posteriori, "A=B" has a contingent primary intension. (N.B. the primary intension of a statement is just the obvious generalization of the primary intension of a term -- in the book I call this a "primary proposition", but I now tend to use the unified terminology.) If A and B have different PIs, there's a centered world where they pick out different extensions, and in which the PI of "A=B" is false. And to say that "A=B" has a contingent PI is just to say that there's a world in which the PI is false.

This is an instance of a very important general principle:

if a statement S is a posteriori, S has a contingent primary
intension.

It's fair to say that this is at the heart of the two-dimensional account of a posteriori necessity. The central claim of this account is

if a statement S is necessary a posteriori, S has a contingent
primary intension and a necessary secondary intension.

That's not too hard to illustrate by working through the standard Kripke cases. I note that there are just possibly some counterexamples to this principle which someone might put forward, though they probably won't be the standard Kripke cases. We'll be discussing potential counterexamples later in the course, but feel free to suggest any now.

But anyway, one can see how all this hooks in with the need for names to have PIs. Presumably a lot of statements involving names will be a posteriori for many or all users, e.g. "London = Londres", "Cicero = Tully", etc. That's just to say that for a given user, there is the epistemic possibility that the statement is false, i.e., there are some scenarios such that if they turn out to be actual, the statement
turns out false. So the very a posteriority of the statement
indicates that the names in question have distinctive patterns of
applications to epistemic possibilities, i.e. that they have
(distinct) PIs.

That's enough for one message. Hopefully it gives useful background
for thinking about issues in the rest of the minutes. More on the
rest later.

--Dave.

Brad writes:

> This question I think is partially addressed by Dave in his last

> primary intension of "Londres" differs from that of "London" (about
> which Pierre has very different beliefs, such as "it is ugly" and "it is
> dirty" and "the food there is awful").

Actually, I wouldn't say that beliefs "constitute" a primary
intension, though there is a relationship between certain core beliefs
and the primary intension. To determine what a PI is, one doesn't
look at beliefs, but at the application-conditions of a concept to the
world. What matters is what the concept picks out in any given
epistemic possibility. So in Pierre's case, we look at what "London"
would pick out for him if various epistemic possibilities turned out
to be actual. That will be the primary intension.

Nevertheless, there is some sort of relationship between an agent's
beliefs involving a concept and the concept's primary intension. We
can think of a primary intension is roughly corresponding to the
agent's "a priori beliefs" or "unrevisable beliefs" involving the
concept. For example, if a user's primary intension for "one meter"
picks out the length of a certain stick, this corresponds to the fact
that it is a priori for that user that the stick is one meter long.
This might be seen as a "core belief" that corresponds to the primary
intension.

Note that not all of an agent's beliefs involving a concept will
 correspond so closely to a primary intension. Indeed, most beliefs
 won't be reflected in the PI at all. Most beliefs about meters, say
 -- that Olympic athletes run 100 meters, that there are about 1600
 meters in a mile, etc -- and aren't reflected in the PI structure.
 This reflects that the beliefs in question are a posteriori, and could
easily be given up if an appropriate epistemic possibility turns out
to be actual.
In Pierre's case, just which of his "London" and "Londres" beliefs will be "core" and which will be "incidental" to his PIs depends to some extent on his psychology. I actually suspect that his belief that Londres is pretty isn't reflected in the "Londres" PI at all. It could epistemically turn out that the place he had heard of in Paris is actually ugly, but he'd still say that "Londres" refers to that city. If so, the PI (the application-conditions of the term) doesn't require prettiness. Perhaps a core belief might be something more like "Londres is the city I heard of a while ago under the name 'Londres'", or something like that; it's harder to see an epistemic possibility in which he'd give that up. As for "London", I suspect that ugliness and dirtiness will likewise be incidental. Maybe "London is where I've been living recently" is a core belief (i.e. he picks out the referent precisely as the place he's been living), or maybe "London is the place people call 'London'" is, depending on just how Pierre's psychology works.

In any case, I think it's a mistake to think about a PI too much in terms of beliefs. It's true that one can try to find core beliefs in the vicinity of a PI, but the fundamental thing is the pattern of application across epistemic possibilities. The beliefs that turn out to be "core" are just those that are seen to hold across any of these epistemic possibilities; but I'd argue that it's this pattern of application that tells us that the beliefs are "core", rather than vice versa. Otherwise, one can be confused by surface conditions of "coreness" that don't really reflect the deep epistemic profile of the concept. So beliefs are really secondary here.

> There is an article by Georges Rey (1983, I think) in which he argues roughly that we must distinguish the meaning of a concept from the beliefs that an agent has *about* that concept. I gather that on the 2d view Dave is giving, that distinction or separation isn't quite right. > Some beliefs (and this is made clear in Dave's last posting) are constitutive of a concept's primary intension. And from Dave's last posting, it seems to be the beliefs that the agent him/herself takes (perhaps implicitly) to be constitutive.

Well, yes and no, as I think the above makes clear. A few things to say. (1) "Beliefs about the concept" taken literally are fairly irrelevant -- e.g., my belief that I have the concept "London". It's beliefs *involving* (or *using*) the concept that are at issue here -- e.g., my belief that London is pretty. I take it that's what you and Rey mean. (2) I agree with Rey that what really matters is the meaning (the PI), not the beliefs, although there may be a correspondence between the meaning and certain beliefs. (3) As above, even at the level of correspondence rather than constitution, it's only some beliefs that are relevant (the core ones).

All that being said, I think you're on the right track with what you say about the beliefs that matter being the ones that the agent implicitly takes to be constitutive. But again, I wouldn't want to *define* a PI in those terms.

>I think that, in the end, this seems ok to me, though I had previously been compelled by Rey's point. Perhaps Rey's point is applicable only to secondary intensions, which seem to be what Rey means by "meaning".
>There is the odd possibility that a person (say a chemist) comes to be so entirely convinced that water is H2O that the belief that water is H2O becomes constitutive of the concept "water". If future advances in science reveal that water is really XYZ (suppose that it turns out that the theory of the elements is entirely mistaken), on the 2d analysis my...
Hypothetical chemist would have to conclude that water does not exist.

Hmm. I suspect that you're probably right that Rey's intended "meaning" is more like a SI. I think the best way to think about the chemist is not as someone who becomes really convinced that water is H2O. Even such a chemist (normally understood) would presumably concede that she was wrong if the stuff out there turned out to be XYZ. That would suggest that her PI isn't really so H2O-ish. Better to think of her as a theoretical chemist who has never had acquaintance with the stuff out there, who only knows molecular chemistry, and who uses "water" more or less as another name for H2O.

Then if the stuff in the lakes turns out to be XYZ, this chemist won't care at all -- she might go on using "water" as a name for H2O (assuming H2O is still taken to exist on the new theory). For her, "water is H2O" really will be a priori.

[Technical note: The issue here is complicated by semantic deference, as in Burge's arthritis cases. If the chemist is like many speakers in intending to defer to usage in her surrounding community, then I guess it couldn't be that "water is H2O" is a priori for her, and on making the XYZ discovery, strictly speaking her utterance of "water is H2O" would be false. But let's say the chemist doesn't much care about the way others use the term, and uses it her own way (with her own full mastery of her own concept). Then the PI will work the way I suggested.

The residual issue (in the non-deferring case) is whether she could truly be said to have our word "water", or a different word altogether (one which happens to have the same sound and the same referent in the actual world). Some might argue that her failure to semantically defer, combined with her different usage, makes it a different word with a different meaning. Others might argue that the commonality in actual reference is enough, given that it's a natural kind term. They could arguably gain support from the way names work (it's epistemically possible that my "Paderewski" and your "Paderewski" could turn out to refer to different people, but as long as they actually refer to the same person, we're arguably using the same name). What to say about natural kind terms here is really a very subtle and difficult question. Fortunately it doesn't matter too much for our purposes.]

Someone following Rey, however, would not have to say this. Instead, one could claim that the chemist's *beliefs* about water are entirely distinct from what his concept of "water" actually means. So it doesn't matter how strongly the chemist believes that water is H2O--if water is really XYZ, the chemist simply has a false belief *about* water.

Well, I'll agree with Rey that the mere strength of belief isn't enough, but I guess I do think that some beliefs matter somewhere. In the first chemist case, we probably would say the chemist has a false belief about water, because it would turn out that her PI lies elsewhere. Similarly for the deferential theoretical chemist. But in the crucial case, the nondeferential theoretical chemist, if the XYZ scenario turned out to be actual, we might say that she doesn't have a false belief about water at all, just a true belief about something that isn't water (though she calls it "water").

(Note that in all three of these cases, there's arguably some match between PI and belief. Arguably, the PI of the first case would involve "watery stuff" and of the second case might involve "what people in my community call 'water'". These plausibly correspond to *other* beliefs of the chemist, e.g. the belief that water is watery...)}
stuff or that it's called 'water' around here, which would then turn out to be the core beliefs. Of course in the third case the core belief would be that water is H2O, and the PI would pick out the H2O-ish thing in all worlds.)

>I certainly don't think that the above worry is a serious problem for
>the 2d account. It seems to me that the above might simply show that we

>general account to be given of the difference between constitutive and
>"incidental" beliefs (beyond the fact that the difference is that an
>agent *takes* certain beliefs to be constitutive and others to be
>incidental)? Perhaps the beliefs that are involved in the descriptions
>used for "reference fixing"?

The latter is more or less what I'd say. They can be seen as those
involved in reference-fixing conditions, and might equally be seen as
those that the agent would hold to be true no matter which broad
epistemic possibility turned out to be actual. But again, the order
of priority is not: give an account of what it is to be a core belief,
and then define a PI in terms of that. Rather, it's: define a PI in
terms of application to epistemic possibilities (i.e. to worlds
considered as actual), and then define core beliefs in terms of that.

>On a related note, I wonder if anyone can explain the following footnote
>from "The Components of Content" (my page 6, but I assume that varies):

>"Godel", on Kripke's account, turn out to be that the referent has to be
>*that man*--Godel! If I'm understanding Kripke correctly here, I can't
>see how this uses something like primary intensions rather than simply
>using something like a secondary intension--the referent in the actual
>world.

Hmm, remember that by this point, Kripke has moved away from the
"modal" considerations in Lecture 1, and is now on to the "epistemic"
considerations in Lecture 2. His point with "Godel" isn't to make the
Aristotle/Hesperus/etc point that it picks out the same guy in all
counterfactual worlds (that's the point about secondary intensions).
His point is rather one about descriptions in the fixation of
reference, and about epistemic possibility (so it's a point about
primary intensions). In particular, he is taking a given description
D (in this case "the person who proved the incompleteness of
arithmetic" or some such), and he is arguing that it is not a priori
that Godel is D. To do this, he considers an epistemic possibility
(the one involving the proof being stolen) and suggests that if that
possibility is actual, "Godel" picks out the stealer, not the prover.

So he is in effect making the point that the primary intension (the
epistemic application-conditions) of "Godel" are not given by D. And
similarly for any other description, he claims. Note that his
methodology presupposes something like a primary intension, in

http://www.u.arizona.edu/~chalmers/class/596b/week4.txt (7 of 88) [4/7/2002 1:48:38 PM]
considering epistemic possibilities and evaluating reference in them. His claim is in effect that the PI isn't given by a description, but rather works by returning whatever lies at the end of an appropriate causal chain from the word in question. (Of course Kripke himself wouldn't put things in those terms.)

Note that this epistemic point, that it is not a priori that Godel is D, is very different from the modal point, that it is not necessary that Godel is D (i.e., that the secondary intension of "Godel" isn't given by D). The latter point Kripke certainly accepts, and corresponds to the sort of point he makes in Lecture 1, but by now he is making a different point. (See the beginning of lecture 2 for explicitness on this.) I take it that your point about "Godel" referring to *that man* across possible worlds is an instance of modal point, not the epistemic point. (In effect, it's the claim that "Godel" is a rigid designator.)

The two points arguably come apart for a name like "Jack the Ripper", for which the modal point holds but the epistemic point arguably doesn't. Arguably, reference is fixed as "the person who committed the murders", and it's a priori that Jack the Ripper committed the murders (if he exists). Note that Kripke will still say that "Jack the Ripper" picks out *that very man* across possible worlds, so the modal point will still hold, even though in this case the epistemic point doesn't. Here, the primary intension of "Jack the Ripper" can be captured by a description, even though the secondary intension can't.

Translated into the 2-D framework, the modal point is that for all names, the secondary intension doesn't correspond to any description (except trivial ones). The epistemic point is that for most names, the primary intension doesn't correspond to any description. As I noted earlier, the modal point is less controversial than the epistemic point.

The distinction between the modal point and the epistemic point is subtle at first, but it's quite crucial to a full understanding of what Kripke's up to and of the 2-D framework, so people should fire away with questions if they're not quite clear on it.

--Dave.

P.S. Sorry about the unintended e-mail earlier.
primary intension of "Londres" differs from that of "London" (about which Pierre has very different beliefs, such as "it is ugly" and "it is dirty" and "the food there is awful").

There is an article by Georges Rey (1983, I think) in which he argues roughly that we must distinguish the meaning of a concept from the beliefs that an agent has *about* that concept. I gather that on the 2d view Dave is giving, that distinction or separation isn't quite right. Some beliefs (and this is made clear in Dave's last posting) are constitutive of a concept's primary intension. And from Dave's last posting, it seems to be the beliefs that the agent him/herself takes (perhaps implicitly) to be constitutive.

I think that, in the end, this seems ok to me, though I had previously been compelled by Rey's point. Perhaps Rey's point is applicable only to secondary intensions, which seem to be what Rey means by "meaning". There is the odd possibility that a person (say a chemist) comes to be so entirely convinced that water is H2O that the belief that water is H2O becomes constitutive of the concept "water". If future advances in science reveal that water is really XYZ (suppose that it turns out that the theory of the elements is entirely mistaken), on the 2d analysis my hypothetical chemist would have to conclude that water does not exist. Someone following Rey, however, would not have to say this. Instead, one could claim that the chemist's *beliefs* about water are entirely distinct from what his concept of "water" actually means. So it doesn't matter how strongly the chemist believes that water is H2O--if water is really XYZ, the chemist simply has a false belief *about* water.

I certainly don't think that the above worry is a serious problem for the 2d account. It seems to me that the above might simply show that we find it difficult to imagine (or rather, that it is unlikely) that the primary intension of a person's concept of water would in fact come to be constituted by a belief that water is H2O. What beliefs *are* constitutive of primary intensions, in general? That is, is there some general account to be given of the difference between constitutive and "incidental" beliefs (beyond the fact that the difference is that an agent *takes* certain beliefs to be constitutive and others to be incidental)? Perhaps the beliefs that are involved in the descriptions used for "reference fixing"?

On a related note, I wonder if anyone can explain the following footnote from "The Components of Content" (my page 6, but I assume that varies):

"But note that even Kripke's (1980) argument against description theories presupposes something like a primary intension. It proceeds by considering the referent of a concept such as "Godel" at various actual-world candidates, thus evaluating the primary intension, and arguing that any given description gives the wrong result. ...."

I'm not entirely clear how this case shows that Kripke presupposes primary intensions. Doesn't the "right result" for the reference of "Godel", on Kripke's account, turn out to be that the referent has to be *that man*--Godel! If I'm understanding Kripke correctly here, I can't see how this uses something like primary intensions rather than simply using something like a secondary intension--the referent in the actual world.
Hello, I know we're not directly discussing PI's in relation to reference anymore, but lately I think I've managed to unravel what little understanding I (thought I had) on this issue. So, apologies for re-opening some discussion, but here goes. A lot of what I took Thony's concern with PI's to be centered on was the convergence of PI's to descriptive content when using them to fix reference. I take it that Kripke (obviously) wants to avoid this possibility, requiring only of PI's that they are part of a causal chain that begins in the referent and links up to the subject (Chalmers too--see p.59 of TCM). My problem is that, pulling PI's away from descriptive accounts and towards causal ones (or at least calling them "compatible" with such accounts) does not make the application of PI's in reference fixing any less mysterious. I'm not sure that we can have cognitive access to things like causal chains, and if so, I'm not sure how any of this would work.

To put it simply, I don't see how something like "watery stuff" can fail to be descriptive (and therefore adopt all the problems of descriptive theories or reference), or (assuming it is not) how calling in something like a "causal chain" makes the application of a PI any clearer. If this is any objection at all then I suppose it would be sufficiently general to make reference fixing for SI's puzzling too. My general problem is that I can't seem to make sense of what we mean when we say "watery stuff" if it is not shorthand for some description of the properties of that stuff. If we want to call it a causal connection (involving some initial dubbing ceremony), then I guess I don't know how we have access to those sorts of connections such that we can accomplish reference fixing.

The point of this is just to express my confusion with exactly what is meant when someone begins talking about a primary intension. "Watery stuff" is clear enough, I suppose, but when I think about what I mean by this, I end up thinking of a bunch of descriptive conditions. There are two ways to run this, I guess. First, the confusion applies to PI's in particular, not SI's. This seems strange, since it would seem very arbitrary that "surface" properties but not the internal structure of something would be subject to description-theory objections (i.e., Kripke's). Second, fixing reference is equally problematic for PI's and SI's. This doesn't seem right either, because we want to preserve the notion that concepts like "watery stuff" apply in all possible worlds (to water) while "Water is H20" is different in that it could have been something else (XYZ) say, before the reference was fixed. So I suppose the modal distinction is preserved or insulated from epistemic worries about fixing reference, but I'm still troubled by the use and applications of things like PI's in the discussion so far, and I'm not sure what the point of the modal issues are if we can't make sense of PI's and SI's epistemically. Is this all clear (or has it been clarified already?). If so, disregard...

Erik L.
Erik asks some important questions:

> Hello, I know we're not directly discussing PI's in relation to reference anymore, but lately I think I've managed to unravel what little understanding I (thought I had) on this issue. So, apologies for re-opening some discussion, but here goes. A lot of what I took Thony's concern with PI's to be centered on was the convergence of PI's to descriptive content when using them to fix reference. I take it that Kripke (obviously) wants to avoid this possibility, requiring only of PI's that they are part of a causal chain that begins in the referent and links up to the subject (Chalmers too--see p.59 of TCM). My problem is that, pulling PI's away from descriptive accounts and towards causal ones (or at least calling them "compatible" with such accounts) does not make the application of PI's in reference fixing any less mysterious. I'm not sure that we can have cognitive access to things like causal chains, and if so, I'm not sure how any of this would work.

Actually, this posting is right on topic for this week's discussion of PI's and the 2-D framework.

Are PI's like descriptions? On my view, in a sense yes, and in a sense no. PI's needn't be linguistic formulae, or correspond to such formulae. A PI is a function from centered worlds to extensions. Sometimes such a function will be completely captured by a description, such that the PI picks out whatever satisfies the description in world: e.g. "the length of such-and-such stick", for the case of 'meter', or "the individual at the center of the world", in the case of 'I'. But this sort of neat expressibility may be quite rare, and certainly isn't universal. The conditions of application in a PI may be too unruly to be captured by any simple formula, or perhaps by any finite formula at all. So we shouldn't expect to always be able to express PI's as simple descriptions.

But still, there's a looser sense in which PI's behave something like a description. Like a description, a PI captures the conditions that an object in the actual world has to satisfy in order to be the referent of one's term or concept. And like a description, it's plausible that a PI is cognitively accessible in principle, at least in the sense that if a given centered world is specified, a thinker can in principle figure out the value of the PI in that world (by figuring out what the extension of our concept or term would be if that world were actual).

Furthermore, one can at least attempt to *approximate* the conditions involved in a PI by a description. Any short description may be imperfect -- there may be cases where the description and the PI give the wrong results, as e.g. in the Kripke cases. But arguably one can give better and better approximations to the PI by giving longer and more involved descriptions, to handle exceptions and the like. It's not clear that any finite description will be perfect: maybe it will be like the case of "knowledge", where one seems to get longer and longer descriptions (cf. Chisholm's thirteen clauses, and Shope's _The Analysis of Knowing_), and one gets the sense that one needs some sort of infinite "fractal" structure to get all the details just right. But in any case one can arguably give better and better descriptions that cover more and more of the cases.

How does all this play out, if something like the causal theory of reference is correct? Well, I wouldn't say that the PI in this case is a causal chain: you're right that we don't have access to causal chains. But note that even in the Kripke cases, we still have
*conditional access* to extension. Kripke's very own methodology is to consider various scenarios as epistemic possibilities, and to figure out what the extension of our terms (e.g. "Godel", "Feynman", "gold") would be if those scenarios turn out to be actual. So we still seem to have cognitive access from a function to from scenarios to extensions. And that's a primary intension.

How can one cash out the primary intension in descriptive form here? Well, as usual, it's not obvious that one can. But one can at least provide approximations. E.g., one might approximate the PI of 'Godel' as "the individual at the other end of a causal chain from my use of the term 'Godel'", or "the person that experts in my community call 'Godel'", or "the person I've heard of under the name 'Godel'", or some such. Some of these are vague (e.g. the first -- what sort of causal chain is required?) and some may be imperfect (e.g. the second -- maybe I misheard and everyone else calls him "Girdle", not "Godel"?), but at least they give a loose approximation. And arguably they can be refined into better and better approximation.

Is there a perfect description? Well, that's still a topic of some debate. Some think that something like the third description above can do the job (metalinguistic descriptivism). And some think that if the causal theory of reference is right, one ought to be able to bundle it all into a description, something like "whatever individual is causally connected to me in the manner specified by the causal theory of reference" (causal descriptivism). Even Kripke thinks that something like the latter might be done (see p. 162 and footnote 38), though he thinks it is trivial. Whether a less trivial description can do the job -- maybe a "cluster" description with causal and metalinguistic elements -- is still arguable.

Anyway, the PI framework doesn't need to take a stand on whether the PI can be captured by a description. I think by now you can see in what sense it is "description-like", in that it in effect gives the conditions a referent must satisfy, and is cognitively accessible. And in any given case, one can at least try approximating the PI by a description. I often give descriptions to express something about a PI myself, but one shouldn't forget that the description is usually just an approximation. But in any case, given that we have conditional access to extension in a given case (as Kripke's own methodology suggests in even his anti-description cases, and as I think is plausible in almost any case), it follows that we have, in effect, cognitive access to a PI.

To put it simply, I don't see how something like "watery stuff" can fail to be descriptive (and therefore adopt all the problems of descriptive theories or reference), or (assuming it is not) how calling in something like a "causal chain" makes the application of a PI any clearer. If this is any objection at all then I suppose it would be sufficiently general to make reference fixing for SI's puzzling too. My general problem is that I can't seem to make sense of what we mean when we say "watery stuff" if it is not shorthand for some description of the properties of that stuff. If we want to call it a causal connection (involving some initial dubbing ceremony), then I guess I don't know how we have access to those sorts of connections such that we can accomplish reference fixing.

Does the above help? Again, "watery stuff" is really a term of art, and isn't really meant as a perfect descriptive characterization of the PI. Using "watery" in its intuitive sense, then the description might give a very loose approximation to the PI, but there are some cases where it might come apart. In the book I think I stipulate...
instead that "watery stuff" is a term of art to capture the conditions involved in the PI of 'water', whatever they are. To give a full accounting of those conditions and of the PI, one can really only consider things case by case: look at scenarios, and see how the extension of 'water' should come out there.

If I were to really try giving a description for the PI of "water", I suppose it would probably involve its superficial properties (though defeasibly, to allow for the epistemic possibility of optical illusion?), and it might also involve a causal connection criterion, perhaps even a condition of causal connection to my use of the token 'water'. And any such description would likely be imperfect. But at least it gives an intuitive idea.

In any case, the complexities of exactly capturing the PIs of our linguistic terms don't really matter much for our purposes in metaphysics. Beyond a certain point, the complexities of "what counts as 'water' in this situation, or in this one" become somewhat terminological. For explanation, for example, what matters is explaining the manifest properties of people such as Godel and stuff such as water, and here the terminological complexities of just who and what gets to count as "Godel" or "water" becomes irrelevant after a certain point. (Even if the PI of 'water' isn't perfectly captured by "watery stuff", it might as well be for many purposes.) It remains the case that getting things just right is very important in the philosophy of language, but 's is not clear that all the fine details matter to the metaphysician or to the scientist. That's why I tended to brush aside some of the fine details in the book.

The point of this is just to express my confusion with exactly what is meant when someone begins talking about a primary intension. "Watery stuff" is clear enough, I suppose, but when I think about what I mean by this, I end up thinking of a bunch of descriptive conditions. There are two ways to run this, I guess. First, the confusion applies to PI's in particular, not SI's. This seems strange, since it would seem very arbitrary that "surface" properties but not the internal structure, of something would be subject to description-theory objections (i.e., Kripke's).

Re SIs, I suppose things are a bit different since it's not part of the package that they are cognitively accessible (in a nontrivial' sense) to anyone who possesses the concept. You need substantial empirical knowledge of the actual world in order to evaluate the SI of one's concept in an arbitrary possible world (e.g., you need to know about the actual structure of water to know that the SI of 'water' picks out H2O across worlds). But I suppose there's a sense in which at least after the fact, SIs are often easier to summarize with descriptions (e.g. "H2O") than PIs are. I'm not sure that this is always so (personally, I think one might even worry about whether any H2O in any world counts as water), and its not clear that there aren't some more resources for expressing PIs (I'll talk about alternative ways of looking at them a bit later), but even if so, I think it's really an issue of relative simplicity, rather than expressing some deep metaphysical difference. (Of course, there is the epistemological difference in cognitive access.)

Second, fixing reference is equally problematic for PI's and SI's. This doesn't seem right either, because we want to preserve the notion that concepts like "watery stuff" apply in all possible worlds (to water) while "Water is H2O" is different in that it could have been something else (XYZ) say, before the reference was fixed. So I suppose the
modal distinction is preserved or insulated from epistemic worries about fixing reference, but I'm still troubled by the use and applications of things like PI's in the discussion so far, and I'm not sure what the point of the modal issues are if we can't make sense of PI's and SI's epistemically. Is this all clear (or has it been clarified already?). If so, disregard...

Well, we want "water is watery stuff" to be true across all worlds considered as actual (i.e., PI true in all worlds), and "water is H2O" to be true across all worlds considered as counterfactual (i.e., SI true in all worlds). Of course one difference is that the necessity of the SI depends on empirical facts about the actual world while the necessity of the PI doesn't. But that just reflects the fact that PIs are much more closely tied to epistemic notions such as apriority than SIs are.

Re epistemic access to PIs and SIs: as I said, I think one has access to a concept's PI merely by possessing the concept (you then have the ability to figure out how it refers if a given world is actual). For an SI, I think one only has conditional access to it: one doesn't have nontrivial access to it merely by possessing the concept, but one does have access given sufficient empirical knowledge. So on my view, one has a priori access to a PI, and a posteriori access to an SI, but one does have some sort of a priori access to the way that an SI depends on the way the actual world turns out.

all

re Dave's answer to Erik's comments about PI's, the questions that follow have really already been answered but I guess I'm just not getting it through my thick scull...

Dave says that primary inentions are functions from centered worlds to extensions, which is straightforward, but given that it may be impossible to specify or spell out the conditions for application, I (still, sorry) don't see how such a function can do us any good...(a function that has no specifiable conditions of application hardly seems like a function at all)

I understand that the PI is supposed to "capture the conditions that an object in the real world must satisfy in order to be the referent of one's term or concept", but given that this must be done on a case by case basis and cannot be cashed out in terms of any description (even if one is available, such a description is not of primary importance, right?)...I still don't understand the "sense" in which anyone who has the concept can "in principle" evaluate PI's except as a matter of personal intuition...it seems to me like everyone will have their own "function" for each PI, which will also be just what they happen to have in mind...I think that Dave intends this not to be a problem....something about not mattering "after a certain point"...this is what I really need explained...why doesn't it matter after a certain point?
I understand what a PI is intended to accomplish and I understand how, in principle, or in some vague sense, it is actually used, but what I'm unclear on is why it is "unimportant" that PI's be such vague and unspecified tools...

Angela asks some good questions, to which I'm not sure I have perfect answers, but I'll do my best.

> Dave says that primary inentions are functions from centered worlds to extensions, which is straightforward, but given that it may be impossible to specify or spell out the conditons for application, I (still, sorry) don't see how such a function can do us any good...(a function that has no specifiable conditions of application hardly seems like a function at all)

Hmm, I'd say a function is a function (i.e. a mapping from one domain to another, here a mapping from worlds to extensions), irrespective of whether there is any easy summary of a "rule" that generates the function. You're right that's its nice to have some sort of summary of a function when one can, but it's not clear to me why it should be essential. In the case of PIs, we've seen that one can get reasonably good approximations of PIs by descriptions, and better and better approximations by more and more complex descriptions. I'd like to think that that's good enough (and in fact, that even the approximability of a PI by descriptions is something of a bonus rather than being essential. But maybe I'm wrong. What do you think is the reason or purpose for which exact descriptive summaries of PIs are essential?

> I understand that the PI is supposed to "capture the conditions that an object in the real world must satisfy in order to be the referent of one's term or concept", but given that this must be done on a case by case basis and cannot be cashed out in terms of any description (even if one is available, such a description is not of primary importance, right?)...I still don't understand the "sense" in which anyone who has the concept can "in principle" evaluate PI's except as a matter of personal intuition...it seems to me like everyone will have their own "function" for each PI, which will also be just what they happen to have in mind...

Right (re your first question). Sometimes there will be a description, but even here we figure out the aptness of a description precisely by seeing whether the evaluation of a description matches our evaluation of the PI at a given world. (Witness Kripke's methodology: he argues against various descriptions by arguing that there are worlds where the description gives the wrong referent. That's to say, the evaluation of the description doesn't match our evaluation of the PI. So there is arguably some sense in which even when a description is available, the PI is prior to the description, at least epistemically. (Though it may be that at some other level, e.g. psychologically or even semantically, it's the description that fixes the PI.)
You're right that "intuition" plays a central role in evaluating PIs. Again witness Kripke's methodology in the theory of reference: he considers his own intuitions about what the referent of "Godel", "Feynman", etc, will be across various situations. One might say this makes it just "personal intuition", but note that we do seem to find considerable agreement across many or most such cases (cf. the proof-stealing scenario), so it's not as if mere personal taste is at play. It seems to be a fact about us that once we know about how the actual world turns out qualitatively, we're in a position to know the reference of our terms and the truth-value of our statements (we'll be focusing directly on this "scrutability" thesis later on). This doesn't appear to be a mere vagary of personal taste, but a reasonably systematic process of reasoning and judgment.

I note that if it's just "personal taste" across possible cases, by similar reasoning it would be just personal taste that determines our judgments of reference and truth-value in the *actual* world (given empirical information about it). On the face of it, that doesn't seem too plausible: although intuition is involved in these judgments (is in almost any judgment), there's plausibly a fact of the matter in both cases about the reference of our concepts and the truth-value of our thoughts, a fact of the matter that we are plausibly capable of figuring out given sufficient qualitative empirical information and a priori reasoning. But if we can do that for qualitative information about the actual world, presumably we can also do it for information about all sorts of other ways the actual world might hypothetically turn out. Just apply the same sort of reference- and truth-figuring processes (after all, if we were all told that the actual world was just that way, we'd be able to figure out the consequences for truth and reference). So I do think something more than just personal taste is present here.

Of course it may be that two users will make slightly different judgments about the truth and reference of their terms across various possible worlds (considered as actual). One way this can happen is for there to be conceptual differences between the two -- i.e. our concepts really do have slightly different PIs as an aspect of their content, as e.g. in a deferential user of "arthritis" and an expert user, or two people with slightly different concepts of "London". But that isn't a problem. Leaving that sort of case aside, I suppose another thing might happen is that we'll make slightly different judgments in borderline or fuzzy cases. I think that sort of thing is relatively unimportant. When it comes to borderline and indeterminate cases, all bets are off. What matters is that we have clear judgments (in principle) about the clear cases.

I also note that it's not clear how having descriptions would help with this problem. If two users have different judgments about reference in a given case, presumably that would require that they have different descriptions. So if you're right that there are a lot of differences in judgment, then there will be a lot of personal descriptions, too. So the issue of intuition and judgment is arguably somewhat independent of the issue of intensions vs. descriptions.

[Side note: There is a question about whether a PI should be defined in terms of a user's best a priori *judgments* about the reference and truth-value of their concepts and thoughts in given epistemic possibilities, or should be defined as what the reference and truth-value of the concepts and thoughts *would be* in those epistemic possibilities, if they turned out to be actual. I hold that these two
notions always or almost always give the same results, but for some purposes it is useful to distinguish them: call them an epistemic PI and a fixing PI.

Re your point above, a user's judgments and intuitions play a role in defining an epistemic PI (though I note that one is idealizing by allowing arbitrary a priori reasoning here). For fixing PIs (which are arguably the most straightforward), however, judgments and intuitions play no role in the definition. All that matters there is patterns of reference and truth. So focus on those if you want to avoid any problems with intuition and judgment.

We can talk more about epistemic PIs and fixing PIs if people like. The issue will come up a fair bit anyway, re the discussion of scrutability. Basically, epistemic PIs as defined are a priori accessible, and fixing PIs as defined fix reference, but one needs epistemic PI = fixing PI in order to have something a priori accessible that fixes reference. The requisite bridge is provided by the "scrutability" thesis that reference of our concepts and truth-value of our thoughts are always knowable in principle given sufficient qualitative information about the world and sufficient a priori reasoning. That's a thesis I've already implicitly appealed to a few times, and which is consistent with e.g. the standard methodology in the theory of reference.

Some might think there are exceptions to this thesis, "inscrutable truths": e.g. if the epistemic theory of vagueness is true, it might provide some. If this were so, it would raise complexities for PIs, e.g. requiring us to distinguish epistemic and fixing PIs. I hold that there are no inscrutable truths, but that's something we'll be discussing at length later.]

I think that Dave intends this not to be a problem....something about not mattering "after a certain point"...this is what I really need explained...why doesn't it matter after a certain point?

I don't remember what I said didn't matter. I think small disagreement about the application of our concepts across cases. That basically suggests that our concepts have slightly different PIs, or that one of us hasn't really reasoned things through, or that we're dealing with a borderline case. But it's not clear that any of those phenomena matter much. Different people do indeed have different conceptual contents (often even associated with the same word), and a little indeterminacy around the edges of a PI doesn't matter any more in principle that indeterminacy around the edges of actual-world application. A general theme is that whatever goes for the actual world goes for possible worlds, too (e.g. re indeterminacy, epistemic access, and the like).

I understand what a PI is intended to accomplish and I understand how, in principle, or in some vague sense, it is actually used, but what I'm unclear on is why it is "unimportant" that PI's be such vague and unspecified tools...

Well, it depends on what you mean by vague and unspecified. "Vagueness" in the sense of indeterminacy at the edges (i.e. worlds in which a PI is borderline true/false) can happen but doesn't seem worse than actual-world vagueness. "Vagueness" in the sense of indeterminacy even on core cases I don't think exists -- for any concept and thought, there is a very wide range of scenarios on which the concept is true or false. "Unspecified" in the sense of
ill-defined I'd also argue with -- PIs have a perfectly good definition (whether epistemic or fixing), associating a concept with a clear value in worlds across a range of cases.

Your central problem is presumably not any of the above, but rather "unspecified" in the sense of not being given by a neat description. I'm still not sure just why this is a problem. I guess the proof has to be in the pudding, but I think that application to a range of issues shows that the notion of a PI can do a lot of explanatory work (see e.g. the content paper), and that indeed much or most of the work that descriptions do for us is in virtue of their determining an intension rather than in virtue of their linguistic form.

There's more to say on this, but I have to go to bed. I may well be missing something, and I imagine you're not the only one who is at least somewhat bothered by the issue, so you or anyone else should fire away and say just what you think we lose by having an intension instead of a description.

--Dave.

P.S. I'm looking forward to everyone else's posts for this week, and to the minutes of Tuesday's meeting. Note that re the "Components of Content" paper, the issues about psychological explanation and belief ascription, etc, aren't central to what we're focusing on this week, though we may come back to them. It's the general framework that's most important, and its application to the understanding of necessity, apriority, reference, and content.

First off, I am in agreement with the idea of notional content. I have always considered the thinkers relation to the concept to be an integral part.

I've been wondering if/how time fits into the picture. It is mentioned in a few spots in Components of Content:, "facts about the current environment...", "Tom is hungry at time t..." Take the Phosphorus/Hesperous example, if I understand correctly, these have different primary intension but fix the same referent, Venus. Can I say that there is a physical difference, namely the space and time, between Phosphorous and Hesperous?

Also, I don't understand what happens in the case where someone ONLY knows about H2O's chemical properties (theoretical chemist). Is this a case of a descriptive concept where the secondary intension is simply the primary intension?

My intuitions about Josh's brain in a vat, as we discussed this afternoon, are that, similar to a paradigm shift in science, water would just mean watery stuff like always, but now it just has a different explanation that the "new man" would need to learn to assign it.

Erik H.
Erik writes:

> different primary intension but fix the same referent, Venus. Can I say
> that there is a physical difference, namely the space and time, between
> Phosphorous and Hesperous?

Well, time is built into the center of the world. In effect, the
center consists of an individual at a specific time (or an ordered
pair of an individual and a time). That's needed for concepts such as
"now", which pick out the current time (i.e. the time at the center),
and for a bunch of related concepts.

I'm not sure exactly what you're asking in the last sentence.
Basically, the idea is that the PI of "Hesperus" picks out (something
like) the bright object visible in the evening sky from the point of
view of the center, and the PI of "Phosphorus" picks out the bright
object visible in the evening sky from the point of view of the
center. In the actual world, the evening object is the morning
object, so those two intensions pick out the same object, namely
Venus. So the two concepts have different PIs but the same referent
(cf. Frege on sense and reference).

Also, I don't understand what happens in the case where someone ONLY knows
about H2O's chemical properties (theoretical chemist). Is this a case of
a descriptive concept where the secondary intension is simply the primary
intension?

I'd say that's close to right. At a first approximation, we can say
the PI and the SI both pick out H2O in all worlds, so it's like a
descriptive concept. On a second approximation, though, one can note
that "hydrogen" probably isn't a descriptive concept. Its PI picks
out some gaslike stuff in all worlds, and its SI picks out some
particular atomic structure in all worlds. Similar for "oxygen". So
it may be that the SI of "H2O" requires just that atomic structure
(with just the right number of protons, neutrons, electrons, etc),
while the PI of "H2O" isn't quite so constrained.

(The PI of H2O is tricky, though. It comes down to tricky questions
about e.g. what we'd say if hydrogen and oxygen exist but are quite
unlike what we thought they were in atomic structure; but nevertheless
there is still a substance with two hydrogen particles and one atomic
particle, or some such. Would we count that as H2O, or would the
change in chemical theory make us throw away the whole concept of
"H2O" and say it doesn't refer? Maybe the former, but it's a subtle
issue. Maybe in the grey area. In any case, though, it does seem
that the PI will allow for at least some smallish variation in
structure that the SI arguably won't.)
Interesting to see people's comments re Josh's case. It would be good if people can be as explicit as possible about how their views on the referent of "water", etc, in these cases fit into the 2-D framework. (E.g. given your views on the reference of the concept and the truth of the thoughts before and after, what is the PI, and what does it pick out in the various centered worlds before and after vat-release?)

A little more on Angela's note from yesterday. Maybe one can think of a PI as something like a tacit descriptive content of a concept. It may not be something that a speaker can directly articulate, and there may not even be any summary of the relevant content in words, but one could argue that in some sense the descriptive content is there at least tacitly, in guiding one's judgments about reference in various epistemically possible cases. Of course we may have to break the link between "descriptive content" and precise linguistic descriptions, though. It will be more like something analogous to descriptive content with the linguistic element removed. (Something like a property that determines reference, or some such.) That's a bit loose, but maybe it helps with the intuitive picture.

--Dave.

Josh raises a couple of interesting brain-in-vat scenarios. There are actually two sorts of question in the vicinity: (a) what to say about the beliefs in question, whether they are true or false before and after escaping from the vat, and (b) whether what one says re (a) can be accommodated within the 2-D framework, and if so, how (what do we have to say about the PI's of the relevant concepts, etc). Personally I'm not certain of the right thing to say about (a) (there are multiple intuitions), but I'd like to think that any reasonable answer to (a) can be accommodated within the 2-D framework somehow. It's a nice test case, though.

Maybe I'll hold off on posting my own response to these scenarios in order to give other people a chance to post their analyses and comments on what's going on here. Fire away!

--Dave.
The following is a case that I don't know what to do with. Suppose scientists pull your brain out of the vat it has been in up until now and tell you that your whole life has been a lie. They created the world you thought you were living in all this time. Suppose you are convinced they are right. But now you are out of the vat and in a real body and can go explore the world. As you leave the laboratory and walk out into the world you see that everything is just like it was in your vat. There is grass, trees, water etc. But then one of the scientists runs up and says, "Ahh. One point we forgot to tell you. The underlying physics of the world is different from the one we presented to you in the vat. From the molecular level on down everything in your vat world was different. For example, water is XYZ."

Case 2a: Same as above except that while I'm still living in my vat world, a dramatic scientific revolution occurs in which physics, from the molecular level on down is determined to be different than we though. For example, water is XYZ. I'm shown how thinking that water is H2O is wrong and actually it is XYZ. After I'm convinced of the new theory I'm pulled out of the vat and everything runs as above except that now the real physics matches my vat physics.

Now here is the puzzle. Primary intentions pick out "watery stuff" in the actual world. My intuition is that the actual world in both cases is the post-vat world. However, if I were the one pulled out of the vat in case 1 I'd say that there is no 'water' in the actual world. There is just watery stuff. But if I were pulled out of the vat in case 2, I'd say there is water in the actual world.

If you share these intuitions, then there seem to be two possibilities: 1) My primary intention of water includes the chemical make up of water or 2) Primary intentions do not fix reference in the actual world but fix reference in some other way.

What do you all think?

Josh

This is a fascinating case, but I'm not so troubled by it primarily because I don't share the feeling that water in post-vat world would be relegated to "watery stuff" if the underlying physics of the world turned out different. In a sense, the scenario is not appreciably different than one in which my "brain in the vat" life was just general ignorance of the way the world really was. For the purposes of fixing reference with a PI, you have to buy that the shift in physics from vat-world to post-vat-world will shift your PI of water, but it's not at all obvious that this would happen. A more plausible scenario (for me, anyway) would have one replacing the physics of water while retaining the PI to fix reference for whatever was watery stuff, in the vat or actual world. Here I think epistemic issues pull away from the modal concerns. Now, given that the PI of water does not change from vat to actual world, the physics of water is not part of its PI, so the first possibility can perhaps be dispensed
with. The second possibility is sort of conditional on the first, in the sense that, if one doesn't think that the PI will shift from vat to actual worlds, then the reference fixing work of the PI is intact. Of course, things get substantially trickier if one shares Josh's intuition on the vat to actual world shift in PI (from water to non-water) from the physics-of-water epistemic shift in these worlds.

"What our grammarian does is simple enough. He frames his formal
reconstruction of K along the grammatically simplest lines he can,
compatibly with inclusion of H, plausibility of the predicted inclusion
of I, plausibility of the hypothesis of inclusion of J, and plausibility,
further, of the exclusion of all sequences which ever actually do bring
bizarreness reactions." -- W.V.O. Quine
re: Josh's scenario...

I guess I just don't share the intuition that I, upon exiting the vat and discovering that water was XYZ, would from that point on be of the opinion that there really was no water. Rather, I would just think that I had been deceived, or had been radically mistaken about what water is....

I understand the temptation, especially given the amount of scientific information that is part of common knowledge, to say that H2O really is part of the primary intension of water, but, the very fact that I (and presumably others) can make sense of counterfactuals like, "Water could have been other than H2O," or "Water might not have been drinkable by humans", or "Water might not have had the property of appearing blue in daylight," etc... strongly suggests that almost nothing of what we know a posteriori of water is contained within the primary intension.

best, Angela

In response to Josh's scenario: my intuition is that the two cases are identical-- and that the new watery stuff is "water", it's just that he/we were wrong about it's makeup.

Erik H.

Regarding the responses to my BIV cases, I'd like to make a few clarifications. There are two ways that I see of accounting for my intuitions. The first is to claim that the chemical make up of water is part of my PI. The second is to claim that my PI is just like everyone else's BUT PIs don't map centered worlds considered as actual onto referents.

I think the second of these claims is the more likely. The idea would
be that PI's perhaps map centered worlds thought to be actual during concept formation onto referents. (I already see several problems with this definition, but that is the basic idea.) Since vat-Josh formed his concepts while thinking that vat-world was actual, he would then map water to clear drinkable liquid in vat-world. And in Vat-world water is H2O.

Josh

Subject: Re: 2D questions
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

Here are a few thoughts on Josh's "water" case. In this message I'll give my own analysis, and in the next I'll give some thoughts on others' analyses.

The first thing to get straight on is whether one thinks the judgments in question are true or false, before and after the vat.

Case 1: I think "water is H2O" in the vat. I escape from vat, find a similar-seeming world, except that the watery stuff is XYZ.

Case 2: I think "water is H2O" in vat, until a within-vat revolution convinces me of "water is XYZ". I escape from vat, find a similar-seeming world, and the watery stuff there is XYZ.

Q1: What (if anything) do I refer to as "water" pre-escape?
Q2: What (if anything) do I refer to as "water" post-escape?
Q3: Is my statement "water exists" true or false pre-escape?
Q4: Is my statement "water exists" true or false post-escape?

There are various things to say here. It's probably simplest to first set aside the belief changes re XYZ and H2O, and think about what "water" might refer to pre- and post-vat in an ordinary BIV case. Here some distinct issues peculate to BIV cases some up. For example, many would say that while in the vat, my term "water" doesn't really refer to anything, and that my thought "water exists" is false. After all, isn't a brain in a vat a classic case of someone who is deceived about the external world?

One could accommodate this line in the 2-D framework by saying e.g.: (1) the PI of "water" picks out something like "the watery stuff in the environment that the being at the center has been causally related to" (not an implausible analysis of my "water" PI), and (2) if I am a BIV, my centered world (i.e. my actual world, not merely the world-as-I-believe-it-to-be) doesn't have anything that satisfies that PI. (There's no watery stuff causally related to me in my actual environment.) So the PI will pick out nothing, and my vatted thought "water exists" will be false.

On this line, what will happen when I come out of the vat? Well, arguably when I emerge for the first time into the "real world", my term "water" doesn't yet refer to actual water, because there's no causal connection yet. But after interacting with the environment for a while, the causal connection will get going, and perhaps eventually my term "water" will come to refer to the actual stuff (H2O).
that all that will be compatible with the PI analysis above: nothing will satisfy the PI at stage 1 (centered on me in vat) at stage 2 (centered on me just after escape), but something may satisfy it at stage 3 (centered on me well after escape), as by then the center will have plenty of causal relations with some watery stuff.

Another line that some philosophers take is that while in the vat, my terms like "water" refers to some chemicals or nutrients in the vat around the brain, because these are what I'm causally connected to. I don't find this very plausible myself, but if one takes this line, one could accommodate it by dropping "watery stuff" from the PI above, and by saying that the PI picks out roughly "the stuff in the environment that is causally responsible for the being at the center's use of the word 'water'". In this case, we'll have "water exists" true at stage 1 (it picks out chemicals), arguably false at stage 2 (t still picks out chemicals, but I suppose that could be true since the chemicals still exist), and true again at stage 3 (by now, the PI picks out real water).

Alternatively, one could be tempted by the idea that while in the vat, one's term "water" refers to something in one's "virtual world", or something like that, so that one's vatted thoughts "water exists" is true. This has the problem of making it hard to express how the BIV is deceived, and could even end up leading to some sort of idealism or phenomenalism. But there is arguably something to the intuition that there's some sense in which the BIV's "water is H2O" is truer than "water is XYZ" (assuming the virtual world is an H2O-world). Maybe one could accommodate this by saying there's two ways to read such thoughts, a strong way in which they all come out false, and a "weak" way where some come out true, or some such. E. g., the "weak" way might involve prefixing "According to the virtual world", or might have a PI involving "seeming-objects which seem to be causally connected to me", or some such. This would be a tricky row to hoe, but maybe there are possibilities. In this case, one could say that reference of "water" gradually shifts after release, just as above.

Anyway, I think one can factor away from these tricky BIV issues for considering Josh's main point. I'm not sure whether Josh's point would work equally well if the vat world were replaced by another planet in which one is brought up, and that brought to earth. That would probably give similar results at least to line 3 above, and arguably to line 2, though maybe not to line 1. But the crucial claims about how "water" refers after release may be similar each way.

What to say about case 1, where I believed "water is H2O", and find out post-vat that the watery stuff is XYZ? I'd be tempted to say, as in the cases above, that immediately post-release my term "water" still refers to whatever it referred to just pre-release: either nothing, or some chemicals, or perhaps some virtual H2O in the virtual world. So my statement "water exists" then will be false, or in any case if true won't be made true by the actual watery stuff. But after a while of interacting with the real environment, my term "water" might well come to refer to the XYZ, and my claim "water exists" will be made true by the actual environment.

I think that's so despite the fact that I believed in the vat that water was H2O. After all, within the vat that belief was potentially malleable (if people had told me the watery stuff was XYZ, I'd have accepted that water was XYZ), so the same ought to be the case outside the vat. In fact, I think that even if no-one outside the vat ever tells me that water is XYZ, my term "water" may eventually come to
refer to the XYZ by virtue of my causally interacting with it, etc. In this case, I'll eventually have a false belief that "water is H2O" but a true belief that 'water exists'.

If that's how things so, I think it's compatible with the PI staying constant throughout. E.g. if the PI is "the watery stuff in the environment that the being at the center has been causally related to", this seems to give the right results: it picks out nothing at stage 1, nothing at stage 2, XYZ at stage 3. And that's so irrespective of my belief changes.

I'd be tempted to say something similar about case 2. Here, I think there still needs to be a gradual reference-shift from vat-reference to actual reference. Even if one thought "water is XYZ" in the vat, and actual watery stuff is XYZ, it's not clear that one's thought (immediately post-escape) "water is XYZ" is true, or at least it's not clear that it's made true by the actual XYZ. It takes some interaction for the term "water" to pick out the actual stuff.

[A side note: It may be that if the scientists tell you immediately "you were in a vat, but now you're out, and fortunately the real world is a lot like you thought the vat world was", you might decide to make a new stipulation that all your words will refer to actual things rather than vat things, rather than keeping a lot of terms around that don't refer to anything useful. That's tricky in some cases: e.g. re "my wife", or "Ethel", say, does one really want to say that the term refers to a person in the actual world who you've never strictly speaking met before? But I suppose one could try to stipulate that at least some terms refer to their qualitative counterparts. If that's so, then "water" might immediately pick out the respective watery stuff.

As for what to say if there are a few small differences between vat world and actual world (e.g. they replaced H2O by XYZ), that's awfully tricky. I guess it depends on one's stipulation. One might stipulate "in case of any differences, my term doesn't refer", or one might stipulate "in case of any differences, my term refers to whatever is superficially similar enough", or some such. In the first case, my post-escape "water exists" might at first be false; in the second; it might be true. But that all depends on just what stipulation one makes. Such a stipulation might well change one's term's PI a little bit, as any new stipulation will.

Probably it's easiest to think about these things in a case where the scientists don't tell you you've escaped, so one isn't faced with the immediate wrenching discovery that forces you to reevaluate your whole conceptual scheme. Instead, maybe do things so that you don't know you've undergone such a radical shift. Even so, we can evaluate truth and reference, and we can still consider what happens if there turn out to be small changes in the environment. That way the "stipulation" aspect is removed.]

Anyway, that's how I'd be tempted to analyze these cases. I think its plausible on most ways of doing things that one's PI stays constant, but its referent may gradually shift, in effect due to a change in the centered world in question (or at least, a change in the location of the center). The one case where my PI may change is the case where I know that I've shifted environments, and decide to restipulate the use of my terms; but that's a very special sort of change.

--Dave.
Some thoughts on Josh's BIV case and on de se representation. . .

The BIV case is a nice case, and a difficult one. I had an answer, but talked myself out of it. Here's another stab. This is in three parts, all rather convoluted.

(1) Part of what is up for issue is whether the primary intension of our concepts like <water> are egocentrically indexical, or whether they are more communal. Suppose that Josh is the only BIV, and that he thinks of water as <the stuff that causes (most of) most of *my* watery experiences>. On this construal of the 1-intension, Josh's water concept refers to certain types of electrodes, or computer programs, or whatever it is that causes most of his watery experiences. (Why do we describe it as his "water concept"? Cos it's connected to his watery experiences, which are connected to our water concept.) This, I take it, is the Putnamian position on BIVs. On a *communal* interpretation of the 1-intension of water, it is <the stuff that causes most of the watery experiences of most of the folks around here.> (There are lots of indexicals in it). Now, whether this concept still refers to the electrodes or programs of whatever depends on whether Josh is the only BIV around. If the vast majority of the folks around here are also BIVs, then perhaps one could argue that even now it still refers to these electrodes. (Of course, the problem is that Josh isn't communicating with any of these - presumably. So maybe the communal condition can't get a toe-hold in giving the referent of an individual BIV's concept.)

But let's suppose that the 1-intension of Josh's <water> is communal, and that he's the only BIV around here. Then, his thoughts about water would be mostly mistaken cos they are about water, and he isn't connected to water in the right way. Although of course his belief that water is H2O would be true if the stuff that causes most people's watery experiences is H2O. Of course, it may not always be easy to tell whether one of his thoughts is true or false, because it may not be clear whether it is about water. Suppose that he thinks that he is having a shower: 'Ah, a lovely shower, this stuff sure is hot' and such like. This might be a true thought if the stuff that is causing his experiences is indeed hot. But insofar as he thinks that the stuff that is hot is the same kind of stuff that everyone else (i.e. non-BIVs) thinks is hot when they are taking a shower, his thought is false. Similar comments applying to his thought, 'It sure is good to run naked through the water of this Bondi surf.' This is true, insofar as it is good to run naked through the Bondi surf, but of course it is false in that Josh-the-BIV is not running anywhere, least of all running naked through the Bondi surf.

(2) Let's push the Putnamian line for a minute and see where it goes. Take Josh-the-BIV's water concept to refer to whatever causes his watery experiences. Post-vat Josh's water concept also refers to the stuff that causes his watery experiences. These two concepts (mental representations) are similar in that they are both related to watery experiences, that is, they are both object concepts that are related to the *phenomenal concept* <watery>. But should we think that there is any sense in which VAT-Josh and post-Vat Josh have a concept, i.e. <water> that can be tracked from
the VAt to after the VAT? I wonder. Both in the Vat and after the vat Josh has a concept that is related to <watery>, but that doesn't seem sufficient to justify the claim that he has a single concept that survives the experience from Vat to actual world, that we can reidentify as the same concept. After all, both my concept of a certain chemical substance (say, glump - suppose that glup is watery) and my concept <water> are connected to <watery stuff>, but that doesn't give me any incentive to identify <glump> with <water>. In order to identify the concept that we are calling Josh's pre-Vat water concept with his post-Vat water concept it needs to be the case that most (much?) of what he has learnt about water in the VAT holds true in the actual world. Does envatted Josh's knowledge of the microstructure of water play an important role here? I don't see why. On an inferential role account of concepts, beliefs about the microstructure of a substance might be just one sort of inferential node among many. If the microstructure of XYZ is such that it behaves in almost all of the same ways that H2O behaves, then we might be inclined to say that Josh has learnt that water is XYZ, or whatever it is in the actual world. (Of course, XYZ can't beahve in all of the same ways that H2O does, otherwise we would be able to discover that some stuff is H20 rather than XYZ.)

To sum: supposing the individualistic spin on water, in which the primary intension is <whatever has been causing *my* watery experiences> we (and Josh) might still be tempted to identify his in-Vat watery concept with his post-Vat watery concept, even thought it refers to a different stuff, because many of the inferential connections that he learnt while in the vat still hold true in the actual world. If post-Vat Josh thinks of his envatted experiences as including water thoughts, then it is clear that he must have a water concept that we can trace from the Vat to the real world.

(3) Here's a similar case to Josh's that puts it in a communal setting. Suppose that we are all shifted to Twin Earth in our sleep. Twin Earth is as the travel brochures describe it: it's the same as earth, except the predominant watery stuff in the environment is XYZ. After a couple of days we would discover that "this stuff in XYZ". I guess most of us would say, "Huh, I guess that water isn't H2O after all, it's XYZ." But it seems that we would all be mistaken. Water is H2O, but this ain't water. Of course, after a couple of years on twin earth, 'water' would come to refer to XYZ. So it seems.

Well, I'm not sure what the point of this scenario is. Maybe it raises the question: 'Is the 1-intension of <water> "the stuff around here that causes most of our watery experiences", or is the 1-intension of water "the stuff that is causing and has caused most of the watery experiences around here at the moment and in the past." The suggestion is that the 1-intension of natural kind terms anchors them to the past (and maybe the future).

Some thoughts on analyses of Josh's case by Josh, Erik, Erik, Angela, and Tim. N.B. This presumes the previous message with my own analysis.

Josh wrote:

> Now here is the puzzle. Primary intentions pick out "watery stuff" in the actual world. My intuition is that the actual world in both cases is the post-vat world. However, if I were the one pulled out of the vat in case 1 I'd say that there is no 'water' in the actual world. There is just watery stuff. But if I were pulled out of the vat in case 2, I'd say there is water in the actual world.

Like others, I'm not sure I share your intuitions here. Maybe there's some reason for saying that post-escape, your term "water" doesn't refer to anything in the actual world. But I think one can argue when it does begin referring to something in the actual world, it will refer just as soon in each case. After all, the only difference between the cases is that in one I believe "water is H2O" and in the other I believe "water is XYZ". This might make a difference to reference if these were "core beliefs" for me and unrevisable, or some such. But in fact it seems that these beliefs are quite revisable, a posteriori beliefs, as reflected by the fact that upon "discovering" in the vat that watery stuff is XYZ, one would say "water is XYZ" is true, not that water doesn't exist. I think the same goes outside the vat. Insofar as my word refers to stuff outside the vat at all, it's in virtue of its role as watery stuff, and it doesn't matter whether it turns out to be XYZ or H2O.

> If you share these intuitions, then there seem to be two possibilities: 
> 1) My primary intention of water includes the chemical make up of water or 2) Primary intentions do not fix reference in the actual world but fix reference in some other way.

Hmm. I don't share the intuitions, but perhaps one can make sense of your intuitions by saying: the PI of water picks out "whatever has the same structure as the stuff I've been related to in my past environment", and going for a view (the third line in my previous post) on which in the vat environment, you're related to virtual-H2O and virtual-XYZ in case 1 and case 2 respectively. Then post-vat, out in the real XYZ-world, your "water exists in this environment" might come out true in case 2 but not in case 1 (because XYZ has the same structure as virtual-XYZ, but not as virtual-H2O). That would seem to give the results of your intuitions, though I don't know whether (a) it gets at what underlies your intuitions, or (b) it's plausible.

[N.B. If things work this way, it's immediately post-escape that the changes will show up, rather than later. I.e. even before causal interaction with the new stuff, my "water exists around here" will be true in case 2 rather than case 1. With enough causal interaction, reference might still shift so that the claim will be true in both cases.]

This analysis may get at something about what you're saying re "PIs
don't fix reference in the actual world". I'd say that even on this analysis, they do fix reference in the actual world, but the actual world is a 4-D spacetime manifold, i.e. it includes all the facts about the past. And here, your PI will fix reference partly by appealing to facts about your past environment (i.e., the way things are in the past environment of the being at the center of the world) rather than your current environment.

(It's plausible that something like that applies to many cases. E.g., if I am transported to Twin Earth without knowing, then presumably my immediate claim "there is water around here" will be false, even though there is watery stuff (in the loose sense) around there. Essentially, this is because the PI of water fixes reference to something like "the watery stuff I have causally interacted with", which involves reference to my past environment as well as my current environment. Of course if I live on Twin Earth long enough, my reference may shift enough so that "there is water around here" will be true; that's also predicted by this PI.)

Looking at your (Josh's) more recent second message, maybe something like this analysis fits.

>Regarding the responses to my BIV cases, I'd like to make a few clarifications. There are two ways that I see of accounting for my intuitions. The first is to claim that the chemical make up of water is part of my PI. The second is to claim that my PI is just like everyone else's BUT PIs don't map centered worlds considered as actual onto referents.

> I think the second of these claims is the more likely. The idea would be that PI's perhaps map centered worlds thought to be actual during concept formation onto referents. (I already see several problems with this definition, but that is the basic idea.) Since vat-Josh formed his concepts while thinking that vat-world was actual, he would then map water to clear drinkable liquid in vat-world. And in vat-world water is H2O.

Well, one problem with what you say above is that if I grow up (in the actual world) thinking water is XYZ, then this formula will predict that my claim "water exists" is false, which doesn't seem right. And more generally it seems that it will be hard to have false beliefs while one is growing up, which seems problematic. Maybe it's better to say that something special is going on with the vat case -- these aren't just any old false beliefs about the world, but a whole virtual environment, one that is so self-consistent and central that it deserves to count in some sense as my "actual environment" while I'm in the vat. If so, then one can argue that my vat terms fix reference to things in my virtual environment, and that even after leaving the vat, they still involve the way things were in the vat environment.

Note again that this doesn't involve ignoring the actual world, but it does involve concentrating on a particular aspect of it, i.e. my past environment, which in this case will be my past virtual environment (which of course is in some sense part of the actual world).

On this way of doing things, the escape from vat to world is just like going from Earth to Twin Earth (in case 1) or like going from Twin Earth 1 to Twin Earth 2 (in case 2). Either way, one shifts environment, and one's initial reference is fixed to the stuff in one's original environment, so the truth of one's immediate-post-move claim "there is water around here" depends on whether there is anything around here with the same structure as the stuff in one's
past environment. So true in case 2 but not in case 1. That seems to accommodate your intuitions, even with a constant PI that fixes reference via the actual world (including past environment).

Anyway, note that one this way of doing things, what makes the differences between the cases isn't just that one had different beliefs in the past about one's environment -- it's that in some sense, one actually had different environments in the two cases (albeit virtual environments, in Josh's version). To see the difference, think about what we'd say if (a) the virtual environment "really had" XYZ structure in it (i.e. if you'd looked under a virtual microscope, that's what you'd have found), but (b) you believe the whole time that there is H2O there (you never look under a microscope). I predict that in this case, Josh will say (or ought to say) that "water is H2O" is false when thought in the vat, and false after escape, while "water is XYZ" is true both times. That suggests that it's the past environment that matters, not the past beliefs.

Of course one can question (a) whether a "virtual environment" is really enough of an environment to make concepts refer and to make beliefs true, and even then one could question (b) whether the "real" XYZ environment really qualifies as having the "same sort of stuff" that is present in the virtual environment (one might argue that there are deep differences between virtual XYZ and real XYZ, so that the "virtual" concept won't pick out the "real" stuff after escape). But assuming one can make a case for the appropriate answer on those two questions, then Josh's position will come out as reasonable, and the PI above seems to capture roughly what's going on.

Re Erik L's, Angela's, and Erik H's messages: I think my intuitions largely agree with these, i.e. that there's no major difference between the two cases: insofar as case 2 "water" picks out the actual stuff post-vat, so does case 1 "water". (Although after going through the above, I have to say that I feel at least some of the tug of Josh's way of doing things, at least on the "virtual environment" reading.) I think one still needs to distinguish what happens immediately after release from what happens after a period of adjustment, though. I'm tempted to say that there is an element in the PI of "water" requiring a previous causal connection to the stuff, so it doesn't refer to the actual stuff immediately (in either case), but only after a while.

If one doesn't agree with the causal requirement, one could go with a looser "the watery stuff around here now" PI, so that I'll come out referring in both cases immediately after escape. But I think the causal requirement is independently plausible.

I do largely agree with what Angela says here:

>I understand the temptation, especially given the amount of scientific information that is part of common knowledge, to say that H2O really is part of the primary intension of water, but, the very fact that I (and presumably others) can make sense of counterfactuals like, "Water could have been other than H2O," or "Water might not have been drinkable by humans", or "Water might not have had the property of appearing blue in daylight," etc...strongly suggests that almost nothing of what we know a posteriori of water is contained within the primary intension.

One thing to note is that "could have" and "might have" counterfactuals are often ambiguous between a PI and a SI reading, i.e. between (broad) epistemic possibility and Kripkean "metaphysical"
or "subjunctive" possibility. I'm not 100% sure which (or both) you're meaning to appeal to here. Arguably one needs both to make best sense of these counterfactuals.

If one accepts Kripke's subjunctive intuition, "water could have been other than H2O" will be true in the epistemic (PI) sense but not the subjunctive (SI) sense. As for "water might not have been blue", etc, this is most straightforward for me to make sense of on the subjunctive (SI) sense: one pictures the actual stuff, i.e. H2O, having a different appearance. On the epistemic (PI) sense, this is harder to make sense of, since water's appearance properties are relatively close to its PI, i.e. are "relatively a priori" of the "water" concept. But presumably one can still make sense of them by considering certain strange (broad) epistemic possibilities, e.g. on which there has been an optical illusion, or water's surface properties are very different from how one thinks they actually are. That reflects the fact that the beliefs in question aren't so "core" as to be unrevisable. As one builds in more and more core surface properties of water, though, this gets harder to do, and the epistemic "might have" claim becomes harder to make sense of.

Re Tim's message:

(1) Tim raises a possibility I didn't mention in the last message, that my vatted "water" concept may be deferential, fixing reference via my community. Still, I'd argue that it seems wrong to say that I defer to the people out there in the real world outside the vat, and it also seems wrong to say that I defer to other BIV's who happen to be out there. (It doesn't seem right to say that those people's reference makes a difference to my reference.) If I'm deferring, it's to people in my "virtual" world, the ones I think I "got" the term from. (I suppose it could be that those virtual people in my world are "avatars" of "real" people or of other BIVs, so I'd be deferring indirectly to those people, but I'll set that possibility aside.)

If that's so, then I don't think deference makes an essential difference to the picture. If the non-deferential concept picks out nothing, or chemicals, or virtual XYZ, so will the deferential concept, on this way of looking at things. The main difference will be the precise nature of the "causal chain" connecting me to the referent, i.e. on whether it needs to go through other "virtual people", or not.

(2) Tim also raises the question of in what sense I'll have the same concept inside and outside the vat. This seems most straightforward in the case where I don't know I've shifted. In that case, there seems to be the same sort of continuity that one would find if I go from one world to another without knowing. I'll deploy a lot of concepts, and they certainly won't be a whole new repertoire that I've acquired overnight -- rather, they'll be the old concepts (although a lot of my resulting beliefs may now come out false). It may be that eventually reference will shift, so that in a certain sense I'll have different concepts -- I'll at least have concepts with a different referent and SI, though not a different PI -- but that's a slightly different phenomenon.

There's also the special case where I'm told I've shifted, and where I make a new stipulation about my concepts so my beliefs don't come out useless. That would plausibly involve a "different concept" in a reasonably strong sense, but that also seems to be something of a special case.
Tim raises some worries about concept identity:

But should we think that there is any sense in which VAT-Josh and post-Vat Josh have a concept, i.e. <water> that can be tracked from the VAT to after the VAT? I wonder. Both in the Vat and after the vat Josh has a concept that is related to <watery>, but that doesn't seem sufficient to justify the claim that he has a single concept that survives the experience from VAT to actual world, that we can reidentify as the same concept. After all, both my concept of a certain chemical substance (say, glump - suppose that glup is watery) and my concept <water> are connected to <watery stuff>, but that doesn't give me any incentive to identify <glump> with <water>.

I presume you're talking about the vatted concept and the long-post-vat concept. In favor or "same concept" is that they have the same PI, and a continuous history of use between them. Against "same concept" is that they have a different referent and SI. What answer one gives will partly depend on whether one individuates concepts by PI, SI, referent, or history of use. I think this is somewhat terminological. I have some temptation toward "same concept", given the centrality of PIs, but then the different in referent and SI is pretty significant, too. As for water/glump, I'm not sure how to imagine the case -- do they pick out the same referent, or not? If the same referent, presumably we have same SI, different PI, so the reverse of the above. If a different referent, presumably we have different PI and SI, which is worse (presumably even if the PI of "glump" involves "watery", it will be in a different way, as it isn't a priori that water is glump). Either way, one relevant different is that the vat case involves sameness of PI and continuity of use, whereas this case doesn't.

To sum: supposing the individualistic spin on water, in which the primary intension is <whatever has been causing *my* watery experiences> we (and Josh) might still be tempted to identify his in-Vat watery concept with his post-Vat watery concept, even thought it refers to a different stuff, because many of the inferential connections that he learnt while in the vat still hold true in the actual world. If post-Vat Josh thinks of his envatted experiences as including water thoughts, then it is clear that he must have a water concept that we can trace from the Vat to the real world.

I think I agree with this, more or less. There are actually two issues: (1) sameness of concept pre- and post-vat, and (2) whether the concept picks out the actual stuff. That the "inferential connections still hold true in the actual world" seems to be getting at (2) rather than (1). In my terms, I'd put it by saying that as long as the actual world isn't *too* different from the vat world, actual watery stuff can come to satisfy the PI of my "water" concept (though possibly with a time lag). I'm inclined to think that (1) doesn't turn so much on the actual facts, but more on facts about the subject's psychological structure (modulo issues about individuating concepts by referent). That seems to fit with your last sentence above.

(3) Tim raises the case where I'm shifted to Twin Earth in my sleep. As I said in the last message, I think Tim is right that my "water" won't initially refer to XYZ, though it may after a couple of years. I think the moral of that is that the PI of "water" anchors one to one's past environment, as Tim suggests. Basically because it picks out (at least in part) the stuff that one has causally interacted with.
in the past. In fact I think that for many of these cases, the present environment is mostly irrelevant (except to determining whether one's beliefs are now true or false, etc). The future environment even more so, though maybe one could come up with cases where it matters.

All thoughts and reactions are welcome!

Here are the minutes from Tuesday. I thank Brad for filling in some details.

The first thing we discussed was why we should care about the primary intentions. Roughly the line was, "if water *is* H2O then why do we care what water could have been. It was suggested that the reason is that if, via the PI we could determine that it was logical impossible for water to just be H2O, then we know that we have more to look for. This, of course, is the basic line for consciousness.

The bulk of the rest of the discussion was on proper names again. Thony argues that if the PI of a name is what picks out its referent, then two names which pick out the same object in our world could pick out different objects in another world. But it seems that as a matter of logic, if 'a=b', where 'a' and 'b' are names, then necessarily 'a=b'

I suggested that in this framework proper names are not being used as labels for objects. Rather they are functions which pick out objects of a certain description.

I think Thony and I now agree that the question is whether names ought to work this way.

Brad tried to provide motivation for thinking that names do in fact have descriptive content. One such motivation comes from considering cases in which co-referring names can't be substituted salva veritate (such as in belief contexts). He also mentioned substitution failures in "simple sentences" (see Saul 1997), such as "Lois Lane kissed Superman before she kissed Clark Kent".

We also briefly discussed again the matter of what the primary intensions of names typically are (such as in the London/Londres case discussed before).

We then discussed my BIV cases. From an intuition point of view we were evenly split about whether or not there was really any water after you were pulled out of the vat. Brad suggested that it may just be very difficult to think of this case as anything other than a person jumping between two possible worlds. This, of course, is impossible. But it does look kind of like that.
I think this is probably getting somewhat off the topic, but I have a general worry about making sense of secondary intensions.

The 2-intension of water is H2O, given that, in this world, we take it that this chemical structure explains the various properties we associate with water. More generally, it seems that secondary intensions are different from the primary intension only when there is some sort of reductive explanation of a particular term or thing (p62).

It is not, of course, directly observable that water is H2O. Rather, it is the result of theory constructed from a variety of experimental results. Consider a possible world in which water is H2O, but in which the natural laws are such that the elements behave radically different than they do in our world. Suppose, for example, that Hydrogen atoms form extremely unstable compounds when they are in the presence of other Hydrogen atoms. In this possible world, the dominant 'watery stuff' is XYZ. Thus, XYZ is the stuff picked out by the primary intension of water. XYZ behaves experimentally much like H2O behaves in our world. But XYZ is not composed of two Hydrogen atoms and an Oxygen atom in this possible world.

It seems to me that the secondary intension of water cannot just be H2O. It must also include a host of other information regarding the underlying physical theory that makes this identification meaningful. If there is a possible world in which XYZ behaves for the most part like H2O, only X, Y and Z are not 2 H's and an O, it seems strange that there is any value in the secondary intension of water picking out H2O, stuff that is, in this possible world, unstable.

If this isn't just confused, it may be that this is a reason why you say primary intensions are particularly important to your account.

Anthony
them in philosophy of language and mind (in giving an account of content that is useful for epistemic and cognitive purposes) and in epistemology.

Within metaphysics, PIs are especially useful for analyzing modal issues. In particular, it seems that PIs are central in assessing conceivability claims, and the sense in which conceivability is a guide to possibility: if P is conceivable, it's generally plausible that there is a possible world satisfying the primary intension of C. And they are central to claims about a posteriori necessity. What's distinctive of a posteriori necessities seems to be that they have a necessary SI but a contingent PI. Given that for many issues in metaphysics we are concerned with questions about the relationship between conceivability and possibility, and about apriority and necessity, PIs seem pretty vital.

> The bulk of the rest of the discussion was on proper names again.
> Thony argues that if the PI of a name is what picks out its referent, then two names which pick out the same object in our world could pick out different objects in another world. But it seems that as a matter of logic, if 'a=b', where 'a' and 'b' are names, then necessarily 'a=b'
> I suggested that in this framework proper names are not being used as labels for objects. Rather they are functions which pick out objects of a certain description.
> I think Thony and I now agree that the question is whether names ought to work this way.

I'm a little concerned about this bit. Remember, one of the central points of the 2-D framework is that when S is necessary (in the usual sense), S has a necessary secondary intension. So what follows from the necessity of "a=b" is that "a=b" has a necessary SI, i.e. that 'a' and 'b' have the same SI. Nothing about PIs follows. In particular the claim that 'a' and 'b' have different PIs is completely compatible with the claim that "a=b" is necessary. (Just look at "Hesperus = Phosphorus", etc.)

Once can think of the PI as being what picks out reference in the actual world (depending on how it turns out) and the SI as picking out reference in counterfactual worlds (given that the actual world is fixed). I.e., PI gives reference across worlds considered as epistemic possibilities, SI across worlds considered as subjunctive possibilities. Given this, then in a case such as the above (with different PI, same SI), 'a' and 'b' will pick out the same referent in all counterfactual worlds (all subjunctive possibilities), as Kripke et al lead us to expect. All that follows from the difference in PIs it is epistemically possible that reference comes apart, i.e. there are epistemic possibilities such that if they turned out to be actual, reference would come apart, which seems to be correct in these cases.

Proper names are still being used as labels for objects in this framework, and they are still rigid designators. They pick out the same object across counterfactual worlds (considered as counterfactual). There's a sense in which actual-world reference is mediated by something a bit like a description (see previous note), but that's a far cry from saying that names here function like descriptions (which are nonrigid, etc, and have very different SIs). Witness the difference between "Hesperus" (the name) and "evening star" (the description).
I had hoped that all this was clear by now, but the above suggests that maybe there is still a little confusion. Or maybe I am just misreading the above, in which case feel free to elaborate on the issue.

>> Brad tried to provide motivation for thinking that names do in fact have descriptive content. One such motivation comes from considering cases in which co-referring names can't be substituted salva veritate (such as in belief contexts). He also mentioned substitution failures in "simple sentences" (see Saul 1997), such as "Lois Lane kissed Superman before she kissed Clark Kent".

This is interesting indirect evidence, but I don't think the case for PIs relies on this sort of evidence. The mere epistemic possibility that Superman is not Clark Kent, and the way the reference of a term varies depending on which epistemic possibility turns out to be actual, is enough to make the case. Again, these things don't imply descriptive reference across counterfactual worlds, but they do arguably imply some quasi-descriptive content across epistemic possibilities.

Incidentally it's probably a good idea not to get too fixated on issues specific to proper names, as many of those issues (especially those of reference via linguistic causal chains) aren't all that crucial to what comes later. Natural kind cases are probably more crucial.

>> We then discussed my BIV cases. From an intuition point of view we were evenly split about whether or not there was really any water after you were pulled out of the vat. Brad suggested that it may just be very difficult to think of this case as anything other than a person jumping between two possible worlds. This, of course, is impossible. But it does look kind of like that.

Well, it may be more palatable to look at this as a person jumping between two very different parts of one world. A bit like going from one planet to another. In this case, going from a "virtual environment" to a real environment. Different environments in one sense, but still all part of the same world (it's a big world!).

Anthony writes:

> I think this is probably getting somewhat off the topic, but I have a general worry about making sense of secondary intensions.

> The 2-intension of water is H2O, given that, in this world, we take it that this chemical structure explains the various properties we associate with water. More generally, it seems that secondary intensions are different from the primary intension only when there is some sort of reductive explanation of a particular term or thing (p62).

Well, I'd say this is often the case (especially for natural kind
terms), but it needn't be the case. E.g. "one meter" has different PI and SI, but no reductive explanation in the vicinity. Similar for "Hesperus". It's true that for natural kind terms, though, we very often identify it with some explanatory microstructure across worlds. So the SI of "water" goes with H2O, of "tiger" goes with some bio-plus-DNA kind, of "heat" goes with molecular motion, etc. I don't think an actual explanation is required -- arguably the SI of "water" picked out H2O in all worlds even before we had an explanation. But it's arguable that the SI of most such terms picks out the explanatory microstructure of the stuff, whatever that happens to be in the actual world, across all worlds.

> It is not, of course, directly observable that water is H2O. Rather, it is > the result of theory constructed from a variety of experimental results. > Consider a possible world in which water is H2O, but in which the natural > laws are such that the elements behave radically different than they do in > our world. Suppose, for example, that Hydrogen atoms form extremely > unstable compounds when they are in the presence of other Hydrogen atoms. > In this possible world, the dominant 'watery stuff' is XYZ. Thus, XYZ is > the stuff picked out by the primary intension of water. XYZ behaves > experimentally much like H2O behaves in our world. But XYZ is not composed > of two Hydrogen atoms and an Oxygen atom in this possible world.

OK, it seems plausible that the PI of "water" picks out XYZ in this world. The Kripkean may well say that the SI of "water" picks out H2O, irrespective of its instability.

> It seems to me that the secondary intension of water cannot just be H2O. > It must also include a host of other information regarding the underlying > physical theory that makes this identification meaningful. If there is a > possible world in which XYZ behaves for the most part like H2O, only X, Y > and Z are not 2 H's and an O, it seems strange that there is any value in > the secondary intension of water picking out H2O, stuff that is, in this > possible world, unstable.

Interesting point. The Kripkean often talks as if any H2O will be water. They will then describe this world as a world in which water molecules are unstable. It does arguably make sense to consider subjunctive possibilities such as "water molecules might have been unstable", or "if water molecules had been unstable, life on earth would not have evolved". If so, then such worlds (considered subjunctively) are worlds with water molecules in them, and thus (presumably) worlds with water in them.

Still, I can see your intuition that thus might not really deserve to count as "water". One could similar consider worlds where H2O molecules make multicolored paints that people hang on walls, or are used in brick buildings, etc. Are these worlds where paintings are made of water, etc? (Even in the subjunctive SI sense?) I can at least see the counter intuition, though I go both ways.

How to accommodate that intuition? Maybe (1) Insist that the SI of water still picks out H2O in all worlds, but say that the molecules only count as H2O if they are quite a bit like our H2O molecules with current chemistry (i.e., being H2O requires more than just having 2 H's and an O).. Or (2) identify the SI of water with something like "H2O, as long as it has at least some of the other chemical or surface properties it has in the actual world". Or (3) go all the way to SI = "watery stuff", which would be a more radical move, letting in XYZ as water in some counterfactual worlds; unorthodox, but some (e.g. David Lewis) have been tempted to argue that there are worlds where water is XYZ.
If this isn't just confused, it may be that this is a reason why you say primary intensions are particularly important to your account.

Well, I do agree that there is an awful lot of slack in what counts as the SI of a given term. It depends on some pretty debatable subjunctive intuitions about what it takes be water in a counterfactual worlds. There is also some slack in a PI, but arguably not so much -- we're somewhat clearer about what we'd count as water in different ways the actual world might turn out. This isn't the main reason I think PIs are more important than SIs (the central reason is that I think PIs tie much more closely to the epistemic notions that are at the heart of content, thought, and modality), but it may be one way of getting at the fact that SIs are most relevant in subjunctive and counterfactual contexts, about which our intuitive descriptions are pretty debatable.

Recent discussion has been interesting, but we've drifted a little from the central topics for which the 2-D framework will be important for us. In particular, the framework is most useful for analyzing the relationship between apriority and necessity, the notion of the necessary a posteriori, the relationship between conceivability and possibility, and the issue of a priori access to modality. Of course all of these have are central to important issues in metaphysics, not least to analyzing epistemic and modal arguments in the philosophy of mind. So it's worth going over a few of these things.

Most of what's contained in this note is very important to the course, so read it carefully.

DEFINITION OF PRIMARY AND SECONDARY INTENSIONS

I'll take a moment to officially define PIs and SIs for statements. So far we've mostly been talking about PIs and SIs for terms, but often it is whole statements that are most crucial. In effect, the PI of a statement is what you get from "composing" the PI and SI of its component terms. Note that I use "primary proposition" and "secondary proposition" for this idea in the book, but now I prefer to use "primary intension" and "secondary intension" for both.

The primary intension of a statement S is a mapping from centered worlds to truth-values. The secondary intension of S is a mapping from uncentered worlds to truth-values. They're defined as follows:

The primary intension of S maps a centered world W to the truth-value of S in W when W is considered as actual (i.e. considered as an epistemic possibility).

The secondary intension of S maps a centered world W to the truth-value of S in W when W is considered as counterfactual (i.e. considered as a subjunctive possibility, with the actual world fixed).
We can give a couple of heuristics for evaluating the PI or SI of a statement S at a world W.

PI Heuristic: If W turns out to be actual, will S turn out to be true?

SI Heuristic: Given that the actual world is the way it is, is S true in world W?

Take W = XYZ-world, S = "water is XYZ". If the XYZ-world turns out to be actual, "water is XYZ" will turn out to be true, so the PI of S is true in W. But given that the actual world is the way it is (i.e. the H2O-world), "water is XYZ" is false in the XYZ-world, so the PI of S is false in W. (I abstract away from centering issues here.)

(My favorite heuristics are actually a bit more streamlined than this, though maybe a bit less self-explanatory:

PI Heuristic: If W is the case, is S the case?

SI Heuristic: If W were the case, would S be the case?

This ties PIs to indicative conditionals (which basically force you to evaluate the antecedent as an epistemic possibility) and ties SIs to subjunctive conditionals (which make you treat the antecedent as some sort of "fantasy"). But I'll say more on this later.)

APRIORITY AND NECESSITY

The 2-D framework can be understood as making the following claims concerning the necessity and apriority of statements S.

NECESSITY THESIS: S is necessary iff S has a necessary secondary intension.

Here, I'm taking "necessary" in the standard Kripkean sense (i.e. "subjunctive necessity"); I'll argue later that this usage is not wholly uncontestable, but set that aside for now). S is necessary in the Kripkean sense precisely if it is true in all worlds considered counterfactually, which is just to say that its secondary intension is true in all worlds. I hope this claim is fairly straightforward, given the definition of a secondary intension.

APRIORITY THESIS (weak form): If S is a priori, S has a necessary primary intension.

The case for this is pretty straightforward. If S is a priori, then plausibly it will be true no matter how the actual world turns out, i.e. it will be true in any world considered as actual (considered as an epistemic possibility). That is, for an arbitrary world W, if W turns out to be actual, S will turn out to be true. That is, the primary intension of S is is true in all centered worlds.

APRIORITY THESIS (strong form): S is a priori iff S has a necessary primary intension.

This makes the further claim that if S has a necessary PI, it is a priori. This isn't entirely straightforward to "prove". Necessary PI means that S will be true no matter how the actual world turns out, but it is still a leap from there to the epistemic claim that we can know S to be true. Maybe S could turn out to be unknowable, for
example. E.g., maybe some really complex mathematical truth could have a necessary PI but not be knowable a priori?

We'll come back to this issue of "scrutability" later. For now, I'd consider the weak form better established than the strong form, but I'd also say its plausible that the great majority of statements with a necessary PI seem to be knowable a priori, so that exceptions to the strong form are rare if they exist.

I'm very interested to see any potential counterexamples to any of these principles (or arguments). It's not impossible that I've overlooked something here, so feel free to jig them up.

A POSTERIORI NECESSITY THESIS: S is an a posteriori necessity iff S has a necessary secondary intension and a contingent primary intension.

This follows directly from the necessity thesis and from the apriority thesis (strong form). I'd say that this is the central claim of the 2-D analysis of a posteriori necessity. It certainly seems to fit all the Kripke examples: "Hesperus is Phosphorus", "water is H2O", etc.

Somebody might deny this thesis (presumably by denying the strong form of the apriority thesis), asserting that there is some other sort of a posteriori necessity. I think it's at least highly plausible that such a posteriori necessities would have to have their roots in considerations quite distinct from the ones Kripke raises, though.

One reason all this is useful is that it lets us jump from epistemic claims about what is and isn't a priori to modal claims about the existence of various possible worlds. E.g. if S isn't a priori, there's a possible world where its PI is false; and even if S is an a posteriori necessity, its PI will be false in some world. If this is so, it's very important to the epistemology of modality, and to the role of epistemic arguments in metaphysics.

What makes all this possible is a central property of the 2-D framework: that it has two dimensions of semantic evaluation (two intensions), but just one space of worlds. Centering aside, PIs and SIs are evaluated at exactly the same worlds. They just give different results because of the different ways the worlds are considered (as actual or as counterfactual). Thus the worlds considered as "epistemic possibilities" for PI purposes are perfectly respectable metaphysically possible worlds: witness the XYZ-world, for example. Just one world, but two different ways of looking at it. That means that when we have an a posteriori necessity, we have a genuine metaphysical possibility in which the PI of the statement is false. That metaphysical possibility may well have consequences for metaphysics.

Again, any potential counterexamples and counterarguments are welcome.

CONCEIVABILITY AND POSSIBILITY

We can also put all this in terms of the relationship between conceivability and possibility. Conceivability is an epistemic notion. There are various notions in the area, as we'll see, but perhaps the simplest is the following. (N.B. I now prefer this way of doing things to the way I do things in the book.):

S is conceivable iff S is not ruled out a priori (i.e., if it is not a priori that not-S).
If the 2-D framework is right, then one will be able to make an inference from conceivability to possibility. If S is conceivable, not-S is not a priori, so not-S has a contingent PI (by the strong apriority thesis), so there is a metaphysically possible world in which the PI of S is true. That's not to say that S itself is "metaphysically" possible in the Kripkean sense (that sense requires a world where the SI is true), but we still have a metaphysically possible world in the vicinity. Call this the CONFOSS PRINCIPLE: If S is conceivable, there is a possible world in which the primary intension of S is true.

We'll be looking at different versions of this claim later, and examining just what it takes to support the relevant versions. But note for now how it fits the Kripkean examples. People often say that the Kripke examples show that there can be no inference from conceivability to possibility. E.g., in the relevant sense of conceivability, "water is XYZ" is conceivable, as is "Hesperus is not Phosphorus", but neither of these is possible. But on the 2-D framework, there is at least a possibility in the vicinity: a possible world in which the PI of "water is XYZ" is true, and one in which the PI of "Hesperus is not Phosphorus" is true.

Most importantly, when you conceive (in the relevant sense) of a scenario in which water is XYZ, or in which Hesperus isn't Phosphorus, you *do* conceive of a perfectly respectable world: the XYZ-world in the first case, and a world in which the evening object isn't the morning object in the second. These worlds don't satisfy the statements in question when they're considered as counterfactual, but they do when they're considered as actual. That's no surprise: after all, one is conceiving the scenarios in question as epistemic possibilities (i.e. considering them as actual), so one would expect that the worlds that correspond to this conceivability are worlds that satisfy S when they are considered as actual. So it's a little more indirect than a simple inference from S is conceivable to S is possible, but we still have conceivability as a guide to metaphysical possibility in some sense.

MODAL RATIONALISM

Note that the two-dimensional framework fits nicely with modal rationalism: the claim that we have a priori access to modality and to the space of possible worlds. Conceivability as described above is a paradigm a priori method. And when we conceive of a scenario in the relevant sense, it appears that we really are conceiving of a possible world (the XYZ-world, or the two-star world). Of course the sense in which it's an S-world is that it satisfies S's primary intension, not its secondary intension. So we have to be careful about just how we describe the worlds in question. But still, conceivability acts as a direct guide to the space of possible worlds. So the way is opened for some sort of modal rationalism.

Of course all this depends on the central claims of the 2-D framework being correct. I think there are probably a few points at which an opponent can argue (e.g. the strong apriority thesis), but it's tricky, and again they'd have to go well beyond Kripke.

PHILOSOPHY OF MIND
All this is very relevant to epistemic arguments against materialism. One response to these arguments is to deny that there is an epistemic gap between physical and phenomenal, and assert that there is an a priori entailment. I sometimes call this "type-A materialism". It's a hard row to hoe, though, because it only seems to work if one accepts a functional analysis of phenomenal concepts, and such an analysis seems very implausible.

So perhaps the most popular response is "type-B materialism": accept that there is an epistemic gap, but deny that there is an ontological gap. This doesn't have the intuitive implausibility of the type-A view, but still holds onto materialism. Typically, one will accept that there is no a priori entailment from physical to phenomenal, but will assert that there is a necessary entailment. So the entailment from physical to phenomenal is an a posteriori necessity.

This view also usually goes along with the claim that conceivability doesn't imply possibility. So zombies (for example) are said to be conceivable but not possible, so materialism is not endangered.

If the central claims of the 2-D framework are correct, this isn't so simple. The type-B materialist holds that "P \rightarrow Q" is an a posteriori necessity, where P is the physical truth about the world and Q is a phenomenal truth. On the 2-D framework, it follows that "P \rightarrow Q" has a contingent PI, so there is a possible world where the PI of P is true, but the PI of Q is false. Under a bit more analysis, the existence of this possible world is highly threatening to materialism.

Similarly, if zombies are conceivable, it follows that there's a possible world in which at least the PI of "there are zombies" is true. From here (under a bit of analysis) one can plausibly get to a world physically identical to ours but different overall, so that materialism comes out false.

The basic reason for all this, of course, is that deep down the Kripkean framework hasn't really broken the link between conceivability and possibility, it has just recast it a little. But we've seen that even Kripke's own results rely on the method of conceivability: conceive of a world, then make sure you describe it correctly. So it arguably supports rather than opposes a modal rationalism at the deep level. If so then the Kripkean framework gives much less support to the type-B materialist than is often supposed.

We'll be going into the full details of how this applies to materialism etc next week, so we can save a detailed analysis of the consciousness issues for then. But it's important to see how the 2-D framework might have significant metaphysical consequences, and how those rest pretty straightforwardly on the central theses of the framework.

For now, I'd be interested to see some discussion of those theses, and of the relationship between apriority and necessity vis-à-vis PIs and SIs, etc. All comments are welcome.

> A quick comment on Dave's comment on my comment on Josh:

[For Dave's comments, and some of my original comments, see below.]

The point I was making about glumpy stuff was this. In Josh's scenario, I'm told (and believe) that I've just left a Vat. Presumably I will also believe that none of the stuff behind my past experiences is the same sort of stuff as the stuff behind my current experiences. In this situation, I want to suggest that we shouldn't reidentify my in-VAt "water" concept with my post-Vat water concept, *even if we're picking out concepts in terms of their primary intensions.* It is true that both in the vat and out of the vat, I have a concept that is closely connected with my phenomenal concept <watery stuff>, and it's a natural kind concept too. Call these two concepts 'Water1' and 'water2' (These are just two names, I'm not yet supposing that these are two distinct concepts). When, out of the vat, I use water2, I don't think of it as applying to the same sort of stuff that water1 applied to. And that, it seems to me, is enough to say that its primary intension is different.

Here's an analogy. Suppose I have two concepts, <glumph> and <water>. I think that glumph and water are distinct natural kinds. Both act in the same (watery) way, indeed, I can't tell them apart. Almost nobody can tell them apart. (Perhaps nobody now living can tell them apart. It's just part of our mythology that there were people - the shabby pedagogues - who could tell them apart.) But I know that the stuff around here is glumph. Still, as far as I'm concerned, I interact with glumph pretty much the same way I would with water. Now, suppose that I move to an area where the watery stuff is not glumph but water. *If I know that this is the case*, I will use a different concept, my <water> concept rather than my <glumph concept>, to refer to the watery stuff around me.

I want to say that this case is precisely analogous to Josh's BIV case in which he believes that he was a BIV. It may look like he is still using his water concept, but he's not. He's using a concept that has the same surface structure, but there's more to PI than surface structure. AT least for Natural Kinds, one has to think that one is talking about the same sort of stuff in order for "two" primary intensions to be the same.

Well, maybe.

> There's also the special case where I'm told I've shifted, and where I make a new stipulation about my concepts so my beliefs don't come out useless. That would plausibly involve a "different concept" in a reasonably strong sense, but that also seems to be something of a special case.

> Tim raises some worries about concept identity:

> >But should we think that there is any sense in which VAT-Josh
> >and post-Vat Josh have a concept, i.e. <water> that can be tracked from the VAT to after the VAT? I wonder. Both in the Vat and after the vat Josh has a concept that is related to <watery>, but that doesn't seem sufficient to justify the claim that he has a single concept that survives the experience from VAT to actual world, that we can reidentify as the same concept. After all, both my concept of a certain chemical substance...
I presume you're talking about the vatted concept and the
long-post-vat concept. In favor or "same concept" is that they have
the same PI, and a continuous history of use between them. Against
"same concept" is that they have a different referent and SI. What
answer one gives will partly depend on whether one individuates
concepts by PI, SI, referent, or history of use. I think this is
somewhat terminological. I have some temptation toward "same
concept", given the centrality of PIs, but then the different in
referent and SI is pretty significant, too. As for water/glump, I'm
not sure how to imagine the case -- do they pick out the same
referent, or not? If the same referent, presumably we have same SI,
different PI, so the reverse of the above. If a different referent,
presumably we have different PI and SI, which is worse (presumably
even if the PI of "glump" involves "watery", it will be in a different
way, as it isn't a priori that water is glump). Either way, one
relevant different is that the vat case involves sameness of PI and
continuity of use, whereas this case doesn't.

To sum: supposing the individualistic spin on water, in which the primary
intension is <whatever has been causing *my* watery experiences> we (and
Josh) might still be tempted to identify his in-Vat watery concept with
his post-Vat watery concept, even thought it refers to a different stuff,
because many of the inferential connections that he learnt while in the
vat still hold true in the actual world. If post-Vat Josh thinks of his
envatted experiences as including water thoughts, then it is clear that he
must have a water concept that we can trace from the Vat to the real
world.

I think I agree with this, more or less. There are actually two
issues: (1) sameness of concept pre- and post-vat, and (2) whether the
concept picks out the actual stuff. That the "inferential connections
still hold true in the actual world" seems to be getting at (2) rather
than (1). In my terms, I'd put it by saying that as long as the
actual world isn't *too* different from the vat world, actual watery
stuff can come to satisfy the PI of my "water" concept (though
possibly with a time lag). I'm inclined to think that (1) doesn't
turn so much on the actual facts, but more on facts about the
subject's psychological structure (modulo issues about individuating
concepts by referent). That seems to fit with your last sentence
above.

(3) Tim raises the case where I'm shifted to Twin Earth in my sleep.
As I said in the last message, I think Tim is right that my "water"
won't initially refer to XYZ, though it may after a couple of years.
I think the moral of that is that the PI of "water" anchors one to
one's past environment, as Tim suggests. Basically because it picks
out (at least in part) the stuff that one has causally interacted with
in the past. In fact I think that for many of these cases, the
present environment is mostly irrelevant (except to determining
whether one's beliefs are now true or false, etc). The future
environment even more so, though maybe one could come up with cases
where it matters.

All thoughts and reactions are welcome!

--Dave.
Here are a few thoughts on Josh's "water" case. In this message I'll give my own analysis, and in the next I'll give some thoughts on others' analyses.

The first thing to get straight on is whether one thinks the judgments in question are true or false, before and after the vat.

Case 1: I think "water is H2O" in the vat. I escape from vat, find a similar-seeming world, except that the watery stuff is XYZ.

Case 2: I think "water is H2O" in vat, until a within-vat revolution convinces me of "water is XYZ". I escape from vat, find a similar-seeming world, and the watery stuff there is XYZ.

Q1: What (if anything) do I refer to as "water" pre-escape?
Q2: What (if anything) do I refer to as "water" post-escape?
Q3: Is my statement "water exists" true or false pre-escape?
Q4: Is my statement "water exists" true or false post-escape?

There are various things to say here. It's probably simplest to first set aside the belief changes re XYZ and H2O, and think about what "water" might refer to pre- and post-vat in an ordinary BIV case. Here some distinct issues peculiar to BIV cases some up. For example, many would say that while in the vat, my term "water" doesn't really refer to anything, and that my thought "water exists" is false. After all, isn't a brain in a vat a classic case of someone who is deceived about the external world?

One could accommodate this line in the 2-D framework by saying e.g.: (1) the PI of "water" picks out something like "the watery stuff in the environment that the being at the center has been causally related to" (not an implausible analysis of my "water" PI), and (2) if I am a BIV, my centered world (i.e. my actual world, not merely the world-as-I-believe-it-to-be) doesn't have anything that satisfies that PI. (There's no watery stuff causally related to me in my actual environment.) So the PI will pick out nothing, and my vatted thought "water exists" will be false.

On this line, what will happen when I come out of the vat? Well, arguably when I emerge for the first time into the "real world", my term "water" doesn't yet refer to actual water, because there's no causal connection yet. But after interacting with the environment for
a while, the causal connection will get going, and perhaps eventually my term "water" will come to refer to the actual stuff (H2O). Note that all that will be compatible with the PI analysis above: nothing will satisfy the PI at stage 1 (centered on me in vat) at stage 2 (centered on me just after escape), but something may satisfy it at stage 3 (centered on me well after escape), as by then the center will have plenty of causal relations with some watery stuff.

Another line that some philosophers take is that while in the vat, my terms like "water" refers to some chemicals or nutrients in the vat around the brain, because these are what I'm causally connected to. I don't find this very plausible myself, but if one takes this line, one could accommodate it by dropping "watery stuff" from the PI above, and by saying that the PI picks out roughly "the stuff in the environment that is causally responsible for the being at the center's use of the word 'water'". In this case, we'll have "water exists" true at stage 1 (it picks out chemicals), arguably false at stage 2 (it still picks out chemicals, but I suppose that could be true since the chemicals still exist), and true again at stage 3 (by now, the PI picks out real water).

Alternatively, one could be tempted by the idea that while in the vat, one's term "water" refers to something in one's "virtual world", or something like that, so that one's vatted thoughts "water exists" is true. This has the problem of making it hard to express how the BIV is deceived, and could even end up leading to some sort of idealism or phenomenalism. But there is arguably something to the intuition that there's some sense in which the BIV's "water is H2O" is truer than "water is XYZ" (assuming the virtual world is an H2O-world). Maybe one could accommodate this by saying there's two ways to read such thoughts, a strong way in which they all come out false, and a "weak" way where some come out true, or some such. E.g., the "weak" way might involve prefixing "According to the virtual world", or might have a PI involving "seeming-objects which seem to be causally connected to me", or some such. This would be a tricky row to hoe, but maybe there are possibilities. In this case, one could say that reference of "water" gradually shifts after release, just as above.

Anyway, I think one can factor away from these tricky BIV issues for considering Josh's main point. I'm not sure whether Josh's point would work equally well if the vat world were replaced by another planet in which one is brought up, and that brought to earth. That would probably give similar results at least to line 3 above, and arguably to line 2, though maybe not to line 1. But the crucial claims about how "water" refers after release may be similar each way.

What to say about case 1, where I believed "water is H2O", and find out post-vat that the watery stuff is XYZ? I'd be tempted to say, as in the cases above, that immediately post-release my term "water" still refers to whatever it referred to just pre-release: either nothing, or some chemicals, or perhaps some virtual H2O in the virtual world. So my statement "water exists" then will be false, or in any case if true won't be made true by the actual watery stuff. But after a while of interacting with the real environment, my term "water" might well come to refer to the XYZ, and my claim "water exists" will be made true by the actual environment.

I think that's so despite the fact that I believed in the vat that water was H2O. After all, within the vat that belief was potentially malleable (if people had told me the watery stuff was XYZ, I'd have accepted that water was XYZ), so the same ought to be the case outside
the vat. In fact, I think that even if no-one outside the vat ever
tells me that water is XYZ, my term "water" may eventually come to
refer to the XYZ by virtue of my causally interacting with it, etc.
In this case, I'll eventually have a false belief that "water is H2O"
but a true belief that 'water exists'.

If that's how things so, I think it's compatible with the PI staying
constant throughout. E.g. if the PI is "the watery stuff in the
environment that the being at the center has been causally related
to", this seems to give the right results: it picks out nothing at stage
1, nothing at stage 2, XYZ at stage 3. And that's so irrespective of
my belief changes.

I'd be tempted to say something similar about case 2. Here, I think
there still needs to be a gradual reference-shift from vat-reference
to actual reference. Even if one thought "water is XYZ" in the vat,
and actual watery stuff is XYZ, it's not clear that one's thought
(immediately post-escape) "water is XYZ" is true, or at least it's not
clear that it's made true by the actual XYZ. It takes some
interaction for the term "water" to pick out the actual stuff.

[A side note: It may be that if the scientists tell you immediately
"you were in a vat, but now you're out, and fortunately the real world
is a lot like you thought the vat world was", you might decide to
make a new stipulation that all your words will refer to actual things
rather than vat things, rather than keeping a lot of terms around that
don't refer to anything useful. That's tricky in some cases: e.g. re
"my wife", or "Ethel", say, does one really want to say that the term
refers to a person in the actual world who you've never strictly
speaking met before? But I suppose one could try to stipulate that
at least some terms refer to their qualitative counterparts. If that's
so, then "water" might immediately pick out the respective watery
stuff.

As for what to say if there are a few small differences between vat
world and actual world (e.g. they replaced H2O by XYZ), that's awfully
tricky. I guess it depends on one's stipulation. One might stipulate
"in case of any differences, my term doesn't refer", or one might
stipulate "in case of any differences, my term refers to whatever is
superficially similar enough", or some such. In the first case, my
post-escape "water exists" might at first be false; in the second; it
might be true. But that all depends on just what stipulation one
makes. Such a stipulation might well change one's term's PI a little
bit, as any new stipulation will.

Probably it's easiest to think about these things in a case where the
scientists don't tell you you've escaped, so one isn't faced with the
immediate wrenching discovery that forces you to reevaluate your whole
conceptual scheme. Instead, maybe do things so that you don't know
you've undergone such a radical shift. Even so, we can evaluate truth
and reference, and we can still consider what happens if there turn
out to be small changes in the environment. That way the
"stipulation" aspect is removed.]

Anyway, that's how I'd be tempted to analyze these cases. I think its
plausible on most ways of doing things that one's PI stays constant,
but its referent may gradually shift, in effect due to a change in the
centered world in question (or at least, a change in the location of
the center). The one case where my PI may change is the case where I
know that I've shifted environments, and decide to restipulate the use
of my terms; but that's a very special sort of change.
Some thoughts on Josh's BIV case and on de se representation. . .

The BIV case is a nice case, and a difficult one. I had an answer, but talked myself out of it. Here's another stab. This is in three parts, all rather convoluted.

(1) Part of what is up for issue is whether the primary intension of our concepts like <water> are egocentrically indexical, or whether they are more communal. Suppose that Josh is the only BIV, and that he thinks of water as <the stuff that causes (most of) most of *my* watery experiences>. On this construal of the 1-intension, Josh's water concept refers to certain types of electrodes, or computer programs, or whatever it is that causes most of his watery experiences. (Why do we describe it as his "water concept"? Cos it's connected to his watery experiences, which are connected to our water concept.) This, I take it, is the Putnamian position on BIVs. On a *communal* interpretation of the 1-intension of water, it is <the stuff that causes most of the watery experiences of most of the folks around here.> (There are lots of indexicals in it). Now, whether this concept still refers to the electrodes or programs of whatever depends on whether Josh is the only BIV around. If the vast majority of the folks around here are also BIVs, then perhaps one could argue that even now it still refers to these electrodes. (Of course, the problem is that Josh isn't communicating with any of these - presumably. So maybe the communal condition can't get a toe-hold in giving the referent of an individual BIV's concept.)

But let's suppose that the 1-intension of Josh's <water> is communal, and that he's the only BIV around here. Then, his thoughts about water would be mostly mistaken cos they are about water, and he isn't connected to water in the right way. Although of course his belief that water is H2O would be true if the stuff that causes most people's watery experiences is H2O. Of course, it may not always be easy to tell whether one of his thoughts is true or false, because it may not be clear whether it is about water. Suppose that he thinks that he is having a shower: 'Ah, a lovely shower, this stuff sure is hot' and such like. This might be a true thought if the stuff that is causing his experiences is indeed hot. But insofar as he thinks that the stuff that is hot is the same kind of stuff that everyone else (i.e. non-BIVs) thinks is hot when they are taking a shower, his thought is false. Similar comments applying to his thought, 'It sure is good to run naked through the water of this Bondi surf.' This is true, insofar as it is good to run naked through the Bondi surf, but of course it is false in that Josh-the-BIV is not running anywhere, least of all running naked through the Bondi surf.

(2) Let's push the Putnamian line for a minute and see where it goes. Take Josh-the-BIV's water concept to refer to whatever causes his watery experiences. Post-vat Josh's water concept also refers to the stuff that causes his watery experiences. These two concepts (mental representations) are similar in that they are both related to watery experiences, that is, they are both object concepts that are related to the *phenomenal concept*
<watery>. But should we think that there is any sense in which VAT-Josh and post-Vat Josh have a concept, i.e. <water> that can be tracked from the VAT to after the VAT? I wonder. Both in the VAT and after the VAT Josh has a concept that is related to <watery>, but that doesn't seem sufficient to justify the claim that he has a single concept that survives the experience from VAT to actual world, that we can reidentify as the same concept. After all, both my concept of a certain chemical substance (say, glump - suppose that glup is watery) and my concept <water> are connected to <watery stuff>, but that doesn't give me any incentive to identify <glump> with <water>. In order to identify the concept that we are calling Josh's pre-Vat water concept with his post-Vat water concept it needs to be the case that most (much?) of what he has learnt about water in the VAT holds true in the actual world. Does envatted Josh's knowledge of the microstructure of water play an important role here? I don't see why. On an inferential role account of concepts, beliefs about the microstructure of a substance might be just one sort of inferential node among many. If the microstructure of XYZ is such that it behaves in almost all of the same ways that H2O behaves, then we might be inclined to say that Josh has learnt that water is XYZ, or whatever it is in the actual world. (Of course, XYZ can't behave in all of the same ways that H2O does, otherwise we would be able to discover that some stuff is H2O rather than XYZ.)

To sum: supposing the individualistic spin on water, in which the primary intension is <whatever has been causing *my* watery experiences> we (and Josh) might still be tempted to identify his in-Vat watery concept with his post-Vat watery concept, even thought it refers to a different stuff, because many of the inferential connections that he learnt while in the vat still hold true in the actual world. If post-Vat Josh thinks of his envatted experiences as including water thoughts, then it is clear that he must have a water concept that we can trace from the Vat to the real world.

(3) Here's a similar case to Josh's that puts it in a communal setting. Suppose that we are all shifted to Twin Earth in our sleep. Twin Earth is as the travel brochures describe it: it's the same as earth, except the predominant watery stuff in the environment is XYZ. After a couple of days we would discover that "this stuff in XYZ". I guess most of us would say, "Huh, I guess that water isn't H2O after all, it's XYZ." But it seems that we would all be mistaken. Water is H2O, but this ain't water. Of course, after a couple of years on twin earth, 'water' would come to refer to XYZ. So it seems.

Well, I'm not sure what the point of this scenario is. Maybe it raises the question: 'Is the 1-intension of <water> "the stuff around here that causes most of our watery experiences", or is the 1-intension of water "the stuff that is causing and has caused most of the watery experiences around here at the moment and in the past." The suggestion is that the 1-intension of natural kind terms anchors them to the past (and maybe the future).

Some thoughts on analyses of Josh's case by Josh, Erik, Erik, Angela, and Tim. N.B. This presumes the previous message with my own analysis.

Josh wrote:

>Now here is the puzzle. Primary intentions pick out "watery stuff" in
>the actual world. My intuition is that the actual world in both cases
>is the post-vat world. However, if I were the one pulled out of the
>vat in case 1 I'd say that there is no 'water' in the actual world.
>There is just watery stuff. But if I were pulled out of the vat in
>case 2, I'd say there is water in the actual world.

Like others, I'm not sure I share your intuitions here. Maybe there's some reason for saying that post-escape, your term "water" doesn't refer to anything in the actual world. But I think one can argue when it does begin referring to something in the actual world, it will refer just as soon in each case. After all, the only difference between the cases is that in one I believe "water is H2O" and in the other I believe "water is XYZ". This might make a difference to reference if these were "core beliefs" for me and unrevisable, or some such. But in fact it seems that these beliefs are quite revisable, a posteriori beliefs, as reflected by the fact that upon "discovering" in the vat that watery stuff is XYZ, one would say "water is XYZ" is true, not that water doesn't exist. I think the same goes outside the vat. Insofar as my word refers to stuff outside the vat at all, it's in virtue of its role as watery stuff, and it doesn't matter whether it turns out to be XYZ or H2O.

>If you share these intuitions, then there seem to be two possibilities:
>1) My primary intention of water includes the chemical make up of
>water or 2) Primary intentions do not fix reference in the actual
>world but fix reference in some other way.

Hmm. I don't share the intuitions, but perhaps one can make sense of your intuitions by saying: the PI of water picks out "whatever has the same structure as the stuff I've been related to in my past environment", and going for a view (the third line in my previous post) on which in the vat environment, you're related to virtual-H2O and virtual-XYZ in case 1 and case 2 respectively. Then post-vat, out in the real XYZ-world, your "water exists in this environment" might come out true in case 2 but not in case 1 (because XYZ has the same structure as virtual-XYZ, but not as virtual-H2O). That would seem to give the results of your intuitions, though I don't know whether (a) it gets at what underlies your intuitions, or (b) it's plausible.

[N.B. If things work this way, it's immediately post-escape that the changes will show up, rather than later. I.e. even before causal interaction with the new stuff, my "water exists around here" will be true in case 2 rather than case 1. With enough causal interaction, reference might still shift so that the claim will be true in both cases.]
This analysis may get at something about what you're saying re "PIs don't fix reference in the actual world". I'd say that even on this analysis, they do fix reference in the actual world, but the actual world is a 4-D spacetime manifold, i.e. it includes all the facts about the past. And here, your PI will fix reference partly by appealing to facts about your past environment (i.e., the way things are in the past environment of the being at the center of the world) rather than your current environment.

(It's plausible that something like that applies to many cases. E.g., if I am transported to Twin Earth without knowing, then presumably my immediate claim "there is water around here" will be false, even though there is watery stuff (in the loose sense) around there. Essentially, this is because the PI of water fixes reference to something like "the watery stuff I have causally interacted with", which involves reference to my past environment as well as my current environment. Of course if I live on Twin Earth long enough, my reference may shift enough so that "there is water around here" will be true; that's also predicted by this PI.)

Looking at your (Josh's) more recent second message, maybe something like this analysis fits.

> Regarding the responses to my BIV cases, I'd like to make a few clarifications. There are two ways that I see of accounting for my intuitions. The first is to claim that the chemical make up of water is part of my PI. The second is to claim that my PI is just like everyone else's BUT PIs don't map centered worlds considered as actual onto referents.

> I think the second of these claims is the more likely. The idea would be that PI's perhaps map centered worlds thought to be actual during concept formation onto referents. (I already see several problems with this definition, but that is the basic idea.) Since vat-Josh formed his concepts while thinking that vat-world was actual, he would then map water to clear drinkable liquid in vat-world. And in vat-world water is H2O.

Well, one problem with what you say above is that if I grow up (in the actual world) thinking water is XYZ, then this formula will predict that my claim "water exists" is false, which doesn't seem right. And more generally it seems that it will be hard to have false beliefs while one is growing up, which seems problematic. Maybe it's better to say that something special is going on with the vat case -- these aren't just any old false beliefs about the world, but a whole virtual environment, one that is so self-consistent and central that it deserves to count in some sense as my "actual environment" while I'm in the vat. If so, then one can argue that my vat terms fix reference to things in my virtual environment, and that even after leaving the vat, they still involve the way things were in the vat environment.

Note again that this doesn't involve ignoring the actual world, but it does involve concentrating on a particular aspect of it, i.e. my past environment, which in this case will be my past virtual environment (which of course is in some sense part of the actual world).

On this way of doing things, the escape from vat to world is just like going from Earth to Twin Earth (in case 1) or like going from Twin Earth 1 to Twin Earth 2 (in case 2). Either way, one shifts environment, and one's initial reference is fixed to the stuff in one's original environment, so the truth of one's immediate-post-move
claim "there is water around here" depends on whether there is anything around here with the same structure as the stuff in one's past environment. So true in case 2 but not in case 1. That seems to accommodate your intuitions, even with a constant PI that fixes reference via the actual world (including past environment).

Anyway, note that one this way of doing things, what makes the differences between the cases isn't just that one had different beliefs in the past about one's environment -- it's that in some sense, one actually had different environments in the two cases (albeit virtual environments, in Josh's version). To see the difference, think about what we'd say if (a) the virtual environment "really had" XYZ structure in it (i.e. if you'd looked under a virtual microscope, that's what you'd have found), but (b) you believe the whole time that there is H2O there (you never look under a microscope). I predict that in this case, Josh will say (or ought to say) that "water is H2O" is false when thought in the vat, and false after escape, while "water is XYZ" is true both times. That suggests that it's the past environment that matters, not the past beliefs.

Of course one can question (a) whether a "virtual environment" is really enough of an environment to make concepts refer and to make beliefs true, and even then one could question (b) whether the "real" XYZ environment really qualifies as having the "same sort of stuff" that is present in the virtual environment (one might argue that there are deep differences between virtual XYZ and real XYZ, so that the "virtual" concept won't pick out the "real" stuff after escape). But assuming one can make a case for the appropriate answer on those two questions, then Josh's position will come out as reasonable, and the PI above seems to capture roughly what's going on.

Re Erik L's, Angela's, and Erik H's messages: I think my intuitions largely agree with these, i.e. that there's no major difference between the two cases: insofar as case 2 "water" picks out the actual stuff post-vat, so does case 1 "water". (Although after going through the above, I have to say that I feel at least some of the tug of Josh's way of doing things, at least on the "virtual environment" reading.) I think one still needs to distinguish what happens immediately after release from what happens after a period of adjustment, though. I'm tempted to say that there is an element in the PI of "water" requiring a previous causal connection to the stuff, so it doesn't refer to the actual stuff immediately (in either case), but only after a while.

If one doesn't agree with the causal requirement, one could go with a looser "the watery stuff around here now" PI, so that I'll come out referring in both cases immediately after escape. But I think the causal requirement is independently plausible.

I do largely agree with what Angela says here:

>I understand the temptation, especially given the amount of scientific information that is part of common knowledge, to say that H2O really is>part of the primary intension of water, but, the very fact that I (and>presumably others) can make sense of counterfactuals like, "Water could>have been other than H2O," or "Water might not have been drinkable by>humans", or "Water might not have had the property of appearing blue in>daylight," etc...strongly suggests that almost nothing of what we know a>posteriori of water is contained within the primary intension.

One thing to note is that "could have" and "might have"
counterfactuals are often ambiguous between a PI and a SI reading, i.e. between (broad) epistemic possibility and Kripkean "metaphysical" or "subjunctive" possibility. I'm not 100% sure which (or both) you're meaning to appeal to here. Arguably one needs both to make best sense of these counterfactuals.

If one accepts Kripke's subjunctive intuition, "water could have been other than H2O" will be true in the epistemic (PI) sense but not the subjunctive (SI) sense. As for "water might not have been blue", etc, this is most straightforward for me to make sense of on the subjunctive (SI) sense: one pictures the actual stuff, i.e. H2O, having a different appearance. On the epistemic (PI) sense, this is harder to make sense of, since water's appearance properties are relatively close to its PI, i.e. are "relatively a priori" of the "water" concept. But presumably one can still make sense of them by considering certain strange (broad) epistemic possibilities, e.g. on which there has been an optical illusion, or water's surface properties are very different from how one thinks they actually are. That reflects the fact that the beliefs in question aren't so "core" as to be unrevisable. As one builds in more and more core surface properties of water, though, this gets harder to do, and the epistemic "might have" claim becomes harder to make sense of.

Re Tim's message:

(1) Tim raises a possibility I didn't mention in the last message, that my vatted "water" concept may be deferential, fixing reference via my community. Still, I'd argue that it seems wrong to say that I defer to the people out there in the real world outside the vat, and it also seems wrong to say that I defer to other BIV's who happen to be out there. (It doesn't seem right to say that those people's reference makes a difference to my reference.) If I'm deferring, it's to people in my "virtual" world, the ones I think I "got" the term from. (I suppose it could be that those virtual people in my world are "avatars" of "real" people or of other BIVs, so I'd be deferring indirectly to those people, but I'll set that possibility aside.)

If that's so, then I don't think deference makes an essential difference to the picture. If the non-deferential concept picks out nothing, or chemicals, or virtual XYZ, so will the deferential concept, on this way of looking at things. The main difference will be the precise nature of the "causal chain" connecting me to the referent, i.e. on whether it needs to go through other "virtual people", or not.

(2) Tim also raises the question of in what sense I'll have the same concept inside and outside the vat. This seems most straightforward in the case where I don't know I've shifted. In that case, there seems to be the same sort of continuity that one would find if I go from one world to another without knowing. I'll deploy a lot of concepts, and they certainly won't be a whole new repertoire that I've acquired overnight -- rather, they'll be the old concepts (although a lot of my resulting beliefs may now come out false). It may be that eventually reference will shift, so that in a certain sense I'll have different concepts -- I'll at least have concepts with a different referent and SI, though not a different PI -- but that's a slightly different phenomenon.

There's also the special case where I'm told I've shifted, and where I make a new stipulation about my concepts so my beliefs don't come out useless. That would plausibly involve a "different concept" in a
reasonably strong sense, but that also seems to be something of a special case.

Tim raises some worries about concept identity:

>But should we think that there is any sense in which VAT-Josh
>and post-Vat Josh have a concept, i.e. <water> that can be tracked from
>the VAT to after the VAT? I wonder. Both in the vat and after the vat Josh
>has a concept that is related to <watery>, but that doesn't seem
>sufficient to justify the claim that he has a single concept that survives
>the experience from VAT to actual world, that we can reidentify as the
>same concept. After all, both my concept of a certain chemical substance
>(say, glump - suppose that glup is watery) and my concept <water> are
>connected to <watery stuff>, but that doesn't give me any incentive to
>identify <glump> with <water>.

I presume you're talking about the vatted concept and the long-post-vat concept. In favor or "same concept" is that they have the same PI, and a continuous history of use between them. Against "same concept" is that they have a different referent and SI. What answer one gives will partly depend on whether one individuates concepts by PI, SI, referent, or history of use. I think this is somewhat terminological. I have some temptation toward "same concept", given the centrality of PIs, but then the different in referent and SI is pretty significant, too. As for water/glump, I'm not sure how to imagine the case -- do they pick out the same referent, or not? If the same referent, presumably we have same SI, different PI, so the reverse of the above. If a different referent, presumably we have different PI and SI, which is worse (presumably even if the PI of "glump" involves "watery", it will be in a different way, as it isn't a priori that water is glump). Either way, one relevant different is that the vat case involves sameness of PI and continuity of use, whereas this case doesn't.

>To sum: supposing the individualistic spin on water, in which the primary
>intension is <whatever has been causing *my* watery experiences> we (and
>Josh) might still be tempted to identify his in-Vat watery concept with
>his post-Vat watery concept, even thought it refers to a different stuff,
because many of the inferential connections that he learnt while in the
>vat still hold true in the actual world. If post-Vat Josh thinks of his
>envatted experiences as including water thoughts, then it is clear that he
>must have a water concept that we can trace from the Vat to the real
>world.

I think I agree with this, more or less. There are actually two issues: (1) sameness of concept pre- and post-vat, and (2) whether the concept picks out the actual stuff. That the "inferential connections still hold true in the actual world" seems to be getting at (2) rather than (1). In my terms, I'd put it by saying that as long as the actual world isn't *too* different from the vat world, actual watery stuff can come to satisfy the PI of my "water" concept (though possibly with a time lag). I'm inclined to think that (1) doesn't turn so much on the actual facts, but more on facts about the subject's psychological structure (modulo issues about individuating concepts by referent). That seems to fit with your last sentence above.

(3) Tim raises the case where I'm shifted to Twin Earth in my sleep. As I said in the last message, I think Tim is right that my "water" won't initially refer to XYZ, though it may after a couple of years. I think the moral of that is that the PI of "water" anchors one to...
one's past environment, as Tim suggests. Basically because it picks out (at least in part) the stuff that one has causally interacted with in the past. In fact I think that for many of these cases, the present environment is mostly irrelevant (except to determining whether one's beliefs are now true or false, etc). The future environment even more so, though maybe one could come up with cases where it matters.

All thoughts and reactions are welcome!

Subject: Minutes from Tuesday
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

Here are the minutes from Tuesday. I thank Brad for filling in some details.

The first thing we discussed was why we should care about the primar intentions. Roughly the line was, "if water *is* H2O then why do we care what water could have been. It was suggested that the reason is that if, via the PI we could determine that it was logical impossible for water to just be H2O, then we know that we have more to look for. This, of course, is the basic line for consciousness.

The bulk of the rest of the dicussion was on proper names again. Thony argues that if the PI of a name is what picks out its referent, then two names which pick out the same object in our world could pick out different objects in another world. But it seems that as a matter of logic, if 'a=b', where 'a' and 'b' are names, then necessarily 'a=b'

I suggested that in this framework proper names are not being used as labels for objects. Rather they are functions which pick out objects of a certain description.

I think Thony and I now agree that the question is whether names ought to work this way.

> Brad tried to provide motivation for thinking that names do in fact have descriptive content. One such motivation comes from considering cases in which co-referring names can't be substituted salva veritate (such as in belief contexts). He also mentioned substitution failures in "simple sentences" (see Saul 1997), such as "Lois Lane kissed Superman before she kissed Clark Kent".

> We also briefly discussed again the matter of what the primary intensions of names typically are (such as in the London/Londres case discussed before).

We then dicussed my BIV cases. From an intuition point of view we were evenly split about whether or not there was really any water after you were pulled out of the vat. Brad suggested that it may just be very difficult to think of this case as anything other than a person jumping between two possible worlds. This, of course, is impossible. But it does look kind of like that.

http://www.u.arizona.edu/~chalmers/class/596b/week4.txt (56 of 88) [4/7/2002 1:48:39 PM]
I think this is probably getting somewhat off the topic, but I have a general worry about making sense of secondary intensions.

The 2-intension of water is H2O, given that, in this world, we take it that this chemical structure explains the various properties we associate with water. More generally, it seems that secondary intensions are different from the primary intension only when there is some sort of reductive explanation of a particular term or thing (p62).

It is not, of course, directly observable that water is H2O. Rather, it is the result of theory constructed from a variety of experimental results. Consider a possible world in which water is H2O, but in which the natural laws are such that the elements behave radically different than they do in our world. Suppose, for example, that Hydrogen atoms form extremely unstable compounds when they are in the presence of other Hydrogen atoms. In this possible world, the dominant 'watery stuff' is XYZ. Thus, XYZ is the stuff picked out by the primary intension of water. XYZ behaves experimentally much like H2O behaves in our world. But XYZ is not composed of two Hydrogen atoms and an Oxygen atom in this possible world.

It seems to me that the secondary intension of water cannot just be H2O. It must also include a host of other information regarding the underlying physical theory that makes this identification meaningful. If there is a possible world in which XYZ behaves for the most part like H2O, only X, Y and Z are not 2 H's and an O, it seems strange that there is any value in the secondary intension of water picking out H2O, stuff that is, in this possible world, unstable.

If this isn't just confused, it may be that this is a reason why you say primary intensions are particularly important to your account.

Anthony

A few comments on the minutes.

>The first thing we discussed was why we should care about the primar
>intentions. Roughly the line was, "if water *is* H2O then why do we
>care what water could have been. It was suggested that the reason is
>that if, via the PI we could determine that it was logical impossible
>for water to just be H2O, then we know that we have more to look for.
>This, of course, is the basic line for consciousness.

Well, many of the reasons for caring about PIs are related to Frege's reasons for caring about senses. In particular, PIs seem to capture the epistemic relations between thoughts and the cognitive contents of
thoughts, and are deeply related to notions such as epistemic possibility and apriority. This leads arguably to a central role for them in philosophy of language and mind (in giving an account of content that is useful for epistemic and cognitive purposes) and in epistemology.

Within metaphysics, PIs are especially useful for analyzing modal issues. In particular, it seems that PIs are central in assessing conceivability claims, and the sense in which conceivability is a guide to possibility: if P is conceivable, it's generally plausible that there is a possible world satisfying the primary intension of C. And they are central to claims about a posteriori necessity. What's distinctive of a posteriori necessities seems to be that they have a necessary SI but a contingent PI. Given that for many issues in metaphysics we are concerned with questions about the relationship between conceivability and possibility, and about apriority and necessity, PIs seem pretty vital.

The bulk of the rest of the discussion was on proper names again.

Thony argues that if the PI of a name is what picks out its referent, then two names which pick out the same object in our world could pick out different objects in another world. But it seems that as a matter of logic, if 'a=b', where 'a' and 'b' are names, then necessarily 'a=b'.

I suggested that in this framework proper names are not being used as labels for objects. Rather they are functions which pick out objects of a certain description.

I think Thony and I now agree that the question is whether names ought to work this way.

I'm a little concerned about this bit. Remember, one of the central points of the 2-D framework is that when S is necessary (in the usual sense), S has a necessary secondary intension. So what follows from the necessity of "a=b" is that "a=b" has a necessary SI, i.e. that 'a' and 'b' have the same SI. Nothing about PIs follows. In particular the claim that 'a' and 'b' have different PIs is completely compatible with the claim that "a=b" is necessary. (Just look at "Hesperus = Phosphorus", etc.)

Once can think of the PI as being what picks out reference in the actual world (depending on how it turns out) and the SI as picking out reference in counterfactual worlds (given that the actual world is fixed). I.e., PI gives reference across worlds considered as epistemic possibilities, SI across worlds considered as subjunctive possibilities. Given this, then in a case such as the above (with different PI, same SI), 'a' and 'b' will pick out the same referent in all counterfactual worlds (all subjunctive possibilities), as Kripke et al lead us to expect. All that follows from the difference in PIs it is epistemically possible that reference comes apart, i.e. there are epistemic possibilities such that if they turned out to be actual, reference would come apart, which seems to be correct in these cases.

Proper names are still being used as labels for objects in this framework, and they are still rigid designators. They pick out the same object across counterfactual worlds (considered as counterfactual). There's a sense in which actual-world reference is mediated by something a bit like a description (see previous note), but that's a far cry from saying that names here function like descriptions (which are nonrigid, etc, and have very different SIs).
Witness the difference between "Hesperus" (the name) and "evening star" (the description).

I had hoped that all this was clear by now, but the above suggests that maybe there is still a little confusion. Or maybe I am just misreading the above, in which case feel free to elaborate on the issue.

>> Brad tried to provide motivation for thinking that names do in fact have descriptive content. One such motivation comes from considering cases in which co-referring names can't be substituted salva veritate (such as in belief contexts). He also mentioned substitution failures in "simple sentences" (see Saul 1997), such as "Lois Lane kissed Superman before she kissed Clark Kent".

This is interesting indirect evidence, but I don't think the case for PIs relies on this sort of evidence. The mere epistemic possibility that Superman is not Clark Kent, and the way the reference of a term varies depending on which epistemic possibility turns out to be actual, is enough to make the case. Again, these things don't imply descriptive reference across counterfactual worlds, but they do arguably imply some quasi-descriptive content across epistemic possibilities.

Incidentally it's probably a good idea not to get too fixated on issues specific to proper names, as many of those issues (especially those of reference via linguistic causal chains) aren't all that crucial to what comes later. Natural kind cases are probably more crucial.

> We then discussed my BIV cases. From an intuition point of view we were evenly split about whether or not there was really any water after you were pulled out of the vat. Brad suggested that it may just be very difficult to think of this case as anything other than a person jumping between two possible worlds. This, of course, is impossible. But it does look kind of like that.

Well, it may be more palatable to look at this as a person jumping between two very different parts of one world. A bit like going from one planet to another. In this case, going from a "virtual environment" to a real environment. Different environments in one sense, but still all part of the same world (it's a big world!).

Anthony writes:

> I think this is probably getting somewhat off the topic, but I have a general worry about making sense of secondary intensions.

> The 2-intension of water is H2O, given that, in this world, we take it that this chemical structure explains the various properties we associate with water. More generally, it seems that secondary intensions are different from the primary intension only when there is some sort of reductive explanation of a particular term or thing (p62).
Well, I'd say this is often the case (especially for natural kind terms), but it needn't be the case. E.g. "one meter" has different PI and SI, but no reductive explanation in the vicinity. Similar for "Hesperus". It's true that for natural kind terms, though, we very often identify it with some explanatory microstructure across worlds. So the SI of "water" goes with H2O, of "tiger" goes with some bio-plus-DNA kind, of "heat" goes with molecular motion, etc. I don't think an actual explanation is required -- arguably the SI of "water" picked out H2O in all worlds even before we had an explanation. But it's arguable that the SI of most such terms picks out the explanatory microstructure of the stuff, whatever that happens to be in the actual world, across all worlds.

> It is not, of course, directly observable that water is H2O. Rather, it is the result of theory constructed from a variety of experimental results. Consider a possible world in which water is H2O, but in which the natural laws are such that the elements behave radically different than they do in our world. Suppose, for example, that Hydrogen atoms form extremely unstable compounds when they are in the presence of other Hydrogen atoms. In this possible world, the dominant 'watery stuff' is XYZ. Thus, XYZ is the stuff picked out by the primary intension of water. XYZ behaves experimentally much like H2O behaves in our world. But XYZ is not composed of two Hydrogen atoms and an Oxygen atom in this possible world.

OK, it seems plausible that the PI of "water" picks out XYZ in this world. The Kripkean may well say that the SI of "water" picks out H2O, irrespective of its instability.

> It seems to me that the secondary intension of water cannot just be H2O. It must also include a host of other information regarding the underlying physical theory that makes this identification meaningful. If there is a possible world in which XYZ behaves for the most part like H2O, only X, Y and Z are not 2 H's and an O, it seems strange that there is any value in the secondary intension of water picking out H2O, stuff that is, in this possible world, unstable.

Interesting point. The Kripkean often talks as if any H2O will be water. They will then describe this world as a world in which water molecules are unstable. It does arguably make sense to consider subjunctive possibilities such as "water molecules might have been unstable", or "if water molecules had been unstable, life on earth would not have evolved". If so, then such worlds (considered subjunctively) are worlds with water molecules in them, and thus (presumably) worlds with water in them.

Still, I can see your intuition that thus might not really deserve to count as "water". One could similar consider worlds where H2O molecules make multicolored paints that people hang on walls, or are used in brick buildings, etc. Are these worlds where paintings are made of water, etc? (Even in the subjunctive SI sense?) I can at least see the counter intuition, though I go both ways.

How to accommodate that intuition? Maybe (1) Insist that the SI of water still picks out H2O in all worlds, but say that the molecules only count as H2O if they are quite a bit like our H2O molecules with current chemistry (i.e., being H2O requires more than just having 2 H's and an O).. Or (2) identify the SI of water with something like "H2O, as long as it has at least some of the other chemical or surface properties it has in the actual world". Or (3) go all the way to SI = "watery stuff", which would be a more radical move, letting in XYZ as water in some counterfactual worlds;
unorthodox, but some (e.g. David Lewis) have been tempted to argue that there are worlds where water is XYZ.

> If this isn't just confused, it may be that this is a reason why you say primary intensions are particularly important to your account.

Well, I do agree that there is an awful lot of slack in what counts as the SI of a given term. It depends some pretty debatable subjunctive intuitions about what it takes be water in a counterfactual worlds. There is also some slack in a PI, but arguably not so much -- we're somewhat clearer about what we'd count as water in different ways the actual world might turn out. This isn't the main reason I think PIs are more important than SIs (the central reason is that I think PIs tie much more closer to the epistemic notions that are at the heart of content, thought, and modality), but it may be one way of getting at the fact that SIs are most relevant in subjunctive and counterfactual contexts, about which our intuitive descriptions are pretty debatable.

Recent discussion has been interesting, but we've drifted a little from the central topics for which the 2-D framework will be important for us. In particular, the framework is most useful for analyzing the relationship between apriority and necessity, the notion of the necessary a posteriori, the relationship between conceivability and possibility, and the issue of a priori access to modality. Of course all of these have are central to important issues in metaphysics, not least to analyzing epistemic and modal arguments in the philosophy of mind. So it's worth going over a few of these things.

Most of what's contained in this note is very important to the course, so read it carefully.

DEFINITION OF PRIMARY AND SECONDARY INTENSIONS

I'll take a moment to officially define PIs and SIs for statements. So far we've mostly been talking about PIs and SIs for terms, but often it is whole statements that are most crucial. In effect, the PI of a statement is what you get from "composing" the PI and SI of its component terms. Note that I use "primary proposition" and "secondary proposition" for this idea in the book, but now I prefer to use "primary intension" and "secondary intension" for both.

The primary intension of a statement S is a mapping from centered worlds to truth-values. The secondary intension of S is a mapping from uncentered worlds to truth-values. They're defined as follows:

The primary intension of S maps a centered world W to the truth-value of S in W when W is considered as actual (i.e. considered as an epistemic possibility).

The secondary intension of S maps a centered world W to the truth-value of S in W when W is considered as counterfactual.
We can give a couple of heuristics for evaluating the PI or SI of a statement S at a world W.

**PI Heuristic:** If W turns out to be actual, will S turn out to be true?

**SI Heuristic:** Given that the actual world is the way it is, is S true in world W?

Take W = XYZ-world, S = "water is XYZ". If the XYZ-world turns out to be actual, "water is XYZ" will turn out to be true, so the PI of S is true in W. But given that the actual world is the way it is (i.e. the H2O-world), "water is XYZ" is false in the XYZ-world, so the PI of S is false in W. (I abstract away from centering issues here.)

(My favorite heuristics are actually a bit more streamlined than this, though maybe a bit less self-explanatory:

**PI Heuristic:** If W is the case, is S the case?

**SI Heuristic:** If W were the case, would S be the case?

This ties PIs to indicative conditionals (which basically force you to evaluate the antecedent as an epistemic possibility) and ties SIs to subjunctive conditionals (which make you treat the antecedent as some sort of "fantasy"). But I'll say more on this later.)

**APRIORITY AND NECESSITY**

The 2-D framework can be understood as making the following claims concerning the necessity and apriority of statements S.

**NECESSITY THESIS:** S is necessary iff S has a necessary secondary intension.

Here, I'm taking "necessary" in the standard Kripkean sense (i.e. "subjunctive necessity"; I'll argue later that this usage is not wholly uncontested, but set that aside for now). S is necessary in the Kripkean sense precisely if it is true in all worlds considered counterfactually, which is just to say that its secondary intension is true in all worlds. I hope this claim is fairly straightforward, given the definition of a secondary intension.

**APRIORITY THESIS (weak form):** If S is a priori, S has a necessary primary intension.

The case for this is pretty straightforward. If S is a priori, then plausibly it will be true no matter how the actual world turns out, i.e. it will be true in any world considered as actual (considered as an epistemic possibility). That is, for an arbitrary world W, if W turns out to be actual, S will turn out to be true. That is, the primary intension of S is is true in all centered worlds.

**APRIORITY THESIS (strong form):** S is a priori iff S has a necessary primary intension.

This makes the further claim that if S has a necessary PI, it is a priori. This isn't entirely straightforward to "prove". Necessary PI means that S will be true no matter how the actual world turns out,
but it is still a leap from there to the epistemic claim that we can know S to be true. Maybe S could turn out to be unknowable, for example. E.g., maybe some really complex mathematical truth could have a necessary PI but not be knowable a priori?

We'll come back to this issue of "scrutability" later. For now, I'd consider the weak form better established than the strong form, but I'd also say its plausible that the great majority of statements with a necessary PI seem to be knowable a priori, so that exceptions to the strong form are rare if they exist.

I'm very interested to see any potential counterexamples to any of these principles (or arguments). It's not impossible that I've overlooked something here, so feel free to jog them up.

A POSTERIORI NECESSITY THESIS: S is an a posteriori necessity iff S has a necessary secondary intension and a contingent primary intension.

This follows directly from the necessity thesis and from the apriority thesis (strong form). I'd say that this is the central claim of the 2-D analysis of a posteriori necessity. It certainly seems to fit all the Kripke examples: "Hesperus is Phosphorus", "water is H2O", etc.

Somebody might deny this thesis (presumably by denying the strong form of the apriority thesis), asserting that there is some other sort of a posteriori necessity. I think it's at least highly plausible that such a posteriori necessities would have to have their roots in considerations quite distinct from the ones Kripke raises, though.

One reason all this is useful is that it lets us jump from epistemic claims about what is and isn't a priori to modal claims about the existence of various possible worlds. E.g. if S isn't a priori, there's a possible world where its PI is false; and even if S is an a posteriori necessity, its PI will be false in some world. If this is so, it's very important to the epistemology of modality, and to the role of epistemic arguments in metaphysics.

What makes all this possible is a central property of the 2-D framework: that it has two dimensions of semantic evaluation (two intensions), but just one space of worlds. Centering aside, PIs and SIs are evaluated at exactly the same worlds. They just give different results because of the different ways the worlds are considered (as actual or as counterfactual). Thus the worlds considered as "epistemic possibilities" for PI purposes are perfectly respectable metaphysically possible worlds: witness the XYZ-world, for example. Just one world, but two different ways of looking at it. That means that when we have an a posteriori necessity, we have a genuine metaphysical possibility in which the PI of the statement is false. That metaphysical possibility may well have consequences for metaphysics.

Again, any potential counterexamples and counterarguments are welcome.

CONCEIVABILITY AND POSSIBILITY

We can also put all this in terms of the relationship between conceivability and possibility. Conceivability is an epistemic notion. There are various notions in the area, as we'll see, but perhaps the simplest is the following. (N.B. I now prefer this way of doing things to the way I do things in the book):
S is conceivable iff S is not ruled out a priori (i.e., if it is not a priori that not-S).

If the 2-D framework is right, then one will be able to make an inference from conceivability to possibility. If S is conceivable, not-S is not a priori, so not-S has a contingent PI (by the strong apriority thesis), so there is a metaphysically possible world in which the PI of S is true. That's not to say that S itself is "metaphysically" possible in the Kripkean sense (that sense requires a world where the SI is true), but we still have a metaphysically possible world in the vicinity. Call this the CONPOSS PRINCIPLE: If S is conceivable, there is a possible world in which the primary intension of S is true.

We'll be looking at different versions of this claim later, and examining just what it takes to support the relevant versions. But note for now how it fits the Kripkean examples. People often say that the Kripke examples show that there can be no inference from conceivability to possibility. E.g., in the relevant sense of conceivability, "water is XYZ" is conceivable, as is "Hesperus is not Phosphorus", but neither of these is possible. But on the 2-D framework, there is at least a possibility in the vicinity: a possible world in which the PI of "water is XYZ" is true, and one in which the PI of "Hesperus is not Phosphorus" is true.

Most importantly, when you conceive (in the relevant sense) of a scenario in which water is XYZ, or in which Hesperus isn't Phosphorus, you *do* conceive of a perfectly respectable world: the XYZ-world in the first case, and a world in which the evening object isn't the morning object in the second. These worlds don't satisfy the statements in question when they're considered as counterfactual, but they do when they're considered as actual. That's no surprise: after all, one is conceiving the scenarios in question as epistemic possibilities (i.e. considering them as actual), so one would expect that the worlds that correspond to this conceivability are worlds that satisfy S when they are considered as actual. So it's a little more indirect than a simple inference from S is conceivable to S is possible, but we still have conceivability as a guide to metaphysical possibility in some sense.

MODAL RATIONALISM

Note that the two-dimensional framework fits nicely with modal rationalism: the claim that we have a priori access to modality and to the space of possible worlds. Conceivability as described above is a paradigm a priori method. And when we conceive of a scenario in the relevant sense, it appears that we really are conceiving of a possible world (the XYZ-world, or the two-star world). Of course the sense in which it's an S-world is that it satisfies S's primary intension, not its secondary intension. So we have to be careful about just how we describe the worlds in question. But still, conceivability acts as a direct guide to the space of possible worlds. So the way is opened for some sort of modal rationalism.

Of course all this depends on the central claims of the 2-D framework being correct. I think there are probably a few points at which an opponent can argue (e.g. the strong apriority thesis), but its tricky, and again they'd have to go well beyond Kripke.
All this is very relevant to epistemic arguments against materialism. One response to these arguments is to deny that there is an epistemic gap between physical and phenomenal, and assert that there is an a priori entailment. I sometimes call this "type-A materialism". It's a hard row to hoe, though, because it only seems to work if one accepts a functional analysis of phenomenal concepts, and such an analysis seems very implausible.

So perhaps the most popular response is "type-B materialism": accept that there is an epistemic gap, but deny that there is an ontological gap. This doesn't have the intuitive implausibility of the type-A view, but still holds onto materialism. Typically, one will accept that there is no a priori entailment from physical to phenomenal, but will assert that there is a necessary entailment. So the entailment from physical to phenomenal is an a posteriori necessity.

This view also usually goes along with the claim that conceivability doesn't imply possibility. So zombies (for example) are said to be conceivable but not possible, so materialism is not endangered.

If the central claims of the 2-D framework are correct, this isn't so simple. The type-B materialist holds that "P \rightarrow Q" is an a posteriori necessity, where P is the physical truth about the world and Q is a phenomenal truth. On the 2-D framework, it follows that "P \rightarrow Q" has a contingent PI, so there is a possible world where the PI of P is true, but the PI of Q is false. Under a bit more analysis, the existence of this possible world is highly threatening to materialism.

Similarly, if zombies are conceivable, it follows that there's a possible world in which at least the PI of "there are zombies" is true. From here (under a bit of analysis) one can plausibly get to a world physically identical to ours but different overall, so that materialism comes out false.

The basic reason for all this, of course, is that deep down the Kripkean framework hasn't really broken the link between conceivability and possibility, it has just recast it a little. But we've seen that even Kripke's own results rely on the method of conceivability: conceive of a world, then make sure you describe it correctly. So it arguably supports rather than opposes a modal rationalism at the deep level. If so then the Kripkean framework gives much less support to the type-B materialist than is often supposed.

We'll be going into the full details of how this applies to materialism etc next week, so we can save a detailed analysis of the consciousness issues for then. But its important to see how the 2-D framework might have significant metaphysical consequences, and how those rest pretty straightforwardly on the central theses of the framework.

For now, I'd be interested to see some discussion of those theses, and of the relationship between apriority and necessity vis-a-vis PIs and SIs, etc. All comments are welcome.

--Dave.
My visa still isn't through, and although there are indications that
it shouldn't be too long now, I won't be there by next Tuesday. This
means I have to rearrange things a little. Week 5 was originally
supposed to be on the "tyranny of the subjunctive", on relationships
between the 2-D framework and indicative and subjunctive conditionals,
and on implications for the analysis of necessity. But that isn't
really written up (except very briefly in the Princeton outline); I'd
been planning to mostly talk about it in class. So as things stand,
we will skip straight to the following topic (the original week 6)
instead.

This topic involves applying the 2-D framework to epistemic and modal
arguments against materialism. The readings are

TCM, Chapter 4 -- mostly pp. 131-149.
N&N, pp. 144-55.
Mind and Modality, Lecture 1 (esp. sections 5-7).

The Mind and Modality notes (on the web) have my currently preferred
formulation of the 2-D argument against materialism. It's a bit
crisper and tighter than the book version, though it comes to much the
same thing in the end. The book version has more discursive detail,
so you'll probably want to look at the two of them together (the real
core of the book argument is pp. 131-36, but pp. 147-49 also has
relevant material). It might also be interesting to look at Kripke's
anti-materialist argument in N&N, which is similar in spirit, and
compare and contrast. (N.B. The Princeton notes have some contrastive
analysis that goes a bit beyond what is in the book.)

Anyway, consider these the readings for next week's discussion. I'll
look forward to seeing your thoughts on them early next week.

As promised, there's also an assignment. I'd like you to take two
terms that Kripke discusses, and translate his discussion into the 2-D
framework. One is "yard", as discussed on p. 76; the other is "cat",
as discussed on p. 122 and pp. 125-6. I'd like you to take every
significant part of Kripke's discussion here and translate it into the
2-D framework. Characterize roughly what the PI and the SI of these
terms look like, at least given Kripke's intuitions. In places where
Kripke considers a hypothetical scenario, you should roughly specify
the world, say whether it is being considered as actual or as
counterfactual, note what the referent of the relevant term or
statement is in that world (considered the relevant way, and according
to Kripke's stated intuitions), and say what the upshot is the for
relevant PI or SI. Try to translate Kripke's more general points in
these passages into the framework too, if you can. If you're so
inclined, you can say whether you agree or disagree with Kripke's
specific and general analyses and why, though that isn't compulsory.

This shouldn't be much work (the passages are pretty short). This
will be due by next Tuesday at noon, Arizona time. Don't be late.
E-mail it directly to me (not to the mailing list). It should be your
own work.

--Dave.
A quick comment on Dave's comment on my comment on Josh:

For Dave's comments, and some of my original comments, see below.

The point I was making about glumpy stuff was this. In Josh's scenario, I'm told (and believe) that I've just left a Vat. Presumably I will also believe that none of the stuff behind my past experiences is the same sort of stuff as the stuff behind my current experiences. In this situation, I want to suggest that we shouldn't reidentify my in-Vat "water" concept with my post-Vat water concept, *even if we're picking out concepts in terms of their primary intensions.* It is true that both in the vat and out of the vat, I have a concept that is closely connected with my phenomenal concept <watery stuff>, and it's a natural kind concept too. Call these two concepts 'Water1' and 'water2' (These are just two names, I'm not yet supposing that these are two distinct concepts). When, out of the vat, I use water2, I don't think of it as applying to the same sort of stuff that water1 applied to. And that, it seems to me, is enough to say that its primary intension is different.

Here's an analogy. Suppose I have two concepts, <glumph> and <water>. I think that glumph and water are distinct natural kinds. Both act in the same (watery) way, indeed, I can't tell them apart. Almost nobody can tell them apart. (Perhaps nobody now living can tell them apart. It's just part of our mythology that there were people - the shabby pedagogues - who could tell them apart.) But I know that the stuff around here is glumph. Still, as far as I'm concerned, I interact with glumph pretty much the same way I would with water. Now, suppose that I move to an area where the watery stuff is not glumph but water. *If I know that this is the case*, I will use a different concept, my <water> concept rather than my <glumph concept>, to refer to the watery stuff around me.

I want to say that this case is precisely analogous to Josh's BIV case in which he believes that he was a BIV. It may look like he is still using his water concept, but he's not. He's using a concept that has the same surface structure, but there's more to PI than surface structure. At least for Natural Kinds, one has to think that one is talking about the same sort of stuff in order for "two" primary intensions to be the same.

Well, maybe.
> and post-Vat Josh have a concept, i.e. <water> that can be tracked from
> the VAT to after the VAT? I wonder. Both in the Vat and after the vat Josh

Tim suggests that maybe the BIV pre- and post-emergence should be
regarded as having two sets of concepts, stemming from the fact that
he knows he has changed environments. I think this isn't implausible.
It's related to what I said earlier about the BIV being able to make a
new "stipulation" about its concepts once it knows it's environment
has changed so much (or once it knows it was previously so deceived,
depending on how you do things).

In the case where the ex-BIV doesn't know about the change, presumably
this won't work -- it will keep using the old concepts, and for a good
while, at least, it will make a lot of claims that are strictly false
(e.g., "there's water around here"). Even if the ex-BIV knows about
the change, presumably it doesn't need to make the stipulation -- it
might correctly say "there's no water around here, just stuff which
looks a lot like the stuff I knew as water". But that would probably
lead to inconvenience and communication problems for the ex-BIV, who
might prefer truth and communication, so it might decide to adopt the
conceptual system of his new community wholesale. Of course the new
community will be using the same words (or same sounds) as the old
community, but that's fairly incidental -- he's really deciding to use
new concepts. So maybe his old "water" concept had as PI "the
watery-looking stuff I was causally connected to", and his new one has
PI "the watery stuff that's around me recently", or "what people call
'water' around here", or something like that.

That does seem to be a special case, stemming from (a) the fact that
he knows about the change, and (b) the fact that due to some sort of
coincidence and conspiracy, his new environment is enough like his old
environment that his old words "sort of" work. If one had (b) without
(a), one presumably wouldn't get this sort of new concept. And if one
had (a) without (b), maybe he'd adopt a new set of concepts, but
presumably they wouldn't have such a close relationship to the old
concepts (quite different semantics, probably different sounds). But
given the special circumstances of (a) and (b), I think Tim's analysis
is pretty reasonable.
>When, out of
>the Vat, I use water2, I don't think of it as applying to the same sort of
>stuff that water1 applied to. And that, it seems to me, is enough to say
>that its primary intension is different.

That's a nice point. The fact that a person knows that a new concept
doesn't apply to what the old concept applies to is a good indication
that it's a different concept. It's a bit like the a posteriority of
\(a=b\) implying that 'a' and 'b' have different PIs. Here, he can
still use his old concept if he wants, and then he'll hold that
"water1 = water 2" is false, and so certainly not a priori. So one
has different concepts. Unlike the case where he doesn't know about
the change, and can't entertain the false identity.

The glumph/water case is a nice way of making the point too. The main
disanalogy is that here one had both concepts beforehand, but
otherwise things seem similar. Again, the fact that "water = glumph"
can be false, or even its non-apriority, seems to be a sign of two
different PIs and two different concepts.

>At least for Natural Kinds, one has to think that one is talking about the
>same sort of stuff in order for "two" primary intensions to be the same.

That has a certain plausibility. Certainly if one has two concepts
'a' and 'b' and holds that "a=b" is false, that suggests two different
PIs for the two concepts.

A slight complication, though: There may be cases where I don't so
much have two concepts, but hold that "what I now refer to as 'a' is
different from what I used to refer to as 'a'" -- e.g., take 'a' =
'here', or 'the president'. Presumably this is compatible with 'a'
having the same PI, just a different referent due to the change in
location. That's due to a special property of indexicals -- they're
not supposed to have a stable referent. Can this happen for natural
kind terms? Well, I suppose it could happen if one goes to twin
earth, keeps using one's old "water" concept, the reference gradually
shifts to XYZ, and only then does one find out about the change. That
might be a case where the PI has stayed constant. So maybe one has to
qualify your thesis above.

What exactly is the different between the ex-BIV shift and these two
cases? Something to do with the fact that natural kind referents
can't shift *quickly*, given just the one concept. In the ex-BIV
case, the old PI should pick out the old stuff just after moving, not
the new stuff. So if one has the possibility of a different
referent so quickly, that indicates a new PI and a new concept. Of
course that constraint doesn't imply to standard indexicals, whose
reference can shift in a flash.

--Dave.
involving quantum mechanics that may have relevance for evaluating the strong apriority thesis; specifically the conditional from "S has a necessary primary intension" to "S is a priori". Consider some quantum mechanical superposed state (of some arbitrary photon impinging on a half-silvered mirror, say). The state is described by the mathematics of Shrodinger's "U" equation, or the linear complex number equations governing the evolution of the photon as it superposes into different possible states. Now, since this is entirely mathematical it ought to have the same status as any "complex mathematical truth"; hence, if the latter has a necessary primary intension so will the former. The actual position of the particle, however (which is what the equations is tracking) is not knowable apriori. After the "reduction" or collapse of the wave function, some distribution of probabilities will tell us where (in what final state) the photon will be, but even now there is no apriori truth--accessible by us anyway--of what the final state of the photon will be in. Worse, there is no way of knowing even while the unitary evolution is underway, although "the position of this particle" is presumably the primary intension of the equation. If we change this to "the possible positions of this particle" then among most construals of the U-evolution (which is supposed to be entirely deterministic prior to collapse) we are not getting the right primary intension. So it seems in this case (although I admit this is the subject of much debate) that, if an equation of this sort has a primary intension (and why shouldn't it, since it is just some mathematical statement), then the real content of it is not knowable apriori. There is a big debate over whether to treat the collapse or state vector reduction as real or imaginary, and also whether to consider the linear superposition of subatomic phenomena as descriptions of real superpositions or just incomplete descriptions of particle positions (I suppose these are slightly different issues), but the point is that in as much as something like a Shrodinger equation has a primary intension, it is about the positions of particles, and this is not knowable apriori in a very clear cut way, in this case.

One other one, take as a formal system the smartest mathematician, construct his Godel number. There is a truth not knowable to any of us but knowable in principle apriori.

Erik L.

"What our grammarian does is simple enough. He frames his formal reconstruction of K along the grammatically simplest lines he can, compatibly with inclusion of H, plausibility of the predicted inclusion of I, plausibility of the hypothesis of inclusion of J, and plausibility, further, of the exclusion of all sequences which ever actually do bring bizarreness reactions." -- W.V.O. Quine

Erik raises a couple of intriguing potential counterexamples to the strong apriority thesis (the claim that S has a necessary PI iff S is a priori). I'll take the second first, as I think I understand it a
bit better.

> One other one, take as a formal system the smartest mathematician, construct his Godel number. There is a truth not knowable to any of us but knowable in principle apriori.

Right. On the assumption that each of us is a finite computational system, it follows by a natural chain of reasoning from Godel's theorem that there are mathematical truths that none of us can know to be true. If G is such a statement for the smartest of us (or for the whole community), then presumably G is a necessary truth, and has a necessary PI (there's no difference between PI and SI for mathematical statements). But none of us can know it a priori. Counterexample?

This is one of the trickiest cases for the strong apriority thesis to handle. But I think it can be handled by noting (as you note in your last sentence implicitly) that we are using an idealized notion of the a priori. S is a priori if it is knowable a priori, and in considering what is knowable a priori we abstract away from our contingent cognitive limitations. On this way of doing things, it's plausible that G comes out to be a priori. It's true that none of us can know it, but that's just because of our cognitive limitations. There are presumably smarter beings that can come to know it a priori. So G is a priori.

[Semi-technical note (don't worry if you don't follow this): To justify this, one can note a result of Kleene's (I believe, though I may be misrecalling the details) to the effect that any arithmetical statement that is undecidable within Peano arithmetic (PA) is decidable in some extension of PA, where the extensions are obtained by repeated "Godelizing" (adding a Godel sentence), onward through the ordinal hierarchy. The trouble with us is that we can't Godelize forever -- being finite systems, we eventually lose track of ordinal counting (which is itself not recursively systematizable). But for any undecidable statement of arithmetic, *some* amount of repeated Godelization will decide it. So all we need is a being smarter than us who can count further through the ordinals. Presumably there's no obstacle to the possibility of such a being; our own specific limits here seem to be contingent cognitive limitations. (Shaughan, feel free to correct or expand on this!)]

This is some heavy machinery to bring out, and arguably there are other strategies. Sometimes I'm even tempted to appeal to the possibility of a being who can go through all the integers at once to determine whether "for all n, P(n)" is true, on the theory that our inability to do this is a contingent cognitive limitation, but that might make one a little queasy. There are also questions about what to say for higher set theory and the like. We'll be coming back to these matters a bit later on, but the important thing to note is that for the strong apriority thesis to be plausible, we have to appeal to a notion of the a priori that idealizes away from our contingent limitations.

Incidentally I discuss the relevance of this sort of analogy to the mind-body discussion in the book briefly around pp. 138-40. The way I prefer to do things now, in terms of positive and negative conceivable (coming up in two or three weeks), it turns out fortunately that one doesn't need to refute this sort of example at least to make the case re consciousness. A thesis slightly weaker than the strong apriority thesis can do the job for the anti-materialist, and this sort of consideration gets factored out.
It still raises independently important issues for modal rationalism, though. Feel free to follow up here, as there are plenty of interesting issues in the vicinity.

Consider some quantum mechanical superposed state (of some arbitrary photon impinging on a half-silvered mirror, say). The state is described by the mathematics of Schrödinger's "U" equation, or the linear complex number equations governing the evolution of the photon as it superposes into different possible states. Now, since this is entirely mathematical it ought to have the same status as any "complex mathematical truth"; hence, if the latter has a necessary primary intension so will the former.

I'm not sure exactly what the sentence is whose PI we are talking about. But in any case I think I might get off the bus here. I don't think the Schrödinger equation has quite the same status as a mathematical truth. As it's being used here, it's a *physical* truth, and as such is both a posteriori and has a contingent PI. Of course the mathematical truth that a certain differential equation has such-and-such solutions is a priori (and has a necessary PI); but here we are concerned with the claim that these solutions correspond to the way things are in physical reality, and that's a different claim altogether.

The actual position of the particle, however (which is what the equations is tracking) is not knowable apriori. After the "reduction" or collapse of the wave function, some distribution of probabilities will tell us where (in what final state) the photon will be, but even now there is no apriori truth--accessible by us anyway--of what the final state of the proton will be in. Worse, there is no way of knowing even while the unitary evolution is underway, although "the position of this particle" is presumably the primary intension of the equation. If we change this to "the possible positions of this particle" then among most construals of the U-evolution (which is supposed to be entirely deterministic prior to collapse) we are not getting the right primary intension. So it seems in this case (although I admit this is the subject of much debate) that, if an equation of this sort has a primary intension (and why shouldn't it, since it is just some mathematical statement), then the real content of it is not knowable apriori.

Well, let's separate a few things. (1) The mathematical fact that the Schrödinger equation has certain solutions. That's a priori and has a necessary PI. (2) The physical fact that the Schrodinger equation describes physical reality. That's a posteriori and has a contingent PI. (3) The physical fact that a certain particle has a certain position. That's highly a posteriori and has a contingent PI.

(More technicalities coming up.)

I think what you may really be talking about, though, is the conditional from initial state of the wave function plus Schrödinger equation (as a physical law) to final state of the particle. The status of this depends on just which interpretation of QM we are using, as the claim the Schrödinger equation is taken to make about physical reality will vary with the interpretation. On the Everett interpretation, I suppose the conditional will be a priori, as the equation is the only dynamics; and indeed, given knowledge of an initial state and of the truth of the interpretation, one can know the (superposed) final state just fine. Something similar arguably goes...
for the Bohm interpretation. As long as we are given full enough information about wave plus particles in the antecedent, then we can come to know the determinate final state no problem. In a "collapse" interpretation, on the other hand, the conditional will never be a priori, as such interpretations have a further nondeterministic part of the dynamics, so we'll at best be able to figure out a probability distribution. Anyway, it seems to me that in each of these cases, a priority and necessity of PI will line up.

Dave,
good point, I was using the "2-D" interpretation of QM with the U equation governing particle positions prior to "collapse" and the probability distributions after the collapse. On this view, the conditional wouldn't be apriori. One further comment, the superbeing you mentioned that can run through all integers to determine "for all n, P(n)" could not be formalizable, by Godel's result. If it was formalizable (and consistent), then it would get stuck too. If such a being could exist, it would be an "oracle" about which we could have no computational knowledge (even in principle).

If we change this to "the possible positions of this particle" then among most construals of the U-evolution (which is supposed to be entirely deterministic prior to collapse) we are not getting the right primary intension. So it seems in this case (although I admit this is the subject of much debate) that, if an equation of this sort has a primary intension (and why shouldn't it, since it is knowable apriori.

Well, let's separate a few things. (1) The mathematical fact that the Schrodinger equation has certain solutions. That's a priori and has a necessary PI. (2) The physical fact that the Schrodinger equation describes physical reality. That's a posteriori and has a contingent PI. (3) The physical fact that a certain particle has a certain position. That's highly a posteriori and has a contingent PI.

(More technicalities coming up.)

I think what you may really be talking about, though, is the conditional from initial state of the wave function plus Schrodinger equation (as a physical law) to final state of the particle. The status of this depends on just which interpretation of QM we are using, as the claim the Schrodinger equation is taken to make about physical reality will vary with the interpretation. On the Everett interpretation, I suppose the conditional will be a priori, as the equation is the only dynamics; and indeed, given knowledge of an initial state and of the truth of the interpretation, one can know the (superposed) final state just fine. Something similar arguably goes for the Bohm interpretation. As long as we are given full enough information about wave plus particles in the antecedent, then we can come to know the determinate final state no problem. In a "collapse" interpretation, on the other hand, the conditional will never be a priori, as such interpretations have a further nondeterministic part of the dynamics, so we'll at best be able to figure out a probability distribution. Anyway, it seems to me that in each of these cases, a priority and necessity of PI will line up.

--Dave.

"What our grammarian does is simple enough. He frames his formal reconstruction of K along the grammatically simplest lines he can, compatibly with inclusion of H, plausibility of the predicted inclusion of I, plausibility of the hypothesis of inclusion of J, and plausibility, further, of the exclusion of all sequences which ever actually do bring bizarreness reactions." -- W.V.O. Quine

----------------------
My visa still isn't through, and although there are indications that it shouldn't be too long now, I won't be there by next Tuesday. This means I have to rearrange things a little. Week 5 was originally supposed to be on the "tyranny of the subjunctive", on relationships between the 2-D framework and indicative and subjunctive conditionals, and on implications for the analysis of necessity. But that isn't really written up (except very briefly in the Princeton outline); I'd been planning to mostly talk about it in class. So as things stand, we will skip straight to the following topic (the original week 6) instead.

This topic involves applying the 2-D framework to epistemic and modal arguments against materialism. The readings are

TCM, Chapter 4 -- mostly pp. 131-149.
N&N, pp. 144-55.
Mind and Modality, Lecture 1 (esp. sections 5-7).

The Mind and Modality notes (on the web) have my currently preferred formulation of the 2-D argument against materialism. It's a bit crisper and tighter than the book version, though it comes to much the same thing in the end. The book version has more discursive detail, so you'll probably want to look at the two of them together (the real core of the book argument is pp. 131-36, but pp. 147-49 also has relevant material). It might also be interesting to look at Kripke's anti-materialist argument in N&N, which is similar in spirit, and compare and contrast. (N.B. The Princeton notes have some contrastive analysis that goes a bit beyond what is in the book.)

Anyway, consider these the readings for next week's discussion. I'll look forward to seeing your thoughts on them early next week.

As promised, there's also an assignment. I'd like you to take two terms that Kripke discusses, and translate his discussion into the 2-D framework. One is "yard", as discussed on p. 76; the other is "cat", as discussed on p. 122 and pp. 125-6. I'd like you to take every significant part of Kripke's discussion here and translate it into the 2-D framework. Characterize roughly what the PI and the SI of these terms look like, at least given Kripke's intuitions. In places where Kripke considers a hypothetical scenario, you should roughly specify the world, say whether it is being considered as actual or as counterfactual, note what the referent of the relevant term or statement is in that world (considered the relevant way, and according to Kripke's stated intuitions), and say what the upshot is the for relevant PI or SI. Try to translate Kripke's more general points in these passages into the framework too, if you can. If you're so inclined, you can say whether you agree or disagree with Kripke's specific and general analyses and why, though that isn't compulsory.

This shouldn't be much work (the passages are pretty short). This
will be due by next Tuesday at noon, Arizona time. Don't be late. E-mail it directly to me (not to the mailing list). It should be your own work.

--Dave.

Subject: assignments
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

I've been over the assignments and made comments on them. I'll send them all back individually. But here are some general comments. First I'll give something like the answers I would have given.

--------------------------------------------
"yard":
PI: picks out the distance from Henry's nose to finger in a given world.
SI: picks out this specific length (the actual Henry length) in all worlds.

Kripke's discussion: The PI of 'yard' picks out the Henry length in a given world. Even so, it's not necessary that the Henry length is a yard.

To see this, take a world where Henry's arm was foreshortened by an accident. Considering that world as counterfactual, it's a world where Henry's arm is less than a yard. I.e., "the Henry length is a yard" is false in that world considered as counterfactual. I.e., the SI of "the Henry length is a yard" is false in that world. So "the Henry length is a yard" is not necessary.

This isn't because the PI of "yard" is a cluster. The point works even when the PI is a non-cluster (as the PI used here shows). Rather it arises because the SI of "yard" is different from the PI, picking out the actual length at all worlds.

(Something else one can say, though Kripke doesn't say it explicitly: It's a priori that the Henry length is a yard. If we take the foreshortened world and consider it as actual, "the Henry length is a yard" comes out true. I.e. the PI of "the Henry length is a yard" is true in that world. Similarly for any world. So "the Henry length is a yard" is a priori. This reflects the fact that at all worlds, the PI of "yard" picks out the Henry length in that world.)

----------------------------------------
"cats":
PI: picks out "that kind of thing", i.e. the things I'm acquainted with as 'cats' or some such, at a given centered world.
SI: picks out a specific biological kind (DNA, evolution history, etc?) at all worlds.

p. 122: "Cats are animals" is not a priori. To see this, take a world where the catlike things are demons, and consider it as actual. Considered this way, we'll say that cats are demons and are not
animals. I.e., "cats are animals" is false in this world considered as actual. I.e., the PI of "cats are animals" is false in this world. So "cats are animals" is not a priori.

This reflects the fact that the PI of "cats" doesn't pick out animals in all worlds. In fact it doesn't pick out any qualitative dictionary definition (for any definition D, "cats are D" isn't a priori), but rather picks out "that sort of thing".

p. 126: Given that cats are in fact animals, then "cats are animals" is necessary. To see this, take the world where catlike things are demons, and consider it as counterfactual. Considered this way, it's a world where the demons aren't cats. So "cats are demons" is false in that world considered as counterfactual. Similarly for any world in which catlike things aren't animals. Considering such a world as counterfactual, we'll always say the nonanimals aren't cats. So "cats are animals" will be true in all such worlds considered as counterfactual. So the SI of "cats are animals" is true in all worlds. So "cats are animals" is necessary. The SI of "cat" picks out animals in all worlds.

(Kripke also reiterates the PI point from p. 122: if we *discovered* that catlike things are demons, we'd say cats aren't animals. I.e. considering the catlike demon world as actual, "cats are animals" comes out false, i.e. "cats are animals" isn't a priori, and the PI of "cat" can pick out nonanimals. But here, we are considering the world as counterfactual, in order to determine what is necessary.)

Similarly even for a world in which catlike things are animals with reptile internal structure. Considering such a world as counterfactual, we'll say it's a world where the catlike reptiles are fool's cats, not cats. So the SI of "cats" doesn't pick out the reptiles in that world. So the SI of "cats" picks out animals with a specific internal structure across worlds, and so it is necessary that cats have that specific internal structure.

Of course I didn't expect precise replicas of this, but I was looking for the central points here to be made. Mostly people did a reasonably good job, showing at least a decent working knowledge of the framework. Often people could have been a bit more complete and explicit in the discussion, though. And people should work on being as precise and rigorous with the language as they can. A few points that came up repeatedly:

(1) Quite a few people didn't distinguish the epistemic discussion on p. 122 from the modal discussion on p. 126 as carefully as they could have. Often people concentrated on the modal point (re rigid designation and the SI of "cat"), without going into Kripke's argument on the epistemic point (re considering the demon world as actual, and consequences for a priority and for the PI of "cat"). It's important to distinguish the epistemic from the modal point, and recognize that what's going on on p. 122 is really quite different from what's going on on p. 126.

(2) Most people didn't address the point about clusters, and the reptile scenario. That's forgiveable, as they were minor points even in context.

(3) Often people didn't quite follow my instructions re the consideration of hypothetical scenarios. In particular, it's
important to note, when a scenario is being considered, whether it is being considered as actual or as counterfactual. Then one can note what results one gets when the scenario is considered this way, and what follows regarding the PI/SI of the concept, and for a priority/necessity. (In general, scenarios considered as actual have consequences for PI and for a priority, on the epistemic side; scenarios considered as counterfactual have consequences for SI and for necessity, on the modal side.) Being careful about this makes it a lot easier to disentangle the issues in (1) above.

Note that Kripke's arguments almost always move from the specific to the general. He considers specific scenarios (as actual or as counterfactual), makes a considered judgment about how to describe them, and draws consequences about the way our terms refer across worlds (in effect about PIs and SIs), and draws conclusions about apriority and necessity. At least, that's the way the argument is presented: it's consideration of scenarios that establishes or supports the conclusions re a priority, necessity, and the like. That's a pretty common order of precedence in this area: one proceeds from a judgment about a scenario or scenarios (considered as actual or as counterfactual) to conclusions about PI/SI, apriority, necessity, etc, rather than vice versa.

(4) A common looseness of language was to move too easily between intensions and extensions. E.g. people would say that the PI is the Henry length, or that the SI is the specific length, or that the SI picks out the actual PI in all worlds, and so on. Remember, a PI is a function, not a length. So one can say things like: the PI *picks out* a length in a given world; or, the *value* of the PI at a given world is a length. But it's best not to say that the PI itself is a length.

For the phrases above, one could say e.g. that the PI picks out the Henry length in a given world, or that it picks out the actual Henry length in the actual world. Or one could just talk about the actual referent, instead of the PI, saying that the actual referent is the actual Henry length. For the second phrase, one could say that the SI picks out the specific length in all worlds. For the third, one could say that the SI picks out the actual referent in all worlds, or that it picks out the actual value of the PI at all worlds, or just that it picks out the actual Henry length at all worlds.

There are various ways to do things, but it's important for many purposes not to mix up intensions and extensions too easily. The central thing is that an intension is a function from worlds to extensions. (Where extensions are things like objects, people, species, lengths, properties, etc.) The intension is not an extension, but it picks out an extension at any given world. I don't think anyone is really confused about this, but it's good to keep the language straight.

(5) Another point about the language concerns just how we talk about evaluating statements at worlds. Given the ambiguity between PI and SI evaluation (i.e. between considering as actual and as counterfactual), one has to be careful about this. It's easy to be unclear by not specifying the sort of evaluation, or in other ways. Here are the sorts of locutions that are reasonable, where W is a world, and "A is B" is a statement.

For PI evaluation (or considering as actual), the following locutions are probably best:
In W considered as actual, "A is B" is true.  
The primary intension of "A is B" is true in W.

The two above are probably the most precise, but one can also 
equivalently say the following without too much inaccuracy:

"A is B" is true in W considered as actual.  
Considering W as actual, it's a scenario where A is B.  
Considering W as an epistemic possibility, it's an epistemic possibility 
in which A is B.  
If W turns out to be actual, it will turn out that A is B.  
If W is actual, A is B.

Exactly the same goes if you substitute "counterfactual" for "actual" 
and "SI" for "PI" in the above, except for the last two, which don't 
have direct analogs. (Maybe a subjunctive such as "If W were the 
case, A would be B"; more on subjunctives and indicatives later.)

Something similar goes for evaluating terms rather than sentences.  
Here you can say things like:

In W considered as actual, "A" refers to X.  
The primary intension of "A" refers to X in W.  
If W is actual, "A" refers to X.

[N.B. "Picks out" is as good as "refers to" here.]

Things one *shouldn't* say:

The PI of "A is B" is true in W considered as actual.  (Redundant!)  
When W is considered as actual, the PI of "A" picks out X.  (Redundant!)  
If W is actual, the PI of "A" picks out X (Redundant!)  
The PI of "A" is actually X.  (Intension/extension mixup.)

One also has to be careful with things like:

In W, "A is B" is true.  
In W, A is B.

When we do this without a PI/SI indicator, or without an "actual" or 
"counterfactual", the usual practice is that we are considering W as 
counterfactual, so it is SI evaluation that's relevant. At least that 
is the standard practice in Kripke and in most contemporary 
philosophy. But in the context of the 2-D framework, it can be a 
little confusing and potentially ambiguous, so it's best to give some 
sort of marker where possible.

----

Anyway, as I said, people did pretty well. More precision and such 
(very important in this area!) should come with practice and 
experience. I'll probably set another assignment like this fairly 
soon, to give more practice at the framework. Maybe including an 
example or two not in Kripke, for you to give your verdicts on the PI 
and SI, etc.

--Dave.

P.S. Now that the assignment is out of the way, I'm looking forward to 
everyone's comments on the week 5 issues as soon as possible.

From owner-modality@LISTSERV.ARIZONA.EDU Fri Mar 12 14:58:13 1999
Like Angela, I am confused about what the secondary intension points to in the case of the forty-second president of the United States. To elaborate on a point that Brad made about Deep Throat in our last meeting, I can think of a few cases where rigid designators don't seem to work the way Kripke intends. For example, Mark Twain; it would seem, given in our actual world that Mark Twain is Samuel Clemmons, Mark Twain would be Samuel Clemmons in all counterfactual worlds (I guess Samuel Clemmons isn't really a secondary intension?). But I can easily imagine a world where Mark Twain was Joe Schmoe. Likewise, I can imagine a world where Marilyn Monroe was not Norma Jean and Aristotle was a woman. I guess this is possible because I am assuming that the primary intension of those names apply to Mark Twain, the author; Marilyn Monroe, the actress; and Aristotle, the philosopher.

But Kripke is intent on showing that names are not descriptive. The name, Marilyn Monroe, refers to, roughly, that woman that we call Marilyn Monroe. I think that Kripke can make a good case in respect to Aristotle (because Aristotle refers to the man and not to the Greek philosopher etc. it makes sense to say that Aristotle could have been a blacksmith.) I think that it does not make as much sense, however, to say that Deep Throat could have been a butcher, Mark Twain could have been a baker, etc. I guess I think that for these sorts of names, something like a descriptive theory is needed.

I would appreciate if someone would expand on how primary and secondary intensions work in respect to definite descriptions and proper names.

Thanks- Rachael

In our last meeting, Dave claimed that definite descriptions like 'the current president of the United States' would not refer to Bill Clinton in a possible world where he was not the current prez even when that world was considered as counterfactual, is this because definite descriptions aren't rigid designators? Also, I'm confused (in these cases) as to what the primary and secondary intensions of such descriptions are like...because it seems as though, given that the referent of a description like 'the current president' doesn't pick out Bill Clinton in all possible worlds when considered as counterfactual, that there is no secondary intension, or if there is, it's not serving the same function as the SI of a rigid designator (because it doesn't seem to fix the reference across worlds given that the actual world is the way it is). A little clarification here would be helpful...

Also, regarding the concept of a priori, or rather the definition that 'x is knowable a priori if x can be known prior to experience,' I don't see why problems like the one presented by Godel's theorem aren't more
troubling...if we have to idealize away from our own cognitive limitations to come up with an appropriate idea of 'in principle a priori knowability' such that we are conceiving of a being that is not subject to the sorts of mathematical counterexamples like Godel's theorem, then it seems as if our concept of a priori knowable breaks down...i.e., how are we to conceive of the distinction between what is knowable prior to experience and what is not for an idealized being like the one needed to avoid the Godel counterexample? It's not clear to me what such a being could or couldn't know without actually having to look...if a priori were defined strictly in terms of the analyticity of statements, then there seems to be less of a problem keeping the distinction between a priori and a posteriori straight when idealizing so far from our own case...but this doesn't seem to be the way Dave wants, centrally, to define the a priori...so is it the case that "knowable prior to experience" is more akin, or closer in kind to an idea like "analyticity" than I think, or what?

angela

From: David Chalmers <chalmers@LING.UCSC.EDU>
Subject:      Primary and secondary intensions
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

Angela, Rachael, and Erik L. raise a few lingering questions about the two-dimensional framework, primary and secondary intensions.

Angela writes about the secondary intensions of descriptions:

> In our last meeting, Dave claimed that definite descriptions like 'the current president of the United States' would not refer to Bill Clinton in a poss. world where he was not the current prez even when that world was considered as counterfactual, is this because definite descriptions aren't rigid designators?

Yes, this more or less comes down to the fact that descriptions aren't rigid designators. Let's take "the 42nd president of the United States" as our description to avoid difficulties due to indexicals and centering. And let's consider a world in which Paul Tsongas is the 42nd president of the United States -- and let's not consider it as actual (as an epistemic possibility), but as counterfactual (as a way the world might have been).

In that counterfactual world, what does "Bill Clinton" pick out? I.e., who is Bill Clinton in that counterfactual world. Certainly not Paul Tsongas! It's Clinton, who presumably is somewhere back in Arkansas in this world.

In that counterfactual world, what does "the 42nd president of the United States" pick out? I.e., who is the 42nd president of the United States in that world? Certainly not Clinton! It's Paul Tsongas, who is busy being president in this world (at least until he has a heart attack).

All this is borne out by the fact that we describe this as a counterfactual world in which Tsongas (not Clinton) is the 42nd president of the US. If "the 42nd president" picked out Clinton in this world considered as counterfactual, it would come out as a
counterfactual world in which Clinton is the 42nd president, which
seems wrong.

This brings out Kripke's central distinctions between names and
descriptions, which is that names are rigid designators and
descriptions are not. That is, names pick out the same individual
across all counterfactual worlds, but descriptions need not -- they
pick out whatever individual satisfies the description, even in
counterfactual worlds.

For example, "Clinton" picks out the same person in all worlds
considered as counterfactual; i.e. the SI of "Clinton" picks out the
same person in all worlds; i.e. "Clinton" is a rigid designator.
Whereas "the 42nd president" picks out whoever is the 42nd president
in a given world considered as counterfactual; i.e. the SI of "the
42nd president" picks out different individuals in different worlds;
i.e. "the 42nd president" is not a rigid designator.

So the SIs of "Clinton" and "the 42nd president" are different. If
they were the same, then "Clinton is the 42nd president" would be true
in all counterfactual worlds, i.e. it would be necessary (in the
Kripkean sense) that Clinton is the 42nd president, which seems wrong.
The Tsongas world itself seems to bear witness to the fact that it is
not necessary that Clinton is the 42nd president. We might say that
SI of "Clinton" goes with the person, while the SI of the "42nd
president" goes with the office.

There is a temptation sometimes to think that the secondary intension
of a term is just *defined* as the function that picks out the actual
referent (e.g., Clinton for "the 42nd president") in all worlds.
(Even some well-known philosophers have interpreted the framework that
way). Of course one could define an intension that works that way,
but that isn't the way secondary intensions (as I've defined them)
work. One simply takes a world, considers it as counterfactual, and
sees what the term picks out there. Kripke's contribution was to make
the nontrivial observation that names pick out the same referent in
all worlds consider this way, whereas descriptions don't. That is, he
made the nontrivial observation that names but not descriptions are
rigid designators. If we defined secondary intensions in the
alternative way suggested above, then it would be trivially true that
names, descriptions, and everything else are rigid designators, so we
would lose both the nontriviality of Kripke's observation.

Indeed, if we did things that way, we'd lose any way to distinguish
between names and descriptions (such as "Hesperus" and "the evening
star") at all. Their primary and secondary intensions would be the
same, and both expressions would pick out the same things in all
worlds. So we'd lose the ability to account for the fact that it is
not necessary that Hesperus is the evening star, and so on. Or at
least, we'd break the tie between secondary intensions and necessity,
which would seem undesirable.

> Also, I'm confused (in these cases) as to what the
> primary and secondary intensions of such descriptions are
> like...because it seems as though, given that the referent of a
> description like 'the current president' doesn't pick out Bill Clinton in
> all poss. worlds *when considered as counterfactual*, that there...is no?
> secondary intension, or if there is, it's not serving the same...function?
> as the SI of a rigid designator (because it doesn't seem to fix the
> reference across worlds given that the actual world is the way it is). A
> little clarification here would be helpful...
The PI of "the 42nd president of the US" picks out the 42nd president in all worlds. The SI picks out the 42nd president in all worlds. The actual referent is Clinton.

The PI of "Bill Clinton" picks out very roughly "the guy I've heard of as 'Bill Clinton'" in all worlds. The SI picks out that very guy in all worlds. The actual referent is Bill Clinton.

This all reflects the fact that the SI of a name picks out the actual referent in all worlds, whereas the SI of a description doesn't. The description still has an SI, as one can still consider a counterfactual world and ask what the description picks out there. It's just that for a description, it needn't pick out the actual referent (as the term isn't a rigid designator). Basically, the SI of a name depends very heavily on the way the actual world turns out (it is very much a posteriori). But the SI of a description depends much less heavily on the way the actual world turns out (sometimes it may be a priori, or sometimes it may be somewhat a posteriori, e.g. due to the presence of a name within the description).

It's still the case that when we consider the Tsongas world as counterfactual, we're holding fixed that the actual world has turned out this way, with Clinton being such-and-such a guy, being the 42nd president, etc. Given that a posteriori information, this tells us that "Clinton" picks out that very guy across all worlds. But even this a posteriori information doesn't tell us that "the 42nd president" picks out Clinton across all worlds. Even knowing how the actual world turned out, the Tsongas world in question is described as a counterfactual world in which Tsongas is the 42nd president, not Clinton.

[All this is complicated a little by the fact that descriptions arguably have *a* reading on which they are rigid designators -- e.g. where one reads "the 42nd president" as something like "the actual 42nd president". On this reading, one could consider the Tsongas world as a world in which the 42nd president isn't president (i.e., the actual 42nd president, Clinton, isn't president), and on that reading, "the 42nd president" would pick out Clinton in the Tsongas world, not Tsongas (and would pick out Clinton in all worlds). But I think this would be a somewhat unusual reading of the description. At most, this would suggest that descriptions are ambiguous between a nonrigid and a rigid reading. The difference between the SIs of rigid terms and nonrigid terms would stay intact.]

Rachael writes:

>Like Angela, I am confused about what the secondary intension points to in the case of the forty-second president of the United States. To elaborate on a point that Brad made about Deep Throat in our last meeting, I can think of a few cases where rigid designators don't seem to work the way Kripke intends. For example, Mark Twain; it would seem, given in our actual world that Mark Twain is Samuel Clemmons, Mark Twain would be Samuel Clemmons in all counterfactual worlds (I guess Samuel Clemmons isn't really a secondary intension?). But I can easily imagine a world where Mark Twain was Joe Schmoe. Likewise, I can imagine a world where Marilyn Monroe was not Norma Jean and Aristotle was a woman. I guess this is possible because I am assuming that the primary intension of those names apply to Mark Twain, the author; Marilyn Monroe, the actress; and Aristotle, the philosopher.

Hmm, interesting. I think one can certainly imagine a world
considered as actual* in which Marilyn Monroe wasn't Norma Jean, etc (just say we discovered that she was really born "Marilyn" and that the "Norma Jean" business was a myth, with the Norma Jean she pretended to be still living happily in Florida as a grandmother). But can we imagine a world considered as counterfactual in which Marilyn wasn't Norma Jean?

Take a counterfactual world where the real Norma Jean (who in the actual world became Marilyn) never went into show business, and that some other blonde actress (Jayne Mansfield, say) took the name "Marilyn Monroe", had some plastic surgery, ended up looking and sounding and living just like the actual Marilyn. Is this a counterfactual world in which Marilyn was Jayne Mansfield? Or is it a counterfactual world in which Marilyn never went into show business, and in which someone else looked and lived like her?

Kripke's intuition is the second, in which case the SI of "Marilyn Monroe" picks out Norma Jean in this world, not Jayne Mansfield. Do you have the first intuition instead? If so, then presumably the SI of "Marilyn Monroe" picks out Jayne Mansfield in this world, and picks out roughly whoever plays the relevant actress role in a given world.

My own intuitions tend to side with Kripke here. It does seem that we can consider counterfactual worlds in which Marilyn Monroe never went into acting, and lived a happy family life in Florida. If so, there are counterfactual worlds where the SI of "Marilyn" picks out Norma Jean, irrespective of whether she's an actress. And it is not obvious to me that we can easily consider a world where Jayne Mansfield really was Marilyn, as opposed to looking and living like her. If so, then the SI of "Marilyn" goes with the person, not the role.

But maybe you have different intuitions here. If you're right, there is at least one reading of some names in which they are nonrigid: "Marilyn Monroe" will pick out whoever plays the actress role in a counterfactual world, irrespective of whether they are the same person as the actual Marilyn. If this is right, then the distinction between names (at least these names) and descriptions would be broken down further.

Anyway, I'm not certain whether you're meaning to endorse these claims, or just the weaker primary intension claim (which applies only to worlds considered as actual). The weaker claim I think is very reasonable; the stronger claim would be unorthodox and many would disagree, but that's not to say that it's untenable. On this reading, I presume you'll have to disagree with Kripke, and argue that it is necessary that Hesperus is the evening star, in all counterfactual worlds, and so on?

But Kripke is intent on showing that names are not descriptive. The name, Marilyn Monroe, refers to, roughly, that woman that we call Marilyn Monroe. I think that Kripke can make a good case in respect to Aristotle (because Aristotle refers to the man and not to the Greek philosopher etc. it makes sense to say that Aristotle could have been a blacksmith.) I think that it does not make as much sense, however, to say that Deep Throat could have been a butcher, Mark Twain could have been a baker, etc. I guess I think that for these sorts of names, something like a descriptive theory is needed.

I would appreciate if someone would expand on how primary and secondary intensions work in respect to definite descriptions and proper names.

Hmm, OK, so maybe you are endorsing the strong claim here. I think
Kripke would argue that Deep Throat could have been a butcher. (One can imagine Nixon saying "if only that damned Deep Throat had never gone into public affairs and had become a butcher instead"). And I think he would argue that "Deep Throat" can't pick out other individuals in other counterfactual worlds. (Of course it can pick out other individuals in worlds considered as actual, as the primary intension is pretty clearly descriptive.)

On your view, it looks like there will be two classes of names, some of which are rigid designators and some of which are not. The rigid ones pick out the same individuals across counterfactual worlds (they have a constant SI), whereas the nonrigid ones don't (they have a descriptive SI). I guess the nonrigid ones will be the ones that "look" descriptive in some sense, or which have strongly descriptive connotations -- Deep Throat, Jack the Ripper, Hesperus, etc, etc? Such names would presumably have very similar PI and SI, captured by the description in both cases. The rigid ones, by contrast (e.g. Rachael Parkinson, Joe Schmoe, etc) will have some sort of subtle PI (maybe captured causally or metalinguistically) and will have an SI that picks out the same person in all worlds.

As I say, that would be an unorthodox but interesting position. (The orthodox position is that all names are rigid, so that their SI picks out the same individual in all worlds.) It might be tricky to draw the line between the two sorts of names. I guess an alternative would be to say that many or all names are ambiguous between a rigid and a nonrigid reading, so that "Deep Throat" etc can be read both ways (on one reading, Deep Throat could have been a butcher, on the other reading, not). Maybe one could even make the case for all names, so that e.g. "Rachael Parkinson" has an alternative descriptive reading on which Rachael had to be called `Rachael' or some such. This would break down the barrier between names and descriptions still further, as we'd now have ambiguity between rigid and nonrigid readings in both cases.

All that applies to secondary intensions, of course. I think the primary intensions of names etc will be fairly unaffected by what we say here about rigidity.

Erik writes about causal primary intensions:

>I have a brief question regarding the admissability of causal primary 
>intensions. This has come up at least twice; once in Tim's response to 
>Josh's BIV scenario, and then again in our first class meeting. So, the 
>problem is, I don't think primary intensions can ever be appropriately 
>thought of as "the cause of my sensation that" or "that which brought 
>about my experience of" or some such, because in any of these cases the 
>primary intension can vary wildly, depending on what the cause happens to 
>be. So some brain in a vat may have a PI of water that appeals to 
>electrodes and stimulation or whatever, and on earth this of course won't 
>make any sense. So "that which causes my x experience" makes a primary 
>intension the same as whatever the cause happens to be , and not the 
>essential notion or properties of the thing itself, apriori. So I think 
>the primary intension has to be necessarily connected to the essential 
>quality of the thing (at least as it is known apriori or conceptually). 
>What we mean by the concept of water, then, is not what causes the water 
>experience (which may have nothing to do with the essence of water itself).

Hmm, I'm not sure I've entirely grasped the problem here. It seems to me that the BIV case as you've described it is compatible with the PI of water being "that which causes my x experience". If that's the PI
for the BIV, then presumably "water" will pick out whatever causes x experiences for the BIV, which will presumably be some assortment of chemicals and electrodes, etc, which is just what you say.

Here there will be no difference between the PI of "water" in the BIV and in you and me. In both cases it might be "what causes my x experiences". Of course the *referent* will be different between the cases: for you and me, the PI will pick out H2O, whereas for the BIV, it will pick out electrodes and such. But the PI and the referent are different things. One shouldn't strictly speaking say that the PI for the BIV involves electrodes, etc. It's important to remember that the PI is a function from worlds to extensions, and the referent is just the extension at the actual world. For the BIV, the PI might be "what causes my x experiences". One can say that the PI *picks out* electrodes and such in its world, or one can say that the *referent* involves electrodes, but these are different claims.

It may be that one wants to reject simple causal PIs for other reasons. E.g., one might reasonably argue that the term "water" for a BIV *doesn't* pick out the electrodes, even though they cause x experiences in the BIV. If that's right, then arguably the PI for "water" has a descriptive component over and above the pure causal component. But that's a subtle matter.

Let me know if I've missed your point here.

--Dave.
Like Angela, I am confused about what the secondary intension points to in the case of the forty-second president of the United States. To elaborate on a point that Brad made about Deep Throat in our last meeting, I can think of a few cases where rigid designators don't seem to work the way Kripke intends. For example, Mark Twain; it would seem, given in our actual world that Mark Twain is Samuel Clemmons, Mark Twain would be Samuel Clemmons in all counterfactual worlds (I guess Samuel Clemmons isn't really a secondary intension?). But I can easily imagine a world where Mark Twain was Joe Schmoe. Likewise, I can imagine a world where Marilyn Monroe was not Norma Jean and Aristotle was a woman. I guess this is possible because I am assuming that the primary intension of those names apply to Mark Twain, the author; Marilyn Monroe, the actress; and Aristotle, the philosopher.

But Kripke is intent on showing that names are not descriptive. The name, Marilyn Monroe, refers to, roughly, that woman that we call Marilyn Monroe. I think that Kripke can make a good case in respect to Aristotle (because Aristotle refers to the man and not to the Greek philosopher etc. it makes sense to say that Aristotle could have been a blacksmith.) I think that it does not make as much sense, however, to say that Deep Throat could have been a butcher, Mark Twain could have been a baker, etc. I guess I think that for these sorts of names, something like a descriptive theory is needed.

I would appreciate if someone would expand on how primary and secondary intensions work in respect to definite descriptions and proper names.

Thanks- Rachael

I have an observation on indicative and subjunctive conditionals that I want to run by all of you. In every example that I have come up with if an indicative conditional has its truth value necessarily, then its corresponding subjunctive conditional also has its truth value necessarily. The truth values may differ, but it doesn't seem that the necessity of those truth values differs. Consider the following examples.

"If the CIA didn't arrange Kenedy's death then someone else did." [Possibly true]
"If the CIA hadn't arranged Kenedy's death then someone else would have." [Possibly false]

"If the stuff in the lakes and rivers is XYZ then water is H2O." [Necessarily False]
"If the stuff in the lakes and rivers were XYZ then water would be H2O."
[Necessarily True]

"If Penguins don't live in Antarctica then my maps are missnaming the southern most continent in the world." [Possibly false]
"If Penguins hadn't lived in Antarctica then my maps would have missnamed the southern most continent in the world." [Possibly false]

Now this could be a fluke and someone may be able to generate a counter-example. But if there is a direct correspondence then surely it is because there is a connection between the necessity of indicative and subjunctive conditionals. And if there is a connection then one wonders whether we could do away with one or the other.

Just some thoughts to chew on.

Josh

Josh writes:

>I have an observation on indicative and subjunctive conditionals that

>with if an indicative conditional has its truth value necessarily,
>then its corresponding subjunctive conditional also has its truth value
>necessarily. The truth values may differ, but it doesn't seem that
>the necessity of those truth values differs. Consider the following examples.

We decided in the break today that the claim was as follows. Let S(IC) be the indicative conditional "If P is the case, then Q is the case", and S(SC) be the subjunctive conditional "If P were the case, Q would be the case." Then the claim is: S(IC) is indicatively necessary or indicatively impossible if and only if S(SC) is subjunctively necessary or subjunctively impossible.

I think I can come up with a few counterexamples, as follows. I've labelled them in Josh's way.

"If the tallest person in England committed those murders, the tallest person is Jack the Ripper".
[Necessarily true.]

"If the tallest person in England had committed those murders, the tallest person would have been Jack the Ripper".
[Probably false, but not necessarily.]

"If H2O is not in the oceans and lakes, water is XYZ".
[Possibly true, possibly false.]

"If H2O were not in the oceans and lakes, water would be XYZ." [Necessarily false.]

It's interesting that many of the standard cases line up together in
Josh's way. It might be an interesting exercise to figure out what those examples have in common which the examples above do not (apart from the property at issue).

--Dave.

I just want to resolve a worry I expressed in seminar last week:

Indicative: If XYZ is in the oceans and lakes, then water is XYZ.
Subjunctive: If XYZ were the liquid in the oceans and the lakes, water wouldn't be.

I argued that it made sense to say "If XYZ were the liquid in the oceans and lakes, water would be XYZ." That is to say, in considering this world as actual, we could discover that we were mistaken in identifying water with H2O, that it is actually XYZ. The sentence looks like a subjunctive one.

The mistake here is that the sentence is actually indicative, roughly equivalent to "If we were to find out that XYZ is in the oceans and lakes, then water is XYZ."

Still, I have a confusion which I'm sure someone will be able to easily dispel. Chalmers suggested that we can match the subjunctive up with secondary intensions and the indicative with primary intensions. It looks like the indicative sentence "If XYZ is in the oceans and lakes, then water is XYZ" applies to the secondary intension of water. What do you think?

-Rachael

I'm not sure if this will be helpful, but here goes...

> Indicative: If XYZ is in the oceans and lakes, then water is XYZ.
> Subjunctive: If XYZ were the liquid in the oceans and the lakes, water wouldn't be.

> I argued that it made sense to say "If XYZ were the liquid in the oceans and lakes, water would be XYZ." That is to say, in considering this world as actual, we could discover that we were mistaken in identifying water with H2O, that it is actually XYZ. The sentence looks like a subjunctive one.

I think you mean to say that this is an indicative conditional--considering the centered world in which XYZ is the dominant watery stuff, water is XYZ.
The mistake here is that the sentence is actually indicative, roughly equivalent to "If we were to find out that XYZ is in the oceans and lakes, then water is XYZ."

Still, I have a confusion which I'm sure someone will be able to easily dispel. Chalmers suggested that we can match the subjunctive up with secondary intensions and the indicative with primary intensions. It looks like the indicative sentence "If XYZ is in the oceans and lakes, then water is XYZ" applies to the secondary intension of water.

What do you think?

-Rachael

It seems to me that this last sentence, "If XYZ is in the oceans and lakes, then water is XYZ", is making a statement about the primary intension of water. The way we pick out water according to the primary intension is that it is whatever plays the role of being the dominant watery stuff in a centered world. If we consider the secondary intension, however, water is H2O. Accordingly, a counterfactual world with XYZ in the rivers and lakes is actually a world without water.

It seems that you can construct these conditionals using terms that make it sound that an indicative cond. is a subjuctive and the reverse. It seems, perhaps, that one needs to simply think about indicative conditionals as those that are saying something like, 'assuming that so and such actually is the case, x follows'. And, similarly, subjunctives are those conditionals that ask you to consider what would follow if something that is not the case, was.

sorry if this is not helpful.

A lot of people talking about indicatives use the Ramsey Test to get assertabilty conditions for indicatives. But to ground truth_1 and truth_2 (and therewith Nec_1 and Nec_2) we need bona fide truth conditions. The worry is that the Ramsey Test brings into play other stuff in our belief corpus, and so might not be capable of fixing truth conditions. Here's one way that the Ramsey Test for indicatives can get going on genuine truth conditions.

Say that a world w2 is epistemically accessible to an agent in w1 just in case for all the agent knows, w2 might be the actual world. Accessibility of epistemic alternatives is an equivalence relation. An agent knows P iff P is true in all the epistemically accessible worlds to the agent. The worry is that the Ramsey Test brings into play other stuff in our belief corpus, and so might not be capable of fixing truth conditions. Here's one way that the Ramsey Test for indicatives can get going on genuine truth conditions.

Say that a world w2 is epistemically accessible to an agent in w1 just in case for all the agent knows, w2 might be the actual world. Accessibility of epistemic alternatives is an equivalence relation. An agent knows P iff P is true in all the epistemically accessible worlds to the agent. Now let's beef up the notion by saying that in this sense of 'knows', an agent knows all the consequences of what she knows. As a limiting case, some agents can know everything there is to know at their worlds. Let K be such an agent at w. Further, take worlds to be sets of propositions. Then:

The indicative "P --> Q" is true at w iff: for any w' such that w' is
epistemically accessible from w to K, the minimal revision of w' to include P includes Q.

I think this gets out of the worry.

Hmm, I'm not sure that that sentence is grammatical! It looks like a
mixture of subjunctive and indicative to me.

One could try making it more indicative all the way by going to:

"If we find out that XYZ is in the oceans and lakes, then water is
XYZ".

Alternatively, one express something like this with a "metalinguistic
subjunctive":

"If XYZ were the liquid in the oceans and lakes, we would say that
'water' refers to XYZ."

Arguably, metalinguistic subjunctives like this, which *mention* the
term 'water' rather than *using* it, come close to tracking the
primary intension of 'water' rather than the secondary intension
(though there are subtleties here).

I think I agree with Anthony's analysis of this. It seems to me that
your (Rachael's) sentence tracks the primary intension of 'water', not
the secondary intension. Taking the secondary intension, 'water is XYZ' will be false in a scenario where XYZ is in the oceans and lakes. But taking the primary intension, it will be true there. Insofar as we judge the indicative conditional above to be true (or assertible), it seems to mirror the primary intension.

Anthony wrote:

> It seems that you can construct these conditionals using terms that make it sound that an indicative cond. is a subjective and the reverse. And, similarly, subjunctives are those conditionals that ask you to consider what wuld follow if something that is not the case, was.

Right, an alternative is to think about the conceptual categories of "epistemic conditionals" and "counterfactual conditionals", or some such, rather than directly in terms of the grammatical categories. Epistemic conditionals are those that consider the antecedent as actual, and counterfactual conditionals are those that consider the antecedent as counterfactual (more or less as you suggest above). It then turns out that most of the time, grammatically indicative conditionals are epistemic conditionals, and grammatically subjunctive conditionals are counterfactual conditionals. But maybe there can be cases or readings where this is not so. In any case, it's the conceptual rather than the grammatical distinction that runs deepest.

The worry is that the Ramsey Test brings into play other stuff in our belief corpus, and so might not be capable of fixing truth conditions. Here's one way that the Ramsey Test for indicatives can get going on genuine truth conditions.

Well, my hope is that we needn't take a stand on whether typical indicative conditionals have truth-conditions or just assertibility-conditions. As we discussed in class last week, the belief-relativity seems to apply only to the way a partial antecedent gets fleshed out into a whole world, rather than to the way that world gets evaluated. And truth_1 just needs the world-evaluation. So even if indicative conditionals with partial antecedents have belief-relative truth- or assertibility-conditions, an objective sort of semantic evaluability across worlds seems to lie in the background.

Still, it would be nice to have some sort of non-relative truth-conditions for indicatives with partial antecedents that comes close to capturing some of the intuitive assertibility-conditions.
So let's see.

Say that a world \( w_2 \) is epistemically accessible to an agent in \( w_1 \) just in case for all the agent knows, \( w_2 \) might be the actual world. Accessibility of epistemic alternatives is an equivalence relation. An agent knows \( P \) iff \( P \) is true in all the epistemically accessible worlds to the agent. Now let's beef up the notion by saying that in this sense of 'knows', an agent knows all the consequences of what she knows. As a limiting case, some agents can know everything there is to know at their worlds. Let \( K \) be such an agent at \( w \). Further, take worlds to be sets of propositions. Then:

- The indicative "\( P \rightarrow Q \)" is true at \( w \) iff: for any \( w' \) such that \( w' \) is epistemically accessible from \( w \) to \( K \), the minimal revision of \( w' \) to include \( P \) includes \( Q \).

Interesting proposal! So basically, the truth-conditions of an indicative will correspond to the assertibility-conditions for an omniscient being. My main worry is that it is not obvious that there is an objective notion of "minimal revision" for an omniscient being. If a being who knows everything (or thinks they do) finds out that their belief that not-\( P \) is false, how will they revise? Presumably there will be lots of different ways to revise. And presumably any such way will require giving up on some other beliefs, and preserving others. The decision between these seems to turn on which linked beliefs are "strongest" or closest to the "core" for such a being.

It seems to me that two omniscient beings might well give two quite different judgments about the indicative above, depending on just which of their beliefs that view as most amenable to revision. If so, the problem of relativity arises once again.

Of course this problem won't arise for indicatives with whole worlds in the antecedents. In this case, there won't be any "slack" in the belief revision process, and the outcome should be determined.

--Dave.
Interesting proposal! So basically, the truth-conditions of an indicative will correspond to the assertibility-conditions for an omniscient being. My main worry is that it is not obvious that there is an objective notion of "minimal revision" for an omniscient being. If a being who knows everything (or thinks they do) finds out that their belief that not-P is false, how will they revise? Presumably there will be lots of different ways to revise. And presumably any such way will require giving up on some other beliefs, and preserving others. The decision between these seems to turn on which linked beliefs are "strongest" or closest to the "core" for such a being.

It seems to me that two omniscient being might well give two quite different judgments about the indicative above, depending on just which of their beliefs that view as most amenable to revision. If so, the problem of relativity arises once again.

I took Thony to be saying that minimal revisions are not belief revisions, but world revisions. The idea is to get the nearest possible P world to w. So for Thony's case you first pick out the equiv. class of epistemically accessible worlds. Then look at all w' such that w' is an epistemically accessible world. P-->Q is true at w if for each w', the nearest P world to w' is also a Q world. It doesn't matter how K will update or revise his beliefs because "nearest P world" is a relation between worlds and is independent of agents.

Now you might argue that the notion of a "nearest P world" isn't clear. In fact I think it isn't at all clear. But pretty much everyone who talks about possible worlds wants to say that there is some such relation. So long as you hold that possible worlds are not themselves dependent on agents then any such relation is going to be objective.

Josh

Subject: Re: truth conditions of indicatives
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: R

OK, so Josh suggests appealing to a non-epistemic notion of "nearness" between worlds to evaluate indicatives. I take it this is supposed to be the same nearness relation that is present in evaluating partial subjunctive conditionals, e.g. on the Stalnaker/Lewis analysis (as Josh points to the fact that everyone accepts this relation already).

If this worked, it would give a nice link between the truth-values of indicatives and subjunctives. The subjunctive "If P, then Q" will be true iff the nearest P-worlds are Q-worlds, where P-worlds etc are worlds satisfying P's secondary intension. The indicative "If P, then Q" will be true iff the nearest P-worlds are Q-worlds, where P-worlds etc are worlds satisfying P's primary intension.

I'm not sure that this is just what Thony intended, since the idea of an omniscient being now seems to drop out of the analysis. But in any case, I worry that the same nearness relation can't plausibly to the job in both cases. Take the conditional with P = "Butterly B flapped
its wings like so last week", and \( Q = "\text{It rained this week}" \). It may well be that the subjunctive "If \( P \) then \( Q \)" is true -- if the butterfly *had* flapped its wings, it would have rained this week. (I'm assuming it didn't actually rain this week.)

But it doesn't seem right to say that the indicative "If \( P \), then \( Q \)" is true. If we were to discover that the butterfly flapped its wings, we wouldn't suddenly decide that it rained. And even an omniscient being probably wouldn't reason in that way, it seems. After all, that being will have a whole lot of beliefs about the way things are this week that would have to be overturned just to accommodate the tiny change in beliefs about the butterfly. It seems more plausible to say that the being would make a few local adjustment in its beliefs about the way things are in the vicinity of the butterfly, in order that it can change those beliefs without having huge effects elsewhere (maybe adjusting beliefs about a few molecules in the vicinity to compensate).

The intuitive moral, I think, is that indicative conditionals require something like "epistemic nearness", which is somewhat different from the sort of "metaphysical nearness" required for subjunctives. Of course one could always just stipulate the latter, but then one is moving a fair distance away from the intuitive correctness conditions for indicative conditionals.

--Dave.

P.S. Re Kripke/Wittgenstein on the social community, I tend to think that this is hopeless as a "solution" to the puzzle, as any in-principle argument that demonstrates indeterminacy in an individual will also demonstrate indeterminacy in a community. After all, in relevant respects, the community can be seen as a big individual, or an individual can be seen as a little community.
My visa still isn't through, and although there are indications that it shouldn't be too long now, I won't be there by next Tuesday. This means I have to rearrange things a little. Week 5 was originally supposed to be on the "tyranny of the subjunctive", on relationships between the 2-D framework and indicative and subjunctive conditionals, and on implications for the analysis of necessity. But that isn't really written up (except very briefly in the Princeton outline); I'd been planning to mostly talk about it in class. So as things stand, we will skip straight to the following topic (the original week 6) instead.

This topic involves applying the 2-D framework to epistemic and modal arguments against materialism. The readings are

- TCM, Chapter 4 -- mostly pp. 131-149.
- N&N, pp. 144-55.
- Mind and Modality, Lecture 1 (esp. sections 5-7).

The Mind and Modality notes (on the web) have my currently preferred formulation of the 2-D argument against materialism. It's a bit crisper and tighter than the book version, though it comes to much the same thing in the end. The book version has more discursive detail, so you'll probably want to look at the two of them together (the real core of the book argument is pp. 131-36, but pp. 147-49 also has relevant material). It might also be interesting to look at Kripke's anti-materialist argument in N&N, which is similar in spirit, and compare and contrast. (N.B. The Princeton notes have some contrastive analysis that goes a bit beyond what is in the book.)

Anyway, consider these the readings for next week's discussion. I'll look forward to seeing your thoughts on them early next week.

As promised, there's also an assignment. I'd like you to take two terms that Kripke discusses, and translate his discussion into the 2-D framework. One is "yard", as discussed on p. 76; the other is "cat", as discussed on p. 122 and pp. 125-6. I'd like you to take every significant part of Kripke's discussion here and translate it into the 2-D framework. Characterize roughly what the PI and the SI of these terms look like, at least given Kripke's intuitions. In places where Kripke considers a hypothetical scenario, you should roughly specify the world, say whether it is being considered as actual or as counterfactual, note what the referent of the relevant term or statement is in that world (considered the relevant way, and according to Kripke's stated intuitions), and say what the upshot is the for relevant PI or SI. Try to translate Kripke's more general points in these passages into the framework too, if you can. If you're so inclined, you can say whether you agree or disagree with Kripke's specific and general analyses and why, though that isn't compulsory.

This shouldn't be much work (the passages are pretty short). This will be due by next Tuesday at noon, Arizona time. Don't be late. E-mail it directly to me (not to the mailing list). It should be your own work.
On pp. 150-5 of N & N, Kripke argues that the identity theorist who claims that "pain = C-fiber stimulation" is necessary a posteriori cannot explain away the apparent contingency of the identity statement in the same way as with "water is H2O" or "heat is molecular motion". In the latter cases, Kripke claims that the apparent contingency is due to the falsity of a qualitatively analogous statement in a qualitatively identical epistemic situation. So, for example, strictly speaking it is false that heat might not have been molecular motion. But what is true is that someone might have the sensation of heat (that is, be in a qualitatively identical epistemic situation as the one I am in when I sense heat/molecular motion) even though the phenomenon being sensed is not molecular motion.

"Pain = C-fiber stimulation" can't be handled in the same way because, Kripke says, being in a qualitatively identical epistemic situation as the one in which I am having pain *is* to have a pain. In the end I might find this satisfying, but it does seem to me worthy of debate/discussion whether or not it is correct to here identify pain with an "epistemic situation". Pains are not conceptual, and there is lots that needs to be said about how they could be properly characterized as constituting a person's "epistemic situation". There is a sense in which it seems that a person (let's call her Jones) who lacked the capacity to feel heat sensations but who had a thermometer built into parts of her body which sent temperature information to her brain could be in the same epistemic situation as a "normal person". That is, she could be in equivalent information states.

In the Mind and Modality notes, Chalmers rejects the "epistemic situation" bit in the above for different reasons. But using the notion of a primary intension, I suppose that one would say that Jones does not have a concept of heat assuming that the actual sensations of heat are part of the PI of "heat". Does this seem right? It probably does, but let's suppose that Jones' judgments about the presence of heat is identical to mine in every way (she makes exactly the same discriminations, for example). I can imagine someone (perhaps a Dennett) arguing that Jones does have our concept of heat, and that the PI of heat involves something that Jones and I share (but which I find difficult to characterize).

Perhaps something similar could be done with "pain". Might this not defuse the argument against materialism? Of course, it depends on a highly contentious analysis of the PI of phenomenal concepts. At any rate, how we are to characterize the PI's of phenomenal concepts seems to be an interesting issue and one that is extremely important in assessing the anti-materialist argument.
Brad raises a few interesting questions re "pain" and "heat". First, he wonders whether it's really right to say our epistemic situation re pain really includes pain. Second, he asks whether someone really needs to have heat sensations to have the concept of "heat" and the associated PI. Third, if the answer to this question is no, he wonders whether the point might be extended to "pain", so someone could have the concept and the PI without having sensations of pain.

(1) Re the first question, of course I think that epistemic situations are inessential here, and that nothing really turns on them in the argument. But I do share Kripke's intuitions that there's a reasonable sense in which when I'm feeling pain, pain is an essential part of my "epistemic situation". Pain is unlike chairs in that way, for example; when I look at a chair, it's arguable that I could be in the same "epistemic situation" in some sense without there being a chair there. This is just what skeptical arguments trade on -- the idea that my "direct evidence" or some such could be as it is for me right now, without various objects in the external world existing.

We might think of "epistemic situation" as being implicitly defined as the situation that is preserved in skeptical scenarios. I can consider a skeptical scenario where I'm in the same epistemic situation but there's no chair, but it's less clear that there's a skeptical scenario where I'm in the same epistemic situation but there's no pain, or no sensation of blue. Arguably, changing those things changes my "direct evidence", and changes the way things are for me now. Of course, this is an intuition and is somewhat loose, but it does seem to get at something central in our thinking about skeptical scenarios and what is held constant.

Personally, I think this gets at some deep differences between the epistemology of conscious experience (in the first-person case) and that of the external world. Somehow our epistemic relation to experience seems more direct and intimate than our epistemic relation to external objects. But that's a long story in its own right (there's a little about this in chapter 5 of the book and in the third M&M lecture).

Of course such views aren't uncontroversial. Some might argue that we really stand in the same epistemic situation vis-a-vis experience as vis-a-vis chairs. And some might argue that if experiences aren't conceptual, it's not really right to speak of them as being "epistemic" -- maybe our epistemic situation should be restricted to our beliefs, or some such. This might be particularly attractive to someone who thinks that the only thing that can justify a belief is another belief (a coherentist as opposed to a foundationalist, for example). Personally, I think there's a very strong intuition that experiences serve as basic evidence and can serve to justify beliefs even if they aren't conceptual, but there is certainly a lot that needs to be worked out there.

Brad wonders whether "Jones" who lacks heat sensations and instead has thermometer readings sent straight to her brain could be said to be in the same epistemic situation. Interesting. I guess I'd say that if the information is all unconscious and unexperienced for Jones, then Jones can consider skeptical scenarios in which the information is
different, etc, and can't rule out the existence of those situations in some intuitive sense, e.g. can't rule them out by "direct evidence". So there is a temptation to say that this info isn't part of the epistemic situation, at least not in the direct way that heat sensations are. Something to do with the skeptic-proofness of one but not the other. Still, there's some sense in which one might want to say that the temperature readings are "evidence" in some pretty direct sense. Maybe to a reliabilist, they'll be as direct evidence as anything (I don't know just what a reliabilist will say here, but maybe others can help me out). So anyway, there are some deep epistemological issues lurking around here.

(2) Do we need to have heat sensations to have the concept and the PI of "heat". Well, on the Kripkean view, the PI of "heat" is more or less "the cause of heat sensations", so the question of whether one can have this concept without heat sensations reduces to the question of whether one can have the concept (PI) of "heat sensations" without heat sensations. That one in effect was question (3).

In suggesting that Jones might have the concept of "heat", I can see three things one might be saying. (a) Jones has the PI "the cause of heat sensations" without heat sensations; (b) The PI of heat is something other than "the cause of heat sensations", and Jones has that PI; or (c) The PI of *our* concept of heat is "the cause of heat sensations", but Jones has a different PI that still qualifies as a concept of "heat".

I'm not sure which of these Brad was pointing to, but all are interesting. Option (a) (which reduces to the pain-like case from question (3)) doesn't seem too plausible here, since heat doesn't cause any heat sensations in Jones, so this PI wouldn't pick out anything. But (b) and (c) are left. I think it's plausible that the PI of Jones' "heat" is something like "the cause of heat judgments", or some such (I'm assuming she is led to the judgments in a blindsight-like way). The real question then is whether that counts as a concept of heat, and as the same as our concept.

One possibility is that the PI of our own concept is "the cause of heat judgments", not "the cause of heat sensations". That's interesting and not obviously false. I guess it comes down to: what do we say about a (broadly) epistemically possible situation in which we have no heat sensations but still have 'heat' judgments (e.g., the broad epistemic possibility that we are like Jones). If that turns out to be actual, will we say that heat is the stuff that causes the judgments, despite the lack of sensations? Maybe we would. If so, the PI of *our* concept is arguably judgment rather than sensation oriented, and Jones can have that PI. This could be the "Dennett"-like option that Brad gestures towards. It's tricky, though. (I mention this sort of possibility in footnote 41 on p. 368 of the book.)

Alternatively, we might say Jones' PI is different from ours, but similar enough that it still counts as a concept of heat. Maybe so, though that would be a largely terminological issue. Personally, I think the previous possibility is more interesting.

(3) Can something similar be done with "pain"? Hmm. First, I note that the Jones case doesn't lend direct support, since we saw that that case can't rest on her having the PI "heat sensations" without heat sensations. But maybe something like this could happen anyway.

Possibilities: (1) Someone could have our PI of "pain" without having
pain sensations. (2) Someone could have a different PI of "pain" without pain sensations, but which would still be a concept of pain.

I have to go out now, so I'll get back to this later. All thoughts are welcome.

--Dave.

On Brad's third point re "pain" etc (continuing from last time). We were talking about the possibility that the PI of "heat" might not essentially involve heat sensations (e.g. maybe just "heat" judgments), and then wondering whether that might be extended to the concept of pain.

((3) Can something similar be done with "pain"? Hmm. First, I note that the Jones case doesn't lend direct support, since we saw that that case can't rest on her having the PI "heat sensations" without heat sensations. But maybe something analogous could happen anyway?

Possibilities: (1) Someone could have our PI of "pain" without having pain sensations. (2) Someone could have a different PI of "pain" without pain sensations, but which would still be a concept of pain.)

I take it the interesting possibility is (1), as we are interested in the PI of our concept. Could Jones have e.g. our PI of "pain", despite her lack of sensations, in the way that she arguably has the PI of "heat"?

One move might be to suggest that the PI of "pain" should be analyzed as something like "the cause of 'pain' judgments", as in the heat case. If so, then Jones could truly say "I'm in pain", despite her lack of true sensations. Is our PI like this? This depends on what we'd say about the broad epistemic possibility that we are like Jones: what if that turned out to be actual? Maybe there's at least some sense in which we'd say that we still have pain, because we'll use "pain" for what causes the "pain"-judgments. That's not entirely clear to me, but maybe.

In any case it seems that one can just re-raise the issue with the concept of "pain qualia". I think it is relatively clear that the (broad) epistemic possibility that we are like Jones is an instance of the (broad) epistemic possibility that we don't have pain qualia. That is, the concept of "pain qualia" will *not* apply in the Jones centered world. (In a world of people like Jones, Dennett-ish people saying "pain qualia don't exist" would be right.) So the PI of "pain qualia" applies *essentially* to qualia-like things.

This in effect reflects Kripke's observation re "pain". Perhaps one could argue about it re "pain", but then one can just re-raise it by explicitly building in "pain feeling" or "pain qualia" or some such into the concept -- i.e. by really specifying that it is a truly phenomenal concept. Once one has done that it seems we have a qualia whose PI applies essentially to pain qualia or something in the
vinicity. After all, we need *some* concept to distinguish our own actual situation from the centered world (considered as actual) in which we are something like Jones. (Unless one denies the distinction, in which case one is presumably denying the epistemic intuitions re qualia, zombies, etc.) And "pain qualia" seems to be just the concept. So beyond a certain point, the trick of pushing things out into the world seems to stop.

At least that's how it seems to me, but I may be wrong about this, so I'd be interested to hear more thoughts. This ties closely to the sort of issue about the content of phenomenal concepts in "The Content and Epistemology of Phenomenal Belief". There I argue that our most crucial phenomenal concepts have the same PI and SI, each picking out the appropriate sort of quality in all worlds. So the structure of phenomenal concepts is indeed special in a way. At least that's what falls out of accepting the epistemic intuitions, re the conceivable of inversions, zombies, etc. If those intuitions are rejected, it may be a different story.

Brad says that this issue re phenomenal concepts impacts the anti-materialist argument in important ways. I think he's right about that, but I'm interested to know how, exactly. E.g., how would it affect the argument I put forward, essentially from the two premises, (1) the epistemic gap and (2) the 2-D analysis of a posteriori necessity? It's not obvious how it affects premise (2). Are you suggesting that it affects premise (1), maybe? If so, I'm interested to hear more.

From: Josh Cowley <josh@MATH.ARIZONA.EDU>
Subject: cognitive deficits
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

Keeping in line with my subject title the following was written while suffering from some cognitive deficits. I'm hoping the reaction of others will help me figure out what I'm worried about here.

I have a question about the section on cognitive limitations (pp. 138-140) Dave says that there is a weak sense in which we can conceive of a world in which the continuum hypothesis is true. But, since we don't know if it is true, it isn't the strong sense of conceivability that we get when we consider a physically identical world without consciousness. I'm wondering why this sense of conceivability is "weak."

I also want to push a worry that Rachael and I were expressing during discussion the other day. Kripke is of the opinion that there is only one actual world, this one. PIs pick out referents at centered possible worlds considered as actual. I take it, that to do this you need to be able to consider any possible world as actual. (First question: Is my last sentence right?) If this is right then consider a world in which I don't exist. (Index I to yourself). I can easily imagine a possible world in which I don't exist (a very unfortunate world). But I'm having trouble considering that world as actual. Now there are some ways of defining actual worlds such that I can consider a world in which I don't exist as actual. It seems like these
definitions do one of two things. Either they make me think of different possible worlds as counter-factual or they make me think of lists of propositions true at this world. At the moment I'm unable to articulate what I mean by that second choice. I'll try and fill it out tomorrow.

Josh

A quick reply to Josh.

>I have a question about the section on cognitive limitations
>(pp. 138-140) Dave says that there is a weak sense in which we can
>conceive of a world in which the continuum hypothesis is true. But,
>since we don't know if it is true, it isn't the strong sense of
>conceivability that we get when we consider a physically identical
>world without consciousness. I'm wondering why this sense of
>conceivability is "weak."

This comes down to the distinction between positive and negative conceivability that we will be discussing. Intuitively, we can't rule out the possibility that CH is true, but nevertheless we can't clearly and distinctly conceive of a scenario in which it is true. Negative conceivability goes with not finding a contradiction; positive conceivability goes with clear and distinct conception of a world, in some intuitive sense. Intuitively, we can flesh out a whole world in the "conceptual imagination" in some sense in which there are zombies, whereas we can't do anything like that fleshing out a world for CH (or not CH). It's more the purely formal inability to rule out the hypothesis.

If you like, think of positive conceivability as being able to conceive of a world verifying P, and negative conceivability as being unable to rule out P a priori. With zombies, we conceive of two distinct worlds, one with consciousness and one with zombies. But we don't have an intuition of conceiving of two distinct worlds, one with CH and the other with not-CH, in the mathematical case. So only the zombie case goes with a distinct positive conceivability intuition.

There's much more to say about this, but this is a start.

>I also want to push a worry that Rachael and I were expressing during
discussion the other day. Kripke is of the opinion that there is only
one actual world, this one. PIs pick out referents at centered
possible worlds considered as actual. I take it, that to do this you
need to be able to consider any possible world as actual. (First
question: Is my last sentence right?)

That's more or less right. It may be that some worlds don't yield determinate extensions or truth-values, though (especially particularly distant worlds, or worlds where certain background assumptions aren't satisfied -- see "The Components of Content").

>If this is right then consider
>a world in which I don't exist. (Index I to yourself). I can easily
>imagine a possible world in which I don't exist (a very unfortunate
>world). But I'm having trouble considering that world as actual.

By "consider a world in which I don't exist", there are two things you
can mean. Basically, one satisfying the PI of "I don't exist" or the
SI. The first will be a world such that when it's considered as
counterfactual, the verdict is that I don't exist. I.e. an instance
of the subjunctive possibility that I don't exist. Essentially,
that's a world in which this very person, David Chalmers, doesn't
exist. The second is a world such that when it is considered as
actual, the verdict is that I don't exist. I.e. an instance of the
epistemic possibility that I don't exist. That's a very weird world,
but in essence it is a centered world without anyone at the center of
that world.

I'm not sure which of these you intend here, but my guess is that it's
the first. If so, that's a slightly odd thing to do, as you're mixing
"considering as counterfactual" (in specifying the world) with
"considering as actual" (in evaluating the world). So there is the
potential for getting mixed up. Still, if you're very careful, I
guess you can do that. I can take worlds in which David Chalmers
doesn't exist and consider them as actual. E.g., I can take a world
centered on Michael Jordan and without David Chalmers. Considering
that world as actual, it's more or less an instance of the epistemic
possibility that I am Michael Jordan and that David Chalmers doesn't
exist (or perhaps of the epistemic possibility that I am Michael
Jordan and that the guy with such-and-such DNA structure etc doesn't
exist). It's tricky, but one can do it.

What makes it so tricky of course is the way that one combines
considering as counterfactual and as actual here. In a way, it's best
to specify the world one is considering using "considering as actual"
terminology all along. For example, one can just talk of the
epistemic possibility that P, for a whole lot of P, in specifying a
world. E.g. the very odd epistemic possibility that I don't exist.
(It's disputable whether this is really a broad epistemic possibility,
but I tend to think that it is, as it isn't a priori that I exist, it
is a posteriori. That's a tricky matter, though.) Then I can say, if
that world (the world with no-one at the center) is actual, I don't
exist. So one can evaluate at least some terms and statements there.

>Now
>there are some ways of defining actual worlds such that I can consider
>a world in which I don't exist as actual. It seems like these
>definitions do one of two things. Either they make me think of
>different possible worlds as counter-factual or they make me think of
>lists of propositions true at this world. At the moment I'm unable to
>articulate what I mean by that second choice. I'll try and fill it
>out tomorrow.

Interesting, maybe these correspond in a way to the above. Your first
choice seems to be the mixed strategy mentioned above (with both
considering as counterfactual and as actual). I'm not sure about the
second choice, but maybe it is like the second option above. This is
all a tricky business so I'm interested to hear more.

--Dave.

P.S. I still need to see the minutes from this week's meeting. And
lots of people still owe their comments re the week 5 readings and
issues. We are falling behind a bit, so I hope people can do this

From: Anthony T Lane <atlane@U.ARIZONA.EDU>
Subject: minutes
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

Here are the minutes from this weeks meeting, compiled by Rachael and myself:

First, we talked about different positions regarding discussion of possible worlds. Kripke seems to suggest that we cannot make sense of considering other worlds as the *actual* world. Once we have identified, for instance, that water is H2O, it does not make sense to consider worlds in which water is something else. This is distinct from considering the epistemic possibility of discovering that water actually is not H2O in this world. We then debated the plausibility of considering other possible worlds as actual--in short, whether PIs are, in fact, of primary importance to the meaning of a concept.

Then we discussed epiphenomenalism. Some members of the class thought that it is possible to accept the possibility of inverted spectra while resisting the notion that phenomenal experiences are causally inefficacious. Tim suggested that this is not the case, and that inverted spectra leads one down the slippery slope to epiphenomenalism. Then we discussed what is at stake if this is conceded.

We then talked about the possibility of identifying particular phenomenal experiences as certain brain states. If this is possible, we debated whether it would be the case that the brain state in question would be, say, the experience of red, even if it were unaccompanied by the corresponding phenomenal experience. Again, we discussed what the crucial *intension* of a concept should be, and debated whether it is just a matter of bashing intuitions if one does not accept the initial idea that the phenomenal experience of having a pain is something that needs to be explained.

Finally, Josh made a point about the possibility of himself not existing, which he has since posted to all.

Anthony and Rachael

From: Rachael J Parkinson <rachaelp@U.ARIZONA.EDU>
Subject: Re: Kripke and the primary intension of "pain"
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

I have a question regarding Kripke's characterization of heat on pg 133 and how it relates to pain. Kripke says, "Here heat is something which we have identified (and fixed the reference of its name) by its giving a certain sensation."(131) This would seem to pick out the primary intension of heat. But, Kripke points out, we have discovered a posteriori that heat is just molecular motion. Given that heat is just
molecular motion, it must be molecular motion in all counterfactual worlds. The primary intension of heat seems to be contingent given what we know about the secondary intension. So if someone were to say that light produces in them the same thing we feel when we feel heat, we would not say that light is heat but that the stream of photons produces a *sensation* of heat.

If we were to discover a posteriori that pain is certain C fibers firing in the brain, it seems like that would become the secondary intension of pain, the way heat is molecular motion is the secondary intension of heat. If this was the secondary intension of pain then it would fix pain to be "the firing of certain C fibers" in all counterfactual worlds. Thus, if someone were to say, light produces in me the same sensation that you feel when you feel pain we would not say that light is pain but that the stream of photons produces a *sensation* of pain.

If one was to argue that the *only* difference between heat and pain is that we have already discovered that heat is explainable in terms of molecular motion while we have not yet discovered that pain is explainable in terms of the firing of C fibers, it seems like the cases are relevantly similar. What do you think?

From: Anthony T Lane <atlane@U.ARIZONA.EDU>
Subject: Re: Kripke and the primary intension of "pain"
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

Some thoughts on Rachael's note:

Kripke urges that, once we have identified heat as molecular motion, we have fixed the reference of 'heat'. As such, 'heat' would still refer to molecular motion if it happened that our nerve endings were different such that we actually had the sensation of cold when exposed to increased rates of molecular motion. I am not sure that I agree with this intuition -- it seems that Kripke is assuming the primacy of secondary intensions in this case. Suppose that one miraculously were to wake up in a world that is mostly like this one. In fact, it is, in many ways, indistinguishable from this one. The sun on ones skin feels warm and snow feels cold. Suppose that some time after relocating to this world one were to discover that heat actually corresponds to reduced molecular motion. The laws of physics in this world, however, are such that things behave exactly as they do in this world. It is not clear to e that one would, in this case, say, "Oh, I guess that what I thought was heat is not actually" upon discovering that heat is not more rapid molecular motion. It seems that this is a case where it is beneficial to think of the PI and the SI and consider which is more important to the concept of 'heat'.

I suppose that, in the case of heat, one could ignore the phenomenal component and say that heat really is only increased molecular motion. As I hope my example above shows, however, this does not seem entirely intuitive. I am not sure, in any case, that the experience of pain is a close analog to this one. Suppose that the phenomenal experience of having a particular pain is found to correspond to a particular brain state. Jane, a cutting edge neuroscientist, is satisfied that this is the case. But, suppose that Jane miraculously finds herself in a world slightly different from this one. Jane thinks she's still on earth, but, upon going to the lab and stimulating her brain in such a way that she is in the
state that she had identified as 'pain', she finds that her phenomenal experience is actually quite pleasant. It does not seem that this is a world in which pain is actually pleasant. Rather, it seems that Jane would admit to having misidentified pain as being a particular brain state

I have a question regarding Kripke's characterization of heat on pg 133 and how it relates to pain. Kripke says, "Here heat is something which we have identified (and fixed the reference of its name) by its giving a certain sensation." (131) This would seem to pick out the primary intension of heat. But, Kripke points out, we have discovered a posteriori that heat is just molecular motion. Given that heat is just molecular motion, it must be molecular motion in all counterfactual worlds. The primary intension of heat seems to be contingent given what we know about the secondary intension. So if someone were to say that light produces in them the same thing we feel when we feel heat, we would not say that light is heat but that the stream of photons produces a *sensation* of heat.

If we were to discover a posteriori that pain is certain C fibers firing in the brain, it seems like that would become the secondary intension of pain, the way heat is molecular motion is the secondary intension of heat. If this was the secondary intension of pain then it would fix pain to be "the firing of certain C fibers" in all counterfactual worlds. Thus, if someone where to say, light produces in me the same sensation that you feel when you feel pain we would not say that light is heat but that the stream of photons produces a *sensation* of pain.

If one was to argue that the *only* difference between heat and pain is that we have already discovered that heat is explainable in terms of molecular motion while we have not yet discovered that pain is explainable in terms of the firing of C fibers, it seems like the cases are relevantly similar. What do you think?

In reply to Rachael and Anthony.

Rachael writes:

If we were to discover a posteriori that pain is certain C fibers firing in the brain, it seems like that would become the secondary intension of pain, the way heat is molecular motion is the secondary intension of heat. If this was the secondary intension of pain then it would fix pain to be "the firing of certain C fibers" in all counterfactual worlds. Thus, if someone were to say, light produces in me the same sensation that you feel when you feel pain we would not say that light is pain but that the stream of photons produces a *sensation* of pain.

If one was to argue that the *only* difference between heat and pain is that we have already discovered that heat is explainable in terms of
molecular motion while we have not yet discovered that pain is explainable in terms of the firing of C fibers, it seems like the cases are relevantly similar. What do you think?

That's an interesting point. I think you're right that *if* we could wholly explain pain in terms of C-fibres, then we might well identify pain (in secondary intension) with C-fibres. The relevant questions are (1) How likely is this explanation, (2) What would follow from the identification?

Re (1), I think Kripke is more or less assuming the epistemic gap between physical states and phenomenal states, and is seeing what follows from that. He thinks it's conceivable (or "seems possible") that one could have an arbitrary physical state without a pain, for example. If so, then there already may be a principled explanatory gap between physical and phenomenal. To close that gap, presumably one would have to argue that there isn't really an epistemic gap after all -- either by arguing that there is an a priori entailment from physical to phenomenal after all, or by arguing that such an a priori entailment isn't required for reductive explanation.

With heat, on the other hand, it's not clear that there is the same sort of epistemic gap. If we conceive of heat as "the cause of heat sensations", and demonstrate that molecular property M is the cause of heat sensations, then we've arguably explained heat in terms of M. Well, maybe not quite, as heat sensations themselves haven't been explained, but we set that aside as a problem for later. Leaving that aside, we can say that M explains heat modulo consciousness (i.e. modulo problems with explaining heat sensations). Similarly, one has an a priori entailment from the physical story to the heat story modulo heat sensations -- no epistemic gap, except for the sensation gap. When it comes to heat, we don't let the sensation gap bother us, as we're concerned with the external phenomenon. But with pain itself (or pain qualia), it's the very sensation we're concerned with, so we can't set it aside in this way. So there is still the apparent epistemic gap.

Of course one could try to argue that there is no epistemic gap, presumably by rebutting the epistemic arguments we considered a few weeks ago. I take it that Kripke thinks that will be an uphill battle, though. In effect, he is here more concerned with the opponent who accepts that there is an epistemic gap but denies that there is an ontological gap. (Arguably the early identity theorists were like this, and many or most contemporary materialists are like this. That's the position I'm calling type-B materialism.) For that opponent, presumably things won't be so easy.

Incidentally we can put the points about epistemic gap and explanation themselves in terms of the 2-D framework. When it comes to explanation phenomenon P, it's arguably the primary intension of "P" that's central to characterizing what needs to be explained. To explain heat, for example, we essentially have to explain what causes heat sensations. To explain water, we explain watery stuff. And so on. The SI doesn't emerge until post-explanation. So something similar applies to consciousness. An explanation will need to entail the PI facts about consciousness; or, we'll need an epistemically transparent (a priori) entailment from physical to phenomenal. We seem to get that sort of entailment more or less when a concept's PI is functional or structural (e.g. the heat case is mostly functional, and the water case is functional/structural). But if the argument re conceptual analysis is right, it's not clear that there is a
functional/structural analysis of the PI of phenomenal concepts. If
so, the epistemic gap looms, and explanation has a hard time getting
off the ground.

(2) Some think that explanation isn't required for identity, and that
maybe we could postulate an identification of pain with C-fibres (and
of phenomenal with physical states more generally) without a prior
explanation. Maybe correlation would give could grounds for the
identity, for example. And some philosophers (e.g. Block, Papineau)
have argued that identities don't need explanation. If we did this,
we could identify pain in SI with C-fibres, and so on. But even here,
I think there would be problems to overcome.

Essentially, even if we can pin down the SI of "pain" (etc.) in
physical terms, there are still problems with the PI. One can argue
that the very conceivability of zombies and the like (i.e. their
broad epistemic possibility, in the considered-as-actual or PI sense)
suggests that there is a world in the vicinity (by the 2-D analysis).
If the materialist is right about the SI of phenomenal concepts, then
this world shouldn't be described as one without pain (when considered
as counterfactual), since the SI of "pain" will be physically
specifiable and so will apply to this world. But it will still be a
world in which the PI of "pain" isn't present. So there is
*something* the world will lack -- essentially the property
corresponding to the PI of "pain". We might think of this as the
"mode of presentation" of pain. Even if we identify the *referent* of
"pain" with a physical state, there is still the "sense" (or the
reference-fixing property or the PI) to worry about -- the way that
physical state is presented to us, if you like. And if the epistemic
intuitions and the 2-D framework are correct, that will correspond to
a nonphysical property in its own right.

The moral of all this is familiar, I think. To save materialism, one
has to either deny the epistemic intuitions, or deny the 2-D analysis
of a posteriori necessity. Either strategy remains open to some
degree, but a materialist has to do a lot of hard work in biting the
bullet on either of them.

Anthony writes:

> Kripke urges that, once we have identified heat as molecular motion, we
> have fixed the reference of 'heat'. As such, 'heat' would still refer to
> molecular motion if it happened that our nerve endings were different such
> that we actually had the sensation of cold when exposed to increased rates
> of molecular motion. I am not sure that I agree with this intuition-- it
> seems that Kripke is assuming the primacy of secondary intensions in this

> mostly like this one. In fact, it is, in many ways, indistinguishable from
> this one. The sun on ones skin feels warm and snow feels cold. Suppose
> that some time after relocating to this world one were to discover that
> heat actually corresponds to reduced molecular motion. The laws of physics
> in this world, however, are such that things behave exactly as they do in
> this world. It is not clear to e that one would, in this case, say, "Oh, I
> guess that what I thought was heat is not actually" upon discovering that
> heat is not more rapid molecular motion. It seems that this is a case
> where it is beneficial to think of the PI and the SI and consider which is
> more important to the concept of 'heat'.

Hmm, tricky. This case is complicated by your hypothesis that one
actually wakes up in this world. In effect, you are considering the
world as actual (wondering what we would say if we found ourselves in
it) rather than considering it as counterfactual. I think you're arguably right that if we found ourselves in this world, in which a different property R was causing heat sensations, we'd be tempted to say that R is heat. But that is arguably compatible with Kripke's framework, on which the PI of "heat" is "the cause of heat sensations" or some such.

(There are tricky issues here, regarding what one would say on first arrival in such a world vs. later on, etc. After a couple of years there, it seems pretty obvious one could correctly call R "heat". Does that apply even on first arrival? Just say one's nerve endings are tampered with so that temperatures below zero make one feel hot. Will one then correctly say that those temperatures are hot temperatures, or will you instead correctly say that cold temperatures are now making you feel hot. I can see both temptations, but I think there's a good case for the latter. That fits the idea that there's at least a time lag, and that the PI of "heat" is more like "what has typically causes heat sensations in me (and my community)", or some such.

But anyway, Kripke's central claim concerns the SI of "heat" rather than the PI. To get at that, we have to consider the world as counterfactual, rather than imagining waking up in it. From our perspective here, is that world (a world where -40 degree temperatures cause hot sensations) a world where -40 degrees constitutes heat. or a world where cold temperatures make people feel hot. Again tricky, but I can see Kripke's case for the latter. At least, the intuition for calling the low temperatures "hot" isn't as strong as when one thinks of waking up in the world (i.e., as when one considers the world as actual). I can still see a case for going both ways, though, which suggests that the SI of "heat" is arguably somewhat ambiguous.

>I am not sure, in any case, that the experience of pain is a close analog to this one. Suppose that the phenomenal experience of having a particular pain is found to correspond to a particular brain state. Jane, a cutting edge neuroscientist, is satisfied that this is the case. But, suppose that Jane miraculously finds herself in a world slightly different from this one. Jane thinks she's still on earth, but, upon going to the lab and stimulating her brain in such a way that she is in the state that she had identified as 'pain', she finds that her phenomenal experience is actually quite pleasant. It does not seem that this is a world in which pain is actually pleasant. Rather, it seems that Jane would admit to having misidentified pain as being a particular brain state.

Interesting. Your intuition about the case seems pretty plausible. It seems unlikely that Jane would correctly call this a situation in which pain is pleasant. Rather, it would be a situation is which she isn't feeling pain. Of course this again is a point about PIs as described, not SIs. The moral of at least this scenario is that (if the situation is possible and if your intuition about describing it is correct) even if the SI of "pain" can be identified with a given brain state, the PI can't be. (In this world considered as actual, the brain state is present but pain isn't.) So there is still the issue about identifying the PI of "pain", as above.

One could also try to make a similar point about the SI of "pain". Let's take your Jane scenario and considered it as counterfactual instead of as actual. Should we (from our vantage point here) describe this as a situation in which Jane is having a pain (it just feels different), or one in which she is not having a pain at all. There is at least some pretty strong intuition that it should be the
latter, I think. If so (and if the situation is indeed possible), then the identification of the SI of "pain" with the brain state will be problematic, too.

In effect the relation between these two cases (considering a pain situation as actual and as counterfactual) parallels Kripke's observation re the semantics of pain. In effect, the fact that we have similar intuitions about saying whether a given scenario involves "pain", irrespective of whether it is considered as actual or as counterfactual, suggests that the PI and SI of "pain" (unlike "water", "heat", etc) are more or less the same as each other. I don't think that point is vital to making the anti-materialist case (the argument would still work even if PI and SI are different, as e.g. above and in the M&M notes), but it's an interesting point re the way the concept works.

Of course the materialist can try to reply by finding some brain state such that one couldn't imagine Jane having that brain state without pain. Maybe C-fibres are a particularly weak sort of state to pick, as we can just imagining wiring the brain so that C-fibres make her go "wow, this feels good", etc. So a better case for the materialist might be one where we have a full functionally-specified state, such that she'll always behave as if she's in pain, etc. Here the anti-materialist will still argue that it's conceivable that she have this without being in pain (cf. zombie cases), but at least it will be trickier for them. Again, the materialist either has to deny the epistemic intuitions (here by going for a functional analysis of the concept of "pain") or reject the 2-D framework (by arguing that the conceptually coherent scenario we are considering as actual doesn't correspond to a possible world at all).

I want to elaborate on the line I was developing on epiphenomenalism (E), and pretty much retract it. My reply to someone this week is to myself - hope that counts. AT least no one else can accuse me of misrepresenting them.

On tuesday Anthony asked why anyone would be tempted towards E. Isn't it obvious that the reason I drive out to watch the sunset is that I like the glorious red qualia that it gives me? Don't I like chocolate, and eat it, because of that chocolatey taste? Qualia seem to be causally efficacious.

Here's how I tried to pump the E intuition. Suppose that we accept the possibility of qualia inversion. Although you and I both like watching orange sunsets, the qualia that they produce in me are unlike the qualia they produce in you. Suppose that what it's like for me to see red is the same as what it's like for you to see green; and what it's like for you to taste ice-cream is what it's like for me to eat chocolate, and vice-versa. Inverted spectra intuitions are, I take it, rather easy to elicit, at least from those who are new to these issues. (Aged and battle-weary philosophers of mind seem not to share them.) I'm eating chocolate because I like its taste (note the reification of tastes). If it doesn't
have the same taste to you, but you still like it eating, the you are eating it for a different reason.

But how does inverted spectra provide an argument for E? My idea was that the very redness of red makes no difference to what it does, all that matters is that this experience be able to interact with my motor center in the right kind of way, and be the same kind of experience that I have when I see strawberries, fire-engines, and so on. The qualia that I have when I see red things can't be causally efficacious, since you experience different qualia, but act in the same type of way.

But this now seems to me to be a bad argument, or at least it's too quick. Two things can have the same causal effects even though they are different things. Thus, in certain conditions a white billiard ball will cause a window to break, and a red billiard ball will cause the window to break under the same conditions. But a red billiard ball has different properties from a white billiard ball. To rehabilitate the argument we need to talk about whether or not certain *properties* are causally efficacious. Rather than reify qualia, we need to talk about things that have the property of giving one a red appearance.

But even here the argument isn't obvious. It may be true that property x and property y have the same causal power in functional system F, but that means that x and y do have causal power within F - not that they have *no* causal power. (I guess the real intuition pump for epiphenomenalism is the zombie argument - but why would you think zombies possible attractive unless you were already an epiphenomenalist? )

Let's back up. The E claim is that the property of having qualia of a certain type are is not causally efficacious. I now think the motivation for it comes from the idea that the causal efficacy of a state/object only depends on its basic physical property, its 'syntax': weight, shape, magnetic force, whatever. (I think that both Scott and Thony said this, or things like it.) From this perspective, *most* properties are epiphenomenal. We say that the age of a vase causes it to be brittle, or valuable, but really these comments are just short-hand way of referring to the causal efficacy of the physical properties of states. The age of a vase causes it to be valuable = people believe that it is old, they believe that old things are valuable, both of these beliefs are physical states in the brain, and in virtue of their physical/syntactic properties, these states cause certain actions such as offering to pay a lot of money for the said vase.

Thus, we might say that age, or value, or qualia of certain kinds are causally efficacious properties in a *derivative* sense. Only syntactical properties are causally efficacious in a primitive or basic sense. It seems that arguments for epiphenomenalism involve fairly large-scale metaphysical commitments re the nature of causation, and the structure of the mind. In short, the only motivation that I can see for E comes from the idea that all causation is bottom up. Talk of people, corporations, and countries, doing things is really just short-hand for the casual activity of basic material states. The debate over free will starts to creep in the backdoor here, so perhaps I'll shut up at this point.

Timothy J. Bayne
RM. 213 Social Science
There's one thing I need clarification on. One of the objections to naturalistic dualism was: There are properties essential to the physical constitution of the world that are not accessible to physical investigation...the zombie world seems physically identical while being physically different.

It seems that your simple response is that these extra properties are phenomenal. But I thought the objection was that there are might be extra PHYSICAL properties (that are presently not available to us).

Likewise, regarding your example of electrons that have hidden (protophenomenal) properties-- that we'd still call an electron that lacked these properties an electron. But again, wasn't the objection that there are extra physical properties (that missing, would presumably make it not an electron)?

The electron seems an appropriate example for I take this objection to be saying. Namely, that there are more (physical but wierd) properties that have yet to be understood with respect to the electron. Some of the physical properties that are presently being asserted are things like, "if we know this we can't possibly know that (and vice versa)" This isn't a phenomenal property but if it's a physical one it certainly isn't explanatory. This is the kind of stuff I would expect the objector to be referring to when talking about hidden physical properties-- the ones we don't "get", but not phenomenal ones.

So the question is, could these weird physical properties be the protophenomenal ones you propose?

-Erik H.

Tim and Erik H. raise interesting issues re epiphenomenalism and re the possibility of new intrinsic physical properties. These bear on the question of what the conclusion of the anti-materialist argument should be. I present it in the book as property dualism, and leave open just what sort. I now think that the conclusion of the argument should be a disjunction of three positions: epiphenomenalism,
interactionism, or "panprotopsychism". This issue isn't really core to the modal issues we're focusing on, but I'll say a bit about it anyway.

Epiphenomenalism is the idea that the phenomenal properties naturally supervene on physical properties and have no effect on them. (One-way psychophysical laws.) Interactionism is the idea that there are two-way psychophysical laws: the physical properties affect the phenomenal properties and vice versa. Panprotopsychism is the "Russellian" position mentioned a number of times in the book, on which the phenomenal is constituted by the unknown intrinsic properties of the physical.

I think the anti-materialist argument is actually neutral on these three, so the decision between them needs to be made on further grounds. I don't think there are yet grounds for a decisive preference in any direction. It seems to me, at least, that all have advantages and disadvantages. Personally, I rank panprotopsychism first (most elegant but also the least clear), epiphenomenalism second (arguably the most conservative, but inelegant), and interactionism third (would require adjusting our view of physics, but not out of the question). But I have days when each appeal.

Tim raises questions about epiphenomenalism, and Erik (in effect) about panprotopsychism. I'll say a bit in reply to Tim in the rest of this message and to Erik in the next.

Re epiphenomenalism first. Tim says quite rightly that the mere possibility that one can keep Q constant while varying P doesn't show that P is epiphenomenal with respect to Q. It might be that P1 and P2 can both cause Q in different circumstances. So if there is an argument for epiphenomenalism, that's not it.

I take it that the argument for epiphenomenalism is more indirect. It proceeds via an argument for property dualism, plus considerations about the causal closure of the physical. If qualia are nonphysical, and if there is a physical sufficient cause of any physical effect, then it seems that qualia are redundant. I take it that few people have the view that qualia are redundant as a premise, but one can see how one could be led to it as a conclusion. E.g., if one has accepted an anti-materialist argument and wants to hold on to the causal closure of the physical.

Just say one has causal closure and property dualism. Then presumably for behavior B, there will be a complete physical explanation P. In our world, there are qualia Q around too. But in other worlds, one has behavior B caused by P with different qualia Q' around, or with no qualia around at all. Even so, it seems that P is sufficient for a complete causal explanation of B -- it's not as if behavior is produced by a different mechanism in each case (as was the case in the causal explanations mentioned earlier). If so, then it seems that Q is causally redundant in the actual world. Barring an odd kind of overdetermination, Q seems to come out epiphenomenal.

Ways out of this: (1) Reject causal closure (go for interactionism). (2) Reject the modal intuitions (deny the possibility of inversions or zombies). (3) Accept overdetermination (both the physical processes and the qualia cause the behavior, redundantly). (4) Go for the Russellian/panproto view on which qualia are still causally relevant by virtue of their status as the categorical basis of physical dispositions.
The fourth would be my own preferred strategy here, as discussed around pp. 153-55 of the book. I think (3) is conceptually problematic, and obviously I don't accept (2). But all are at least respectable alternatives to consider.

I do think epiphenomenalism is a respectable alternative too. We have very strong intuitions of causal relevance for qualia, but those can be explained on Humean grounds: what we really know is that there is a constant regularity between qualia and behavior, from which it is natural to infer causation. But all our evidence is compatible with epiphenomenalism. So if there is reason to reject epiphenomenalism, it has to be based on further grounds, I think.

A couple of comments re Tim:

> causal power. (I guess the real intuition pump for epiphenomenalism is the zombie argument - but why would you think zombies possible attractive unless you were already an epiphenomenalist?)

I've heard this said before, but personally I think it gets the order wrong. Hardly anyone is "already an epiphenomenalist" in this context, but plenty of people find zombies conceivable. Maybe there is an argument from that *to* epiphenomenalism, although that is contestable. But in any case plenty of nonepiphenomenalists seem to accept the conceivability of zombies -- e.g. all the type-B materialists (Tye, Loar, Levine, Hill, Yablo, etc), and quite a few interactionists and others. More generally, I think one can assess the epistemological arguments against materialism prior to one's commitment on the metaphysical issue re epiphenomenalism.

> Let's back up. The E claim is that the property of having qualia of a certain type are is not causally efficacious. I now think the motivation for it comes from the idea that the causal efficacy of a state/object only depends on its basic physical property, its "syntax": weight, shape, magnetic force, whatever. (I think that both Scott and Thony said this, or things like it.) From this perspective, *most* properties are epiphenomenal. We say that the age of a vase causes it to be brittle, or valuable, but really these comments are just short-hand way of referring to the causal efficacy of the physical properties of states. The age of a vase causes it to be valuable = people believe that it is old, they believe that old things are valuable, both of these beliefs are physical states in the brain, and in virtue of their physical/syntactic properties, these states cause certain actions such as offering to pay a lot of money for the said vase.

I'm not sure that this is getting at the real crux of the pro-epiphenomenalist argument in the qualia case. The argument you're giving will apply for *any* high-level property, including those which are clearly logically supervenient. I think such arguments will generally be suspect, as there's no reason to think that both micro properties and logically supervenient macro properties can't simultaneously be causally relevant (as e.g. with molecules and billiard balls being simultaneously causally relevant). Of course there is more to say there.

But in any case the special force of pro-epi considerations in the qualia case derives from the apparent failure of logical supervenience. That doesn't hold in those other cases, which have no apparent epistemic gap on close examination. But there is at least an apparent gap in the qualia case, which can be extended into an argument against logical supervenience and against materialism, etc, until (under certain assumptions) one gets to epiphenomenalism. Of
course there are contestable steps there. But take away the epistemic
arguments, and I think the distinctiveness of the considerations re
epiphenomenalism here are removed; and conversely, it's the apparent
epistemic gap re qualia that gives pro-epi considerations here their
distinctive force.

> In short, the only motivation that I can see for E comes from

> and countries, doing things is really just short-hand for the casual
> activity of basic material states. The debate over free will starts to
> creep in the backdoor here, so perhaps I'll shut up at this point.

Well, maybe that is the only motivation for a *general* epiphenomenalist thesis, re arbitrary high-level properties. I think that motivation would be suspect, though it's an interesting issue in its own right. But in any case I think the motivation for epiphenomenalism re qualia rests on distinct considerations.

There are a few issues here. First we need to get clear on the nature of the new "hidden" properties. Perhaps this talk of "new" physical properties might suggest that they are just properties that will be invoked by a completed physics that we haven't yet discovered but eventually will, by scientific investigation and the like. Or perhaps that will never be discovered, but still have the same sort of general shape as existing properties. That would in effect by the "appeal to new physics" strategy considered in Chapter 3 of the book, which I argue there doesn't work. The trouble is that the new properties will still be introduced in a structural/dispositional way, and there will be no a priori entailment from these structural/dispositional properties to phenomenal properties, at least if the general epistemic considerations re qualia are valid. Those considerations seem to apply to any structural/dispositional properties, even as yet undiscovered one.

The move I'm suggesting here is a more radical one. Maybe in imagining a "physically identical" world, we are imagining a world that is the same in all structural/dispositional respects, but not the same in all *intrinsic* respects. That's to say, the "accessible"
properties that one holds constant are the structural/dispositional ones, but maybe there are further "hidden" intrinsic properties that are crucial to the physical world. And maybe those intrinsic properties entail the existence and nature of qualia.

So we now at least have some sort of property dualism, i.e. a dualism of "accessible" dispositional properties (I'll leave out "structural" from now on) and of "hidden" intrinsic properties. One might argue that this is out of the frying pan straight back into the fire, as the new protophenomenal properties seem to be epiphenomenal to the dispositions we know and care about. After all, the structural/dispositional properties seem to make up a seamless causally closed network. If the hidden intrinsic properties are indeed epiphenomenal with respect to the others, then it seems we at most have a terminological variant of the original property dualism (we're calling the new fundamental properties "hidden physical properties", but it doesn't really change the shape of the view). But I think there is one way of looking at this view so it at least has an interestingly different shape.

The interestingly different view is the one that locates the "hidden" intrinsic properties as the categorical bases of the dispositional properties. It's often held that dispositions need categorical basis -- where one has a disposition to cause Y, one needs some underlying intrinsic property X that actually does the causing of Y. E.g., a glass's fragility is a disposition, and its categorical basis is the molecular structure of the glass or some such.

Arguably, that applies all the way down to microphysics. Russell argued that physics tells us all about the *structure* of causal relations in the physical world, but it doesn't tell us what ultimately does the causing. Mass, for example, is treated by physics as a sort of disposition (the disposition to resist acceleration, be attracted by gravity, etc), but physics doesn't say anything about the basis of those dispositions -- what mass is "in itself". And more generally, one might argue that matter needs to have some intrinsic properties, not just dispositions, but physics is silent about that intrinsic nature.

So the interesting hypothesis is that we *need* certain "hidden" properties of the physical world to serve as the intrinsic basis of physical dispositions. These intrinsic properties will be what underlies the mass disposition that physics talks about, the charge dispositions, etc. Physical observation doesn't tell us anything about these properties, as we know about them only by their effects, and as far as the effects are concerned, arguably, any intrinsic basis will do. The hypothesis that physics needs hidden intrinsic properties is controversial, but many philosophers have found it attractive.

And note: *this* sort of hidden physical property is not epiphenomenal with respect to physical dispositions. The hidden properties here serve as the basis of physical dispositions, and arguably it is these that ultimately do all the causing. In fact the world might be seen as ultimately consisting in a bunch of causal and other nomic relations between a whole lot of intrinsic properties, which reveal themselves to us only structurally. So the hidden properties are at the very basis of the causal network.

So, now we have an interesting possibility re qualia. Maybe it's the case that the structural/dispositional physical properties don't entail qualia, but perhaps the hidden intrinsic properties do?
all, we have no idea what those properties are like. Maybe they are themselves phenomenal properties, or some other more fundamental properties that entail phenomenal properties -- what I call protophenomenal properties. If so, then when imagining a zombie world, we're imagining a world with the same dispositional properties but different (or no) hidden intrinsic properties. So the conceivability of zombies is compatible with entailment by dispositional plus intrinsic physical properties. The cost of course is the presence of fundamental phenomenal or protophenomenal properties at the very fundamental level of the physical world. This is the position that I call "panprotopsychism". (In the book, "Russellian monism" or some such.)

In a way you can see this view as motivated by the presence of two metaphysical problems simultaneously: (1) What are the unknown hidden intrinsic properties of the physical world?; (2) How can we locate intrinsic phenomenal properties vis-a-vis the physical world? On having things put this way, it's natural to try to solve both at once: if the hidden intrinsic properties are themselves qualia (or protoqualia), then we both have a hypothesis about their nature and an integrated location for qualia in the physical world, as the categorical basis of physical dispositions.

Of course the view is highly speculative and has a number of problems it needs to face up to. But it has clear attractions also, not least the promise of an integrated, relatively monistic world view.

Anyway, with all this in hand, I'll get back to Erik's questions. Erik asked first, why can't the new properties just be ordinary physical properties, rather than phenomenal or protophenomenal properties? I think the answer is: first, the properties need to be intrinsic rather than dispositional, to avoid the usual problems with entailment. Second, the properties need to serve as the categorical basis of physical dispositions, to avoid epiphenomenalism. And third and most important, in order to deal with the qualia problem, the new properties have to either themselves be phenomenal properties, or they have to collectively constitute phenomenal properties -- i.e. they have to be phenomenal or protophenomenal. (Where protophenomenal is just a label for novel fundamental properties that are not themselves phenomenal but collectively constitute phenomenal properties.)

If the properties don't have this intimate relation to phenomenal properties, we'll still have the usual problems with zombies and the like. I.e. we'll still have the coherence of zombie worlds with the same accessible and hidden properties but no qualia; one could know all about the accessible and hidden properties without knowing about qualia; etc. But if they are phenomenal or protophenomenal, then it won't be coherently conceivable to have them instantiated without qualia, and in principle someone who knew all about the properties in question will be able to know about qualia. So these will need to be special sorts of properties.

> Likewise, regarding your example of electrons that have hidden >(protophenomenal) properties-- that we'd still call an electron that >lacked these properties an electron. But again, wasn't the objection that >there are extra physical properties (that missing, would presumably make >it not an electron)?

This gets at a question I've been avoiding until now. In what sense (if any) do these hidden properties count as *physical* properties, and so on what sense (if any) is the panprotopsychist view a variety
of physicalism? In the book, I mostly treat the view as if it is not a version of physicalism, but even there I say the issue is mostly terminological, and what matters is the shape of the view.

I think the issue comes down to: in what sense (if any) is a world with the same dispositional but different "hidden" properties "physically identical" to ours? In particular, does such a world truly count as containing mass, charge, electrons, etc? The neutral answer is: in the vicinity of mass, charge, electrons, etc, there are dispositional properties and intrinsic properties. The world in question has the dispositional properties but not the intrinsic properties.

But one might still press, and say -- but does it *really* contain mass, electrons, etc? This seems to be a largely terminological issue. We're considering a certain world -- the world with the same dispositional shape, different intrinsic properties -- as counterfactual, and evaluating the referent of "mass", "electron", etc, there. This comes down to an intuitions about the secondary intension of "mass", "electron", etc. I think it is highly plausible that the *primary* intension of these terms goes with certain dispositional properties (we fix reference to mass as "what plays the mass role", etc). But do the *secondary* intension go with the disposition or with the underlying basis?

In the book, I say that my intuition is that the world in question contains electrons, mass, etc. After all, the entities in question look like electrons, quack like electrons, interact like electrons, etc, and there's an intuition that that's enough to make them electrons. If so, the SI of "electron" (etc) goes with the disposition. But I can also see the opposing intuition. This would be the semi-Kripkean intuition that to be an electron (or mass), you have to have the "underlying nature" of electronhood (or mass), and here, that underlying nature is given by the intrinsic property. If so, something with a different intrinsic nature won't count as an electron, and the SI of "electron" goes with the intrinsic property, not the disposition.

If one takes the former view, then arguably the intrinsic properties are not physical properties, as they aren't the referent of paradigm physical terms like "mass", etc. And the zombie world in question will be correctly described as having mass (etc), so it will be a physical duplicate of our world. On this view, one might argue that the panprotopsychist view is not a variety of physicalism, as the physical properties are structural/dispositional, not intrinsic.

If one takes the latter view, then arguably the intrinsic properties are paradigm physical properties, as they are the referent of paradigm physical terms like "mass", etc. And the zombie world in question won't be correctly described as having mass (etc), so it won't be a physical duplicate of our world. On this view, one might argue that the panprotopsychist view is a variety of physicalism, where our fundamental physical properties turn out to be protophenomenal.

Ultimately (as I think I say in the book) I think the issue here is largely terminological, and nothing much turns on the semantic intuitions. We can say that the panprotopsychist view is in a sense physicalist, and in a sense property dualist. It certainly has a dualism of dispositional and intrinsic properties; the only question is whether to call them "physical". I can see the case for going both ways, but in any case the shape of the view is what matters. And I think the shape of the view is pretty clear.
If one takes the version of the view on which the intrinsic properties are physical properties, then arguably we have "saved" physicalism in some sense from the anti-materialist arguments. But I think it's clear that the view that results is still quite radical, with new fundamental protophenomenal properties responsible for the emergence of qualia, and in some ways more in the spirit of property dualism than physicalism. At the end of the day it's the view rather than the label that matters.

>So the question is, could these weird physical properties be the protophenomenal ones you propose?

Yes, that's exactly it. I intended to gesture toward that idea in the passage you're talking about, but maybe the discussion wasn't too clear. (The view first comes up in considering the physicalist "objection" on pp. 136-38. On p. 138, I mention the ensuing possibility that physical entities have an intrinsic protophenomenal nature as a view that I'll return to. This was in effect a pointer to the discussion on pp. 153-56, which is the main discussion of the panprotopsychist view in the book, though it's also discussed in the context of an informational view on pp. 301-8.)

But anyway, the view that fundamental protophenomenal properties serve as the "hidden" intrinsic categorical basis of fundamental physical dispositions is a very important view, no matter how one classifies it. It's a little on the wild and crazy side, but personally I find it the most elegant resolution of the mind-body problem if it can be worked out. It's compatible with all the epistemic intuitions re qualia, and at the same time is compatible a causal role for qualia *and* with the causal closure of the physical (qualia don't so much "change" the physical causal network as lie at its very basis). And the view has more of a monist flavor than the epiphenomenalist and interactionist alternatives, without the "dangling" entities that these views have. So there's a lot to be said for it.

On the negative side, one has to solve the problem of just how all these fundamental protophenomenal properties in physical systems come to constitute the (unified, bounded, homogeneous, structured, coherent) phenomenal experience we know and love. (See pp. 305-8 for a little discussion of this.) That's a highly nontrivial problem, and it's not obvious that it's solvable. But it's not obvious that its unsolvable, either. So it's a very interesting topic for further research.

--Dave.
things certain names under certain conditions;, i.e. if we found out that x was different in structure, would we still call it x. Kripke, or at least Kripkeans, take the results of these intuition pumps to tell us something interesting about *the world*, or about *properties*. They tell us that certain properties (x, y) are metaphysically linked: although there are possible world in which x and y come apart, they are identical (?) in all the metaphysically accessible worlds. Chalmers, I take it, responds thus: "the intuition pumps are persuasive, but they don't show what you (Kripkeans) take them to show. They tell us something about *language*, about our *concepts* <x> and <y>, and nothing about the world or about the structure of properties (x, y). Kripke's analysis doesn't show that the structure of possibility is other than what we have thought, all it shows is that we were misdescribing it (TCM 134)."

Two questions: (1) Is this the right way to characterize the dispute? (2) Isn't the connection between concepts and properties more intimate than Chalmers' line allows? If a concept applies in one scenario and not in another, doesn't that imply that the two scenarios do not share all of the same properties? Don't we generally decide whether or not we are dealing with the same property in different cases by deciding whether or not the same concept applies?

If we accept the move from conceivability to logical possibility, then (I think) we are accepting that there is definitely some connection between concepts and properties: a coherent use of concepts implies that the state of affairs (the articulation of properties) picked out by the concepts is logically possible. No doubt there is much to say on how properties and concepts are related, but I'll leave this here.

>I asked Josh and Thony the following question last week but our discussion
>got cut off so I thought I'd open it up. My query is this: in big picture
>terms, what exactly is the disagreement between Kripke and Chalmers.
>Here's how I think it goes - but I'm not clear that I've got it right.

Interesting question. It's not entirely clear to me that there is a clear disagreement. Kripke doesn't use the 2-D framework, but it's not clear that he says anything that is strictly incompatible with it. And we have seen that Kripke seems to endorse a certain link between
conceivability and possibility, suggesting that when one apparently conceives of a world, there is at least a possible world in the vicinity, though it may be misdescribed. That view can be translated into the 2-D framework too.

I suppose one central disagreement is that I am more sympathetic with descriptive views of reference than he is, and this shows up in my explicit use of the notion of a primary intension, something he stays away from. But one might argue that the notion of a primary intension is at least implicit is some of Kripke's discussion, as when he evaluates what the referent of our terms would be if we discovered certain epistemic possibilities to be actual.

I suppose that one difference is that Kripke sees epistemic matters such as apriority as *purely* epistemic in some sense and not modal, whereas I think it is often useful to understand them in modal terms. On my view, one can see epistemic possibilities as possible worlds in their own right, where our terms have a distinctive pattern of application to those worlds; and there is a corresponding notion of necessity, 1-necessity or primary necessity, which is in many ways just as important as the notion of subjunctive necessity (2-necessity) that Kripke concentrates on, and which has deeper ties to epistemic notions.

Probably in the end these are the most important difference -- a difference of emphasis on PI vs. SI considerations, a willingness to see some sort of quasi-descriptive component in meaning, and a willingness to understand epistemic notions in modal terms. But these don't immediately manifest themselves in first-order issues or doctrines. It is more a different in emphasis, and in the lens through which one looks at the central issues.

Personally, I like to think of the 2-D framework as a good way of analyzing and making sense of what Kripke is up to in N&N, rather than as any sort of radical revision of the views there. Of course Kripke might see things differently.

> Kripke elicits a bunch of intuitions about whether we'd call certain things certain names under certain conditions;, i.e. if we found out that > x was different in structure, would we still call it x. Kripke, or at least Kripkeans, take the results of these intuition pumps to tell us > something interesting about *the world*, or about *properties*. Kripke's analysis doesn't > show that the structure of possibility is other than what we have thought, > all it shows is that we were misdescribing it (TCM 134)."

Well, I don't disagree with the claims you attribute to Kripke here. It's quite compatible with the 2-D framework to say that Hesperus is identical to Phosphorus in all possible worlds, and that the property of being hot is the property of having fast molecules in all possible worlds. So I can agree that the objects and properties in question are metaphysically linked here; or better, that there is just one object or property in each case, with two different terms picking it out.

Of course I think there is more to the story than this. In making the
above claims I am dealing with 2-possibility and secondary intensions. One can also invoke 1-possibility and primary intensions, and explain the a posteriority of "Hesperus is Phosphorus" in terms of the fact that its PI is false in some centered worlds, and so on. But to say this is not to back any of the above.

It's true that I am also inclined to think that some of these issue are vague and depend on the terminology. For example, it's not obvious to me that the SI of "heat" really picks out the motion of molecules rather than the cause of heat sensations in all possible worlds. But again, this isn't to retract the claim about properties. It's just to say that the reference "heat" is somewhat ambiguous between two properties, the molecule property and the heat-sensation property (N.B. this isn't an issue about PI vs. SI; rather, it's an ambiguity merely in the SI). But like any ambiguity, this can easily be cleaned up or stipulated away, and after doing this, we'll have a perfectly good term, "heat" or "heat*" which works just the way kripke says it does, referring to the molecule property, and picking out that very property in all worlds. We can then say that heat (or heat*) is identical to molecular motion in all worlds. So I don't think the point about vagueness and ambiguity is central here.

Deep down you are probably right that I am more deflationary about the metaphysics of properties and possibility here than Kripke is, but it's not obvious how to articulate that. Sure, the property of heat and the property of molecular notion are the same property. But the fact that "heat is molecular motion" is an a posteriori necessity here is largely due to our conceptual structure, with two distinct concepts that pick out the same property in different ways. Similarly, it's true that it's necessary that water is H2O, and that fact is entirely independent of us. But the fact that "water is H2O" is an a posteriori necessity simply arises from the coreference of the terms and the 2-D structure of the concepts. Even here, it's not entirely clear what Kripke would disagree with, so I'm not sure that I've really isolated a substantive disagreement.

As for the conceivability/possibility thesis you mention, Kripke shows every sign of agreeing with it, so it's not clear that this is a disagreement.

> Two questions: (1) Is this the right way to characterize the dispute? (2) Isn't the connection between concepts and properties more intimate than Chalmers' line allows? If a concept applies in one scenario and not in another, doesn't that imply that the two scenarios do not share all of the same properties? Don't we generally decide whether or not we are dealing with the same property in different cases by deciding whether or not the same concept applies?

Well, of course I think there are two ways in which concepts can apply to scenarios: the PI way and the SI way (considering the scenarios as actual and counterfactual). We can take these cases one at a time.

Taken in the SI way (considering scenarios as counterfactual): if a concept applies in one scenario but not in another, then the SI of the concept applies to one world and not to the other, so the worlds certainly have different properties (as SIs are properties in their own right). For example, the fact that the concept "water" applies to H2O in the H2O-world (considered as counterfactual) but not to XYZ in the XYZ-world (considered as counterfactual) goes along with the fact that they have different properties: H2O has the property of being water and XYZ does not! It will also be the case that we can
determine whether we have same property X in two scenarios by seeing whether the concept "X" applies to those scenarios (considered as counterfactual). So there's nothing here with which I disagree.

Taken the PI way (considering scenarios as actual): if a concept concept applies in one scenario but not in another, then the PI of the concept applies to one world and not to the other, so the worlds certainly have different properties (as PIs are properties in their own right). For example, the fact that the concept "water" applies to H2O in the H2O-world (considered as actual) but not to H2O in a world where H2O is a coal-like solid (considered as actual) goes along with the fact that they have different properties: H2O in the first world has the property of being watery stuff but in the second world does not! So your first claim will hold good even for PIs.

The second claim is a bit trickier. Can we decide whether or not' we are dealing with the same property by seeing whether the same concept applies (to a scenario considered as actual)? Well, in a way yes, in a way no. The concept "water" will apply to first but not the second of the scenarios considered above. But arguably both scenarios contain the property of being water. If so, then the application of the concept "water" (in PI) is not a perfect guide to the presence of the property of being water (the property is present in the second H2O-world, even though the PI of "water" doesn't apply there). On the other hand, the application of the concept "water" to these scenarios (considered as actual) *will* be a good guide to the presence of a certain property, the property determines by the PI of water, i.e. the property of being watery stuff. The concept "water" applies to the first but not the second scenario (considered as actual), and the property of being watery stuff is present in the first but not the second. So even here, the application of a concept is a good guide to the presence of a corresponding property -- it's just that in this case, it's the PI property that's relevant, not the SI property.

Let me know if I've misunderstood your claim here.

> properties and concepts are related, but I'll leave this here.

Right. On my view, the connection between concepts and properties is particularly intimate, more intimate than some opponents will allow. (So I'm not sure why you say above that that connection may be more intimate than *I* allow.) In particular, I think that when one has two a priori distinct concepts, there are two distinct properties in the vicinity, namely the two reference-fixing properties, or PI properties. (If "A = B" is a posteriori, the PI of "A" is a distinct property from the PI of "B".) This issue comes up a bit in the PPR symposium we'll be looking at shortly.

Re moving from conceivability to possibility, you're right again. Of course I think there are two such moves in the vicinity: the move from 2-conceivability to 2-possibility and the move from 1-conceivability to 1-possibility. Either way there will be a link between concepts and properties. In fact, I think in both cases, the link between conceivability and possibility and the link between concepts and properties stand and fall together. To see this in a bit more detail:
Thesis 1: 1-conceivability implies 1-possibility.

Thesis 2: Distinct concepts yield distinct properties. I.e., if "A" and "B" are distinct concepts, in the sense that there are 1-conceivable scenarios to which "A" applies but "B" does not, then the PI of "A" and the PI of "B" are different properties, in the sense that they are not necessarily coextensive.

Proof:

Left-to-right: Assume 1-conceivability implies 1-possibility. Let "A" and "B" be distinct concepts. Then there are 1-conceivable scenarios to which "A" applies but "B" does not (i.e., "A != B" is 1-conceivable). It follows that "A != B" is 1-possible, and there are 1-possible scenarios to which "A" applies but "B" does not. So the PI of "A" is not necessarily coextensive with the PI of "B", so these are distinct properties.

Right-to-left: Assume that different concepts yield different properties. Let "A != B" be 1-conceivable. Then "A" and "B" are distinct concepts, so yield distinct properties, so the PI of "A" is a property distinct (and not necessarily coextensive with) the PI of "B". So there is a world to which the PI of "A" applies but the PI of "B" does not. So "A != B" is 1-possible.

Much the same goes for the corresponding claims regarding 2-conceivability, 2-possibility, and SIs. One needs a little more to generalize the right-to-left proof for conceivability-to-possibility links in cases other than identity statements, but it is not to difficult.

So, we can see that the sort of 2-D view to which I subscribe (and which I think is independently plausible) has a particularly strong link between concepts and properties (distinct PIs yield distinct properties, etc) and between conceivability and possibility (1-conceivability implies 1-possibility, etc), and that these two properties of the framework go together.

It seems, then, that it is an opponent who will have to resist this strong link between concepts and properties, at least if they want to resist the move from (ideal) conceivability to possibility. We'll see some instances of that strategy when we discuss the papers by Loar and by Hill & McLaughlin in the PPR symposium. Essentially, these people reject the 2-D framework as a complete account of a posteriori necessity, reject the central claim that an a posteriori necessity must have a contingent primary intension, and deny the strong link between concepts and properties and between conceivability and possibility. It seems that's what an opponent (at least a type-M materialist) needs to do, if they want to hold onto the epistemic intuitions but still hold on to materialism. That's something we'll be looking at in depth soon.

--Dave.
Dave recently responded to Tim's question re "the big picture disagreement" between 2D views and those in N&N by (among other things) noting that:

> I suppose that one difference is that Kripke sees epistemic matters such as apriority as *purely* epistemic in some sense and not modal, whereas I think it is often useful to understand them in modal terms. On my view, one can see epistemic possibilities as possible worlds in their own right, where our terms have a distinctive pattern of application to those worlds; and there is a corresponding notion of necessity, 1-necessity or primary necessity, which is in many ways just as important as the notion of subjunctive necessity (2-necessity) that Kripke concentrates on, and which has deeper ties to epistemic notions.

There may be another way of getting at this point of tension between the two views. This relates to some of Josh's worries about worlds considered as actual. On the 2D view of things, considering a (centered) possible world as actual is straightforward enough, and there is a well-defined and well-behaved notion of necessity and possibility that corresponds to the application conditions of terms in worlds-considered-as-actual. One reason why this is easy to do on the 2D view is that worlds are considered purely qualitatively (see TCM, p.367n30). And so, a la Lewis, the actual world is privileged not because it is actual, but because we happen to inhabit it: other worlds are truthfully called "actual" by their inhabitants.

But Kripke doesn't seem to want to think of worlds in that way. He even scorns the literature on trans-world identity for being confused: these philosophers wouldn't have such difficulty if they didn't think that worlds could only be given qualitatively (p.76). Worlds, on the Kripkean view, are *always* counterfactual worlds---at least that seems to be the way Kripke talks: worlds are total ways the world *might have been* (p.18). So, it's no wonder he focuses on SI's---strictly speaking, he has nothing else to talk about.

Thony

"Curious green ideas sleep furiously."

Thony writes:

> There may be another way of getting at this point of tension between the two views. This relates to some of Josh's worries about worlds considered as actual. On the 2D view of things, considering a (centered) possible world as actual is straightforward enough, and there is a well-defined and well-behaved notion of necessity and possibility that corresponds to the application conditions of terms in worlds-considered-as-actual. One reason why this is easy to do on the 2D...
view is that worlds are considered purely qualitatively (see TCM, p.367n30). And so, a la Lewis, the actual world is privileged not because it is actual but because we happen to inhabit it: other worlds are truly called "actual" by their inhabitants.

Well, I wouldn't go so far as to say that the 2-D view is Lewis-like. Lewis's view holds in effect that all worlds are equally "concrete", and that what distinguishes the actual world is just that we are in it. But it's quite compatible with the 2-D framework to say that only the actual world is concrete while the others are abstract, and this concreteness distinguishes it from the other worlds, not just the fact that we are in it. Or to use other language, we can say that there is a large space of (abstract) possibilities, but only one of the possibilities is *realized*, namely this one.

Of course, one can consider any possible world as actual, but that's not to say that the actual world isn't privileged. This world is not merely considerable-as-actual -- it *is* actual!

But Kripke doesn't seem to want to think of worlds in that way. He even scorns the literature on trans-world identity for being confused: these philosophers wouldn't have such difficulty if they didn't think that worlds could only be given qualitatively (p.76). Worlds, on the Kripkean view, are *always* counterfactual worlds---at least that seems to be the way Kripke talks: worlds are total ways the world *might have been* (p.18). So, it's no wonder he focuses on SI's---stricly speaking, he has nothing else to talk about.

Hmm, lots of interesting issues here. I suspect that the issue vis-a-vis qualitative specification and transworld identity is to some extent separable from the issue about considering as actual and as counterfactual, though there are links.

Kripke says that possible worlds *needn't* be specified in mere qualitative terms, though he also allows that they *can* be. So I can if I like specify a counterfactual world in terms of the distribution of qualities, but I can also specify it as one in which *Nixon* does such-and-such, and so on. Kripke thinks this cleanly bypasses any problems about "transworld identity". Of course there might still be a problem concerning identity across worlds given qualitatively, since Kripke at least allows the latter, but the fact that one needn't always specify a world qualitatively means that there isn't a problem about transworld identity *in general*.

As for worlds being considered as counterfactual, it's true that insofar as Kripke explicitly talks about what is true in a world, he is always considering those worlds as counterfactual, and thus in effect invoking SI evaluation. He does seem to often *implicitly* consider worlds as actual and evaluate the referent of our terms there (as with considering the epistemic possibility that Godel stole the proof, or thinking about what we'd say if we discovered that the catlike things were demons); but he doesn't explicitly put this in terms of evaluating terms in possible worlds. So at least as far as his explicit framework goes, possible worlds are always considered as counterfactual (though I'd argue that he is implicitly endorsing something more).

(You're right that thinking of worlds as ways things might have been goes along with considering them as counterfactual. One way of bringing out the 2-D distinction is to say that worlds considered as actual are ways the world *might be*, while worlds considered as counterfactual are ways the world *might have been*. This goes along
with the ties to indicative and subjunctive mood in conditionals and elsewhere. Kripke always focuses on the latter, it seems.)

What's the relation between the two points: allowing us to stipulate worlds nonqualitatively, and always considering worlds as counterfactual? The former does not seem to imply the latter: someone might accept that we can stipulate counterfactual worlds qualitatively but also accept that we can consider worlds as actual (whether qualitatively or nonqualitatively). And the latter does not seem to imply the former: someone might always consider worlds as counterfactual but also always consider them qualitatively ("through a powerful telescope"), not allowing nonqualitative stipulation. So the two points seem independent to some degree.

Still, maybe there is some indirect link. One way to get at this is to ask whether it is possible, when considering worlds as actual, to stipulate them nonqualitatively as well as considering them qualitatively. To a certain degree this seems to be possible: for example, I can stipulate that I am talking about the epistemic possibility that Nixon was Kennedy's brother, rather than considering the world "given qualitatively" and trying to see whether it is an instance of the epistemic possibility that Nixon was Kennedy's brother. So to that extent Kripke's point holds even here. (Of course, in both cases one needs to be careful that one is not making an incoherent stipulation.)

Still, there's a difference here in that arguably the notion of transworld identity doesn't make as much sense when talking about worlds considered as actual. I can consider the epistemic possibility that Hesperus is not Phosphorus (that's pretty straightforward), but presumably that's not a world where *this very thing* (i.e. Hesperus/Phosphorus/Venus) is not *that very thing* (i.e. Hesperus/Phosphorus/Venus). Presumably that would be incoherent. So when we stipulate the epistemic possibility, one is not making a stipulation about the very things from the actual world.

Arguably, the notion of transworld identity does not really make sense when applied to worlds considered as actual, as opposed to worlds considered as actual. The reasons for this are subtle but come down at least in part to the failure of substitutivity in epistemic but not in modal contexts (and ultimately in indicative but not in subjunctive contexts). Epistemic possibilities are not "object involving" in quite the same way that subjunctive possibilities are. So *de re* (object-involving) possibility and necessity may not really be coherent here in this domain.

For example, it seems one can't quantify into 1-modal contexts: "it is 1-necessary that x is hot" isn't really coherent. E.g., it is 1-necessary that Hesperus is the evening star, but it isn't 1-necessary that Phosphorus is the evening star, even though both are names for the same thing; and there isn't really any other way to make sense of the claim without such names. So for the epistemic modality, any modal claims involving x seem to be relative to the label under which x is picked out. This doesn't apply to subjunctive modality: "it is 2-necessary that x is hot" makes sense, and any label for x will yield the same truth-value here, as long as it's a rigid designator.

(In a way, this is saying that Quine's critique of quantified modal logic and essentialism was right about epistemic modality, though not about subjunctive modality. So we have a "split decision" in the battle between the likes of Quine and the likes of Kripke. A point
like this is made John Burgess in a very nice recent paper in the 1997 Canadian Journal of Philosophy supplement on "Meaning and Reference").

Anyway, nothing here contradicts anything that Kripke says, exactly.

>From the 2-D perspective, one can say that he is focusing on the sort of possibility and necessity (namely subjunctive possibility and necessity) where de re possibility and necessity does make sense, and it's quite an achievement of his to make sense of it. At the same time, there are other notions of possibility and necessity out there (e.g. broadly epistemic possibility and necessity) where de re possibility and necessity doesn't make sense.

Of course it's no surprise that Kripke, who was such a major contributor to quantified modal logic, was particularly interested in investigating notions of modality for which quantification into modal contexts makes sense (which will be just those for which *de re* modality makes sense). So it's no surprise that he was led to focus on subjunctive modality, and on worlds considered as counterfactual. (More on this in the "tyranny of the subjunctive" material.)

But anyway, none of this implies that there's anything problematic or second class about epistemic modality and considering worlds as actual. Things here just work a different way. One can take on board all of Kripke's points about subjunctive modality, and still hold that there are other interesting modal notions and other corresponding ways of looking at possible worlds.

Or so it seems to me. But feel to elaborate on this interesting issue.

I have a question concerning the possibility of psychophysical laws, given the anti-materialist argument we've been discussing.

One of the straightforward problems that one adopts, if the non-(logical supervenience) of consciousness is granted, is the rather unpalatable possibility of epiphenomenalism with respect to conscious experience. Chalmers' remarks that this may not be so bad, and that, if the argument goes through, we may simply "have to get used to it". But I take it that Chalmers' (self-admitted!) speculation about the possibility of internal, protophenomenal features of an "expanded" physical framework, who's current postulates are all external, relationally specified properties (i.e., of the fundamental physics variety) is meant to provide a possible future development of a causal role for phenomenal properties. (Is this true?). I have two questions. First, if we have some set of internal (protophenomenal) properties related by psychophysical laws, and still the external, physical properties related by physical laws, then don't we just push the problem of interaction (and thus epiphenomenalism) back a step?

Second, if we have the psychophysical laws connecting internal to external properties--protophenomenal to physical--wouldn't this fly in the face of a) the non-(logical supervenience) of the phenomenal on the physical and

b) the assumption that the physical world is causally closed? All of this is to suggest that there doesn't seem to be much room for psychophysical laws, at least in so far as they may provide possible answers to the problem of epiphenomenalism. One response may be that considering psychophysical laws qua answers to epiphenomenalism is not necessary, anyway. But I take it that a "completed" scientific account of phenomenal properties in a theory of the mental would have something like this in mind.

(There are really two (or more) possibilities for the role of psychophysical laws relevant here. Qua answer to epiphenomenalism, the laws would be causal. A "weaker" interpretation would assign psychophysical laws the role of correlating internal (protophenomenal) to external (physical) states in a way that yielded information about regularities between the two. I suppose I'll need to think things through more for the weak case, but it seems that the same sort of objections stated above will present themselves.)

Let me know what you think.

Erik

"What our grammarian does is simple enough. He frames his formal reconstruction of K along the grammatically simplest lines he can, compatibly with inclusion of H, plausibility of the predicted inclusion of I, plausibility of the hypothesis of inclusion of J, and plausibility, further, of the exclusion of all sequences which ever actually do bring bizarreness reactions." -- W.V.O. I realize that what follows is actually last weeks topic, but here goes anyway...

In an attempt to avoid all out epihenomenalism, it is suggested in TCM and in Metaphysics of Modality that there might be a causal role for the phenomenal if the intrinsic properties of micophysical stuff is actually phenomenal or protophenomenal, this is a possibility I take it because we understand this stuff only in virtue of its extrinsic properties, which leaves the intrinsic nature up for grabs...if the intrinsic properties were phenomenal or protophenomenal, then perhaps they could form the underlying basis for the physical realm, and therefore somehow be causally related, even though the physical system is causally closed...

I have two questions about how this might go, first, if protophenomenal properties are intrinsic, then what access will we ever have to them such that laws relating them might be developed? Also, how is it that "principles associating physical dispositions with (proto)phenomenal bases" is less problematic than laws relating phenomenal properties and
Both Erik L. and Angela raise questions about panprotopsychism, vis-a-vis epiphenomenalism.

Well, one has to get the shape of the view straight. On the
"panprotopsychist" view, one has still has a causally closed physics.
In fact physical laws have just the same shape as before. We have
just "colored in" physics by specifying the categorical basis of the
physical dispositions.

Think of it this way. Take physics at face value as true. Even so,
one arguably realizes that physics only tells us about the "structure"
in relations between things, and tells us about things only be their
effects. What is a particle? What is mass? Physics doesn't say. We
just know about the effects of these things.

More technically, we just know about the *dispositions* in the
vicinity of charge and mass and electrons. We know about them solely
in terms of their characteristic effects, which are well spelled-out

by physics. But arguably, wherever one has a disposition, one needs a categorical basis. That's just to say, whenever one has a causal role, one needs something to do the causing! That thing will be the "intrinsic" nature of mass, or charge, or an electron. Physics doesn't tell us about it -- it is in effect hidden from sight, in a sort of Kantian way -- but arguably we still have reason to believe it exists.

On this view, every physical property -- mass, charge, etc -- has a categorical bases, or an intrinsic nature. A fundamental particle will have an intrinsic nature given by the nature of its charge and mass, etc. The world itself is a giant network of causal interactions among these intrinsic properties and the particles that have them. The interactions are structured just physics says -- the laws of physics specify the dynamics perfectly. It's just that physics tells us only about the structural part, and we can't forget the intrinsic part too.

Panprotopsychism is the view that these intrinsic properties are phenomenal or protophenomenal. So the physical world consists ultimately in interactions among phenomenal or protophenomenal properties. It doesn't look that way to us, because we see the properties only from the "outside" (except in our own case!), in terms of the structure of their interactions. But on this view, it's that way all the same. After all, it's no surprise that we don't know the nature of the intrinsic properties of the physical.

Now to Erik's questions:

(1) Doesn't this just push the problem of interaction and epiphenomenalism back a step? I'd like to think not. The beauty of doing things this way is that we *know* that the intrinsic properties are causally relevant. They are the things that do the ultimate causing! E.g., when mass causes another mass to be attracted, what is really happening is that there is a causal relation between their intrinsic bases, i.e. (on the panprotopsychist view) the relevant protophenomenal properties. The world is ultimately a network of causal interactions among just these properties! So they are causally relevant from the "bottom up".

(2) What about causal closure? Another beauty of this view is that one can hold onto causal closure. We haven't introduced new causal "gaps" from phenomenal propeties to fill. Rather, they just play the role of supporting the causation that was there all along. Interactions among particles etc can be just as they were before; it's just that we now know that the ultimate nature of those particles is protophenomenal.

(3) What about psychophysical laws? These have a slightly different shape on this view. They don't connect physical properties to phenomenal properties "dangling" outside the system. Rather, they will in effect connect "dispositional" properties (e.g. the characteristic causal role of mass) with the "intrinsic" properties that underlie the disposition (and that are ultimately doing the causing). In effect, they are connecting the "outside" of physical entities to the "inside".

Arguably, the truly fundamental laws in this world are laws connecting the basic intrinsic properties to each other. E.g. protophenomenal property 1 (the mass property) and protophenomenal property 2 (the charge property) interact with each other in such-and-such a way. The "dispositional" physical properties just come from our viewing all
this from the outside in terms of structure, and the "psychophysical laws" from our trying to fill in the dispositions with intrinsic properties again. But at least from our perspective, it's useful to see these psychophysical laws here, as the dispositional stuff is what we're familiar with (from physics etc), and the intrinsic stuff is all a bit of an unknown. So one can hope that a final science of consciousness might make some progress in connecting the two, and in particular telling us just which intrinsic properties play which dispositions.

(4) Logical supervenience on the physical? As I said in the earlier message, there's a sense in which this view sees phenomenal or protophenomenal properties as part of the physical world. After all, they are the categorical bases of physical dispositions, and arguably are the "ultimate nature" of the physical. But still, they don't logically supervene on the physical properties we know and love, because those are dispositional properties, and intrinsic properties don't supervene on dispositions. It would be logically possible to have the same dispositions but a different intrinsic basis, etc. But here, the failure of supervenience isn't due to the intrinsic properties being "outside" the network. It's because it's the intrinsic properties that "carry" the dispositions, serve as their "insides", and ultimately do the causing.

Angela writes:
>
> I have two questions about how this might go, first, if protophenomenal properties are intrinsic, then what access will we ever have to them such that laws relating them might be developed? Also, how is it that principles associating physical dispositions with (proto)phenomenal bases is less problematic than laws relating phenomenal properties and physical properties? I'm not sure how one can posit a "transformation operator, for example" given all that has gone before about the utter impossibility of cashing out phenomenal properties in functional or dispositional terms.
>
> so, it seems as though epiphenomenalism cannot be avoided without undermining the anti-materialist arguments...
>
> angela

Good questions. First of all, let me say that I'm not suggesting that the problems you mention are any easier on a panprotopsychist view than on an epiphenomenalist view. But I don't think that they're necessarily harder, either.

E.g., for your first problem about "access", obviously we don't have much access to epiphenomenal phenomenal properties, except in our own case. And indeed one can argue that almost any view will have some sort of epistemic barrier of this sort, even a type-B materialist view: one can't monitor qualia in other systems directly, and there are always multiple epistemic possibilities. So the panprotopsychist view isn't obviously worse off here.

Similarly for the second problem. Our "transformation operator" isn't going to try to reduce phenomenal properties to dispositional ones. We are just going to try to find a law connecting the two (laws that connect distinct things, of course). That will be hard for an epiphenomenalism, but there's no reason why it should be impossible in principle. Hopefully a panprotopsychist can do the same.
How do we find the laws? Well, first of all, by correlating and systematizing first-person data and its relation to third-person data in one's own case. And second, by gathering data about consciousness in others (under certain assumptions, e.g. reliability of verbal report), and relating it to the third-person data. And third, by careful analysis and thought-experiments etc, which can deliver useful conclusions. This way we at least get a stock of regularities and correlations at the "macroscopic" level to start with. Then we try to boil these down to a simplest form and ultimately find "fundamental" principles that support these macroscopic regularities. A form of inference to the best explanation, if you like. That might be difficult and speculative, but not obviously impossible. It will be hard enough coming up with one good set of fundamental laws that fits the data, so if we do find a good hypothesis that explains the data we have, we'd have some good reason to believe it.

The panprotopsychist can avail herself of all of this. The only extra thing is that the panprotopsychist has strong constraints on the form of the fundamental laws. The basic psychophysical will ultimately connect fundamental physical dispositions to fundamental protophenomenal properties, right down at the microphysical level. Presumably there will be just a few such laws, one for every fundamental physical property.

That puts a lot of constraints on the form of the panprotopsychist's fundamental psychophysical laws, which might either be a blessing or a curse. A blessing because the extra constraint narrows down the hypothesis space and tells us something about where to look. A curse because it may be all the harder to come up with laws that do the job. It's not at all obvious that we can derive all the facts about the macrophenomenology we know and love as a consequence of a whole bunch of protophenomenal properties we know and love. That's the biggest problem for the view -- what I call the "combination" or "constitution" problem in the book and elsewhere (see e.g. pp. 305-8). How does all those zillions of protophenomenal properties add up to a unified, bounded, grainless, structured phenomenal consciousness? It's not obvious that they can, but it's not obvious that they can't.

*If* this problem can be solved, then I think the panprotopsychist view is the best solution to the mind-body problem by a mile. If it can't, then we have to look at other options. I'm hoping that we will get a better sense of the possible solutions to this problem for the panprotopsychist in coming years.

I have a brief question regarding the admissability of causal primary intensions. This has come up at least twice; once in Tim's response to Josh's BIV scenario, and then again in our first class meeting. So, the problem is, I don't think primary intensions can ever be appropriately thought of as "the cause of my sensation that" or "that which brought about my experience of" or some such, because in any of these cases the...
primary intension can vary wildly, depending on what the cause happens to be. So some brain in a vat may have a PI of water that appeals to electrodes and stimulation or whatever, and on earth this of course won't make any sense. So "that which causes my x experience" makes a primary intension the same as whatever the cause happens to be, and not the essential notion or properties of the thing itself, apriori. So I think the primary intension has to be necessarily connected to the essential quality of the thing (at least as it is known apriori or conceptually). What we mean by the concept of water, then, is not what causes the water experience (which may have nothing to do with the essence of water itself).

Anyway, this isn't a major point, but it keeps bothering me. I would be interested to hear any defence of causally-based primary intension, or where I have gone wrong or oversimplified the issues here.

Erik L.

The visa has been approved (hooray), but the paperwork still needs to come through, so I probably won't be there until next week. Meantime we have fallen behind a little and some people still haven't posted their week 5 contributions, so we can spend a little more time on that. I am particularly interested in comments on the general form of the argument as e.g. laid out in "Mind and Modality" -- if the argument is to be questioned, where will one question it? Which premise, or which reasoning?

Meantime we should move onto week 6 (the original week 7) readings sometime soon. This will concentrate around the PPR symposium on my book, in which all the respondents were type-B materialists, it turns out. Some of the material is on the web (all accessible via "online papers on consciousness"). I suggest starting with Yablo's "Concepts and Consciousness" (which is excellent); you could also take a look at his "Textbook Kripkeanism and the Open Texture of Concepts" which covers the same ground in a bit more detail, although this isn't as vital. You should also look at Brian Loar's important paper "Phenomenal States", not from the symposium, but which sets out a sophisticated type-B view which he reiterates in the symposium. Finally there is my response "Materialism and the Metaphysics of Modality" which goes over a lot of these issues more carefully.

The other three papers (Hill/McLaughlin, Loar, Shoemaker) are not online, and I will have to fax or express mail them over tomorrow. In the meantime the papers I mentioned should be a good starting point. Any comment on those papers and on the general dialectic will be welcome. Time for bed now.

--Dave.

Dear all,

I have put sent some papers by express mail to Ann Hickman. They should be there by Wednesday or Thursday. The papers include

(1) PPR symposium papers by Hill & McLaughlin, Loar, Shoemaker, Yablo.
(2) Chalmers, "Materialism and the Metaphysics of Modality".
(3) Hill, "Imaginability, Conceivability, Possibility, and the Mind-Body Problem"
(4) Levine, Review of _The Conscious Mind_
(5) Evans, Reference and Contingency
(6) Jackson, Finding the Mind in the Natural World.
(7) van Cleve, Conceivability and the Cartesian argument for dualism
(8) Yablo, Does Conceivability Imply Possibility?

The most important papers to look at immediately are the papers in (1). Yablo's paper in (1) is on the web, but I included it for completeness. The same goes for (2). (3) is a useful paper to look at in association with Hill & McLaughlin's paper in (1), as it elaborates one of the central ideas. (4) gives another type-B materialist reply to the sort of arguments I give. All of these are relevant to our current and forthcoming discussion of the modal argument and the dialectic with the type-B materialist.

(5) and (6) are papers relevant to previous issues. (5) is an important early paper by Evans on some ideas in the 2-D framework. (6) gives a very nice sketch by Jackson of some core issues relating metaphysics, modality, and materialism, and also talks about the role of the 2-D framework here. I think some people might find this particularly clear and useful.

(7) and (8) will be relevant to the forthcoming discussion of conceivability and possibility (coming up fairly soon).

I will ask Ann to either (a) make copies for everyone, or (b) leave the papers somewhere where everyone can grab them and photocopy them for themselves. [Probably it will be (b), but I'll try for (a).]

In the meantime people should have read the Loar and Yablo papers and my PPR reply from the web, and might start discussing those issues shortly. (Both the Loar and Yablo papers on the web are particularly good, and nice statements of a type-B materialist position.)

Right now I'm still hoping I might arrive by next Tuesday in time for class, but we'll see.

--Dave.

Sender: "Philosophy 596B: Mind and Modality"
<MODALITY@LISTSERV.ARIZONA.EDU>
From: David Chalmers <chalmers@LING.UCSC.EDU>
Subject: arrival
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

Dear all,

Amazingly enough, the visa paperwork has made it to Arizona, and now I only need to wait for the FedEx and get the visa itself in Sydney. It looks likely that I will be arriving in Tucson at 3:59pm next Tuesday. I was hoping to be there in time for class, but I guess not. Still, I would like to meet once or even twice next week if that is possible. Once to have a general meeting to go over topics so far, and once for a full to discuss some of the papers I recently sent, especially the material in the PPR symposium and related issues about the 2-D modal argument against materialism. That would get things nicely caught up and under control in time for spring break, and ready for real momentum in the second half of term.

Would having a meeting at 5pm on Tuesday work for everyone? And is there another time that might work, e.g. sometime on Thursday? Please e-mail me to let me know whether you could make these meetings and what time would work best.
On other topics, I'm looking forward to seeing everyone's week 6 contributions as soon as possible (and also this week's minutes, of course). Looking at my web site log, I haven't seen as many hits on the relevant material from arizona.edu as I would have liked. Everyone should have downloaded and printed

http://ling.ucsc.edu/~chalmers/modality.html

and

http://ling.ucsc.edu/~chalmers/princeton.html

as both are very important. The second outlines a lot of relevant material for the course in a definitive-ish (although brief) form, and the former should clarify quite a few things more discursively. The former in particular is vital to this week's readings (especially section 3). Of course you should also be looking at the other web material (e.g. Loar and Yablo).

The papers I sent should be there very soon, and Ann will either copy them for everyone or leave them somewhere where you can grab them to copy.

I'm looking forward to finally seeing everyone soon!

--Dave.

Anthony T Lane <atlane@U.ARIZONA.EDU>

This might be a silly question, and I apologize if we've already covered this:

In reading your response to Shoemaker (Section 4) I was struck by how much phenomenal zombies are like us (or we like them...). Am I right in thinking that zombies think that they "know what it's like" to see red, and might even run arguments for dualism on the strength of these beliefs?

You suggest that the judgments of zombies are a) unjustified and b) negatively rational. I'm not quite sure what you mean by 'negatively rational'-- is it just that they don't reason in a way we consider justified, but nevertheless manage to avoid errors? (If the results of their reasoning processes are the same as ours, might we not say that their beliefs are formed by a process that is at least as reliable as our own?)

I suppose this is basically the line that eliminativists take. Are we to be assured of the fact that we have phenomenal experiences on the basis of the intuitive arguments in Ch.1? If zombies have the same beliefs, isn't hard to resist a skeptic/eliminativist who claims that we are really no different?

Anthony

> what?

A minor point: I wouldn't say "knowable prior to experience here", but
rather "knowable independent of experience". It may be that it takes
experience to acquire the relevant concepts, for example, so some a
priori P can only be known by experiencing beings. Strictly speaking,
the crucial thing is that experience doesn't contribute to the
"justification" of the knowledge in question, given that one has the
concepts. One might better define things by saying that P is a priori
when P can be known in a way such that experience does not contribute
to the justification of P, or such that P has an
experience-independent justification. (An example: perhaps one might
hold that only a being with red experiences can have the concept of
"red", in which case "all red things are colored" would only be
knowable by experiencing beings, but might still be a priori.)

Anyway, your point is interesting. It's certainly true that if we
idealize the notion of apriority, then it becomes harder to know
whether a given P is a priori. I take it that we can agree that there
is still a distinction between P such that a human can know it
independently of experience, and P such that some being can know it
independently of experience. Call the former "human apriority" and
the latter "ideal apriority". Your point is that it is harder to know
whether P is ideally a priori than whether it is humanly a priori.

Of course it may not be trivial to know whether a given P is even
humanly a priori. Take for example some complex P in mathematics (or
maybe philosophy), such that only a genius mathematician, in 200 years
time, will come to know that P. Then we ordinary folk aren't in a
good position to know whether P is a priori. But I guess one might
say, at least some human can know whether P is a priori. At least,
some human can know P in an a priori way, and from there it hopefully
won't be too hard for them to conclude that P is knowable a priori (as
long as they know that they know that P, and as long as they know that
they know it a priori). Whereas for ideal apriority, maybe none of us can know.

I think this is a consequence of the notion of ideal apriority that we just have to accept. Presumably there are some P such that no human can know P, but such that smarter beings could know P independently of experience (e.g., P = the Godel sentence of the human mathematical community, or some such). Then P is ideally a priori, but we can never know that. This is to say that ideal apriority can be "epistemically opaque", in that we can't always know whether P is ideally a priori.

It's not clear to what extent this is really an objection to the notion. Plenty of properties are epistemically opaque. E.g., truth is epistemically opaque -- we can't always know whether P is true. Similarly, necessity is epistemically opaque, and so on. It may still be that we can chart interesting relations between these notions, make argument that particular statements are or are not true/necessary/apriori, and so on.

One objection might be that the epistemic opaqueness makes the notion less useful, and makes in particular makes it harder to judge its application in a given case. E.g., one might object that one could never know, for a given P, that P is not a priori -- we might know that *we* don't know it a priori, but not that no being could. Still, this doesn't seem to be a problem for many P. E.g. let P be "Bill Clinton is the 42nd president of the USA". It seems pretty clear that no being could know this a priori. That is, we are justified in saying this is not ideally a priori, even though we can't simulate the thinking of the smart beings in question.

I think the moral is that although we can't know exactly what smarter beings could know, so we can't know exactly what is ideally a priori, one can still come to justified conclusions about many things that such beings could and couldn't know, so one can still come to justified conclusions about what is and isn't ideally a priori. For example, we can know that "2+2 = 4" is ideally a priori, and that "there is a telephone on this desk" is not.

I suppose the central question in our context is whether "there are no zombies" (or strictly, "P -> Q" where P is the complete physical truth and Q a phenomenal truth) is more like the case of the Godel sentence or the case of the telephone. If one accepts the epistemic intuitions, it certain does not *seem* to be a priori, and it seems that *we* can't know it a priori. But maybe it is ideally a priori, in that a less limited being could know it a priori? In which case our epistemic intuitions here merely reflect our cognitive limitations?

That's a deep question. It corresponds to the possibility of what I was calling on Tuesday "type-C materialism", the idea that there is an a highly nonobvious a priori entailment from physical to phenomenal (so that zombies are prima facie conceivable but not ideally conceivable, etc). I don't have anything definitive to say about this.

I do hold out hope that it is in some ways more like the telephone case than the Godel sentence case, though. That is, I think we have some reason to believe that it is not just not a priori for us, but it is not a priori for any being. There is the point, for example, that if there is even an ideal a priori entailment from physical to phenomenal here, then there must be some sort of a priori conceptual
analysis of phenomenal concepts in functional and structural terms. And I think we are in a position to say with justification that any such analysis would be a misanalysis -- it simply gets the meaning of the concept wrong. Of course an opponent could respond by saying that I only say this because of my cognitive limitations, and that if I was less limited I could see the deep a priori equivalence between phenomenal and functional concepts. The dialectic gets a little fuzzy around here, but my own view is that even if we can't rule out type-C materialism definitively, there is a strong prima facie case against it.

(Incidentally this brings out why doing things in terms of "analyticity" might not help here. If the type-C materialist were right, maybe there could be an analytic but highly nonobvious equivalence between phenomenal and functional concepts. We already know that analytic truths aren't always trivial -- witness the tricky analysis of the concept of "knowledge". So maybe it could turn out that analyticity is epistemically opaque, just as ideal a priority is.)

That being said, it's a complex issue and a very worthwhile avenue to explore. If anyone wants to follow up on this, e.g. writing a paper exploring the type-C materialist position and the slack opened up in the argument by the difference between prima facie and ideal conceivability, etc, I'd be delighted.

--Dave.

Anthony writes:

> In reading your response to Shoemaker (Section 4) I was struck by how much >phenomenal zombies are like us (or we like them...). Am I right in >thinking that zombies think that they *know what it's like* to see red, >and might even run arguments for dualism on the strength of these beliefs?

That's right. I discuss that at length in Chapter 5 of the book (which we haven't covered). I call it the "Paradox of Phenomenal Judgment". It certainly leads to some interesting tensions, thugh I argue that it doesn't lead to any fatal flaws.

> You suggest that the judgments of zombies are a) unjustified and b) >negatively rational. I'm not quite sure what you mean by 'negatively >rational'-- is it just that they don't reason in a way we consider >justified, but nevertheless manage to avoid errors? (If the results of >their reasoning processes are the same as ours, might we not say that >their beliefs are formed by a process that is at least as reliable as our >own?)

By "negatively rational", I mean that they don't make mistaken inferences, errors of reasoning, etc. Nevertheless, they are still wrong, and unjustified, at least on my view, as they don't have the positive evidence that we do that justifies our belief in experience. (The evidence is provided by experience itself!) I'm not sure I'd put...
things in terms of reliability, exactly, as one can argue that the zombie's belief-formation process is unreliable here -- after all, it produces a lot of false beliefs!

>I suppose this is basically the line that eliminativists take. Are we to be assured of the fact that we have phenomenal experiences on the basis of the intuitive arguments in Ch.1? If zombies have the same beliefs, isn't hard to resist a skeptic/eliminativist who claims that we are really no different?

Someone could certainly try to do that. In response I'll say two things. First, I don't think zombies have exactly the same beliefs as us here, as many of our phenomenal concepts and beliefs are themselves partly constituted by our experiences, experiences which the zombie lacks. (See "Mind and Modality" lecture 3 here.) But even setting that point aside, I think the skeptic/eliminativist would only have a good argument here under the assumption that the justification of a belief always inheres in other beliefs. If so, and if my zombie twin had the same beliefs, I'd be in trouble. But I think it is independently implausible that the justification of our beliefs always inheres in other beliefs. In particular, I think it is plausible that beliefs are often justified by *experiences*, and that experiences provide direct evidence for our beliefs.

If that's right, then my phenomenal beliefs have justification that the zombie lacks: the zombie is in a very different epistemic situation, and lacks all my evidence. If so, then the mere possibility of a zombie forming the same beliefs in an unjustified way doesn't undermine the justification of my own beliefs here. I still know I have experiences, because of my first-person evidence! Now maybe the zombie *thinks* he has that evidence too, but he is wrong and unjustified in thinking so. Again, it's the experiences themselves that justify all the beliefs in question.

Anyway, this is a subtle and interesting dialectic, though a bit outside the issues we are focusing on here. There's a lot more on it in Chapter 5 of the book and in "The Content and Epistemology of Phenomenal Belief" (online).

Subject:  Comments on Loar and Hill/McLaughlin
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

Here are some thoughts about the strategy taken by Loar and Hill/McLaughlin regarding the a posterioricity of psychophysical identities.

I agree with Chalmers that it is not enough for the type-B materialist to explain why zombies are conceivable. They also have to give an account of why the conceivability in such cases is an unreliable guide to possibility.

I don't think that the cognitive accounts that Loar and H & M give are *as* irrelevant to the issue of whether conceivability is a guide to possibility as Chalmers suggests. Chalmers contends that we could give a
psychological account of the conceivability of any state of affairs (such as mathematical beliefs). He claims further that Loar's notion of a recognitional concept does no extra work beyond establishing that physical and phenomenal concepts are cognitively distinct. But there does seem to be the difference, as Loar discusses, that phenomenal concepts pick out their referents directly. This is a feature unique to phenomenal concepts. Agreeing again that a cognitive explanation alone does not fully address the anti-materialist argument, I do think that the case of phenomenal concepts can be distinguished from all other concepts in a way that gives the materialist a foot-hold for developing a response.

But what more can the materialist say in order to motivate his or her position? Unless given strong reasons to the contrary, we ought to accept that conceivability entails possibility. Loar and H & M seem to accept this burden. (There is more to be said here about *who* has the burden of proof--the materialist or the anti-materialist. The above claim provides reason to think that the materialist has the burden. I suspect others will disagree--I'd be interested in any arguments for the contrary position.)

Loar's conclusion seems to be rather weak--for all we know, phenomenal concepts pick out the same properties as physical concepts. But how could we discover or determine that they do in fact have the same referents? It isn't clear to me what Loar has to say about this, especially give his agreement that identity statements involve a prior analyses.

H & M suggest that the materialist view has greater coherence, simplicity, and does not violate other intuitive doctrines such as the causal efficacy of the mental. Chalmers suggests that these points are being forced to do double-duty here. I have to go now (!) so I won't discuss this issue, though I hope that I can pick up on it later since it seems crucial if we grant that the conceivability of zombies has an *interestingly* distinctive cognitive explanation.

Brad
not to worry, for I will be given a drug before hand such that all of my memories are erased. Most people have an equally strong intuition that I should worry, and thus they think that continuity of one's body is sufficient for one's continued existence. (I'm glossing over a lot of the details here, hopefully most will be familiar with the paper.)

The moral that at least some have drawn from this is that, with a few exceptions, thought-experiments (or thought-experiments that go beyond what we know to be nomologically possible) are unreliable. (Kathleen Wilkes says *something* like this, as does Mark Johnston.)

There are a number of things that Yablo might say about this case. His first line of response (p. 38) doesn't look promising - nobody is conflating metaphysical possibility or conceivability with epistemic possibility here. He might want to push the second line (p. 39), for he says that 'it is all too easy to believe that much of the current controversy over conditions of personal identity and survival... owes more to our meaning slightly different things by "person" and "survive" than to any real clash of modal intuitions' (p. 39) But this doesn't look like it will work here, for it is one and the same person who can conceive of a scenario that supports P, and can also conceive of a scenario that also supports not-P. Perhaps what he should say is something like the following: whether one's ability to conceive of P provides good reason for thinking that P is (metaphysically) possible depends on the situation/background against which one is imagining P (see p. 28). The difference between the two scenarios is the context in which the P fact is imagined. To use an analogy, the difference is something like that between imaging a tiger in a zoo and imaging a tiger in a wild, and finding that in the first situation one can imagine the tiger to be polka-dotted, but in the second situation one cannot. And this of course is perplexing, because whether or not tigers can be polka-dotted should not depend on their immediate environment. I take it that Yablo needs to argue that the imagined context in Williams's scenario's is not as benign as putting one's imagined tiger in the wild or in the zoo - he needs to argue that it actually changes what it is that one is imagining. Here's another example. it would be a bad result for perception if two lines drawn on a piece of paper looked parallel during the week, but appeared to curve on weekends. But it's not so bad when two lines that appear to be parallel when viewed by themselves, seem to curve when embedded in a larger picture of other lines that curve. Then we have grounds for explaining the latter case as one of perceptual illusion. Yablo needs to explain why the context of one (or both) of Williams's scenarios creates a modal illusion. Of course, he may well be able to do that, but no-one seems to have had much success at this task.

(2) A second worry that I have is one that I've bought up before. It's the problem of inter-subjective disagreement concerning essentialism about one's own identity. Yablo several times refers to the Kripkean intuition that one's origins are essential to one. Some (Aristotelians?) some to think that although one's origins are not essential to one, one's species membership is. Others (an undergrad professor of mine) think that neither one's origins nor one's species membership are essential to one. He thought that he could conceive of himself as being a poached egg (an ordinary poached egg, not an eggy creature that walks and talks). Assuming some form of modal factualism, on which at most one of these positions is correct, how do we decide which one is? Again, it seems to me that neither (1) nor (2) (see p. 39) will work here. Will (3) work? Are there defeaters for one or more of these positions? Perhaps this is where the argument would turn. Perhaps the Kripkean would claim that I couldn't have been a poached egg, for if I could, then you might just as easily have been the same poached egg, but, necessarily, I couldn't have been you. But what is
one's reason for thinking that the last claim is true? That one cannot imagine a situation in which I am you? But that seems to be just what is in question. Yablo could also argue that the disagreement between the Kripkeans, Aristotelians and the poached egg people is contaminated by theoretical commitments, but again, this would have to be argued.

Now, of course, there are lots of modal problems that (almost) everyone agrees on, e.g., I could have had something different for breakfast this morning. So the argument cannot be that people fail to exhibit agreement on a lot of modal statements. But to say this isn't to say much. The problem seems to be that there are lots of important modal statements that people don't agree on, and it's not clear that they are making some non-modal factual error or logical error that would explain their modal disagreement (p. 39). The situation here seems to be akin to that of religious discourse, and to some extent moral discourse. Most people agree on most moral judgments, but that doesn't make the job of trying to understand why there is a residue of basic and fundamental moral disagreement any easier.

(3). Why does Yablo think that 'it is inconceivable that addition facts should vary between possible worlds'? (p. 32) Presumably it's not because of some inductive generalization. It's not as if he's tried to conceive of \(2+3=5\) in one world, and \(2+3 \neq 5\) in some other world and failed, tried to imagine \(3+3=6\) in one world and \(3+3 \neq 6\) in some other world and failed, and so on, and thus induced that all arithmetical statements have their truth-values necessarily. Has he directly tried to imagine all arithmetical truths having their truth-values contingently? How would one do that? I have some sense of what is involved in entertaining the thought \(<\text{all arithmetical statements have their truth-values contingently}>\), but I have no idea of how to submit this thought to imaginative scrutiny.

To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

Loar's talk of different modes of presentation...phenomenal states are presented, or represented in our concepts differently from physical states, which are mediated by perception of extrinsic qualities rather than directly presented by intrinsic qualities...seems to be offering an explanation of why we can (and maybe necessarily do) have different concepts for possibly the same properties, but I'm not clear on exactly where Loar's mode of presentation considerations are supposed to push on the anti-materialist argument...is he claiming that the conceivability of zombie worlds doesn't warrant the move from conceivability to possibility because we are fooled into
thinking that they can actually come apart just because we can conceive of them coming apart (due to the fact that they are presented via different modes?) In other words, is he offering evidence to the effect that conceivability doesn't necessarily track possibility given the unique quality of phenomenal states? Because it seems to me that the ideal conceiver would not be mistaken by different modes of presentation, but as this has not come up as a response to Loar (to my knowledge) I wonder if I am understanding the argument or not....

From: Erik J Larson <erik1@U.ARIZONA.EDU>
Subject:      Re: Loar's mode of presentation argument
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

I take it that Loar is making the point that the conceptual independence of the phenomenal and physical is consistent with psychological differences and doesn't necessarily tell us anything about differences in expressed properties, which is just to say that the epistemic premise concerning conceptual distinctness does not entail the metaphysical conclusion concerning anti-materialism. So I take it that Loar's "mode of presentation" argument is intended as a counterexample to the move from conceivability to possibility.

I accept Chalmers's reply to Loar, i.e., that he presupposes strong psychophysical necessities rather than explaining them. So I'm not so worried about Loar, specifically. My worry is more generally the move from an epistemic premise to a metaphysical conclusion. Loar points out one possible way in which we may fail to draw solid metaphysical conclusions from epistemic considerations. The argument may be flawed in its specific guise. But I think there is a general confusion here, about exactly what the anti-materialist argument can sustain metaphysically given the epistemic starting point. I am tempted to say that the (anti-materialist) argument establishes this: Because we cannot see any necessary connection between physical and phenomenal states--the conditional P->Q is not a priori--we cannot positively establish the truth of materialism. I take it that the argument is stronger: Because physical and phenomenal states necessarily have different primary intensions, materialism is false (add in "there is a logically possible world where P holds but not Q and so on"). The second formulation of the argument gets to the conclusion, but it seems that it rests on much shakier epistemic ground.

Maybe we should add some antecedent clause, to the effect that "If we have access to the correct primary intensions of phenomenal and physical states, and if we are able to completely specify (without fear of confusion or cognitive obscurities etc) these intensions...", then we get necessarily distinct primary intensions and a positively conceivable zombie scenario and a good foothold on the anti-materialist conclusion. But for myself, all I can see is the former argument--we cannot see any necessary connection between physical and phenomenal states. And this is just a fact about what we can and can't see, and not much more. So I'm looking for someone to pull me out of the epistemic trap, so to speak (I'm guessing it will be Dave).

Erik
"What our grammarian does is simple enough. He frames his formal reconstruction of K along the grammatically simplest lines he can, compatibly with inclusion of H, plausibility of the predicted inclusion of I, plausibility of the hypothesis of inclusion of J, and plausibility, further, of the exclusion of all sequences which ever actually do bring bizarreness reactions." -- W.V.O. Subject: A Comment on Hill
Status: RO

Hill makes some interesting points about having access to the same property via two different modalities. I take it that he doesn't want his argument to rest on the distinction between a property and its mode of presentation (65). Rather, he wants to exploit the distinction between two types of imagination. So I *think* that he wants to claim that a property can be presented to types of imagination under the same mode of presentation, and yet these two presentations differ in their intrinsic character. I'm not sure his case for this claim (if it is his claim) can be maintained.

As I read him, Hill attempts to motivate this line by arguing that the same property (under the same mode of presentation?) can be presented to two different senses, and yet these two presentations can differ in intrinsic character: "Is it possible for psychological mechanisms to produce radically different experiences if those experiences are in fact presentations of the same property? Well, yes, this happens all of the time in the case of perceptual presentations. Compare a visual presentation of the surface of a piece of sandpaper with a tactual presentation of the same surface. Any two such presentations will be quite different in point of intrinsic character; but still the properties that are presented by the former will overlap with the properties that are presented by the latter (p. 67)." The trouble with this example is that in seeing a piece of sandpaper one is given a lot of information about it that one does not get in touching it, and vice-versa, and arguably that is what makes the experience of seeing that something is shaped like X different from feeling that it is shaped like X.

What we want is a case in which one *just* gets information about the paper's surface structure, and the nature of this experience is different depending on the modality, without the mode of presentation being different. It is not obvious that in such a case there would be a difference between the visual-experience and the tactile experience. (Part of the problem here is knowing what it would be like to *just* see the surface structure, or just feel the surface structure - but leave that aside.) Despite his avowed intentions, Hill seems to be simply back into the distinction between a property and its mode of presentation: there's the one property of the surface structure of the paper, and it has two modes of presentation. Seeing that something is square, and feeling that it is square may both involve the single property of squareness, but it also seems to involve two distinct modes of presentation: feeling-square and looking-square. 'Feeling-square' and 'looking-square' seem to be
distinct properties.

This issue is basically Molyneaux's question to Locke: suppose that a person blind from birth were suddenly to regain their sight, would they be able to identify objects without touching them? Or would they have to discover that feeling-square and looking-square both converged on a single property, being square? Put the issue another way: is it contingent that something looks square iff it feels square? (Perhaps we should relativise this to ideal circumstances: X looks square under ideal conditions iff it feels square under ideal conditions.

It seems important to distinguish between two types of sensory concepts here. The first type refers to properties that are accessible to different modalities, but are such that the different modalities experience them in such a way that the perceiver may not realize (even under ideal circumstances) that she is experiencing the same property. Surface structure, or squareness, may be such a property. The second type refer to properties that seem to be accessible, in some sense, to only one sense modality. (Phenomenal) red and the sounds of middle C might be such properties. Although the concept <red> and <middle C> are not "tied" or "restricted" to particular modalities - arguably they wouldn't be *concepts* if their inferential range were restricted to a modality - they do seem to be grounded in a single modality in the way that, say, <square> is not (even for a blind person).

But one might come back and say that the property red can be directly detected on the basis of non-visual cues - this is what Mary can do. The counter-reply is that Mary can use some kind of red concept, but not her concept of phenomenal red, which refers to the qualia. But now one wants to know about <visual squareness> and <tactile squareness>. Exactly how are these related? they seem to be sensory concepts, but they don't seem to be modality specific in the way that, say, <phenomenal red> is. What one attempts to refer to in thinking that X looks square is a fact about X that is also directly accessible to other modalities. Arguably, this is not the case with (phenomenal) red. In judging that X looks red, there is (arguably!) no commitment to thinking that that same property can be directly identified via some other mode of access. I take it that Hill would not like this result. He would want to resist the idea of a property (phenomenal-red, visual-squareness) that is logically modality specific.

The upshot: Hill's "2-types of imaginability" position seems to collapse into, or at least require, a "two modes of presentation" position - and he doesn't want that (I take it).

cheers,

Tim

Hm ph. (520) 298 1930
Someone asked that I post the readings for next meeting (after spring break). This meeting will be "week 8" from the syllabus, on "Does Conceivability Entail Possibility?". The main readings are:

Chalmers, Mind and Modality, part 2.
Yablo, Is conceivability a guide to possibility?
van Cleve, Conceivability and the Cartesian argument for dualism

We won't be going over the Yablo and van Cleve in huge detail, but they provide very interesting and useful background material for the general issues here, so you should go over them carefully. In seminar I will be developing the various distinctions between different kinds of conceivability in section 2.3 of the Princeton lectures, and will probably also go over the varieties over modal rationalism in 2.4. So you should concentrate especially on those sections and try to understand them and come with any questions. We'll be going over the material in 2.5 and later in coming weeks.

You should also read the Hill paper on conceivability from Philosophical Studies, if you haven't already, and Loar's paper "Phenomenal States", as these are both quite relevant.

We've talked a lot on the mailing list about general issues about consciousness and the 2-D framework, but I'd like to see us start to concentrate a bit more on the issues re modality, modal arguments, the epistemic/modal bridges, strong necessities, modal space and modal rationalism, and so on (i.e., the issues in "week 6" onward). I'd particularly like to see people getting into the details. It's good to have a broad understanding, but at the end of the day the details are where the cash value is, and there are all sorts of interesting things going on in and around the details here. And I'll be expecting term papers that really go into things carefully. So in the meantime I'd be pleased to see comments on the ins and outs of the arguments, distinctions, and the general dialectic here. That goes both for the material I've presented and for the material in the readings. The mailing list might be a particularly good place to go into these things, as it's arguably easier to go into the details carefully outside real time.

It might be good to meet twice again the week after spring break, if we can (week 9 is very light on reading, so it would make sense to schedule a double-whammy then). I go out of town on Thursday night, but Thursday at 3 would probably work for me. Let me know if it doesn't work for any of you.

--Dave.
Some comments on Yablo,

(1) I have some worries about the reliability of conceivability that Yablo either doesn't mention, or doesn't take as seriously as he should. The first is the fact that one's modal intuitions can be influenced by how the scenario that one is being asked to imagine is described. The locus classicus of this is Bernard William's wonderful paper *The Self and the Future*. In the first scenario, information from my brain is extracted and placed in your brain, and vice versa. Most people have a very strong intuition that my identity goes with my information, and thus the continuity of one's body is not sufficient for one's continued existence. In the second scenario, I am told that I will be tortured tomorrow, but not to worry, for I will be given a drug before hand such that all of my memories are erased. Most people have an equally strong intuition that I should worry, and thus they think that continuity of one's body is sufficient for one's continued existence. (I'm glossing over a lot of the details here, hopefully most will be familiar with the paper.)

The moral that at least some have drawn from this is that, with a few exceptions, thought-experiments (or thought-experiments that go beyond what we know to be nomologically possible) are unreliable. (Kathleen Wilkes says *something* like this, as does Mark Johnston.)

There are a number of things that Yablo might say about this case. His first line of response (p. 38) doesn't look promising - nobody is conflating metaphysical possibility or conceivability with epistemic possibility here. He might want to push the second line (p. 39), for he says that 'it is all too easy to believe that much of the current controversy over conditions of personal identity and survival... owes more to our meaning slightly different things by "person" and "survive" than to any real clash of modal intuitions" (p. 39) But this doesn't look like it will work here, for it is one and the same person who can conceive of a scenario that supports P, and can also conceive of a scenario that also supports not-P. Perhaps what he should say is something like the following: whether one's ability to conceive of P provides good reason for thinking that P is (metaphysically) possible depends on the situation/background against which one is imagining P (see p. 28). The difference between the two scenarios is the context in which the P fact is imagined. To use an analogy, the difference is something like that between imaging a tiger in a zoo and imaging a tiger in a wild, and finding that in the first situation one can imagine the tiger to be polka-doted, but in the second situation one cannot. And this of course is perplexing, because whether or not tigers can be polka-doted should not depend on their immediate environment. I take it that Yablo needs to argue that the imagined context in Williams's scenario's is not as benign as putting one's imagined tiger in the wild or in the zoo - he needs to argue that it actually changes what it is that one is imagining. Here's another example. It would be a bad result for perception if two lines drawn on a piece of paper looked parallel during the week, but appeared to curve on weekends. But it's not so bad when two lines that appear to be parallel when viewed by themselves, seem to curve when embedded in a larger picture of other lines that curve. Then we have grounds for explaining the latter case as one of perceptual illusion. Yablo needs to explain why the context of one (or both) of Williams's scenarios creates a modal illusion. Of course, he may well be able to do that, but no-one seems to have had much success at this task.

(2) A second worry that I have is one that I've bought up before. It's the
problem of inter-subjective disagreement concerning essentialism about one's own identity. Yablo several times refers to the Kripkean intuition that one's origins are essential to one. Some (Aristotelians?) some to think that although one's origins are not essential to one, one's species membership is. Others (an undergrad professor of mine) think that neither one's origins nor one's species membership are essential to one. He thought that he could conceive of himself as being a poached egg (an ordinary poached egg, not an eggy creature that walks and talks). Assuming some form of modal factualism, on which at most one of these positions is correct, how do we decide which one is? Again, it seems to me that neither (1) nor (2) (see p. 39) will work here. Will (3) work? Are there defeaters for one or more of these positions? Perhaps this is where the argument would turn. Perhaps the Kripkean would claim that I couldn't have been a poached egg, for if I could, then you might just as easily have been the same poached egg, but, necessarily, I couldn't have been you. But what is one's reason for thinking that the last claim is true? That one cannot imagine a situation in which I am you? But that seems to be just what is in question. Yablo could also argue that the disagreement between the Kripkeans, Aristotelians and the poached egg people is contaminated by theoretical commitments, but again, this would have to be argued.

Now, of course, there are lots of modal problems that (almost) everyone agrees on, e.g., I could have had something different for breakfast this morning. So the argument cannot be that people fail to exhibit agreement on a lot of modal statements. But to say this isn't to say much. The problem seems to be that there are lots of important modal statements that people don't agree on, and it's not clear that they are making some non-modal factual error or logical error that would explain their modal disagreement (p. 39). The situation here seems to be akin to that of religious discourse, and to some extent moral discourse. Most people agree on most moral judgments, but that doesn't make the job of trying to understand why there is a residue of basic and fundamental moral disagreement any easier.

(3). Why does Yablo think that 'it is inconceivable that addition facts should vary between possible worlds'? (p. 32) Presumably it's not because of some inductive generalization. It's not as if he's tried to conceive of \(<2+3=5> in one world, and <2+3 not=5> in some other world and failed, tried to imagine <3+3=6> in one world and <3+3 not=6> in some other world and failed, and so on, and thus induced that all arithmetical statements have their truth-values necessarily. Has he directly tried to imagine all arithmetical truths having their truth-values contingently? How would one do that? I have some sense of what is involved in entertaining the thought <all arithmetical statements have their truth-values contingently>, but I have no idea of how to submit this thought to imaginative scrutiny.

I e-mailed Alvin about using the library tomorrow. He was planning on using it 2-4, and suggested we split the difference and meet at 3:45. So that can be our tentative plan. It occurred to me also that we didn't consider the possibility of meeting earlier, e.g. at 2 or even at 12 (that way maybe Thony could make it). It probably won't be practical to make such a change even if theoretically possible, but just in case, could everyone e-mail me immediately after getting this and tell me whether an earlier time would work?

I'll be interested to hear everyone's thought on the issues about conceivability and possibility over e-mail. There are lots of interesting open issues here to discuss -- e.g. concerning (1) the definition of different kinds of conceivability (ideal conceivability, positive conceivability, etc); (2) the gap between prima facie and ideal conceivability, and our epistemic access to the latter; (3) the issue of how good a guide secunda facie conceivability is to possibility, and whether there are some interesting counterexamples (I'm very interested to hear of any!); (4) the difference between negative and positive conceivability and whether there is anything in the "twilight zone" between these (i.e., ideally negatively conceivable but not ideally positively conceivable); and so on. All thoughts on these and other relevant issues are welcome!

I should remind people that this is just like any other class where writing is due every week; not handing in work is a black mark. Now that we have real meetings, I'll relax the requirement that everyone should post at least one non-reply contribution per week. At least one reasonably substantial contribution is expected per week, but it can be a reply to or an extension of someone else's contribution.

The only reading for tomorrow are sections 2.5 and 2.6 of Mind and Modality (which hopefully you've read already). For next week, the readings are

TCM, Section 2.5
Block & Stalnaker, Conceptual analysis and the explanatory gap [web]
Byrne, Cosmic hermeneutics.
Horgan, Supervenience and cosmic hermeneutics

Block and Stalnaker is available on the web via my "online papers on consciousness" page. I have put Byrne and Horgan in the purple folder in the department office; make yourself a copy.

--Dave.
either doesn't mention, or doesn't take as seriously as he should. The first is the fact that one's modal intuitions can be influenced by how the scenario that one is being asked to imagine is described. The locus classicus of this is Bernard William's wonderful paper *The Self and the Future*. In the first scenario, information from my brain is extracted and placed in your brain, and vice versa. Most people have a very strong intuition that my identity goes with my information, and thus the continuity of one's body is not sufficient for one's continued existence. In the second scenario, I am told that I will be tortured tomorrow, but not to worry, for I will be given a drug before hand such that all of my memories are erased. Most people have an equally strong intuition that I should worry, and thus they think that continuity of one's body is sufficient for one's continued existence. (I'm glossing over a lot of the details here, hopefully most will be familiar with the paper.)

The moral that at least some have drawn from this is that, with a few exceptions, thought-experiments (or thought-experiments that go beyond what we know to be nomologically possible) are unreliable. (Kathleen Wilkes says *something* like this, as does Mark Johnston.)

There are a number of things that Yablo might say about this case. His first line of response (p. 38) doesn't look promising – nobody is conflating metaphysical possibility or conceivability with epistemic possibility here. He might want to push the second line (p. 39), for he says that 'it is all too easy to believe that much of the current controversy over conditions of personal identity and survival... owes more to our meaning slightly different things by "person" and "survive" than to any real clash of modal intuitions" (p. 39) But this doesn't look like it will work here, for it is one and the same person who can conceive of a scenario that supports P, and can also conceive of a scenario that also supports not-P. Perhaps what he should say is something like the following: whether one's ability to conceive of P provides good reason for thinking that P is (metaphysically) possible depends on the situation/background against which one is imagining P (see p. 28). The difference between the two scenarios is the context in which the P fact is imagined. To use an analogy, the difference is something like that between imagining a tiger in a zoo and imagining a tiger in a wild, and finding that in the first situation one can imagine the tiger to be polka-doted, but in the second situation one cannot. And this of course is perplexing, because whether or not tigers can be polka-doted should not depend on their immediate environment. I take it that Yablo needs to argue that the imagined context in Williams's scenario's is not as benign as putting one's imagined tiger in the wild or in the zoo – he needs to argue that it actually changes what it is that one is imagining. Here's another example. it would be a bad result for perception if two lines drawn on a piece of paper looked parallel during the week, but appeared to curve on weekends. But it's not so bad when two lines that appear to be parallel when viewed by themselves, seem to curve when embedded in a larger picture of other lines that curve. Then we have grounds for explaining the latter case as one of perceptual illusion. Yablo needs to explain why the context of one (or both) of Williams's scenarios creates a modal illusion. Of course, he may well be able to do that, but no-one seems to have had much success at this task.

(2) A second worry that I have is one that I've bought up before. It's the problem of inter-subjective disagreement concerning essentialism about one's own identity. Yablo several times refers to the Kripkean intuition that one's origins are essential to one. Some (Aristotelians?) some to think that although one's origins are not essential to one, one's species membership is. Others (an undergrad professor of mine) think that neither one's origins nor one's species membership are essential to one. He...
thought that he could conceive of himself as being a poached egg (an ordinary poached egg, not an eggy creature that walks and talks). Assuming some form of modal factualism, on which at most one of these positions is correct, how do we decide which one is? Again, it seems to me that neither (1) nor (2) (see p. 39) will work here. Will (3) work? Are there defeaters for one or more of these positions? Perhaps this is where the argument would turn. Perhaps the Kripkean would claim that I couldn't have been a poached egg, for if I could, then you might just as easily have been the same poached egg, but, necessarily, I couldn't have been you. But what is one's reason for thinking that the last claim is true? That one cannot imagine a situation in which I am you? But that seems to be just what is in question. Yablo could also argue that the disagreement between the Kripkeans, Aristotelians and the poached egg people is contaminated by theoretical commitments, but again, this would have to be argued.

Now, of course, there are lots of modal problems that (almost) everyone agrees on, e.g., I could have had something different for breakfast this morning. So the argument cannot be that people fail to exhibit agreement on a lot of modal statements. But to say this isn't to say much. The problem seems to be that there are lots of important modal statements that people don't agree on, and it's not clear that they are making some non-modal factual error or logical error that would explain their modal disagreement (p. 39). The situation here seems to be akin to that of religious discourse, and to some extent moral discourse. Most people agree on most moral judgments, but that doesn't make the job of trying to understand why there is a residue of basic and fundamental moral disagreement any easier.

(3). Why does Yablo think that 'it is inconceivable that addition facts should vary between possible worlds'? (p. 32) Presumably it's not because of some inductive generalization. It's not as if he's tried to conceive of \(<2+3=5> \) in one world, and \(<2+3 \text{ not}=5> \) in some other world and failed, tried to imagine \(<3+3=6> \) in one world and \(<3+3 \text{ not}=6> \) in some other world and failed, and so on, and thus induced that all arithmetical statements have their truth-values necessarily. Has he directly tried to imagine all arithmetical truths having their truth-values contingently? How would one do that? I have some sense of what is involved in entertaining the thought \(<\text{all arithmetical statements have their truth-values contingently}>\), but I have no idea of how to submit this thought to imaginative scrutiny.

This is interesting. Of course not everyone has both intuitions. I'd
be surprised if "most people" have the first intuition, for example.
I think a lot of people intuitively think that identity goes with the
brain, so in the first case I won't survive in the new brain. And the
strength of the second intuition is unclear. But I suppose that *if*
one has both intuitions, then one seems to be suggesting that
continuity of info is sufficient for survival, and that continuity of
brain/body is sufficient for survival. As it stands, those intuitions
aren't quite contradictory -- maybe one can survive either way?
Though it would seem to commit one to the possibility of double
survival in certain cases, which seems odd (unless one has a rule for
deciding when both criteria are present in separate cases).

But anyway, let's ignore the non-contradictoriness and think about
what to say if we really did have two contradictory intuitions here:
i.e. we find A positively conceivable, B positively conceivable, where
the possibility of A contradicts the possibility of B. I think in
such cases, one can argue that one is being inconsistent in one's
evaluation of the conceivable scenarios, and that further rational
reflection will reveal this, so both won't turn out to be ideally
positively conceivable. If the A is truly (i.e. ideally) positively
conceivable, then analysis of this will reveal that B is not, and vice
versa. And indeed I think this mirrors our reaction to the cases.
Even if one has a momentary feeling that both intuitions are
reasonable, a bit of reflection reveals the conflict and leaves us at
best uncertain, or perhaps withdrawing one of the claims completely.

Of course that's just the case where both intuitions are had in one
person. Where conflicting intuitions re personal identity are had by
two different people, it's tricky. Just say A says he can conceive of
teletransportation being survival and B says he conceives of it being
death. I suppose that's not automatically a contradiction, as maybe
they are conceiving different "further facts" in addition to the micro
facts: if one is a nonreductionist about PI one might well think that
both survival and death are positively conceivable here.

So let's take a strong case, where A says teletransportation survival
is not conceivable, and B says that it is; and B says that
teletransportation death is not conceivable, where A says that it is.
These intuitions are clearly in conflict. One possibility is that A
and B have different concepts of "survival" and "death": perhaps B has
a deflationary concept of "functional survival", whereas A has an
inflationary concept of "intrinsic survival", for example. In that
case, we might find that on disambiguation, the two agree on the relevant intuitions (teletransportation is always functional survival, never intrinsic survival). Though it may be that B will say that intrinsic survival does not exist; in that case A and B will differ not on what's conceivable but on what's actual.

Another possibility is that both are to some degree irrational, or at least are making claims that are infected by theory or wishful thinking as much as direct conceivability. For my part, for example, I think that both teleport survival and teleport death are prima facie negatively conceivable, and I don't have strong intuitions about how best to describe the positively conceivable teleport scenario. So maybe A and B should best be agnostic, though they may have reasonably strong intuitions here. Or maybe it's a place where continued rational reflection can reveal that one is right and the other wrong.

Tim also raises the case where P is conceivable against one background but not against the other. In such a case I'm tempted to say that what's here at issue is prima facie conceivability, and that even secunda facie reflection indicates that one ought to treat the two cases equally. Maybe background can bias one in a certain direction prima facie, but this biasing role should be factored out on ideal reflection.

Tim's case of conflict over essentialism is tricky. As noted in class, this is a case of secondary conceivability, i.e. intuitions about what is secondarily possible (conceivable/possible in worlds considered as counterfactual). That's often a posteriori, but arguably should be a priori conditional on the empirical non-modal facts being all in or not at issue. So what's the a priori disagreement here? Different concepts of person or object? Maybe, but doesn't seem too promising. Insufficient rational reflection? I think Kripke would say your teacher is just wrong, and not being properly rational, but of course it's not clear how to adjudicate that. Vagueness/indeterminacy/ambiguity? I'm tempted to say that the whole question of what is essential to X is somewhat vague, and I can often go that way. So maybe the fact of the matter is indeterminate, and the two are "precisifying" in different ways.

I'd like to say that insofar as the matter is determinate, it's settleable by rational reflection, and vice versa. So any irresolvable rational dispute (given that the empirical facts are in) corresponds to an indeterminacy. That's more or less the scrutability claim we'll be discussing, and it's somewhat controversial, but not wholly implausible, I think.

This also touches on the question of disagreement over a priori truths by apparently rational being. E.g., Graham Priest, a very smart philosopher, thinks contradictions are sometimes true. Most others think it is a priori (and obvious) that they never are. Is he being irrational? Well, he at least seem sane and a good reasoner. But I guess one has to say that at some level he is not being rational, even though he is to some extent "procedurally rational". Maybe some conceivability disagreements are analogous to this, where someone says something that is a priori false despite seeming procedurally rational. Maybe even the poached egg case, at a deep level?

So there are various resources for someone who endorses a conceivability-possibility link, but clearly none of this is obvious or trivial. All thoughts are welcome.
P.S. Re mathematics, I think Yablo thinks it is a priori that 3+3=6, so it isn't conceivable otherwise. If P is a priori, not-P is not negatively conceivable or positively conceivable. In any case I take it that there's no positive reason to think it conceivable that 3+3 is not 6; and the fact that it is a priori suggests that any scenario will verify "3+3=6". (Given that arbitrary a priori reasoning is allowed in seeing what verifies what.)

This seems to me to get things around the wrong way. We think that 3+3=6 is a priori *because* its negation is inconceivable, not vice-versa. This is a bit clearer with respect to geometrical truths, it seems to me. Why did Kant think that Euclidian geometry was a priori true of this world? (It's not as if it comes with a label stuck to it: 'a priori'.) He tried to conceive (imagine? visualize?) a physical world in which geometry was non-Euclidean, and failed. It seems to me that thinking P is a priori involves attempting to conceive of not-P, and being unable to. (Perhaps that should be: one is justified in thinking that p is a priori if (only if?) one has tried to conceive of not-P and been unable to.

Dave,

I didn't understand why the Mary argument is meant to involve negative possibility, while Zombies involve positive possibility. When I think about the Mary argument, (I try to) clearly and distinctly conceive of a scenario in which Mary knows all the physical facts, but can't work out the phenomenal facts. She knows all about red, she doesn't know what red is like. In those moments in which I find the argument compelling, I think that I have C and D conceived of just such a scenario. I don't see the asymmetry between the Zombie case and the Mary case.

What am I missing here?

Re Mary: It's true that one positively conceives of Mary, knowing all the physical facts but being unable to figure out the phenomenal facts. So Mary's situation is positively conceivable. But the question I was concerned with is whether "P and not-Q" (P = all the physical truths, Q = a phenomenal truth) is positively or negatively conceivable, as it's the conceivability or otherwise of this statement that hooks into the argument against materialism. Positively conceiving Mary isn't positively conceiving of a situation where P and not Q. Rather, the Mary scenario gives one good reason to believe that Q is not a priori deducible from P. That is, "P -> Q" is not a priori, i.e. "P and not-Q" is negatively conceivable.

I.e., what the Mary scenario suggests is that Mary can't a priori rule out the epistemic possibility that P is true and Q is false. That's not yet to say that such a scenario is positively conceivable. It may well be, and personally I think it is (e.g. via conceiving of zombies and inverted spectra), but that takes further argument, somewhat akin to the conceivability argument itself.

Re mathematics, Tim suggests interestingly that we say "3+3=6" is a priori precisely because we can't conceive otherwise. One subtlety here: presumably lots of complex mathematical statements M are such that we can't conceive otherwise, i.e. we can't positively conceive that not-M, but only because we can't positively conceive of either M or not-M. So perhaps the claim about "3+3=6" should rather be that in every situation of which we can positively conceive, "3+3=6" is verified. And the suggestion is that it's because "3+3=6" has this property that we say it's a priori.
Personally, I'm not certain of this. I agree that if "3+3=6" was *not* verified in some positively conceivable scenario, that would be good reason to say it's not a priori. But I'm not sure that things work the other way. Maybe there can be support for apriority which is not grounded in trying to positively conceive otherwise. E.g., a mathematical proof seems to give support for a priority that doesn't come from trying to positively conceive otherwise. Of course one can still worry about the status of the axioms and inference rules here -- maybe those are so grounded? But this is far from obvious.

One worry is that if this were the only support for an a priority claim, such a claim would always be open to the objection that we haven't tried hard enough to conceive of relevant scenarios in which P is false, or that we're suffering from lack of imagination. Maybe that is a reasonable strategy for some apriority claims (e.g. Euclid's), but it's not clear that all apriority claims are vulnerable to this sort of objection. In particular, I think we have grounds for saying that "3+3=6" is a priori without relying solely on our inability to conceive otherwise.

Maybe Tim is right that truth of P in all positively conceivable scenarios gives one reason to think P a priori. As such, it might only be defeasible reason, though. E.g. maybe Euclid did have good though defeasible reason to think Euclidean geometry a priori. Of course this eventually got defeated both by people positively conceiving of other geometries and by showing the formal consistency of other principles. It's not obvious to me that support for the a priority of all truths has this form, but it's an interesting claim.

Of course the fact that not-P is not *negatively* conceivable would be very good reason to say that P is a priori. But that's pretty trivial: to say that not-P is not negatively conceivable is to say that we can a priori rule out the epistemic possibility that not-P, which is more or less to say that we can a priori rule in P.

But it could be the case that P is true in all positively conceivable scenarios, while not-P is still negatively conceivable. E.g. because (1) we can't rule out the possibility of positively conceivable scenarios where P fails, or (2) maybe P is an odd sort of truth that is verified in *all* ideally positively conceivable scenarios, but still is not a priori. (My favorite example of the latter is "There are inconceivable features of the world.

--Dave.

I'm still having problems with the notion of ideal conceivability (IC). A couple of the suggested definitions of IC are, "conceivable on ideal rational reflection," "conceivable after all possible reasoning is done," and perhaps "will remain conceivable given any more reasoning." Roughly my worry is that IC winds up being trivially identical with logical possibility. Here is how the argument goes.

Being a non-ideal rational agent I don't know how to define ideal
rational reflection except as something like,
   (A) "given some initial premises or concepts, reasoning which
       results in all and only logically possible conclusions."

I don't mean to say that we can't say anything about ideal rationality. We can give descriptions of what rationality for us is. And the more detailed this description gets the closer we will be to describing ideal rationality. We can even suggest the removal of some of our cognitive constraints such as the lack of time. But having limited rationality places limits on what we can ultimately say about ideal rationality. What we have to go to in the end is that ideal rationality is whatever achieves (A).

Is there anything wrong with this? It looks like it is. The current debate is whether conceivability implies or is a guide to logical possibility. I take it our argument is that ideal conceivability is a guide to logical possibility. Now we need only show that secunda facie conceivability is a good guide to ideal conceivability. But if ideal conceivability is not merely a guide, but is just defined by logical possibility, the all the arguments that the conceivable doesn't imply the possible can be used to say that the secunda facie conceivable doesn't imply the IC.

What is needed is some way of defining IC that doesn't ultimately rest on logical possibility.

I have a hypothetical scenario to propose regarding the bounds of ideal a prioricity (consider it actual if you have a difficult time believing it). (joke)

Consider an apriori genius, a true "head-case", that spends most of her time in deep meditation and spends little time gathering empirical information. My intuition is that she might eventually come to be able to deduce the physical structure of her brain. After all, all the fundamental physical stuff: space, time, and matter, is right there in her head-- so it might very well be retrievable introspectively (especially in her state of being relatively clear of empirical clutter).

In short, my point is that even in meditating with respect only to a priori/ a priori deducible concepts, we might have access to physical truths as we do mathematical ones; my worry is that this "objective viewing of the mind" looks a posteriori minus the senses.

My questions:
Does the head-case case seem like a logically possible case of ideal a prioricity?

If so, how would the a priori theorist deal with my concerns? For instance, what is fundamentally different from her internal monitoring of her brain, than if she stared at her hand? Are BOTH cases a posteriori?

Erik H.
All,

I've been thinking about some ways of making the positive/negative conceivability (PC/NC) distinction clearer. Here are some thoughts on the matter.

First, NC is a bit trickier than we have been taking it to be. The official line is that something is NC iff there is no apparent contradiction in it. There aren't contradictions in *things*, so we have to be clearer about what we mean. One option is to say that a state of affairs S is NC iff the statement expressing S is apparently satisfiable. The trouble is that satisfiability requires us to picture a scenario (clearly and distinctly) which makes the statement expressing S come out true. But this is just what PC was supposed to be. So the satisfiability route won't work. The reason it won't work is instructive, though: any way of cashing out NC which is semantical will likely run into the same problem.

Maybe we can think of NC along *formal* lines. Say that a statement P is NC iff P is not apparently a contradiction, where "contradiction" is understood purely formally (as a matter of syntax, if you like). This won't quite do either: we need to add a patch to the effect that P is not apparently a contradiction, nor is it apparent that on the assumption of only P we can derive a contradiction. But the patch is in the same spirit: derivability is not a semantical consideration.

As for PC, we can treat that as a thorough-going semantical notion. A statement P is PC iff P is apparently satisfiable. Saying that P is (apparently) satisfiable requires us to picture a world in which P comes out as true. And this is what we want out of PC.

Drawing the lines in this way has some nice features. For one thing, it explains why NC seems easier to do. It's pretty hard to reason formally without relying on semantic considerations, and so it's easy to overlook formal contradictions (especially when they are derived somewhere down the line). In the Goldbach case, for instance, it is easier to pump intuitions to the effect that it is NC either way. But you can't pump any PC intuitions at all here: they aren't both satisfiable, not even apparently. Also, PC and NC can still be combined with the other dimensions of conceivability we talked about the other night.

Cheers,
Thony
To: MODALITY@LISTSERV.ARIZONA.EDU

Re Thony's comments on positive and negative conceivability. The first thing to note is that as defined, the various sorts of conceivability are all predicates of *statements* S. So S is negatively conceivable if there is no apparent contradiction in the hypothesis that S, or if one cannot rule out S a priori. Then one gets prima facie or ideal negative conceivability depending on whether one goes with surface reasoning or ideal reasoning. I think it's right to say that this is a semantic notion. Syntactic considerations re formal logic don't really play a part here. Even the talk of "contradiction" is not really essential; it's the inability to rule S out a priori that's central.

Re positive conceivability, "apparently satisfiable" is not a bad way to get at this, but of course that will come down to what "satisfiable" means here. If satisfiable means "possible", this comes down to something like van Cleve's definition of strong conceivability. One trouble there is that we want type-B materialists to come out saying zombies are conceivable but not possible; but on this definition, it's not clear that zombies will come out conceivable for a type-B materialist, as they will judge that zombies are impossible. Maybe there's a sense in which zombies are still "apparently possible" for the type-B materialist, but it's tricky to bring it out. That's why I go with clear and distinct conceptions instead (which is maybe more or less what Thony means by "picturing a world").

Re Josh's comment on ideal conceivability, I talked about this to some extent in our meeting yesterday. It's certainly true that defining "ideal reasoning" here as reasoning that tracks possibility will not be helpful, as it will render the conceivability/possibility thesis trivial. So we need some substantive notion of ideal reasoning.

Or at least, we need a substantive notion of better and worse reasoning. What's really needed is some kind of partial ordering on the space of reasoners, such that for a pair X and Y, it can be the case that X is "less limited" than Y, because X does not suffer from some cognitive limitation that Y suffers from. E.g., X has more memory or attention capacity than Y, or more concepts, or makes better inferences, and so on.

In addition to this, we also need the notion of "P is conceivable for X" (a sort of prima facie notion). Putting these two things together, we can say that P is ideally conceivable if there is some X such that P is conceivable for X, and for all Y that is less limited than X, P is conceivable for Y.

This does require the notion of a cognitive limitation and the corresponding partial ordering. I think we at least have a good intuitive grasp on this notion, though I don't claim it's 100% well defined. And I don't think it's defined in terms of logical possibility.

Still, maybe Josh's point that our own limitations limit what we can say about ideal rationality can be transferred here to the point that our limitations limit what we can say about cognitive limitations! (Maybe there are cognitive limitations we're unaware of, for example.) I'm not sure how much of a problem that is. As long as we have a good tacit grasp of the notion of a cognitive limitation, the notion of
ideal conceivability will be well-defined; what's required for the definition is that for X and Y, our statement "X is more limited than Y" can be true or false, irrespective of whether we can determine the truth or falsity. Of course this puts certain limits on our epistemic access to ideal conceivability, but we knew that already.

I suppose one might object that our notion of a cognitive limitation is so vague that for particularly advanced X and Y, our statement "X is more limited than Y" is neither true nor false, even though in some sense it "should" be true or false. I'm not sure exactly how coherent that is. At least, it seems that we can here defer to our smarter counterparts who can make the determination, so the truth of our statements of cognitive limitations is to some extent parasitic on their judgments. Or maybe one can just say that the very fact that the claim in question "should" be true or false suggests that our claim is true or false, it's just that we don't know it. (Like saying that certain mathematical statements are true/false even though we don't know it.) A tricky issue.

The strategy mentioned above also helps with the potential circularity problem. We want to connect possibility to ideal conceivability, but ideal conceivability is defined in terms of possibility (what various possible smarter beings can conceive). The conc-poss claim wasn't really intended as a reductive definition of possibility, so I'm not sure how much of a problem that is, but in any case, I'd like to think that any circle here is informative rather than vicious. Even if we defined ideal conceivability in terms of what certain conceivable beings could conceive, thus might be nontrivial, as long as we have facts about what we can conceive to get things off the ground. We can conceive of beings who lack some of our cognitive limitations, and they will be able to conceive of things that we can't conceive, among which things will be beings smarter than them, who will be able to conceive of things that they can't conceive, and so on. So maybe the circle here will be "expanding" and will eventually settle on a useful substantive notion of ideal conceivability.

At least, it would be nice if it did! But I can't claim that anything here is crystal clear. All thoughts are welcome.

Van Cleve suggests that a proposition P is *weakly conceivable* for S iff S does not "see" that P is impossible. I realize that it is perhaps undesirable to include possibility in one's definition of conceivability. Nevertheless, I thought that weak conceivability sounds rather like negative conceivability. Van Cleve dismisses weak conceivability as a guide to possibility because of the Goldbach example: since we seem to be unable to see either that Goldbach's Conjecture is true or that it is false, we do not see either G or not-G as impossible, Thus, since we can weakly conceive of both and they are contradictory, weak conceivability cannot be a guide to possibility.

I do not really see how negative conceivability is different weak
conceivability. We could introduce the notion of ideal weak conceivability, which would presumably rule out the contradiction implied by the GC case-- presumably there is an ideal concever who can see that either G or not-G is impossible. Or, if by "seeing" we mean "clear and distinct perception", it does not seem clear that we can weakly conceive either G or not-G.

I think the point I am trying to make here is somewhat similar to Josh's--it seems that, even though the definitions of the various types of conceivability do not explicitly refer to possibility, the notion of possibility is in some sense required to make sense of conceivability.

You're right that negative conceivability is a lot like van Cleve's weak conceivability (and positive conceivability is a lot like van Cleve's strong conceivability). I prefer to define it without making direct reference to possibility and impossibility: P is prima facie negatively conceivable if one cannot rule out P a priori, and P is ideally negatively conceivable if not-P is not a priori.

van Cleve's notion is obviously similar to this, at least if we restrict to the domain of primary possibility and conceivability. For P to be prima facie negatively conceivable (for S) is for S to rule P out a priori, which is for S to judge a priori that the actual world is a world where P is false, which is for S to judge a priori that all worlds considered as actual are worlds where P is false, which for S to judge a priori that P is 1-impossible, which is almost for P to be weakly conceivable for S. The main loophole is the chance that one might see that P is 1-impossible without judging this a priori; if so, P might be negatively but not weakly conceivable. That sort of loophole is common for 2-possibility, but rare for 1-possibility.

either G or not-G.

Right, weak conceivability isn't a good guide to possibility for the
same reason that prima facie negative conceivability isn't (e.g. the
cases you discuss above). Your two suggested corrections to the
notion correspond to ideal negative conceivability and to prima facie
positive conceivability respectively, both of which are much better
guides to possibility.

I think the point I am trying to make here is somewhat similar to Josh's--
it seems that, even though the definitions of the various types of
conceivability do not explicitly refer to possibility, the notion of
possibility is in some sense required to make sense of conceivability.

Well, I'd like to think my way of defining things doesn't import the
modal notion as directly as van Cleve's. As usual, though, modal
notions may be playing a subtle role, especially in the idealized
version (which is in effect about what *can* be known a priori by some
possible being).

From: Angela J Burnette <aburnett@U.ARIZONA.EDU>
Subject:      Re: positive and negative conceivability, ideal conceivability
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

Regarding Josh's comments about ideal conceivability and Dave's responses,
there seems to be some slippage between thinking of the ideal
conceiver as being a better reasoner in terms of further
reasoning/cognitive powers and being a better reasoner in terms of
different reasoning/ cognitive powers...Sometimes it has been asserted
that the ideal concever is merely faster, older, and the like, but
basically of the same kind, and at other times the ideal concever has had
capabilities predicated of it that would seem to suggest that its powers
of conceivability are of a different kind altogether, for example Brad's
speculation that the ideal concever could possess the concepts of what
it's like to be a bat(shouldn't such phenomenal concepts be instrinsic to
the bat by definition?), or the idea that the ideal concever could be
aware of its own cognitive limitations (it seems like it could be aware
of ours, but not its own if it merely possesses further reasoning
powers, beings that are like us should be cognitively closed to their
own cog. limitations)... it seems to me that we can only legitimately
abstract away from
our own case if we are considering further reasoning which is basically of
the same kind as our own...i.e. something like faster reasoning by a being
with infinite time and memory... but if
we are considering a concever who is better in virtue of being a
different kind of reasoner, then I'm not sure we are warranted in our
abstractions...an additional worry for me is that in order to get the move
from conceivability to possibility off the ground we have to posit a
conceiver who would not need to make that jump...i.e., it is unclear to me
that something like what Josh has argued for isn't the case because
positing the ideal concever is like collapsing the explanatory gap rather
than bridging it...So, I would like some clarity on either why nothing
said of the ideal concever makes him of a different kind than us, or, why
this isn't a problem for abstracting away from our own case...
I have a concern similar to Angela's re the ideal conceiver. We need a notion of ideal rational reflection, but it seems that it must be of a kind that we can plausibly extend from our own cognitive powers. This would seem to preclude an ideal conceiver capable of understanding its own cognitive limitations or anything as miraculous as that.

We need a notion of "rational reflection" that is not different in kind than what we presently have (or any natural extension of that). Given this more modest extension of reasoning powers, however, there should be plausible counterexamples to the thesis from apriori reasoning to necessity. The Godel case, for one. This goes as follows. Given a minimum requirement for rationality--say, that any rational process could be described systematically or as a sequence of steps--we could not have an ideal conceiver solving any number-theoretic statements (Diophantine equations, say) without limit. This would place the notorious Godel formula outside the limits of ideal rational reflection. If, on the other hand, the ideal conceiver could have apriori access to the primary intensions of G statements, we would of course thwart these cases as real counterexamples, but at the expense of rendering the notion of "rational reflection" or more generally "thought" very vaguely defined, and of little help in the task of extending the scope of conceivability outward from our own case, for which, as Angela points out, we should have something of the same "kind".

So I think we've got, on the one hand, some potent counterexamples to theses like strong aprioricity and negpos, and on the other we've got a notion of "thought" or "rational reflection" that pulls too far away from our own case.

Re Angela's and Erik's comments on ideal conceivability:

Angela writes:

>Regarding Josh's comments about ideal conceivability and Dave's responses,
>there seems to be some slippage between thinking of the ideal conceiver as being a better reasoner in terms of further reasoning/cognitive powers and being a better reasoner in terms of different reasoning/ cognitive powers...Sometimes it has been asserted that the ideal conceiver is merely faster, older, and the like, but basically of the same kind, and at other times the ideal conceiver has had capabilities predicated of it that would seem to suggest that its powers of conceivability are of a different kind altogether, for example Brad's speculation that the ideal conceiver could possess the concepts of what it's like to be a bat(shouldn't such phenomenal concepts be intrinsinc to the bat by definition?), or the idea that the ideal conceiver could be aware of its own cognitive limitations (it seems like it could be aware of ours, but not its own if it merely possesses further reasoning powers, beings that are like us should be cognitively closed to their own cog. limitations)...

Well, it's true that we don't have an exhaustive list of the relevant cognitive limitations. It would be nice if we did, but at least so far, it isn't in sight. Still, what matters is that we have a determinate enough concept of limitation such that there's a fact of the matter about whether A is less limited than B (whether or not we now explicitly include that limitation in any list).
The case where B has concepts that A does not seems to be a straightforward case of that. So if B is just like us except that B has further concepts (further phenomenal concepts, say), then it seems reasonable to say that B is less limited than us in the relevant sense. So I'd like to think this isn't an unreasonable idealization. Indeed, in the standard definition of apriority, we say P is a priori if someone *who has the relevant concepts* can know P with experience-independent justification. On this definition it seems reasonable to say that there can be a priori relations among alien phenomenal concepts, even though we don't have those concepts.

You raise the interesting issue of whether any non-bat could have a concepts that can describe a bat's experience. This is tricky, but I'm not sure why it should be ruled out by definition. I can conceive of what it is like to be certain other humans (at least in certain respects, e.g. visually) even though I'm not them. And arguably I might conceive roughly of what it's like visually to be a dog, even though I'm not a dog. There's nothing contradictory about the idea that my phenomenal concepts might apply to another being's experience. And if I can do it with dogs, there's no obvious reason why some other being could do it with bats.

Problems would arise if it turns out that there are some phenomenal concepts that simply can't be had by other beings. Or perhaps, phenomenal concepts that simply can't be had by sophisticated beings. Just say experience E (perhaps the experience of stupidity?) could not be had by a sufficiently smart being, and further that such a being could not even form a direct concept of that sort of experience. If that were the case, then arguably the idealization here won't help in determining what's a priori or ideally conceivable re E (relatively ideal conceivers won't even have the concept!). That would be awfully tricky; but it's not obvious that such concepts exist.

If such concepts exist, they don't raise problems for the inference from ideal conceivability to possibility, but they might raise difficulties for the inference from possibility to ideal conceivability. These are problems in the same vicinity as the "open inconceivabilities" I mentioned last week. I think such inconceivabilities are probably the biggest obstacle to "pure modal rationalism"; but even the "strong modal rationalism" that survives without them is pretty strong. And of course, it is not obvious that such inconceivabilities really exist.

Re your second problem above: we are aware of some of our cognitive limitations, so why shouldn't a less limited being also be aware of theirs? And maybe they could even be aware of cognitive limitations they we haven't thought of yet? This is not to say that they can transcend those limitations, of course, any more than we can.

In both cases, I'd like to think that we're bringing in idealizations that are of a sort familiar from our own cases. We know some people have concepts that others lack, and we know that we're aware of some cognitive limitations. So it doesn't seem too great a stretch to shift to beings with concepts that we lack, and beings that are aware of cognitive limitations that we haven't thought about. Once we have the latter, we then have the "bootstrapping" possibility of removing those limitations in turn. So I'd like to think that this sort of idealizing can take us a fair way. Exactly where it takes us, of course, is not entirely obvious.

> it seems to me that we can only legitimately
abstract away from our own case if we are considering further reasoning which is basically of the same kind as our own... i.e. something like faster reasoning by a being with infinite time and memory... but if we are considering a conceiver who is better in virtue of being a different kind of reasoner, then I'm not sure we are warranted in our abstractions...

The case of more concepts is like the cases of time and memory, I hope. Maybe the "second-order" idealizations (the ones we haven't thought of) go beyond this. And maybe that does raise a question about how well we can judge whether something is ideally conceivable or not. Of course there is a legitimate epistemic worry here: ideal conceivability is not epistemically transparent to us. But that's compatible with saying (i) there's a fact of the matter about whether P is ideally conceivable (whether or not we can know it), and (ii) in many cases, we can know whether or not P is ideally conceivable (e.g., we know it's ideally conceivable that something exists, and we know it's not ideally conceivable that 0+0=1). So there's a fair amount we can know, even if things get hazy around the edges.

an additional worry for me is that in order to get the move from conceivability to possibility off the ground we have to posit a conceiver who would not need to make that jump... i.e., it is unclear to me that something like what Josh has argued for isn't the case because positing the ideal conceiver is like collapsing the explanatory gap rather than bridging it... So, I would like some clarity on either why nothing said of the ideal conceiver makes him of a different kind than us, or, why this isn't a problem for abstracting away from our own case...

Hmm. I suppose the idea here is that (on the type-B position) a relatively ideal reasoner would just see that zombies are impossible, and would not be able to (positively or negatively) conceive of zombies? It's not obvious to me why this should be the case. Even the first half isn't obvious, but the second half is particularly unclear to me. What will rule out the clear and distinct conception of zombies for the ideal reasoner? Maybe something substantive in the a priori domain -- but then we just have type-A or type-C materialism, which is compatible with strong modal rationalism. If it's just that the reasoner knows that zombies are impossible, it seems to me that he/she would say, OK, zombies are ideally conceivable, they're just not possible. Presumably the ideal reasoner will be able to form just as clear and distinct a conception as we can, absent some substantive a priori obstacle.

So anyway, if this is right, it seems to me that we're not buying the conceivability/possibility link trivially. Someone like a type-B materialist who denies the link will still deny it on this way of putting things. Of course *if* there is a deep a priori contradiction in the notion of a zombie just that a relatively ideal reasoner will find it, then zombies will come out both conceivable and impossible, but that's as it should be.

(Maybe this does argue for not defining "positively conceivable" in terms of "seems possible", though. One could (could) argue that for the ideal reasoner, all and only the possible will seem possible, in which case the CP link will be trivial. This claim about the ideal reasoner is not obvious to me, but in any case, one can avoid the trivializing conclusion by going for a definition of positive conceivability that is not cast in terms of possibility. E.g., the clear and distinct conception idea.)
Let me know if I've missed some of the point here.

Erik writes:

Again, I'm not sure what's miraculous about understanding one's
cognitive limitations. Even we can do that!

> formula outside the limits of ideal rational reflection.

Well, even with the step-sequence restriction (a computability
restriction, let's say), any given statement of mathematics (our Godel
sentence G, say) could arguably still be knowable by *some* relatively
ideal reasoner. (This arguably follows from the considerations about
iterated Godelization that I previous attributed to Kleene, but which
Shaughan tells me should be attributed to Feferman.) Of course no
reasoner would know every truth, but every truth might be known by
some sufficiently sophisticated reasoner, which is all we need.

It's also not obvious why the computability restriction is essential.
I'd argue that we can form a pretty decent conception of e.g. a being
who can check out the truth of P(n) for all n at once. The idea is
that when we can determine the truth of P(n) for any given n, but
can't determine the truth of forall(n) P(n), this is due to a
limitation on our part (e.g. seriality, or finite parallelness) that
can be idealized away from. Of course the idealized being here won't
be computable, but it's arguably still quite coherent. Though maybe
it will still induce queasiness.

> If, on the other
> hand, the ideal conceiver could have apriori access to the primary

> something of the same "kind".

Right. If we simply defined the ideal reasoner as being able to
determine the truth of any mathematical statement M, that would by the
conclusion too cheaply. I'd like to think that neither of the methods
of idealization suggested above is quite as cheap as this, though. In
each case we're abstracting away from a clear cognitive limitation on
our part, such that we have at least a rough and ready conception of
what a being that does not suffer from that limitation might be like.
So I think we've got, on the one hand, some potent counterexamples to
theses like strong aprioricity and negpos, and on the other we've got a
notion of "thought" or "rational reflection" that pulls too far away from
our own case.

Right. I'd like to think that the idealizations suggested above give
at least a potential "middle road". Of course the question is whether
such a middle road will work across the board. If we characterize the
reasoning powers too weakly, we get the counterexamples to
scrutability, negpos, etc. If we characterize them too strongly, we
buy the conclusion at cost of making it entirely trivial. I'd like to
think the middle road above yields the desired conclusion while
earning it nontrivially. The hope is that something like this will
work across the board. But I don't have anything like a proof of
that.

The first antecedent clause you mention seems to be required, but not the
second one (the ability to completely specify the intensions). I assume
that by "specify the intensions" you mean something like to be able to
give a description. But notice that we haven't really done that for
water, but instead use the phrase "watery stuff" as shorthand or to get a
grasp on the intension. Yet, we aren't troubled with the identification of
water and H20.

What is required is the assumption that our considerations of actual and
counterfactual scenarios (conceiving of worlds as actual or
counterfactual) engages our primary intensions and can be used as evidence
for the nature of those intensions.

Your worry about getting out of an epistemic trap, though, is interesting.
It seems to me that one can always raise worries about going from an
epistemic conclusion to a metaphysical one--that follows straightforwardly
from the fact that we can't rule out evil demons and the like. But if we *assume* that mad-dog skepticism is false, then I'm not sure we should
be all that worried about the move from conceivability to possibility
(being careful in the ways we have discussed, that we are correctly describing the world that we are conceiving, etc.).

Right, I think that's what he's up to. He's trying to give reasons why even primary conceivability does not track primary possibility. He thinks that certain phenomenal and physical concepts can have different modes of presentation but still have the same primary intension across possible worlds, or as he puts it, "express the same property". If that were so -- i.e. if cognitively unconnected concepts could have the same primary intension -- he'd certainly have a way to block the epistemic/modal bridge. But I think his explanation ends up assuming what he needs to explain.

(N.B. This harks back to an earlier post of Tim's re Hill, which I haven't answered. Tim suggested that Hill didn't want to rely on a distinction between property and mode of presentation; so that on his view two cognitive distinct concepts might have the same mode of presentation. I'd be surprised if this were Hill's view, though. I think he thinks that the concepts in question have different modes of presentation; it's just that those modes express (not just refer to) the same property. It's almost definitional in much of philosophy that a mode of presentation is precisely what account for the cognitive distinctness of two concepts.

Tim's examples of tactile and visual experience of a property seem to involve a difference in both mode of presentation and in expressed properties. One concept fixes reference by "what causes this visual experience", one by "what causes this tactile experience"; different reference-fixing properties, even if the same property referred to. Of course if there are concepts like this which are a priori connected (a la Molyneux), then we'll have the same expressed property, but the thesis in question won't be endangered.)

Re ideal conceivers, I'm not sure why the two modes of presentation might not still be distinct even for them. Maybe the ideal reasoner
will know that the two concepts pick out the same property, just as
Loar and others type-B materialists "know" this. But Loar and the
others can still conceive of zombies, etc. So it seems to me that the
ideal reasoner might equally still find zombies conceivable, even if
he/she knows that they aren't metaphysically possible. To deny that
would require an a priori connection between the concepts, and I don't
think Loar thinks there is such a thing.

Maybe the ideal reasoner could close the gap *if* the epistemic
distinctness of the concepts was due to a cognitive limitation on our
part. But I don't think that's really what Loar thinks. He says
explicitly somewhere that even ideal reasoning won't connect the
concepts a priori. As before, I think that's the central distinction
between the type-B and type-C materialists.

The argument may be flawed in
its specific guise. But I think there is a general confusion here, about
given the epistemic starting point. I am tempted to say that the
(anti-materialist) argument establishes this: Because we cannot see any
necessary connection between physical and phenomenal states--the
conditional P→Q is not apriori--we cannot positively establish the truth
of materialism. I take it that the argument is stronger: Because
physical and phenomenal states necessarily have different primary
intensions, materialism is false (add in "there is a logically possible
world where P holds but not Q and so on). The second formulation of the
argument gets to the conclusion, but it seems that it rests on much
shakier epistemic ground.

Well, the second is closer. I'd rather say something like "because
physical and phenomenal concepts are not a priori connected, they have
distinct primary intensions, so [via a chain of reasoning] materialism
is false". Now, your objection is that the argument establishes only
that we can't see the connection between the intensions. I can see
two ways this might do. (1) We can't see an a priori connection, but
a smarter being could see an a priori connection. (2) There's no a
priori connection, but the two primary intensions are identical all
the same. The first is the type-C materialist position; the second is
the type-B position. The first preserves a deep epistemic/modal link,
so perhaps you're pointing to the second.

What's wrong with the second? Well, my argument relies on one of the
various epistemic/modal bridging principles (whether the strong a
priority thesis, or the positive conceivability to possibility thesis,
or...), which seem to hold in all the usual cases. So denying them
arguably would lead to a sui generis exception, which might be seen as
ad hoc. And arguably this would make metaphysical modality brute and
inexplicable. But the central reason against them I think is the
argument against "modal dualism" that I outline toward the end of the
PPR reply. We'll be talking about those considerations in more detail
in a couple of weeks.

Maybe we should add some antecedent clause, to the effect that "If we have
access to the correct primary intensions of phenomenal and physical
states, and if we are able to completely specify (without fear of
confusion or cognitive obscurities etc) these intensions...", then we get
necessarily distinct primary intensions and a positively conceivable zombie
scenario and a good foothold on the anti-materialist conclusion. But for
myself, all I can see is the former argument-- we cannot see any necessary
connection between physical and phenomenal states. And this is just a
fact about what we can and can't see, and not much more. So I'm looking
> for someone to pull me out of the epistemic trap, so to speak (I'm
guessing it will be Dave).

Well, hopefully the above helps. Your point here is that if we don't
have perfect a priori access to primary intensions, we can jump to
false conclusions. And that seems right. Again, there seem to be two
different sorts of gap. First, we haven't done enough (or good
even a priori reasoning, so we think the two concepts have
different PIs even though better reasoning would reveal they are the
same. ("A=B" is a priori, we just haven't figured that out yet.)
Second, the two concepts have the same PI even though that's not
brought out by any amount of a priori reasoning ("A=B" is not a priori
but is still 1-necessary). Type-C and type-B respectively, again.
The former position keeps the epistemic/modal bridge but exploits our
potential cognitive limitations. The second junk's the bridge. I'm
not sure which exactly you're pointing to here. On my view, the
second is problematic because of modal dualism, and the first is
problematic because it seems that the only remotely tenable way to
support it is some sort of analytic functionalism, which seems to get
the meaning of phenomenal concepts wrong.

The general question of a priori access to primary intensions is very
interesting and important, though. It connects to the scrutability
issue. Basically, some parts of the 2-D framework assume that for a
concept C and a given world W, given a specification of W, we can a
priori determine what the reference of C in W (considered as actual)
is. Same for truth-value of statements S. That seems to plausibly
fit many cases, the armchair methodology in the theory of reference,
etc. But it does presuppose something like the generalized
scrutability thesis: that given a complete qualitative description of
the actual world (and of actual-world candidates), one can know the
reference of our terms and the truth-value of our statements.

What is scrutability is false? E.g., just say the epistemic theory of
vagueness is correct, so one can't know the truth-value of some "X is
tall" given complete qualitative info. Or just say there are
mathematical statements that are true and necessary but not a priori?
Then in a certain sense, the primary intensions of the relevant terms
and statements are not a priori accessible. E.g. the math statement
might have its primary intension true in all worlds, but we couldn't
know that. And something similar for the vague statement.

In these cases, I think one can say that the notion of a primary
intension splits into two notions. There is the *fixing intension*,
which goes with what the reference or truth-value in a given world
would really be (if that world is actual). And there is the
*epistemic intension*, which goes with the best a priori judgment
about what the reference or truth-value in a given world will be.

In the vagueness case, the fixing intension of "X is tall" might be
true or false in all worlds, while the epistemic intension is
indeterminate in many of them. In the mathematical case, the fixing
intension of P might be true in all worlds, while the epistemic
intension is indeterminate. And so on.

I'd like to think that the scrutability thesis is true, so these cases
can't arise. If so, the fixing intension and the epistemic intension
are always the same. If such cases do arise, though, things get
tricky.

What if an opponent suggests that the consciousness case is like this?
In fact, Joe Levine and Andrew Melnyk have both suggested that a loophole may arise from the assumption of accessibility of primary intensions (see Levine's review). I think that inaccessibility of PI may not be enough for the materialist here. In the cases above, this inaccessibility delivers inscrutable truths (gaps between negative conceivable and possibility). But zombies are positively conceivable, so the opponent needs strong necessities, not just inscrutable truths. And it's not clear that inaccessibility of PIs can deliver strong necessities. At the very least, it would need a much more radical form of inaccessibility (e.g. one that positively misleads us about a PI, rather than just not telling us everything).

Subject: Re: ideal conception
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: RO

I want to echo some of Angela's concerns here, and particularly take issue with point ii) that Chalmers makes:

> The case of more concepts is like the cases of time and memory, I hope. Maybe the "second-order" idealizations (the ones we haven't thought of) go beyond this. And maybe that does raise a question about how well we can judge whether something is ideally conceivable or not. Of course there is a legitimate epistemic worry here: ideal conceivability is not epistemically transparent to us. But that's compatible with saying (i) there's a fact of the matter about whether P is ideally conceivable (whether or not we can know it), and (ii) in many cases, we can know whether or not P is ideally conceivable (e.g., we know it's ideally conceivable that something exists, and we know it's not ideally conceivable that 0+0=1). So there's a fair amount we can know, even if things get hazy around the edges.

Josh posed a concern about whether we have cognitive limitations that limit what we can say about our cognitive limitations. Dave responded by suggesting that we have a grasp of our own cognitive limitations which we can use as a springboard to get to an ideal conceiver. We can conceive of beings which lack our cognitive limitations, those beings can conceive of smarter beings which lack their cognitive limitations and so forth in an expanding circle. Hopefully, this will eventually give us a useful notion of an ideal conceiver.

But this seems problematic to me. Given that we may not be aware of our own cognitive limitations, it seems that we do not really have access to ideal conceivability. (point ii) How do we know that it is not conceivable that 0+0=1 or that there are round squares? Perhaps we have a cognitive limitation that we do not come close to recognizing which prevents us from seeing that these things *are* ideally conceivable. If we do not have access to what an ideal conceiver can conceive of, this seems to seriously hamper our ability to do metaphysics, particularly when it comes to determining logically possible worlds.

It's true that our epistemic access to ideal conceivability is limited
by not knowing exactly what a relatively ideal conceiver could and
couldn't conceal. But I'd like to think it isn't this limited. I
think we *know* that 0+0=1 and we know that this is a priori.
Similarly, I think we know that it is a priori that there are no round
squares. Given that we know that, we know that round squares are not
(positively or negatively) conceivable even for a relatively ideal
reasoner, and the same for 0+0=1.

It seems to me that to be skeptical about these things is just to be
skeptical about whether we really know a priori that 0+0 is not 1.
After all, if a smart enough being can conceive of a world such that
if that world is actual, 0+0=1, then we can't know a priori that 0+0
is not 1. Now maybe that's an interesting sort of skepticism, but I
don't think talk of ideal conceivability makes it more or less
plausible. I take it most of us think we have reasons to think
"0+0=0" is true and a priori; so we have good reason to believe that
even an ideal conceiver couldn't conceive otherwise.

Similarly, I think we have reason to believe that "round squares do
not exist" is a priori, so we have good reason to believe that even
relatively ideal reasoners can't conceive of them. And we have good
reason to believe that "there is a phone on this desk" is a
posteriori, and that even a relatively ideal reasoner could conceive
otherwise. That's to say, we have good reason to believe that any
amount of further and better reasoning isn't going to change the
status of the knowledge here.

The moral, perhaps, is that even though we can't give an exhaustive
characterization of what makes for relatively ideal reasoning, that
doesn't mean we have no grip on what sort of things relatively ideal
reasoning can and can't tell us. To be skeptical about that, I think,
would be to be skeptical about our reasoning processes in general.

--Dave.
In Dave's response to Angela re the capabilities of the "ideal conceiver", he suggests that, "...Arguably, I can conceive roughly of what it's like visually to be a dog, even though I'm not a dog." This seems to be accurate. Whereas we have rod and cone structures in our eyes, dogs only have rod structures (I think..). Given that we have good reasons for thinking that cones are responsible for our experience of color, we think that dogs see in black and white. It seems quite straightforward to imagine the visual experiences of a dog-- they are probably somewhat like the experience of seeing a black and white movie.

It seems to me that it is somewhat more difficult to conceive of a dogs olfactory experiences. Avalanche rescue dogs are capable of quickly detecting the odor of people buried beneath considerable amounts of very hard snow (3 meters or more, sometimes). They are further able to distinguish the smell of the buried victim from the smell of the person handling them and other rescuers on the scene. I was once buried in a snow cave some six feet below the surface, and the rescue dog found me and had dug down to me in about 2 minutes.

I don't have the faintest idea what it would be like to be able to make the kinds of olfactory discriminations that dogs are capable of making. It does not seem to be me to be particularly likely that even an ideal conceiver would be able to do this. I seems fairly straightforward to imagine a what a dog's visual experiences are like because we assume that their visual experiences are somehow less rich than our own. But, given that dogs have olfactory capabilities far superior to ours, it just doesn't seem plausible to suggest that any non-canine being, however idealized and with whatever instrumentation you please, could conceive of what a dog's olfactory experiences are like.

I'm not sure if all of this amounts to anything (except praise for the virtues of dogs).

Anthony
Both open inconceivabilities and inscrutabilities fall into (or are closely related to) the "twilight zone" of statements that are negatively conceivable but not positively conceivable, but they are different. Informally, the difference is that open inconceivabilities (e.g., "there are inconceivable features of the world") are verified as *false* in all complete positively conceivable scenarios, whereas inscrutabilities (e.g., some wondrous mathematical statement?) are *unsettled* in some complete positively conceivable scenarios.

I'll work through this and some other relevant things in more detail. To start, here are some of the definitions.

S is in the TWILIGHT ZONE if S is negatively conceivable but not positively conceivable. [N.B. "Ideal primary" is assumed throughout.]

NEGPOS PRINCIPLE: If S is negatively conceivable, S is positively conceivable. [I.e., there is nothing in the twilight zone.]

D is PC-COMPLETE if (a) D is positively conceivable, and (b) if D-and-F is positively conceivable, then D implies F.

Note: This is a slight variation on the definition of PC-completeness given before. It's straightforwardly equivalent to the previous definition, but is hopefully a little more intuitive. Also, recall that "A implies B" should always be read as "A -> B is a priori".

S is an INSCRUTABLE TRUTH if S is true and some PC-complete truth D does not imply S.

SCRUTABILITY OF TRUTH: If D is a PC-complete truth and S is true, then D implies S. [I.e., there are no inscrutable truths.]

Explanation: scrutability of truth says that all truths are implied by a complete qualitative description (i.e. a PC-complete description) of the actual world.

Next we generalize this to all possible worlds:

S is a GENERALIZED INSCRUTABLE if there exists some PC-complete D such that D-and-S is negatively conceivable, but D does not imply S.

D is NC-COMPLETE if (a) D is negatively conceivable, and (b) if D-and-F is negatively conceivable, then D implies F.

GENERALIZED SCRUTABILITY: If D is PC-complete, D is NC-complete.

Note: I didn't define generalized inscrutables, as opposed to generalized scrutability, in the lectures or notes, but the definition here is the natural one. Basically we take the definition of an inscrutable truth and relax the requirement that D hold of the actual world, and that S be true there.

Similarly, generalized inscrutability is the natural generalization of the inscrutability of truth. In effect, it says that for any possible world, a complete qualitative description of that world leaves nothing unsettled. It's easy to see that generalized scrutability as defined says precisely that there are no generalized inscrutabilities. (If this isn't obvious to you, working through it should be a worthwhile exercise.)
S is an OPEN INCONCEIVABILITY if S is negatively conceivable, but for all PC-complete D, D implies not-S.

NOINCONCEIVABILITY: No S is an open inconceivability.

It's straightforward to see that if S is an open inconceivability, it cannot be a generalized inscrutable, and vice versa. If S is an open inconceivability, it is verified as false in every PC-complete scenario, so it can't be left unsettled in any PC-complete scenario, which is what inscrutability requires. More formally: S is an open inconceivability \( \iff \) for all PC-complete D, D implies not-S \( \iff \) there is no PC-complete D such that D-and S is negatively conceivable \( \rightarrow \) S is not a generalized inscrutable.

It's nevertheless true that both open inconceivabilities and generalized inscrutables, if they exist, would provide counterexamples to NEGPOS and inhabitants of the twilight zone. To see this:

(i) If S is a generalized inscrutable, then there is some PC-complete D such that D-and-S is negatively conceivable but D does not imply S. In this case D-and-S is negatively conceivable but not positively conceivable (if D-and-S were positively conceivable, D would not be PC-complete). So D-and-S is in the twilight zone.

(ii) If S is an open inconceivability, then S is negatively conceivable. But S is not positively conceivable: If S were positively conceivable, then there would be some PC-complete D such that D implies S.** So S is in the twilight zone.

[** This is a general principle about PC-completeness that is nontrivial but not hard to argue for. If S is positively conceivable, one can in effect construct D by conjoining as much as one can to S while still retaining positive conceivability. A maximal such conjunction will be PC-complete. The nontrivial part is making the case that there will always be a maximal conjunction here, as opposed to an ever-increasing series without a maximal element, but I think that case can plausibly be made. If the claim is doubted, we need to slightly modify the definition of open inconceivability.]

So, if NOINCONCEIVABILITY or GENERALIZED SCRUTABILITY is false, then NEGPOS is false.

The reverse also holds, as I said in class. Here's the proof I didn't have time to give. Just say NEGPOS is false, and there is some S that is negatively conceivable but not positively conceivable. Is S ruled out by all PC-complete D? If yes, then S is an open inconceivability, so NOINCONCEIVABILITY is false. If no, then there is some PC-complete D such that D does not imply not-S. But D cannot imply S (if it did, then S would be positively conceivable). So S is a generalized inscrutable, and GENERALIZED SCRUTABILITY is false.

All that is to say that NEGPOS is equivalent to NOINCONCEIVABILITY and GENERALIZED SCRUTABILITY. Or more informally, that the character of the twilight zone is exhausted by open inconceivabilities and generalized inscrutables.

All this provides a closer analysis of modal rationalism. Pure modal rationalism says that S is positively conceivable iff it is negatively conceivable iff it is possible. Weak modal rationalism says just that
if S is positively conceivable, it is possible (i.e. there are no strong necessities). Strong modal rationalism says that if S is negatively conceivable, it is possible (i.e. there is nothing in the twilight zone).

PURE MODAL RATIONALISM:  pos con <-> neg con <-> pos
WEAK MODAL RATIONALISM:  pos con -> poss
STRONG MODAL RATIONALISM: neg con -> poss
NEGPOS:                   neg con -> pos con

It's not hard to see that pure modal rationalism is equivalent to the conjunction of weak modal rationalism and the negpos principle. Clearly, PMR entails WMR and NEGPOS. In the reverse direction, if WMR and NEGPOS hold, then neg con -> pos con -> poss. It's obvious that poss -> neg con (if something is possible, it can't be ruled out a priori), so the circle is closed: neg con <-> pos con <-> poss.

So, pure modal rationalism is equivalent to the claim that there are no strong necessities and nothing in the twilight zone. This in turn is equivalent (via the previous discussion) that there are no strong necessities, no generalized inscrutables, and no open inconceivabilities. Hence these three problems exhaust the obstacles to pure modal rationalism.

Personally, I am fairly confident about ruling out strong necessities (and thus about weak modal rationalism), e.g. by the arguments we've discussed in class. I am less sure about ruling out generalized inscrutables, but I'd like to think there are none, and that there are at least some decent arguments for thinking so. And I'm less sure in turn about open inconceivabilities, which seem to be harder to get a grip on (as we found in class). If we were able to rule out all three, though, the resulting pure modal rationalism would certainly give a very clean and elegant picture of the epistemology of modality, and of the shape of the modal universe.

--Dave.

Dave specified that the only properties that we consider when talking about the possibility of open inconceivabilities are those that are nonrelational and nondispositional. I suppose that this rules out the case I'm about to make. At the moment, however, I'm not entirely clear how we can distinguish properties in this way.

Consider two universes, U1 and U2. Both contain only two particles, and in each the distance between the two particles is diminishing such that, at a certain point, the two particles will pass very close to each other and then continue off for a very long voyage into infinity, assuming no interaction between them. In U1, however, there is a force of gravity such that the two particles will actually start orbiting around each other. The two particles never get very close together, however, as, in each world, one of the particles spontaneously decays with an infinitesimal release of energy (and it's the same particle in each world that decays, if one can make sense of such a notion). U1 and U2 have identical histories and,
it seems, there is no possible way for any conceiver to tell the two worlds apart.

I'm assuming that not even an ideal conceiver will be able to discern differences in uninstantiated laws, as our ideal conceiver would then be, I presume, quite inconceivable to us. Now I assume my example is ruled out given that the only difference in U1 and U2 is in terms of a dispositional property. Presumably, a red thing that exists in this universe but which will not, at any time in its history, interact with any other matter (it spontaneously coalesced out of a little patch of energy, suppose) is still red.

It seems to me that in both cases, if it is meaningful to talk of properties at all, it is only insofar as a property has the potential for being discerned by some agent. But it is not clear to me why a property may then be ruled out simply because the event that would have instantiated that property never came to pass.

Anthony writes:

> Dave specified that the only properties that we consider when talking about the possibility of open inconceivabilities are those that are non-relational and nondispositional. I suppose that this rules out the case I'm about to make. At the moment, however, I'm not entirely clear how we can distinguish properties in this way.

Actually, I didn't mean to rule out the possibility that dispositional or relational properties could be inconceivable. I was just pointing to intrinsic (nondispositional, nonrelational) properties as a particularly fruitful class where inconceivable properties might be found. But that's not to say that they might not be found elsewhere.

Anthony goes on to give the example of two universes with the same histories, but different uninstantiated laws, and suggests that the difference between these worlds might be inconceivable. The way I see things, both worlds are quite conceivable, and indeed Anthony did a nice job of describing them for us so we can conceive of each of them. What's true is that the difference between the worlds is not "perceivable" -- they will "look" the same to a being within those worlds, for example. But this just suggests that there is more to conceiving that perceiving. There are other examples of that: e.g. where one conceives of different theories compatible with the same empirical evidence (as e.g. in interpreting quantum mechanics), or where one conceives of unperceivable objects (e.g. a "peekaboo unicorn").

> It seems to me that in both cases, if it is meaningful to talk of properties at all, it is only insofar as a property has the potential for being discerned by some agent. But it is not clear to me why a property may then be ruled out simply because the event that would have instantiated that property never came to pass.

Hmm, I think many would question the first claim. One could argue
that in just this case, there's a real difference in properties of the worlds (a difference in laws) that would not be "discerned" by an agent in those worlds. I suppose one could argue that it is "discernible" in that there are some counterfactual states of affairs where the difference could show up. But in some cases (e.g. the unicorn or the theories) even this might not hold.

Nevertheless, in all these cases the properties can be *conceived* by some agent. I think that corresponds to the thesis some people were defending in class -- that it's not meaningful to talk about properties that can't be conceived by any agent. I'd be interested to see any arguments for that thesis.

--Dave.

            <MODALITY@LISTSERV.ARIZONA.EDU>
From: Timothy J Bayne <bayne@U.ARIZONA.EDU>
Subject:      An inscrutable truth? Probably not.
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: R

Here's an argument for an inscrutable truth. It's open to a number of objections - one of which I think is good.

(1) There are truths about bat experiences. There are true statements of the form "Being a bat is like. . .". Call these truths BE-truths.

(2) Bats have bat experiences, but they cannot believe any truths about bat experiences, because the lack the requisite concepts.

(3) You can only believe a truth about bat experiences if you yourself have battish (batty?) experiences.

(4) Nothing but a bat can have battish experiences.

Therefore,

(5) nothing can know BE truths.

In short: The only things that could are bats, but they can't, cos they don't have justified beliefs at all (or, at least, they don't have justified beliefs about their experiences.)

Some comments.

You might reject (1). I take it Dave (and Nagel) won't. They hold that there are intrinsic aspects of experience, that can only be known by having the experience.

You might reject (2). You might say that having an experience is not just necessary for having knowledge about that experience, but that it is also *sufficient*. We're in deep water here, but I think most would grant that you need more conceptual sophistication to know about your own experience than just the experience itself. You might reject (4). Why can't there be superbats? Superbats are just like bats - they have the same experiences as bats - but they have the conceptual sophistication to know about their own experiences. This is probably the weakest link in the argument. In fact, I guess I think that this objection is right.
Tim's bat example is interesting. I should note that this isn't really being put forward as an instance of an inscrutable truth, but rather as an instance of an unknowable (perhaps even unbelievable) truth. It's important to note that these are not the same thing (though arguably inscrutable truths, if they exist, will be unknowable).

Of the categories we've been talking about, the truths in question are probably most relevant to open inconceivability than anything else. One might use Tim's argument to say: (i) to conceive of these truths, one needs to have battish experiences; (ii) only bats can have battish experiences; (iii) bats don't have the relevant concepts; so (iv) no possible being can conceive of these truths.

Tim's superbat objection would strike at premise (ii) here, and indeed that seems reasonable. One might try getting around this by talking about "dumb bat experiences", the sort that can only be had by an unintelligent bat. Superbats could never have these experiences, I presume! But maybe they could form the concepts some other way.

Another relevant route is to question (i) (which corresponds to Tim's (3)). Arguably one can conceive of some experiences without having had those exact experiences, but rather by having experiences that are relevantly related to them. Hume's "missing shade of blue" is an example. And maybe e.g. we could use our own experiences to form concepts of certain "proto-experiences" that compose them, and then recombine the protoexperiential concepts to form concepts of experiences that we've never had. Maybe that sort of thing could lead a being without bat experiences to form concepts of bat experiences (and even of "dumb bat experiences"). It's not obvious that this is possible, but it's not obvious that it's impossible, either.

--Dave.
All, some thoughts on open inconceivabilities--OI's--(and why I can't conceive of any).

The general strategy is to show that, on the assumption that S is negatively conceivable we can show that there is a PC-complete D such that D --> S. After doing that, we can look at problematic points of the argument.

So, let S be any (primarily ideally) negatively conceivable statement. Let R be an ideal rational agent. S is thus negatively conceivable by R in the limit. That is, there is some ordinal stage of R's reasoning sigma, such that: R sees no contradiction in S at sigma and R sees no contradiction in S at all ordinals > sigma. Let D be the generalized conjunction of a maximal consistent subsets of the statements that R has marked as "conceivable" such that S is a conjunct of D. D is a complete description of a world, we just need to see that it is a "PC"-description. To see this, note that if R tags a statement as noncontradictory in the limit, then the statement is noncontradictory. That is, it has a satisfying structure. So D has a satisfying structure. But surely D must then be PC-complete. D-->S, and so we're done.

Two things worth pointing out:
(1) Most of the work above is being done by tacit appeal to the equivalence I see between NI-in-the-limit to PC: if we are serious about full rationality in the limit (to the point of fixed points of ordinal updates), then this seems to me to be plausible. What else could we mean by NC in this case other than something like satisfiable?

(2) We need to explain away claim to OI status that statements like "There are inconceivable features of the world" might seem to have. I think that's pretty easy. First, they equivocate on "inconceivable"--sure there might be features which are inconceivable to us, but that's no surprise. And that doesn't establish that there are OI's. What's relevant is whether there are statements which are in the limit NC but not PC (and we're nowhere near the limit). But, if a statement is in-the-limit NC iff it is PC, then this is not possible.

Thony

"Curious green ideas sleep furiously."

Thony puts forward a general argument against the existence of open inconceivabilities. In fact he gives much more: an argument that
anything that is ideally negatively conceivable is also positively conceivable. If successful, such an argument would establish the negpos principle, and rule out both open inconceivabilities and inscrutable truths.

Let S be any (primarily ideally) negatively conceivable statement. Let R be an ideal rational agent. S is thus negatively conceivable by R in the limit. That is, there is some ordinal stage of R's reasoning such that: R sees no contradiction in S at sigma and R sees no contradiction in S at all ordinals > sigma. Let D be the generalized conjunction of a maximal consistent subsets of the statements that R has marked as "conceivable" such that S is a conjunct of D. D is a complete description of a world, we just need to see that it is a *PC*-description. To see this, note that if R tags a statement as noncontradictory in the limit, then the statement is noncontradictory. That is, it has a satisfying structure. So D has a satisfying structure. But surely D must then be PC-complete. D-->S, and so we're done.

Hmm. I'm not certain what you mean by "consistent" above. I think you mean something like "not contradictory". If so, then there will plausibly be such a D, and the D in question will be NC-complete. The crucial question, as you say, is whether D is also PC-complete. If D is PC, it will be PC-complete. But what reason is there to believe that D is PC?

Your argument turns on a "satisfying structure". I need to know just what a "satisfying structure" is. I see about three possibilities:

1. If a satisfying structure is merely a model that gives an interpretation for the terms such that D comes out true in that model, then there will certainly be a satisfying structure, but it's not at all obvious why the existence of such a structure implies positive conceivability, given that e.g. such a model may assign an interpretation of the terms in D quite different from our ordinary interpretation.

2. If a satisfying structure is a model such that the interpretation of D in the model is determined by the ordinary semantics of the terms in D, then it's less obvious that such a model will exist. If one is loose enough about what counts as preserving the ordinary interpretation of the terms, perhaps there will be a model, but in this case the inference from the existence of a model to the positive conceivability of D is again far from clear.

3. If a satisfying structure is just a possible world in which D is true, or even a positively conceivably situation in which D is true, then it's not obvious why such a satisfying structure should exist. Or at least, that's just what's at issue.

To clarify, you might show in detail how the argument would run for (a) D = the conjunction of all the physical truths about the world with some purported inscrutable truth (e.g. a statement about tallness, on the epistemic theory; or a mathematical statement that is true but not a priori), and (b) a purported open inconceivability such as "there are inconceivable features of the world". As it stands your argument seems to rule these things out perhaps just a little too easily, but maybe the details will help.

Two things worth pointing out:

1. Most of the work above is being done by tacit appeal to the equivalence I see between NI-in-the-limit to PC: if we are serious about full rationality in the limit (to the point of fixed points of ordinal
> updates), then this seems to me to be plausible. What else could we mean
> by NC in this case other than something like satisfiable?

Well, NC in the limit means absence of any contradiction detectable
through reasoning. That definition doesn't make any obvious claims
about satisfiability. Certain weak forms of satisfiability may
follow, but these don't obviously guarantee positive conceivability.
And for strong forms of satisfiability that guarantee positive
conceivability, it's not obvious why satisfiability in these senses
follows from NC-completeness. At least, such a link is just what's at
issue. But any argument for the link would be gratefully received!

Subject: A problem for the notion of a single ideal conceiver
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: R

The case Tim mentioned about "dumb bat experiences" makes me think of a
related possible area of open inconceivabilites. Actually, I want to
present a case in which there are truths which can be conceived of by some
being but not by an ideal conceiver. I'm not sure whether such truths
should be called open inconceivabilities. Such a case might require us to
either 1) revise our notion of conceivability such that it doesn't depend on
a single ideal concever but rather on being conceivable by *some* being, or
2) reject modal rationalism. I actually prefer 1. (I can't recall whether
the notion of a single ideal concever was crucial in the first place. We
seem to have presupposed it in discussion.)

OK, so the case goes like this. It seems that there *could* be a being
whose conscious experience is holistically tied to its concepts. This is
like an extreme case of Tim's bat case. The idea is that when one of these
beings acquires a new concept, all of its conscious experiences are modified
(slightly or radically, however you like). Assuming that having a concept
of this being's phenomenal states requires having that state, then *any*
being which has different concepts (and certainly an ideal concever which
has all possible concepts) cannot have a concept of these experiences.
Actually, as the preceding sentence shows, there is no being which can have
all possible concepts.

Here is a similar case. Imagine a being whose conscious experiences are
holistically tied to its *beliefs* rather than its concepts. Any change in
belief changes all the qualitative feels of its experiences. So such a
being who believes that P will have perhaps radically different types of
phenomenal experiences from an identical being that believes that not-P or
believes neither P nor not-P. Now, surely our ideal concever believes P,
not-P, or has neither belief. If it believes P, then it can't have the
experience of a being (in the hypothetical species) that believes not-P or
neither, etc....

Now surely the beings that I've imagined are possible. I think that even
human beings have some of these properties. In the conceptual case, imagine
the difference between seeing a chessboard and lacking the concept of chess
and seeing a chessboard *as* a chessboard. In the belief case, imagine the
difference between eating cowbrain and not knowing what you are eating and
eating the brain and knowing it (yuk!).

I don't think we want to call the cases I've discussed open
inconceivabilities. After all, they are conceivable by *some* being, just
not by the ideal conceiver we've hypothesized. Do we need a single ideal
conceiver? It seems like we don't, though I haven't thought this out.
Things seem to get pretty messy without the notion of a single ideal
conceiver. But I suppose we already had a gap between human conceivability
and ideal conceivability. Now we have a gap between *any* being and "total
conceivability"—that is, between what any particular being can conceive and
the totality of things conceivable by at least one being.

Brad discusses some problems for the notion of an ideal conceiver. I note that we decided that this notion might be problematic and was unnecessary: instead of defining ideal conceivability in terms of what an ideal conceiver can conceive, we can define it in terms of conceivability "in the limit" among non-ideal conceivers who get smarter and smarter (e.g., P is ideally conceivable if there is some X such that P is conceivable for X and P is conceivable for all beings less limited than X). That being said, the problem still raises issues even for the modified view of ideal conceivability.

> OK, so the case goes like this. It seems that there *could* be a being whose conscious experience is holistically tied to its concepts. This is like an extreme case of Tim's bat case. The idea is that when one of these beings acquires a new concept, all of its conscious experiences are modified (slightly or radically, however you like). Assuming that having a concept of this being's phenomenal states requires having that state, then *any* being which has different concepts (and certainly an ideal conceiver which has all possible concepts) cannot have a concept of these experiences. Actually, as the preceding sentence shows, there is no being which can have all possible concepts.

> Here is a similar case. Imagine a being whose conscious experiences are holistically tied to its *beliefs* rather than its concepts. Any change in belief changes all the qualitative feels of its experiences. So such a being who believes that P will have perhaps radically different types of phenomenal experiences from an identical being that believes that not-P or believes neither P nor not-P. Now, surely our ideal conceiver believes P, not-P, or has neither belief. If it believes P, then it can't have the experience of a being (in the hypothetical species) that believes not-P or neither, etc....

Interesting cases. These seem to be somewhat similar to the "dumb bat experiences", in that they are experiences that can only be had by beings below a certain level of sophistication. As such, then none of our "sufficiently smart" beings will be able to have those experiences. Does it then follow that these experiences are not ideally conceivable?

That conclusion seems to follow, *unless* there is a way the beings in question can conceive of the experiences without actually having them. We've seen that this can happen at least in some cases, e.g. Hume's "missing shade of blue", and novel experiences that involve recombination of elements of familiar experiences. Perhaps something like that could happen here. E.g., perhaps a smart being with a rich conceptual system could still conceive of the phenomenology of a being with a limited conceptual system, perhaps by "scaling down" their own phenomenology in their imagination, or by some sort of analogical conception. Similarly, a being that believes P can arguably conceive what it's like to believe that not-P, perhaps by "changing the polarity" of their current belief in the imagination. E.g., even though I believe I was born in Australia, I think I can conceive of the phenomenology of believing I wasn't born in Australia, even though I don't have that phenomenology myself.

Of course it isn't obvious that these methods will work for every possible case. But it's not obvious that they won't. If they do, things are OK. If they don't, it would cause trouble for the concept.
of ideal conceivability, and certainly for the link between ideal conceivability and possibility. The possibilities in question would come out to be open inconceivabilities by the official definition, which might seem odd.

An alternative would be to create a new class for statements that are conceivable by some beings but not by smarter beings; but then the question is how to distinguish between the "coherent" cases like this (e.g. the ones just discussed) from the "incoherent" ones that are implicitly contradictory. That's particularly problematic if there are cases (a) involving concepts that can only be had by limited beings and (b) that involve subtle incoherencies on the part of those beings. We want to class these with the "incoherent" cases, but clearly the criterion of being undermines by rational reflection won't do, as beings that could perform the rational reflection wouldn't have the concepts! Maybe there is an alternative way of running the counterfactuals -- e.g. they're incoherent because *if* a being could have the concepts and be smarter, they would uncover a contradiction. Such a counterfactual would have an impossible antecedent and might thus be considered problematic, but arguably counterfactuals with impossible antecedents can sometimes have truth values.

In any case, this would clearly be a bit of a mess. So let's hope that such cases can't really arise! I.e., let's hope that the experiences in question can at least be conceived of by smarter beings, even if they can't be had by smarter beings.

I think Brad's example of "a being whose conscious experiences are holistically tied to it's beliefs" is exactly the case with humans in the actual world. A change in belief DOES change the qualitative feel of things--and in a new way. As far as the ideal conciever goes though, being ideal and all, can't it conceive of what it's like to believe not-p while believing p? The ideal conciever has considered both of them already and decided that p is the case, but probably "remembers" what it was like to belive not-p. So, using Brad's example, the ideal conciever would be able to conceive of how you feel when you're eating cow brain in the case where you know what it is AND the case where you don't. Of course, there is going to be a different qualitative feel to the ideal conciever because it can't remove itself wholly from being an ideal conciever as opposed to the person actually EATING cow brain, but we would call what it is doing, "remembering", to be a form of "concieving of": [what it is like to eat cow brain without knowing that it is cow brain] wouldn't we?

erik h.

PS (I hope it is OK to refer to the ideal conciever as "it" )

Here is an argument that I think shows there are no open conceivabilities. First some of Dave's definitions:

> S is an INSCRUTABLE TRUTH if S is true and some PC-complete truth D does not imply S.

> S is a GENERALIZED INSCRUTABLE if there exists some PC-complete D such that D-and-S is negatively conceivable, but D does not imply S.

> S is an OPEN INCONCEIVABILITY if S is negatively conceivable, but for all PC-complete D, D implies not-S.

Because of the truth constraint in the def of INSCRUTABLE TRUTH I'm going to focus on a comparison of generalized inscrutable (GI) and open inconceivability (OI).

The primary difference between GI's and OI's is that for GI's no D implies S while for OI's all Ds imply -S. However, S is negatively conceivable for both GI and OI. What I'm not getting is how something can be negatively conceivable and yet be false in every conceivable world. Let's say that I know S is false in some PC-complete D. This is the same as saying that if I add S to D then I get a contradiction. Now if S implies a contradiction in every PC-complete world I can imagine then it seems to me that S leads to an obvious contradiction. But that is to deny that S is negatively conceivable.

Now if S isn't even negatively conceivable then I see no reason for thinking S is possible. On the other hand if S doesn't imply a contradiction in every world then there is some D such that S is either true or undecided. In the latter case we just have an inscrutable truth.

Because of the truth constraint in the def of INSCRUTABLE TRUTH I'm going to focus on a comparison of generalized inscrutable (GI) and open inconceivability (OI).

The primary difference between GI's and OI's is that for GI's no D implies S while for OI's all Ds imply ~S. However, S is negatively conceivable for both GI and OI. What I'm not getting is how something can be negatively conceivable and yet be false in every conceivable world. Let's say that I know S is false in some PC-complete D. This is the same as saying that if I add S to D then I get a contradiction. Now if S implies a contradiction in every PC-complete world I can imagine then it seems to me that S leads to an obvious contradiction. But that is to deny that S is negatively conceivable.

Hmm. Let's take a statement such as "there are inconceivable features of the world". It's true that this is false in any PC-complete D, and combined with any such D leads to a contradiction. But that's not to say that S alone leads to a contradiction, or that S is negatively conceivable. That would requires that not-S is a priori. Now if one could know a priori that there is some PC-complete description of the actual world, then it would more or less follow from the above that one could know a priori that not-S. But it's not obvious that we can know the antecedent a priori, and indeed that's what's at issue. So, it seems that for this argument to rule out open inconceivabilities, we'll first need a way to rule out open inconceivabilities!

Now if S isn't even negatively conceivable then I see no reason for thinking S is possible. On the other hand if S doesn't imply a contradiction in every world then there is some D such that S is either true or undecided. In the latter case we just have an inscrutable truth.

Well, for an open inconceivability S, there is the chance that (i) S may imply a contradiction in all positively conceivable worlds, but (ii) S may not imply a contradiction in all possible worlds. If there are open inconceivabilities, there may be more possible worlds than positively conceivable worlds.

--Dave.

Dave responded to Tim and Brad's cases by suggesting that beings can conceive of experiences without really having them. Hume's "missing shade of blue" may be such a case, and yet it seems to be much more simple than the "dumb bat" cases we've been discussing. I am not sure that it is possible for an ideal conceiver to conceive of what it's like to be a bat simply by scaling down his own phenomenological experiences. This is because the difference in phenomenological feel between an ideal conceiver and a bat seems to be a difference of kind and not of degree. I can not conceive of what it's like to be an ant by simply imagining myself, only much stupider.
Also, even if an ideal conceiver were to conceive of what it's like to be a bat by simply scaling down his own phenomenology, it seems that he would still have a lot of extra baggage in virtue of being an ideal conceiver that would taint his conception. I can remember what it's like to be five, but I don't know that I really have a pure concept of the feel of what it's like to be five because I have so much 'experience and wisdom' that lurks in the background when I try to conceive of it. (I can never really conceive of the wonder I felt toward the world because now I can better explain the world... Of course I could just take the little wonder that I feel now and multiply it, but I'm not sure that that really does the trick.)

I guess a lot rides on what is required to have a positive conception of another's experience- my intuitions seem to be that you do need to have the experience in order to conceive of it. (Of course, a person who has never had a headache can presumably conceive of what it's like to have a headache, but that brings up an epistemological problem- unless he's had the headache- how does he know that he's getting it right? Likewise for the ideal conceiver and the dumb bat.)

A short note on Horgan and properties . . .

Horgan asks what information the Demon needs in order to complete the task of cosmic hermeneutics. The demon knows:
(1) All the a priori accessible truths;
(2) All the microphysical facts.

What else does it need? Horgan suggests that identity statements might do the trick. If all the macrophysical objects (states of affairs, etc.) are (ontologically, rather than conceptually) identical to various concatenations of microphysical objects, then macrophysical states of affairs necessarily supervene on microphysical states of affairs, *without the introduction of brute metaphysical relations,* which Horgan finds problematic.

But, says Horgan, there's a problem. "It is most implausible, on the face of it, to suppose that every sortal and non-sortal *property* expressible in our higher-level vocabulary is also finitely expressible in microphysical vocabulary. Surely nobody seriously believes that that there is a single finitely-long microphysical predicate which expresses the property of being a chair, or being a coffee pot, or thinking of Vienna" (23).

I think that the above is true, but I (very tentatively) suggest that there may be around this particular problem. My suggestion is that the materialist go nominalist on properties, (as many of them are wont to do anyway). There ain't no such thing as the property of being a chair, or being a coffee pot, and so on. There are, of course, chairs, but 'there are chairs' is true not because of a property of chairhood (conceived of as some unviersal over and above the microphysical structure of the world), but because certain concrete particulars (tropes) stand in certain relations to each other. Now surely (some) relations are included in the basic microphysical facts that the demon knows - at least facts about the relations that microphysical particles bear to one another. The nominalist about properties would suggest that those property facts such as there are logically fall out of (are entailed by) the microphysical facts (where these include microphysical relations). My materialistic nominalist might agree that she can't define <chair> in reductive terms, but she can reduce the (finite) chair tropes, such as there are, to (1) and (2). Insofar as there are properties, they are fully ontologically reducible. Now, it may be that there are independent problems with this suggestion - it may not get you anywhere near cosmic hermeneutics - but that's another story.

PS. I don't find nominalism about properties attractive, but many do.

Well, it's a thought.

t.

Timothy J. Bayne
RM. 213 Social Science
Tim writes:

>Horgan asks what information the Demon needs in order to complete the task
>of cosmic hermeneutics. The demon knows:
>(1) All the a priori accessible truths;
>(2) All the microphysical facts.
>
>What else does it need?

Pardon me for using this to get into a digression from Tim's point, to
address some general points re Horgan's framework and some things that
came up in class today.

Of course on my view, nothing else is needed. Or at least, (1) and
(2) are enough if we add (a) an indexical truth (saying where the
demon is now), (b) phenomenal truths, and (c) a that's-all truth. But
leaving those "complications" aside, it's not clear why we need to add
more.

In the dialectic as Horgan sets it up, he first grants the demon
knowledge of (2), then asks what else is needed to get to macro
knowledge. Clearly, *some* sort of bridge is required to get to macro
concepts. He canvases laws (no good), identities (no good), before
settling on "meaning constraints". This is a little different from
(1) above: as Horgan understands meaning constraints, they include a
posteriori constraints such as the constraint that "water" picks out
H2O. One might argue that this supplementation of the demon's
physical knowledge base with ineliminably a posteriori knowledge
weakens its claim to be engaging in "cosmic hermeneutics". But in any
case I think that the demon doesn't need a posteriori meaning
constraints. A priori meaning constraints (the sort that correspond
to primary intensions) are enough for the demon to figure out the
macro truths in these cases. I think Horgan now accepts this and
regrets giving in to a posteriori meaning constraints here.

Further, it's arguably best not to put things in terms of giving the
demon "meaning constraints" at all (even the a priori sort), if these
are understood a further class of truths. E.g. it's not clear what
set of explicit a priori truths about "knowledge" will enable the
demon to give the right verdict on all the Gettier-et-al cases.
Rather, I think it's best just to give the demon the concept of
knowledge, and argue that armed with microphysical facts, that
concept, and sufficient a priori reasoning, the demon can figure out
the knowledge facts. More generally, I think that one just needs to
stipulate that the demon has the relevant concepts. Explicit "meaning
constraints" aren't necessary here and are a bit of a distraction. Of
course it may be that in giving the demon the concept we're giving it implicit meaning constraints, in some sense, but we needn't build that into the picture directly, and we certainly needn't give the demon any special truths directly in its inference base (as (1) above might suggest).

Horgan's different way of doing things relates to his "naturalized semantics" approach that someone (Brad?) mentioned in class. In effect, he argues that meaning constraints aren't really problematic, as they're just another class of high-level fact. Eg. the demon can figure out English truths by looking at English speakers, figuring out what their terms mean, and seeing whether or not their statements are true. And can presumably figure out meaning constraints the same way, including explicit truths about what `water' in English refers to, etc..

I find this picture a little hard to follow, though. First, if we are really getting the meaning constraints "for free" via naturalized semantics, why bother building them in in the first place? The answer, presumably, is that even in the naturalized semantic case, we need *some* bridge to get us from microphysics to what is "true in English" and so on -- after all, we'll be stating such claims using such non-microphysical concepts as "true". So presumably, we'll at least need some bridge re the concepts of "truth", "reference", etc, otherwise we'll never be able even to get to claims about what is true in English, etc, even on the naturalized semantics approach. And presumably the bridge that is needed will be precisely something like meaning constraints for the concepts of "truth", "reference", etc. So it seems to me that Horgan can't really get the meaning constraints as cheaply as he'd like: he has to *start* with at least some of them.

I don't think starting with these meaning constraints is problematic myself (one just has to suppose that the demon has the concepts of truth, reference, etc), but it does suggest that the naturalized semantics approach can't do all Horgan's work for him. In essence, we have to suppose that the demon *has* and *uses* some of the relevant concepts, and doesn't just *mention* them as part of a third-person interpretation. At least, it has to have the concepts of truth, reference, etc. And once we've done that, we might as well give the demon arbitrary concepts. That way, to see if any truth T is derivable by cosmic hermeneutics, we just give the demon the concepts in T, physical knowledge, and let things rip. No need to do everything resolutely in the third-person, restricting the demon to "X's utterance of T is true" and such. The demon can just tell us, T!

The two approaches might even come apart in some cases. E.g. just say nonmental truths are a priori entailed by physical truths, but mental truths aren't. And now consider "water is wet". On the "concept use" approach to cosmic hermeneutics, where we give the demon (say, an idealized version of me) the concepts, then it will be able to figure out from microphysics etc that water is wet. On the "naturalized semantics" approach, though, the demon may not be able to figure out what "water" in English refers to, as that will probably depend on various mental facts about the intentions and beliefs, etc, of English speakers, which aren't accessible by hypothesis. If so, it will come out that cosmic hermeneutics doesn't even work for "water is wet", despite a priori derivability. I think that's the wrong result, and we want an understanding of CH so that CH is possible for "water is wet" in this case. If so, I think we need the concept-use approach.
What else does it need? Horgan suggests that identity statements might do the trick. If all the macrophysical objects (states of affairs, etc.) are (ontologically, rather than conceptually) identical to various concatenations of microphysical objects, then macrophysical states of affairs necessarily supervene on microphysical states of affairs, *without the introduction of brute metaphysical relations,* which Horgan finds problematic.

Well, I'd argue that bringing in identities as basic here may well bring in something *brute* in some sense. Something like the type-B materialist bringing in a brute fact that pain = C-fibre firing, or some such. If there is no epistemic link from microphysics to that, then we have at least an epistemic bruteness, if not a metaphysical bruteness. And it would seem that as with a posteriori meaning constraints, we'd have then given up on pure cosmic hermeneutics. But set that aside.

But, says Horgan, there's a problem. "It is most implausible, on the face of it, to suppose that every sortal and non-sortal *property* expressible in our higher-level vocabulary is also finitely expressible in microphysical vocabulary. Surely nobody seriously believes that there is a single finitely-long microphysical predicate which expresses the property of being a chair, or being a coffee pot, or thinking of Vienna" (23).

I think that the above is true, but I (very tentatively) suggest that there may be around this particular problem. My suggestion is that the materialist go nominalist on properties, (as many of them are wont to do anyway). There ain't no such thing as the property of being a chair, or being a coffee pot, and so on. There are, of course, chairs, but 'there are chairs' is true not because of a property of chairhood (conceived of as some universal over and above the microphysical structure of the world), but because certain concrete particulars (tropes) stand in certain relations to each other. Now surely (some) relations are included in the basic microphysical facts that the demon knows - at least facts about the relations that microphysical particles bear to one another. The nominalist about properties would suggest that those property facts such as there are logically fall out of (are entailed by) the microphysical facts (where these include microphysical relations). My materialistic nominalist might agree that she can't define *chair* in reductive terms, but she can reduce the (finite) chair tropes, such as there are, to (1) and (2). Insofar as there are properties, they are fully ontologically reducible. Now, it may be that there are independent problems with this suggestion - it may not get you anywhere near cosmic hermeneutics - but that's another story.

Hmm, interesting. I'm not sure I completely follow. What are the "bridges" that we are adding to get us from microphysics to macro truths? Horgan canvased the possibility of adding identities such as "water = H2O", but the trouble was that analogous identities don't seem available in many other cases (chairs, coffee pots, thinking). You're suggesting maybe adding token reductions? I presume that would be something like "this P1 is a chair", "this P2 is a chair", and so on for every chair in the world? I guess the trouble, as you suggest, is that this doesn't look much like cosmic hermeneutics. Rather, it's more like taking microphysics and tagging every chair explicitly as a chair, every coffee pot explicitly as a coffee pot, and so on. Not much surprise that we can get to the chair facts from there!

I think your suggestion here might end up being relevant to a metaphysical reduction, as opposed to the sort of epistemic reduction
Horgan is after. It might be that a token-token but not type-type identity is enough to save physicalism as a metaphysical doctrine (though there are many tricky issues here); and a tropewise reduction of properties might do much the same thing. But in building in so many references to specific instances, it seems to build in too much to qualify as cosmic hermeneutics. Rather, this might lead to a way in which physicalism could be true *without* cosmic hermeneutics being possible! That would be interesting, though of course at the end of the day I think such a combination isn't tenable. If there are these tropewise identifications, there ought to be some way of figuring out the identifications themselves a priori from the physical facts.

All,

Some thoughts on cosmic hermeneutics (CH) and reductive explanation (RE).

There seems to be a bit of carelessness in talk of the possibility of CH with respect to what information we are to give a Laplacian-type knower: is it all the physical facts, or is it all the facts about physics? Byrne, e.g., seems to run the two together. But surely these are are conceptually distinct sets of facts, and their difference hinges on where we put natural laws. I think there is a dilemma lurking nearby, so I want to try to draw it out. (I'm not sure what force the dilemma might have for particular theories, over and above being a useful guide to taxonomy.)

Let F be the set of facts we give to an ideal knower, and let P be the conjunction of all the microphysical facts, and let L be the conjunction of all the (true) physical laws. By hypothesis P is in F. The question is whether L is also in F. If L is *not* in F, then I think we are getting into Byrne's worry about conceivability. It is hard to see how one can get from low-level sentences describing mass, charge, spin and so on to high-level descriptions about juiciness or whatever without using the sort of bridge laws that are conjuncts of L. And if that's right, then it isn't very clear in what sense it is a priori that F implies a given macro-event M. (And, if I read Josh's worry re Aristotle correctly, this is similar in spirit to his point.)

Now suppose that L *is* in F. So we give the ideal knower both all the micro-facts and all the causal laws. But then CH is possible iff the deductive-nomological theory of explanation is right. Right to Left: If the D-N model is right, then since explanation is just a deduction from conditions and laws to empirical facts, clearly CH is possible—CH amounts to "large scale" D-N prediction/explanation. Left to Right: If CH is possible, there is a deduction from F to M. But F= (P, L), where P is the description of all the physical conditions (antecedent circumstances) and L is the statement of all the general laws. M is just a macro empirical fact. But these are the sufficient ingredients for the D-N model of explanation.
I don't think there are any particularly strong conclusions here: if L is not in F, then we might want a bit more said about what is clearly and distinctly conceivable about CH. If L is in F, then CH is possible iff D-N explanation is right. And, by extension, since advocates of CH seem to think that a RE of A in terms of B is possible iff CH with respect to B implies A, then CH is possible iff D-N model for RE is right.

Well, I guess I mean *I* don't want to draw any strong conclusions, since I'm not sure that I'm convinced that D-N explanation is so bad (Salmon and his ilk not withstanding). I might be convinced, and just don't know it, though.

Thony

>Thony, Just a point of clarification. I take it that at least part of your point about the D-N model is that, if we have committed ourselves to the D-N model to hold that CH is possible, this is potentially problematic (disastrous?) to the CH thesis, since there are well-known problems with D-N as an adequate model of scientific explanation (e.g., Salmon's point that D-N is neither necessary or sufficient for explanation). (I realize that this is an extrapolation, since you say that there *aren't* any particularly strong conclusion here*, but I think it's clear that a commitment to a D-N model of explanation would be bad, so I suppose I would want to add that, if you are correct, there IS a strong conclusion here; namely, there is something amiss with the CH thesis on this score.)

>Erik

>(p.s. there is no way out for you, if you do not answer me I will hunt you down for further clarification)

>"Curious green ideas sleep furiously."

Clarificatory point. I thought that the CH claim is that a being with (1) all the physical facts; and (2) all a priori knowledge; can (3) come to know all the facts, where (3) should be read as, 'can at one time know everything there is to know'. But in fact Byrne nor, as far as I can tell, Horgan, puts the CH conclusion in this way. Rather, they say that for *any* truth, one can come to know it, not that the Laplacean demon can...
come to know all the truths at once (although Horgan seems to gesture in this direction in at least one place). Call the former claim the existential claim, and the latter the universal claim.

The problem is this: as far as I can see, the Demon might know everything, but can it know that it knows everything? We, as theorists, can stipulate the 'that's all' fact for any world, but how does one establish the that's all truth from *within* a world? One might believe that one knows everything, and it might even be true that one knows everything, but how could the belief that one knows everything be justified? (Why hasn't this objection been levelled against theistic omnipotence? Because God is said to *create* everything, and thus (it seems) God knows when God knows everything. I think that's the reason.)

As I said, I think that Byrne (and perhaps) Horgan reject the universal claim in favor of the existential claim, and the existential claim isn't open to this problem. Or is it? Consider the claim: 'The demon knows everything'. The demon will (I guess) believe this, but how can it know it? But is this a truth? No. Is it a truth that the demon has true beliefs about everything? That may be true. Can it know that it has true beliefs about everything (i.e. can it know that it believes every truth). ? Again, I don't think so: how could you be justified that your set of beliefs is exhaustive? So, it seems that there is a particular truth that the demon cannot *know*.

Here's an objection I tried to develop, but the wheels fell off. If someone can put them on again, go ahead! Suppose a weird world, in which p is true iff the demon doesn't believe it. The fact of believing p causes p to be true no longer, and the fact of not-believing p causes p to be true. Now, if you put the demon outside of the world (as Horgan does) you might be able to say that, necessarily, there are no such facts p. But - as far as I can see - putting the demon inside the world seems to open up the possibility of such facts.

Problem is, fully developing this objection involves saying something about the relation of p and the physical facts. It needs to be the case that the demon can know the physical facts on which p supervenes, otherwise this isn't a counter-example to CH. And if looks like if the demon does know the physical facts on which p supervenes, and it knows all the a priori facts, then it will be able to work out whether or not p is true. In other words, the defender of CH seems to be within her rights in claiming that the notion of a p truth is incoherent.

I think we are supposed to give the demon (a) all the microphysical
facts and (b) all the microphysical laws. Just (a) will be enough if
one is a Humean about laws and causation (in that case (b) will follow
from (a) a priori). On a non-Humean view, one will need both, to
bring in facts about laws, causation, dispositions, counterfactuals,
etc.

>Let F be the set of facts we give to an ideal knower, and let P be the
>conjunction of all the microphysical facts, and let L be the conjunction

It's not clear to me whether you intend L to be the collection of
microphysical laws, or of physical laws more generally (including
macrophysical laws). In the first case, L will be in F, as suggested
above. In the second case, L will not be in F, but the advocate of
cosmic hermeneutics will argue that L follows from F a priori.

How do we get from microphysical facts and laws to facts about
juiciness, etc? Presumably, by virtue of possessing the concept of
juiciness. The CH claim is that armed with this concept, one grasps
how this situation applies to various epistemic possibilities, and in
particular, that one can know how it applies to a possibility
microphysically described. So e.g. one will be able to get from a
structural/functional characterization of an apple to knowledge of
whether it is juicy. E.g., look to see how much water it contains!
Where we've antecedently figured out what is water in the world, by
the "watery stuff" method. And the CH advocate will argue that it is
not a priori conceivable that something satisfies this physical
characterization without being juicy. Etc.

Of course whether this is really possible for concepts such a
juiciness is just what the debate over CH is about. I am personally
agnostic about whether it is possible, though I'm sympathetic with the
idea. What I do think is that the juiciness facts follow a priori
from the physical plus phenomenal facts. Once one allows the demon to
have phenomenal facts too, e.g. about what the apple looks like, then
its task is much easier.

>D-N model of explanation.

Well, the laws most relevant to micro-macro D-N explanation are
micro-macro bridge laws. And we certainly won't be giving the demon
knowledge of micro-macro bridge laws. So L as construed here won't be
in F. With knowledge of bridge laws, the demon's task would be much
easier, but (as Horgan notes at one point) it trivializes things. It
will turn out that CH is true even on a property dualist view of
qualia, for example. (Even on my view of qualia, there are bridge
laws!) So CH would certainly not imply reductive explanation or any
such thing. For CH to be interesting, the demon needs to be able to
figure things out from microphysical facts and laws alone, in
combination with its possession of the high-level concept.

As Tim notes, there are various problems with the D-N model of
explanation. But I think most of those can be set aside here. The
most central point is that it is widely agreed now that D-N makes a
terrible model of *reductive* explanation (although Ernest Nagel
originally intended it this way). In helping itself to bridge laws,
D-N makes the reductive project relatively trivial, not obviously
reductive, and consistent with the falsity of materialism, as the
qualia example suggests. So most people now think reductive
explanation requires a stronger constraint.

(p.s. there is no way out for you, if you do not answer me I will hunt you
down for further clarification)
All,

Some thoughts on cosmic hermeneutics (CH) and reductive explanation (RE).

There seems to be a bit of carelessness in talk of the possibility of CH
with respect to what information we are to give a Laplacian-type knower:
is it all the physical facts, or is it all he facts about physics?
Byrne, e.g., seems to run the two together. But surely these are are
conceptually distinct sets of facts, and their difference hinges on where
we put natural laws. I think there is a dilemma lurking nearby, so I
want to try to draw it out. (I'm not sure what force the dilemma might
have for particular theories, over and above being a useful guide to
taxonomy.)

Let \( F \) be the set of facts we give to an ideal knower, and let \( P \) be the
conjunction of all the microphysical facts, and let \( L \) be the conjunction
of all the (true) physical laws. By hypothesis \( P \) is in \( F \). The question
is whether \( L \) is also in \( F \). If \( L \) is *not* in \( F \), then I think we are
getting into Byrne's worry about conceivability. It is hard to see how
one can get from low-level sentences describing mass, charge, spin and so
on to high-level descriptions about juiciness or whatever without using
th sort of bridge laws that are conjuncts of \( L \). And if that's right,
then it isn't very clear in what sense it is a priori that \( F \) implies a
given macro-event \( M \). (And, if I read Josh's worry re Aristotle
correctly, this is similar in spirit to his point.)

Now suppose that \( L \) *is* in \( F \). So we give the ideal knower both all the
micro-facts and all the causal laws. But then CH is possible iff the
deductive-nomological theory of explanation is right. Right to Left: If
the D-N model is right, then since explanation is just a deduction from
conditions and laws to empirical facts, clearly CH is possible---CH
amounts to "large scale" D-N prediction/explanation. Left to Right: If
CH is possible, there is a deduction from \( F \) to \( M \). But \( F = \{ P, L \} \), where \( P \)
is the description of all the physical conditions (antecedent
circumstances) and \( L \) is the statement of all the general laws. \( M \) is just
a macro empirical fact. But these are the sufficient ingredients for the
D-N model of explanation.

I don't think there are any particularly strong conclusions here: if \( L \) is
not in \( F \), then we might want a bit more said about what is clearly and
distinctly conceivable about CH. If \( L \) is in \( F \), then CH is possible iff
D-N explanation is right. And, by extension, since advocates of CH seem
to think that a RE of \( A \) in terms of \( B \) is possible iff CH with respect to
\( B \) implies \( A \), then CH is possible iff D-N model for RE is right.

"What our grammarian does is simple enough. He frames his formal
reconstruction of K along the grammatically simplest lines he can,
compatibly with inclusion of H, plausibility of the predicted inclusion
of I, plausibility of the hypothesis of inclusion of J, and plausibility,
further, of the exclusion of all sequences which ever actually do bring
bizarreness reactions." -- W.V.O. Quine
Tim writes:

>Clarificatory point. I thought that the CH claim is that a being with (1) 
>all the physical facts; and (2) all a priori knowledge; can (3) come to 
>know all the facts, where (3) should be read as, 'can at one time know 
>everything there is to know'. But in fact Byrne nor, as far as I can tell, 
>Horgan, puts the CH conclusion in this way. Rather, they say that for 
>*any* truth, one can come to know it, not that the Laplacean demon can 
come to know all the truths at once (although Horgan seems to gesture in 
>this direction in at least one place). Call the former claim the 
>existential claim, and the latter the universal claim.

I think it's probably better to interpret CH as making at most the 
existental claim. The universal claim may have problems. E.g. there 
is a "paradox of the knower" due to Montague and Kaplan that raises 
Godel-style problems with the idea of a being who knows all truths.

One might argue that the existential claim entails some version of the 
universal claim, since the conjunction of all truths is itself a 
truth, so the existential claim applies to it. In response, a CH 
advocate might suggest (1) that they are only dealing with finite 
claims (it's not clear whether or not this would be ad hoc), or at 
least (2) that the notion of the conjunction of all truths is not well 
defined. Alternatively, they could put forward a slightly different 
version of CH (see below).

>As I said, I think that Byrne (and perhaps) Horgan reject the universal 
claim in favor of the existential claim, and the existential claim isn't
open to this problem. Or is it? Consider the claim: 'The demon knows everything'. The demon will (I guess) believe this, but how can it know it? But is this a truth? No. Is it a truth that the demon has true beliefs about everything? That may be true. Can it know that it has true beliefs about everything (i.e. can it know that it believes every truth)? Again, I don't think so: how could you be justified that your set of beliefs is exhaustive? So, it seems that there is a particular truth that the demon cannot *know*.

Well, *if* the demon has the that's-all fact in the antecedent part of its knowledge base, this obstacle will be removed. Again, you can raise questions about whether a demon could really have that antecedent knowledge, but we are just stipulating it here. I also note that "the demon knows everything" will likely actually be *false*, at least for the existential version of CH, as here the demon knows truths one at a time, not all at once. Maybe the demon will believe "everything is knowable", although there are tricky issues even there.

Here's an objection I tried to develop, but the wheels fell off. If someone can put them on again, go ahead! Suppose a weird world, in which p is true iff the demon doesn't believe it. The fact of believing p causes p to be true no longer, and the fact of not-believing p causes p to be true. Now, if you put the demon outside of the world (as Horgan does) you might be able to say that, necessarily, there are no such facts p. But as far as I can see - putting the demon inside the world seems to open up the possibility of such facts.

Nice objection. In fact there is a perfectly straightforward such P. Let's assume that the demon doesn't in fact know all truths (we're going with the existential rather than the universal version, after all). So there is some truth Q that the demon doesn't know. So let R = "Q and the demon does not know that Q". R is clearly true. But if the demon were to come to know that R, he would thereby come to know that Q, so P would be false. Hence the demon cannot know that R!

This is precisely the "paradox of knowability" that we discussed in class. There is a bit of literature on it. It clearly poses a problem for some formulations of CH. It can't be the case that all truths are knowable for the demon, and it can't even be the case that given full physical knowledge, all truths are knowable.

The best response, I think, is to go back to the conditional formulation, which says that the *conditional* from microphysics to any given truth (i.e. \(P+T+I \rightarrow Q\) for any Q) is knowable a priori. In the case where Q is the paradoxical R above, the demon can't know that R, but it can still know a priori that *if* P+T+I, then R. Of course, on the hypothesis of P+T+I, the demon will be able to figure out both that Q above is true and that he doesn't know it, so he'll be able to figure out R. Because the antecedent here is merely hypothetical, this doesn't imply that he actually knows R, but he can still figure out the conditional a priori.

Problem is, fully developing this objection involves saying something about the relation of p and the physical facts. It needs to be the case that the demon can know the physical facts on which p supervenes, otherwise this isn't a counter-example to CH. And if looks like if the demon does know the physical facts on which p supervenes, and it knows all the a priori facts, then it will be able to work out whether or not p is true. In other words, the defender of CH seems to be within her rights in claiming that the notion of a p truth is incoherent.
I think your P is actually coherent, as above. In the case where the
demon *knows* all the microphysical facts, it will be able to figure
out Q, and "I didn't know that Q", but it coming to know these things
it will render "Q and I don't know that Q" false, so the original
truth was still arguably unknowable. But if we put things in the
conditional format, there doesn't seem to be a problem with the demon
knowing a priori that *if* microphysics is like so, then P is true,
even though P itself is unknowable.

--Dave.

Cosmic Hermenudics.

I want to push the Aristotle problem I was suggesting in class. The
basic idea is that we have a person who has all the concepts of
Aristotle (ie. no modern science) and is an ideal reasoner. We then
give him all the micro-physical truths and the "that's all" fact.
Now consider Aristotle's favorite wooden chair. The question I have
is whether Aristotle can get from the micro-physical truths to "There
are macro objects in the world." Without any further concepts. In
particular whether he needs reductive concepts linking macro objects
to micro-physical stuff.

Many psychologists have suggested that we have an innate concept of
object and that the concept doesn't really change as we age. Spelke
has suggested four principles which characterize our object concept.
1) An object is a connected and bounded region of matter that
maintains itself when in motion.
2) Principle of continuity: Roughly this says that objects do not teleport.
3) Principle of contact: Objects don't move unless touched by
something that is moving.
4) Principle of solidity: One object cannot pass through another
object (without damage).

Suppose that something like this is right. Presumably, Aristotle had
this concept of object. Now the question is whether he can find
anything in the micro-physical description of the world that matches
this concept of object. The problem is that the modern view of
quantum mechanics has things violating every one of these principles.

Principle 1): From the micro-physics standpoint "matter" is all over the
place. The only boundaries we can draw are based on densities.
We might be able to come up with a sense of "connected" which involves
the forces which make one chunk of matter more dense than another.
But nothing in QM is connected in the macro sense of "touching."
Finally, matter does not maintain its connectedness while in motion.
Electrons leave my body every time I stand up from my couch and touch
something metal. In fact the micro-physical elements in every object
are constantly being exchanged with elements from other objects as
well as being in constant motion within an object.

Principle 2): There is a phenomena in QM known as quantum tunneling.
Basically elements at the QM level simply move from one place to
another without existing anywhere in between. At the level of individual QM elements this is happening all the time. Furthermore, there is a finite probability that this could happen to a macro sized object as well. But if our concept of macro sized objects doesn't allow for this then how is our ideal Aristilian reasoner going to figure out that some particular portion of space time currently has an object in it.

I'll skip 3 and 4 as I think the point has been made. We get from everyday objects to particle physics by reductive analysis. Objects are collections of molecules. Molecules are composed of atoms. Atoms are composed of some elementary particles. An ideal reasoner with only Aristotle's concepts and a theory of elementary particle physics won't find objects in a quantum mechanical description of the world. Nothing behaves the way objects do when described by quantum mechanics. In a molecular description of the world we get collections of things that do behave like objects. In an atomic description of the world we get things that behave like molecules. Finally, in a QM description of the world we get things that behave like atoms. But I think you really do need the intervening concepts to get from QM to objects.

Hi everyone,

I've been thinking that Horgan may be too dismissive of the possibility that quantum indeterminacy could spell trouble for the supervenience thesis. He points out that DM and S are "logically independent", and apparently thinks that any quantum indeterminacy in physics would apply only to DH.

I want to attempt to develop a quantum counterexample to CH and the supervenience thesis. Consider a conditional whose antecedent contains a complete specification of microphysical facts for some time slice, and whose consequent contains the set of macrophysical facts entailed by the antecedent. Apply this to the Shrodinger's cat thought experiment, where a photon impinges a set of half-silvered mirrors with probability one-half of deflection or penetration and thereby either triggers or fails to trigger a mechanism which breaks a flask of poison in a sealed container containing a live cat. The idea is that the cat's life status is indeterminate while the photon is superposed over possible states in the deflective mirror apparatus, until someone opens the container, collapsed the superposed "wave-function" and either observes a healthy cat or a dead one. Now, given the interpretation of quantum theory that posits a real indeterminacy (takes a realist interpretation on the wave-function and its collapse), it would seem that there would be one perfectly well-formed macro-fact--the cat being either alive or poisoned to death--that cannot be entailed by the antecedent of the CH conditional. The cat example seems contrived (it is) but the breakdown of the CH thesis (S) would seem to follow antime we want to know macro-facts about the future that have to be entailed from prior microphysical facts that enter into quantum superpositions, generally.

I'm thinking that Horgan dismisses quantum indeterminacy because he
considers only cases of entailment from some set of microphysical facts to
some other set, such as the conditional from rates of decay for the
particles of a radioactive element to a specification of a particular
detail's emission, and other standard examples of quantum indeterminacy.

That being said, the anticipated objection is that some interpretations of
quantum theory do not take a realist line on the wave-function collapse.
(I don't remember all the details of the various interpretations, so I'll
say more generally that some interpretations apparently can accomodate the
collapse without conceding fundamental indeterminacy). Still, if it is at
least plausible that quantum theory may turn out to be fundamental to a
completed physics, then in that conceivable scenario the supervenience
thesis of CH will fail to hold, and so the argument against
materialism--predicated on the distinction between failed supervenience
only in the phenomenal case and not for standard physical macro
objects--would seem to be in big trouble. This strikes me as odd, since
the cogency of the argument would then hinge on the contingencies of our
physical theory qua quantum indeterminacy. It seems strange to say that
IF our physical theory turns out such and such, then we have a good
argument agaiant materialism, but possibly not. It also seems strange that
the anti-materialist argument should be put forth so assertively given our
epistemic confusion about QM in general, since it seems that the failure
of CH and S is at least possible on some interpretations, and in that case
the argument wouldn't be very compelling.

Erik

"What our grammarian does is simple enough. He frames his formal
reconstruction of K along the grammatically simplest lines he can,
compatibly with inclusion of H, plausibility of the predicted inclusion of
I, plausibility of the hypothesis of inclusion of J, and plausibility,
further, of the exclusion of all sequences which ever actually do bring
bizarreness reactions." -- W.V.O. Quine

Some thoughts on Josh's email. I'm not sure that the features of quantum
mechanics Josh notes are necessarily all that problematic for cosmic
hermeneutics. Although I do not know all that much about QM, I think that,
when we say that an atom is a certain size, we specify a sphere within
which there is a fairly good chance of finding the appropriate electrons.
Although this certainly allows that there is some amount of fuzziness in
the boundaries of objects, this does not necessarily undermine the
possible success of cosmic hermeneutics-- given the exceedingly high
probability of electrons and so forth occupying particular regions of
space, the 'macro' properties of solidity and so forth arise.

I think the root of Josh's worries seems to be the quantum indeterminacy
stuff. The Heisenberg Uncertainty Principle asserts that we cannotknow
both the location of a particle and its velocity beyond a certain level of accuracy. This arises because, in the process of measuring, we must interact with the particle— if we measure the velocity of a particle, we alter its position, and so forth. A LaPlacian Demon, I presume, is not constrained by this as it simply knows all of the microphysical facts of the universe at a particular instant. I wonder whether this bypasses the problems of indeterminacy with which we are faced when we study quantum phenomena.

Lots of interesting issues about QM and cosmic hermeneutics. Josh suggests that one cannot get from QM to "there are macro objects" a priori, as the concept of an object involves various principles (connectedness, continuity, contact, solidity) that are false in QM.

I think it's certainly right that QM poses problems here. When
philosophers talk about microphysics in this context they usually assume some sort of classical mechanics. This makes things easier, as one has definite entities with definite position, velocity, mass, etc, right at the bottom level. From there, it's easy to get to macro position, velocity, shape, size, mass density, etc. But from QM, this isn't so easy.

Of course one thing one might do is cheat, and say: in the base, we'll allow not just microphysics but chemistry. Then we'll be allowed facts about definite molecules with definite positions, masses, etc. And from there we can get the macro stuff out. We still have an interesting and substantive thesis, which will still probably capture what's at issue between someone like me (or Jackson, Lewis, etc), and someone like Byrne, Block, or Stalnaker. But still, this leaves open the interesting question of just what follows from microphysics alone, whether chemistry follows from microphysics, etc.

On Josh's principles: of course violations at the micro level alone may not matter too much, as it's at the macro level that we expect to find objects. But serious violations at the macro level will matter. One strategy would be to argue that such violations won't happen, or will happen only rarely. E.g., quantum tunnelling discontinuities are presumably rare at the macro level, so they may not rule out objects there. And maybe (maybe) there is some way to make sense of connectedness using the QM notion of decoherence, etc. So I think there are strategies here.

A more detailed answer depends really on what interpretation of QM one gives. Without such an interpretation, one can't really know what QM is saying about microphysics. With such an interpretation, I think one gets different results re cosmic hermeneutics.

(1) Bohm interpretation (with particles governed by the wave function): Here there isn't too much trouble for cosmic hermeneutics. One has definite particles all the way down, just as on a classical view. So no more problems deriving macro objects here than on a classical view.

(2) Everett interpretation (with a giant superposed wave function with all possibilities at once): Here, one certainly can't derive macro "truths" from the wave function. E.g., the "truth" that the cat is alive or the point is pointing up won't follow from the superposed wave function. But arguably, on the Everett view these aren't really truths. The cat is really a superposition of both alive and dead in reality, and so on. And of course we don't expect indeterminate matters to be settled by cosmic hermeneutics on microphysics, any more than questions of tallness are.

Alternatively, one can say that the sense in which the cat is "really" alive is relative to my own mind -- my mind splits into a component, one of which sees a dead cat and one (this one) an alive cat. If so, the cat status won't follow from microphysics, but it will follow from microphysics plus facts about my mind. What to say here depends on whether mental facts are derivable from physical facts. If they are derivable, then the cat status will follow from physical facts plus an indexical about where *I* am. If they are not derivable, then we need mental (e.g. phenomenal) truths in the inference base. I take the latter option, of course. Basically, on this version of the Everett view, cosmic hermeneutics is radically false, as the apparent "determinacy" in the world stems from the minds of observers and not from the world. But one still has derivability from the microphysical
(3) Collapse interpretation (on which there is just a wave function which "collapses" into a relatively definite state every now and then): This is probably the hardest case. The collapse will be in microphysics, so one will be able to know that the pointer or cat wavefunction has collapsed. But there is still a question of how one gets from even a collapsed wavefunction to macro truths -- e.g. from a macro object's wave function to facts about its position -- and whether this is a priori. The position etc of an object or particles will correspond to a certain eigenvalue, but it's not clear in what sense the mapping from microphysics to position is a priori, as it's not obvious in what sense taking the eigenvalue is part of the concept.

Perhaps the easiest thing is to build this matter into the interpretation itself, so that the wavefunction is to be counted as specifying these positions etc via eigenvalues (that's part of what the wavefunction means). If one does that, then arguably one can get from the wave function to positions, velocities, etc, of various entities, and then eventually to macro determinacies, at least in some cases (cases where the wave function has collapsed appropriately, so that things actually have a determinate position, etc).

The alternative is to say that we can't get this from the wave function alone, and that we need to introduce substantive "bridge principles" to get from wave function to macro position, etc. On the previous view, these bridge principles are a priori, but if that's denied, then they are substantive and a posteriori. On such a view cosmic hermeneutics will need to be denied. But arguably that's appropriate. The "thin" nature that we are building into microphysics on this interpretation arguably needs to be supplemented with further laws (these bridge laws) to determine a macro world. So the bridge laws should be taken as a further part of the theory. I have heard some people (e.g. Shelly Goldstein at Rutgers) argue for this explicitly, and some others seem to be implicitly committed to such a view.

Personally, I prefer the former view, but I think it is a difficult and somewhat open question. The ontology of these collapse interpretations has not been worked out as well as it might be, I think.

Overall: Clearly the answer depends on the interpretation. But I think we find a pattern: in the cases where the microphysics gives us a *complete* theory of the fundamental laws and such (e.g. Bohm, some collapse interpretations), cosmic hermeneutics is possible. In cases where microphysics is an *incomplete* theory, and where further fundamental laws are needed (e.g. some collapse and Everett interpretations), cosmic hermeneutics is impossible. But in each case, the macro truths (insofar as there are such truths) follow a priori from the fundamentals, whatever those are.

Presumably, given an interpretation of QM, with all the relevant concepts, and with all the relevant facts, even Aristotle would be able to figure out the truths about macro objects (insofar as there are such truths) from the relevant facts. In the Bohm case it's easy; in the Everett case he may need facts about minds; in the collapse case he may or may not need further principles, depending on just what we give him as "built into" the microphysical concepts. But in each case some sort of macro picture should emerge, insofar as there is such a picture (of course, in some version of the Everett
interpretation, there simply is no macro picture in the world as opposed to in the mind).

Erik L. considers a case involving Schrodinger's cat, where an observation triggers a collapse in the cat's wave function at time t, so it goes from a superposition of alive and dead to being alive (let's say). So we're assuming a collapse interpretation here. Erik suggests that the facts that the cat is alive isn't entailed by the microphysics here.

I think it's right that the cat's status isn't entailed by microphysics before time t. But that's not a problem for cosmic hermeneutics; rather, it's a problem for "cosmic number-crunching". In this case, Laplace's number-crunching demon can't even predict the future evolution of the wave function from the previous state. But the hermeneutic demon is given *all* the facts about the wavefunction across space and time, so this isn't a problem for him.

Given all the microphysical facts (including facts after t), presumably examination of the post-t wave function will reveal that the cat is alive rather than dead. One will find particles with definite locations constituting a cat walking around, etc, with a beating heart, etc, rather than a cat lying down with no heartbeat, etc. At least, that's so modulo the issues about interpretation of collapse formalisms discussed above. But any such problems won't stem merely from indeterminate evolution between past and future states of the wave function, which the interpreting demon can take for granted.

Erik suggests that given the possibility that CH fails for QM, one should be careful putting forward anti-materialist arguments given the failure of CH in the phenomenal case. I do agree that QM should make us cautious here. But I'd like to think that on a careful examination of QM, the interpretations on which CH fails are precisely those in which the relevant microphysics is an incomplete theory. So one still has an inference from failure of CH to expansion of ontology.

Anthony notes another way of resisting the conclusion that QM falsifies CH. If in QM, particles have "fuzzy" location, that may be enough to give enough macro determinacy for our purposes. I think that's more or less right, though the details of this fuzziness depend a lot on the interpretation of QM. On the Bohm interpretation, the particles have definite interpretations and the wave function corresponds to our epistemic probabilities of finding them in certain definite places, so one has probabilistic access to the truth of the sort Anthony suggests. Of course in this case the demon will strictly speaking have access to the positions of the underlying particles, not just to the wave function, so he won't have problems. As Anthony notes, the demon is not constrained by our limitations of measurement -- he knows all the determinate facts!

On other interpretations, things are a bit more complicated, as there really aren't particles with determinate positions in the general case. Here it's not just a problem of access to the facts, but of there not being facts. So one can't really even talk of "the probability that the particle is in position X". The wave function gives the full state of the particle, and that's that. But still, some of the time, the wave function will specify a definite position (as eigenvalue of position operator), which will help. And other times, it will specify a determinate range of positions (as a range of
eigenvalues), which will presumably correspond to the sort of "fuzzy" location Anthony mentions. And maybe such micro fuzziness could add up to a sort of macro determinacy.

There is a worry that some such fuzziness can be amplified at the macro level rather than cancelled out. That gets quite tricky, and again depends on the QM interpretation. On collapse interpretations, it will be the case that at least sometimes, the amplified fuzziness will be collapsed out, so in those cases we'll have a relatively determinate state. On Everett interpretations, the fuzziness may amplify indefinitely and forever (!), so there really won't be any determinacy to be found in the physical state alone; any determinacy will then have to be found in the mind.

Anyway, plenty of issues here.

--Dave.

In looking back over the Horgan and Byrne readings on cosmic hermeneutics, I am somewhat puzzled about the significance of the CH-thesis. It seems that Horgan is interested in the possibility of CH because it provides a way of capturing the physicalist claim that all facts are necessitated by the microphysical facts. Now, there is no *immediately* obvious contradiction in claiming that all the facts are necessitated (this is a metaphysical notion) by the microphysical facts and yet for a demon (an ideal reasoner) who knows all these microphysical facts to be unable to deductively infer from this knowledge all true propositions. I say there is no obvious contradiction in holding these two views because the former is about metaphysics and the latter is about epistemology.

Nonetheless, this physicalism minus CH seems to create a gap between reality and our knowledge of reality (or at least its intelligibility) which is extremely unpalatable. The problem is that those who deny CH have to claim that we arrive at micro to macrophysical identity statements (I hope this is an ok way of characterizing "water = H20") in some other way than the analysis approach suggested by Chalmers, Jackson, and even Loar. The analysis approach renders the identity intelligible. But I suspect that any other way of arriving at such identities falls short of intelligibility.

This came out of discussion of the Byrne article a couple weeks ago--the denial of an a priori entailment of the macro from the micro leads to a new skeptical hypothesis, such as the "problem of other chairs"! If I know all the microphysical facts of the thing I'm currently sitting on, I can still wonder "Is it a chair?" Here is a more specific way of bringing out this point. Suppose, as I think Block, Stalnaker, and Byrne would probably say, we arrive at identities through the observation of correlations. Chemists observe a correlation between "being a water sample" and "being an H20 sample" and conclude on grounds of parsimony perhaps that "water = H20". But if our reasons for believing in the identity claim is merely that they are correlated, then we can certainly raise the worry that the property of
this stuff in virtue of which it falls within the (secondary) intension of "water" is a different property from the property in virtue of which it falls within the intension of "H₂O".

I believe that Block and Stalnaker claim that identities don't need explanation. But they also seem committed to the view that identities can't be understood—they just have to be taken as brute. Physicalism minus CH seems to lead to the view that there are strong necessities everywhere, and that our hermeneutic demon would have to know the microphysical facts PLUS these strong necessities in order to deduce all the facts. This really seems outside the spirit of physicalism.

Brad,

I'm going to pick on just a specific part of your message here; namely, your point that micro to macro identity statements might be had by taking note of correlations between properties. I would argue that mere correlations cannot possibly constitute sufficient grounds for identity. For example, there is a high correlation between the occurrence of a storm and a rapid fall in barometric pressure, but claiming an identity here would be absurd. However we arrive at identities, it can't be from just observed correlations, even if this constitutes an initial heuristic for focusing attention on certain properties over others.

Brad

I'm obviously in sympathy with what Brad wrote re cosmic hermeneutics. One of the problems with denying CH, I'd argue, is that it creates apparent epistemological problems where we had none before. If there are two different epistemic possibilities compatible with all the physical (and phenomenal) facts, it's not clear how we are to choose between them. At least we have a substantive skeptical problem. But on the face of it there is no such problem for chairs, tables, etc. (Of course there is such a problem relative to the phenomenal facts alone, but not relative to the physical and phenomenal facts.)

There is an interesting question about how one gets to micro-macro identity without CH. One thing Block/Stalnaker et al might say is that one gets such an identity when one has a reductive explanation, but deny that reductive explanation is to be cashed out in terms of a priori entailment. Another thing would be to deny that reductive explanation is required at all, as that's an epistemic matter where
identity is ontological. I would tend to agree with Brad that either way, we are left with "brute" identities that are very difficult to integrate with our view of the world and that border on being unintelligible.

Block/Stalnaker et al would argue that these identities are perfectly intelligible once we get out of our a priori straightjacket. Combinations of empirical evidence plus considerations of simplicity can make such identities very plausible even where there is no transparent epistemic connection from micro to macro. One might say that the identity is the "best explanation" of the empirical evidence, including correlation. And they would argue that it is OK for an identity to be "brute" in this way, as identities don't need to be explained. They use "Samuel Clemens = Mark Twain" as an example here -- how would one explain that? But they'd say that nevertheless, such identities are perfectly intelligible.

Now, I'd argue that for standard identities, some sort of epistemic entailment from a more fundamental base still holds (e.g. one could deduce that Mark Twain is Samuel Clemens from all the physical plus phenomenal facts), and this is what renders the identity there intelligible and "non-brute". Where the identity needed in the mind-brain case would seem quite "brute". But clearly B&S don't agree with either of these points.

I don't think B&S need say that every correlation implies an underlying identity. They could deal with some cases (e.g. the ones Erik L. raises) by putting some conditions on them. E.g., one would at least require the correlated events to occur at the same point in space and time. And they would argue that it can't be the case that there is an obviously causal process mediating the relation between the two (as with storm and pressure). And so on. So maybe they could motivate identities in the water-H2O cases and mind-brain cases without being committed to every correlation implying identity.

N.B. One note: Physicalism minus CH need not quite require strong necessities as defined (these involve positive conceivability without possibility), but they will at least lead to inscrutable truths (which come down to negative conceivability without possibility). I don't think inscrutable truths are quite as problematic as strong necessities, but they still have lots of problems, and in particular seem unsuited to play much of a role in epistemic matters such as as explanation.

--Dave.
imagine the visual experiences of a dog-- they are probably somewhat like
the experience of seeing a black and white movie.

It seems to me that it is somewhat more difficult to conceive of a dog's
olfactory experiences. Avalanche rescue dogs are capable of quickly
detecting the odor of people buried beneath considerable amounts of very
hard snow (3 meters or more, sometimes). They are further able to
distinguish the smell of the buried victim from the smell of the person
handling them and other rescuers on the scene. I was once buried in a
snowcave some six feet below the surface, and the rescue dog found me and
had dug down to me in about 2 minutes.

I don't have the faintest idea what it would be like to be able to make
the kinds of olfactory discriminations that dogs are capable of making. It
does not seem to be me to be particularly likely that even an ideal
conceiver would be able to do this. It seems fairly straightforward to
imagine what a dog's visual experiences are like because we assume that
their visual experiences are somehow less rich than our own. But, given
that dogs have olfactory capabilities far superior to ours, it just doesn't
seem plausible to suggest that any non-canine being, however idealized and
with whatever instrumentation you please, could conceive of what a dog's
olfactory experiences are like.

I'm not sure if all of this amounts to anything (except praise for the
virtues of dogs).

Anthony
For next week's meeting, we will focus on possible worlds. The readings should be in the purple folder by sometime Wednesday. They are

- Lewis, Possible worlds
- Adams, Theories of actuality
- Stalnaker, Possible worlds
- Lewis, Selections from "On the Plurality of Worlds"

These present three different ways of understanding the nature of possible worlds. Lewis argues that possible worlds exist in just the same way that the actual world does (modal realism, or concrete modal realism). Adams and Stalnaker argue that possible worlds should be understood as some sort of abstract objects, or as "ersatz" worlds constructed via a linguistic or propositional construction. (The last part of Adams on "world-stories" is particularly relevant.) The Lewis book selections defend modal realism in more detail, and give a critical discussion of some "ersatz" proposals.

If you can, it might also be good to look at the Lewis book as a whole. This goes exhaustively into all sorts of issues here -- why modality is important (chapter 1), objections to his modal realism (chapter 2), and pros and cons of the various "ersatz" constructions (chapter 3). It's also a wonderful clear book to read. It's out of print, unfortunately, and too long to reproduce wholly here, so I will copy just parts of chapters 2 and 3. The chapter 3 material (which in essence can be seen as a response to the Adams and Stalnaker proposals) is particularly relevant for our discussion.

We'll discuss those general issues in the first half of next week's meeting. In the second half we'll try to apply the issues in the general context of conceivable worlds, two-dimensionalism, etc. In particular, we will see if we can justify the claim that the space of ideally conceivable worlds exists in at least the sense that standard possible worlds exists (e.g. an "ersatz" sense). We'll talk about why such worlds might be needed; and we will see whether we can go through an "ersatz" construction so that this space of worlds makes coherent sense. This will correspond do what I say extremely briefly in Mind and Modality 2.9, (i) and (ii). It would help to look at that, and also at what I say re the need for conceivable worlds in 3.2 of "Materialism and the Metaphysics of Modality". If you can, think about how one might go about making up an ersatz construction (perhaps starting from concepts and the notion of apriority, and perhaps one or two other primitives) that will deliver the right results.

In the meantime, on the mailing list this week it would be good to see a detailed discussion of some of the issues re scrutability and cosmic hermeneutics. E.g. Horgan, Byrne, Block and Stalnaker, my discussion, and any general thoughts you might have. We didn't get a chance to go over Block and Stalnaker exhaustively in class, so it might be particularly useful to hear any comments on the details of their paper.
I have a question about possible worlds:

A possible world is the set of stuff that is causally connected in space and time. How do you treat the effect of "consideration" of a possible world on the actual world. For example, this actual world is now different than it would have been had we not considered a possible world where there are talking donkeys. How is this reconciled?

Erik H.

On Erik H.'s point re possible worlds: I think it's clearly true that a world where I'm thinking of talking donkeys is different from a world where I'm not. More generally, a world W1 where I'm thinking of world V1 is different from a world W2 in which I'm thinking of world V2. But this doesn't imply that there is causal interaction between V1 and W1. Rather, V1 and W1 have been the way they are all along!

Still, there is a deep question about just how one can think about something that one can't causally interact with. This bothers quite a few people thinking about the epistemology of possible worlds. One can at least say in reply that the problem here isn't obviously worse than the problem in mathematics, where one can apparently think about the number 2 without causally interacting with it. Someone who believes that possible worlds are "abstract objects", like mathematical objects, might well hope that the two problems will have the same sort of solution (whatever that is). Lots of solutions have been offered, but I don't think any single solution has widespread acceptance.

--Dave.
We ended last time by sketching the truth-conditions for modal sentences using a "conceivable worlds" semantics. Maybe I missed something. I thought the semantics should go something like the following:

(*) Nec P is true_1 iff: for any conceivable world w, P is true_1 at w.
(**) Nec P is true_2 iff: for any conceivable world w, P is true_2 at w.

But (**) doesn't at all correspond to Dave's definition (if I recall). I would have thought the above was the natural way to do things since it recursively calls truth_1 or truth_2 for non-modal sentences, which we already have worked out (the general sketch of the 2D framework does that). The problem is with (**). The semantics is supposed to hold out the possibility that the class of conceivable worlds is not co-extensive with the class of metaphysically possible worlds. But (**) makes appeal to conceivable worlds where P is true_2, and truth_2 is what some might call "metaphysical truth" (type-B materialists, e.g.). Combining that with (**), though, we get that there are no truths P such that Nec P is true_2. And this is awkward for conceivable world semantics. In fact, it might give someone reason to doubt that there is anything useful (apart from defeating materialism) in the semantics. On analogy with possible worlds semantics, conceivable worlds semantics needs the claim to usefullness. Fixing (**) might be problematic too: (**) is the natural way of giving modal semantics, and changing only (**) without substantively changing (*) looks ad hoc.

This points to another confusion I've been entertaining on 2D semantics. It's probably a little off topic, so we'll get to it in a week or two. But the main idea is to what extent the 2D semantics for terms meshes with the 2D semantics for sentences. In particular, in figuring the truth_1 of a sentence S, it looks like every term in S must be mapped to its referent_1. Likewise for truth_2. Are there sentences S for which the natural truth_1 conditions might depend on some term in S being mapped to its referent_2?

you have here: it's not a million miles from what I would say, but I
would change some details. In particular, I wouldn't put the
left-hand sides as "'nec P' is true_1" and "'nec P is true_2", as the
two right-hand sides can have different actual truth-values for many
P, but the left-hand sides cannot, at least at the actual world. (If
a statement is true_1 at the actual world it is true_2 there, and vice
versa.) So it's better to write the left-hand sides as "P is
1-necessary" and "P is 2-necessary", or "nec_1 P" and "nec_2 P", or
some such.

> I would have thought the above was the natural way to do things since it

For the reasons above, I think it's best not to think of 1-necessity
and 2-necessity as the primary and secondary intensions of a single
concept of "necessity". Rather, it's that the concept of "necessity"
is ambiguous, and we need to disambiguate two distinct concepts.
Probably these concepts are best regarded as not themselves having a
deep 2-D structure -- it's not as if the notion of "necessity" (or
"1-necessity" or "2-necessity") picks out different things depending
on how the actual world turns out. At least, nothing in the 2-D
considerations alone suggest that conclusion, though one might
conceivably come up with other arguments for it.

> The problem is with (**). The semantics is supposed to hold out
> the possibility that the class of conceivable worlds is not co-extensive

I don't quite follow your claim at the end. Even with the semantics
you suggest above, won't "2+2=4" and "water is H2O" be examples of
truths P such that Nec P is true_2 (as P will be true_2 in all
conceivable worlds)?

But anyway, I think one has to be careful about equating truth_2 with
"metaphysical truth". Actually, I'm not sure what "metaphysical
truth" is, but I imagine above comes to much the same thing as
equating 2-necessity with "metaphysical necessity", so I'll consider
that claim instead. It's true that on the 2-D picture, and on the
modal rationalist view, 2-necessity (as defined here) and metaphysical
necessity more or less coincide (at least on one plausible way of
reading the latter). But on a view with strong necessities, the two
may come apart, as such a view will have fewer metaphysically possible
worlds than conceivable worlds. For example, it might just be that
"the gravitational constant = XXX" is metaphysically necessary but not
2-necessary as defined here.

On views with strong necessities, I suppose P will be metaphysically
necessary is P is true_2 in all metaphysically possible worlds. Given
that the spaces of conceivable and metaphysically possible worlds come
apart on such a view, metaphysical necessity and 2-necessity (as
defined above) will come apart similarly.

> In fact,
> it might give someone reason to doubt that there is anything useful
> (apart from defeating materialism) in the semantics. On analogy with
> possible worlds semantics, conceivable worlds semantics needs the claim
to usefullness. Fixing (***) might be problematics too: (***) is the natural way of giving modal semantics, and changing only (***) without substantively changing (*) looks ad hoc.

I don't quite follow this, but maybe you can elaborate. Again, I prefer to simply disambiguate the concept of necessity, rather than give it a 2-D modal structure. I think one can make the case for such ambiguity on independent grounds in any case, as e.g. we'll do this week in the material on subjunctives and indicatives.

This points to another confusion I've been entertaining on 2D semantics. It's probably a little off topic, so we'll get to it in a week or two. But the main idea is to what extent the 2D semantics for terms meshes with the 2D semantics for sentences. In particular, in figuring the truth_1 of a sentence S, it looks like every term in S must be mapped to its referent_1. Likewise for truth_2. Are there sentences S for which the natural truth_1 conditions might depend on some term in S being mapped to its referent_2?

Hmm, interesting. Again, a statement is true_1 at the actual world iff it is true_2 there. And a term's (actual) referent_1 will always be its (actual) referent_2 -- both are just the term's actual referent! It's only in non-actual possible worlds that these things come apart. But I suppose your suggestion might come to the possibility that to evaluate the truth_1 of S at some non-actual possible world, we need to consider the referent_2 of some term in S there, which would then depend on a posteriori facts about the actual world.

The short answer, I think, is that this can't happen. Truth_1 is defined so that it depends only on facts about the world in question (plus a priori analysis). Some statements, e.g. "The actual president is Bill Clinton" might make reference to the actual world, but they can still be evaluated in a single-world way. E.g. to evaluate the truth_1 of the statement above at a world where George Bush is president, we consider that world as actual, and determine that if that world is actual, the statement is false. That's to say, one never needs to import the *actual* referent of "the actual president" in evaluating the truth_1 of this statement at world W. One only ever imports what the referent would be *if* W were actual.

Of course one could try to come up with sentences that don't work this way, but I think that more or less by virtue of the way truth_1 is defined, the best we'll see is a pattern akin to the above. But I'm interested to see attempts, in any case!

I have two questions- In seminar we were talking about other possible worlds which have the same history or are on the same time as our world (for example, consider a world where all the history up to this point is exactly identical with ours, only this seminar never took place.) It seems that this world is spatio-temporally related to ours? If so, should we
consider it as another possible world or part of this world?

One could even make the argument that this no-seminar world is causally related to ours if, from considering the other possible world, my actions are affected. (I imagine how unbearable life would be without this seminar and so decide that I should take it.) Likewise, we could imagine this type of causal interaction with respect to Erik H's talking donkey world.

Finally, in response to Erik H, David suggested that the problem Erik poses can be compared to problems in mathematics... we can contemplate the number 2 without causally interacting with it. But, as Dave points out, this seems a more viable solution if we consider possible worlds as abstract entities, like numbers. Does the problem of how one can think about something one can't causally interact with remain if we consider actual worlds as literal, the way Lewis does?

I don't think that we should say that this other world is spatio-temporally related to ours. For one, that other world does not appear to be spatially related to this one. Further, I think it's best to restrict temporal relatedness to within-world events. I remember there was debate about this in the seminar. But I don't find any problems with this restriction, nor does it really make sense to me to say that two events that are in different worlds occur at the same time in some absolute sense. Rather, when we describe two worlds that have the same history up until a particular time (within each world), events across worlds that we want to describe as "happening at the same time" ought to be described rather as occupying symmetrical locations in their respective world-histories.

Brad

Lewis distinguishes between two kinds of parsimony. A theory is qualitatively parsimonious if it posits fewer kinds of entities. A theory is quantitatively parsimonious if it posits fewer tokens of the kinds it posits. His claim is that people are interested in qualitative not quantitative parsimony.

Lewis thinks that his realism about possible worlds is qualitatively, but not quantitatively parsimonious. "You believe in our actual world already. I ask you to believe in more things of that kind, not in things of some new kind." (p185) I'm curious whether that claim is really true. I don't know if this makes sense but see what you think.

There seem to be two kinds of things that a Lewisian view posits that belief in only one actual world doesn't posit. First is logical space. On a one world view logical space is perhaps a concept or an abstract object or whatever. But whatever kind of thing it is, it is something we already have. It isn't clear this is true for Lewis. Logical space seems to at least be a set of super-universal laws that place constraints on how possible worlds can be. Consider the law of non-contradiction. If possible worlds are concepts or abstract objects then non-contradiction is just like other things which govern concepts or abstract objects in our world. But for Lewis this is a law external to our world or any other world. It has to be a different *kind* of law. If purely logical laws bug you then consider Lewis'es claim that all worlds have some kind of space time. Certainly, this isn't a logical truth. So if true it has to be a law which governs how possible worlds can be. This is a different kind of
thing than the laws within our world.

The second kind of thing that a Lewisian view posits that a one world view doesn't is entities that we are not spatio-temporally or causally connected to in any way. We have some kind of spatio-temporal connection to everything that exists in our world, including the world itself. Perhaps we have some logical or conceptual connections to other worlds and their contents. But there will be entities which exist yet I have no spatio-temporal connection to. This is a different kind of entity.

I'm not sure how compelling this is but Lewis does seem to be a bit less parsimonious than he thinks.

I'm not sure how compelling this is but Lewis does seem to be a bit less parsimonious than he thinks. </fontfamily>

A few quick thoughts on possible worlds.

In effect, Rachael and Brad bring up the question of how we are to define the notion of "spatiotemporally related". The problem is that if there are counterfactual worlds where I am doing something else now, it seems that my counterpart is in some sense temporally related to me -- he exists at the same point in time, after all. (Some philosophers, and maybe even Lewis, would deny that we can have this sort of "transworld identity" between points in time, just as they deny transworld identity for individuals, but I leave that point aside for now.) Intuitively (as Brad suggests), there is a stronger notion of spatiotemporal relatedness, such that for two entities to be spatiotemporally related they have to be in the same world, so that my counterpart won't count. But Lewis clearly can't just define spatiotemporal relatedness that way, as he wants to define "being in
the same world" in terms of spatiotemporal relatedness, so the
definition above would lead to a circle. So the question is whether
we can find an independent definition of the stronger notion.

One thing to try might be defining the relation in terms of the
existence of a continuous path from A to B. Another thing would be to
import causal relations here. A third thing would be to take this
sort of spatiotemporal relatedness as a primitive, as e.g. some do on
the relational theory of spacetime. On such a theory, two beings or
events in the same world might stand in the relation of e.g. A
preceding B, or A being a certain distance from B, where these are a
primitive sort of relation that only holds, intuitively, "within" a
spacetime manifold. But maybe there are better suggestions here. All
ideas are welcome.

I think Rachael is right that on Lewis's view, the epistemology of
possible worlds becomes more problematic. The analogy with
mathematics works better for the ersatz theorist, as we're invoking
abstract objects in each case. It's by no means obvious how we can
have knowledge of abstract objects without causally interacting with
them, but at least there is an intuition here that it's not entirely
unreasonable. But in all other cases of concrete objects, it seems
that knowledge requires something like causal interaction, or some
other intimate epistemic acquaintance.

In response, Lewis argues (pp. 110-12) that the relevant distinction
isn't that between the concrete and the abstract, but rather that
between the contingent and the necessary. Knowledge of the contingent
requires some sort of acquaintance, but knowledge of the necessary
doesn't. So I guess the debate comes down to which of these
demarcations is most relevant for isolating the sort of knowledge that
seems most clearly to require causal (or other) acquaintance. Any
thoughts on Lewis's discussion here are welcome.

Re Josh on Lewis on parsimony: I think these are good points. In
response, Lewis might say that anyone who is serious about modality
will need modal principles or "laws" governing logical space, so he
isn't any worse off. Josh might say: it's one thing to have such laws
governing abstract objects, another to have them governing concrete
objects. Lewis might say: what's the big deal about concreteness? A
modal law is a modal law. OK, I need modal laws governing concrete
things, whereas you need modal laws governing abstract things, but
that doesn't put us in obviously different boats. In any case, we
already have modal laws governing concrete things (e.g. the principle
of non-contradiction governs concrete things in the actual world).

I think I tend to share Josh's intuition here, but it's a complex
dialectic.

Josh's second point is that Lewis needs concrete entities we're not
spatiotemporally related to, and that's something new. I think Lewis
would agree, but argue that this doesn't involve any new *fundamental*
 sorte of thing. After all, we both have concrete objects, and
spatiotemporal relations. Lewis just says something different about
when objects stand in those relations. That's a nonfundamental
"something new" analogous to me holding that there are swans in
Australia where you deny it. And Lewis might argue that the principle
of parsimony really on applies to fundamentals, rather than to these
complex combinations.
First, I want to give a brief response to Dave on the parsimony issue. I don't think Lewis can say that modal laws are modal laws be they laws for concrete or abstract objects. If possible worlds are concrete then modal laws exist independent of any one possible world. They are in some sense external to the worlds themselves. On the other hand, if possible worlds are abstract objects (or fictions, etc.) then the laws governing them will be laws within the actual world. Furthermore, there will presumably be other laws governing abstract objects of other sorts (i.e. numbers), so modal laws will not be a new kind of thing.

Turning to yesterday's discussion, I'm unclear exactly what the difference between and inscrutable truth and an open inconceivability is. Both, I take it, are cases that are negatively conceivable but not positively conceivable. Both are possible. Perhaps open inconceivabilities are things that are to weird to have a concept of, but I don't think we want to use "weirdness" as a formal distinction (though I admit it is an informal distinction). So what did I miss?

Josh

> exactly identical with ours, only this seminar never took place.) It seems
> that this world is spatio-temporally related to ours? If so, should we
> consider it as another possible world or part of this world?

I don't think that we should say that this other world is spatio-temporally related to ours. For one, that other world does not appear to be spatially related to this one. Further, I think it's best to restrict temporal relatedness to within-world events. I remember there was debate about this in seminar. But I don't find any problems with this restriction, nor does it really make sense to me to say that two events that are in different worlds occur at the same time in some absolute sense. Rather, when we
describe two worlds that have the same history up until a particular time (within each world), events across worlds that we want to describe as "happening at the same time" ought to be described rather as occupying symmetrical locations in their respective world-histories.

Brad
For next week's meeting we are focusing on modal rationalism. This will be the culmination of the current phase of the course. In the first half of the meeting we'll go over the "master argument" for modal rationalism (and against modal dualism) as presented in section 3.5 of "Materialism and the Metaphysics of Modality" and section 2.9 of "Mind and Modality". In the second half we will tie up some loose ends re inscrutability, open inconceivabilities, etc (corresponding roughly to 2.6 of "Mind and Modality"), and look at the general shape of modal rationalism.

In the following week, we'll return to some issues concerning the two-dimensional semantic framework. First, we'll finally get to the material on "the tyranny of the subjunctive", concentrating on links to issues concerning subjunctive and indicative conditionals. Second, we'll look at the application of the framework to issues concerning the contents of thought, and in particular issues concerning internalism, externalism, and narrow content (the central reading will be my paper "The Components of Content"). Third (in what I think will be the final week), we'll look at some objections to the 2-D framework as an account of the content of thought, e.g. those raised by Block and Stalnaker (separately and together), and will look at some of the intricacies, limitations, and open questions about the framework.

In the meantime, I look forward to seeing everyone's discussion of the material on possible worlds that we covered this week.

Finally, there is a party tomorrow (Saturday) night at Stuart Hameroff's house, which is where I'm staying. It will go from 7pm onward, and beer, wine, and food will be provided. The majority of the people there will be doctors, nurses, and such from the hospital (Stuart is an anesthesiologist who dabbles in consciousness research), but there will be a few philosophers and such there. The house is at 2144 E. Camino El Ganado, in the foothills. To get there: go north on Campbell from River for a couple of miles until just after Campbell "divides", turn left on Camino La Zorella (the second left after the divide), left again on Camino Escalante, and right on El Ganado. The house is on the corner; easiest to use the second driveway on the left. Sorry about the short notice -- hope you can make it!

--Dave.
or number, if I didn't see the world first. How can we tell that the effects of experience haven't influenced the data here?

Also, if we were to have used modal rationalism to help hypothesize physical truths in science, would we have ever come up with quantum mechanics? They defy what seem logically possible (annihilation and creation of particles & immediate effects across space).

Dave, I don't understand the part where you say that "we need the modality of ideally conceivable worlds = possible worlds...even if some of these worlds aren't metaphysically possible." And then in the next paragraph, "there is no bar to the existence of logically possible worlds." (Mind and Modality 2.9)

Subject: Re: Type-A possibilities
Status: RO

I've been thinking lately about the possibility of a type-A defense of materialism. Here's why. Given that a type-b defense a) requires some conceptual analysis (eg apriori reasoning) to connect physical and phenomenal states that are prima facie under different descriptions, and b) such conceptual analysis, if one grants the cogency of the 2D framework, will not deliver strong necessities (necessary aposteriori statements with necessary primary intensions) but rather more Kripkean-like examples (water = h20) that have contingent primary intensions, then c) the type-b position will end up postulating a space of metaphysically possible worlds to deny the possibility of zombies in order to break the conceivable to possibility link, whereby it (materialism) will run aground by biting the bullet of modal dualism--having as it were no good motivation on its behalf other than its consistency with the antecedent claim that materialism must be true. So, that is a lot to say, and a lot to argue about, and I want to just grant it all--whatever more may be said of it or against it--and consider the type-a position here.

In the type-a, I take it that there is an apriori necessity (and hence a necessary primary intension), because there are not distinct sets of terms that fall under different descriptions, and so the explanatory gap is illusory (and temporary). Consider two claims 1) Phenomenal stuff doesn't exist and only physical stuff does (in the sense that an eliminativist means), and 2) Phenomenal stuff does exist. This is something like Goldbach's conjecture in at least this respect--if it turns out that 1) is true then it would seem that it is necessarily true, since the claim would then come down to evaluating P = P by substitution with P(physical) = Q(phenomenal), which is necessarily true (physical states are equal to themselves necessarily), in which case 2) would become necessarily false. Then we would be *misdescribing* a possible world where 2) held, since we could not be conceiving of a world where something that was necessarily false was in fact the case.

Now, it seems that the legitimacy of the type-a position comes down to whether we can cash out the truth, and hence necessity, of 1) apriori. This amounts to getting an apriori "bridge" between apparently different states such that we can see phenomenal states as physical states (I think this is close to something a type-a would hold). Churchland, et al (ie, Churchland) motivates this possibility by appealing to the progress of
science changing our concepts of things (roughly, the way we conceptualize
the world and our experiences), which amounts to a "wait and see" reply to
claims of the antecedent absurdity of supposing the primary intensions of
physical and phenomenal states may come together some day. But why not?
What IF the formation of our primary intensions of physical and phenomenal
states are themselves contingencies that are subject to change and
alteration; alteration that we as of yet cannot envision, but that remains
nonetheless an open question to be filled in, say, by a completed
neuroscience? To be somewhat more speculative, what if a completed
cognitive science discovered ways in which we systematically misuse
concepts to create illusions of separation between actually, ideally,
unified phenomena? Might THIS science be in a position to provide a road
map for creating the a priori bridge between physical and phenomenal
intensions? And if this is at least possible, might materialism be true
after all?

Erik

Erik L. canvasses the possibility of a sort of type-A materialism. In
terms of the later taxonomy in which type A split into two parts (type
A and type C), Erik's suggestion is a sort of type-C materialism, with
an a priori connection that is not obvious to us yet, but which may
become obvious on some sort of conceptual development.

>What IF the formation of our primary intensions of physical and phenomenal
>states are themselves contingencies that are subject to change and

> unified phenomena? Might THIS science be in a position to provide a road
> map for creating the a priori bridge between physical and phenomenal
> intensions? And if this is at least possible, might materialism be true
> after all?

Interesting. The suggestion is that our primary intensions themselves
may change over time. In response the anti-materialist might make
various points. E.g. (i) it's hard to find cases in science where
primary intensions change a great deal -- do you have some analogous cases in mind? Or (ii) in cases where primary intensions do change, one can make the case that the change is largely terminological, and that there's an alternative history where the word stayed with the old primary intension, and perhaps a new word was developed for the new intension.

But perhaps most important is (iii), if the old term really did have a primary intension, then *that* primary intension determines a perfectly good property (function from worlds to individuals), and presumably the anti-materialist argument will still work for *that* property. Perhaps the term later comes to have a new intension that the argument doesn't work for, but that doesn't stop the argument working for the old intension.

One can imagine something like this happening e.g. if the PI of "consciousness" gradually moved from a purely phenomenal notion to a functional notion (as might well happen as a matter of sociological fact). The later functional PI won't support an anti-materialist argument, but nevertheless the earlier phenomenal PI will. As long as (i) the early term has a PI not entailed by the physical facts, and (ii) the statement "consciousness exists" or some such, with the early term, expresses a truth, then the argument will still go through.

When I visited Alvin's seminar on consciousness last spring, one of the students (Kurt, I think) read a very interesting paper that defended more or less the line you're suggesting. He argued that the PI of some concepts (e.g. "life") has changed, and that a changed PI for "consciousness" could save materialism. In response I argued that (i) it's not so clear that the PI of "life" (as opposed to some beliefs about it) has changed, and (ii) a simple change in PI isn't enough to do the job for the materialist, for the reasons outlined above.

So it seems to be best for the type-C materialist not to say that the PI will change, but rather that the PI of our concept will turn out to be other than we think it is. E.g., perhaps further a priori reasoning will reveal that there is a deep a priori functional analysis of our concept of consciousness, and we just haven't figured that out yet. If so, then the PI of our concept has been functional all along. We just haven't done all the reasoning required to bring that out.

Maybe the line you're suggesting could in fact have that consequence. It's tricky because the "cognitive science" part is presumably empirical, whereas what's required for a PI is a priori. Still, the suggested claim that we "misuse" concepts suggest a failure of rationality on our part, one that could be corrected by more ideal reasoning. One would hope that we could detect that failure within the a priori domain, though. If all that's going on is the Loar-style point that we have distinct concepts, apriori-unconnectable, that nevertheless refer to the same physical stuff, then we have type-B materialism. I presume that's not what you want. But to get the difference, it's crucial that the concepts be connectable in the a priori domain.

Of course, to get that connection in the a priori domain, we will need to figure out that deep down there is a structural or functional analysis of the concept of phenomenal consciousness. I've given reasons to be skeptical of that claim; on the face of it, such an analysis is just changing the subject. But the type-C materialist could always argue that the apparent failure is because of a deep
cognitive blindness on our part (shades of McGinn, except here perhaps the blindness is correctable). That would be a tricky case to make, but there's interesting ground to be plowed over here.

--Dave.
Here's a bit of an exchange from last week about 2D semantics. I think I have a conjured sentence that fits the bill. I'll put it below.

>>This points to another confusion I've been entertaining on 2D semantics. It's probably a little off topic, so we'll get to it in a week or two.
>>But the main idea is to what extent the 2D semantics for terms meshes with the 2D semantics for sentences. In particular, in figuring the truth_1 of a sentence S, it looks like every term in S must be mapped to its referent_1. Likewise for truth_2. Are there sentences S for which the natural truth_1 conditions might depend on some term in S being mapped to its referent_2?

> Hmm, interesting. Again, a statement is true_1 at the actual world iff it is true_2 there. And a term's (actual) referent_1 will always be its (actual) referent_2 -- both are just the term's actual referent! It's only in non-actual possible worlds that these things come apart. But I suppose your suggestion might come to the possibility that to evaluate the truth_1 of S at some non-actual possible world, we need to consider the referent_2 of some term in S there, which would then depend on a posteriori facts about the actual world.

> The short answer, I think, is that this can't happen. Truth_1 is defined so that it depends only on facts about the world in question (plus a priori analysis). Some statements, e.g. "The actual president is Bill Clinton" might make reference to the actual world, but they can still be evaluated in a single-world way. E.g. to evaluate the truth_1 of the statement above at a world where George Bush is president, we consider that world as actual, and determine that if that world is actual, the statement is false. That's to say, one never needs to import the *actual* referent of "the actual president" in evaluating the truth_1 of this statement at world W. One only ever imports what the referent would be *if* W were actual.

So here's the sentence:

($) The water in The River Thames is H20.

What I want to know is whether this is necessary or not where what we are interested in is how "water" is evaluated in worlds considered as actual, but where "The River Thames" is given the semantic value when considered counterfactually. That is, in computing the semantic value of ($) we want the referent given by the PI of "water" but the SI of "The River Thames". If I'm right, this isn't possible on the 2D account. So there is a space of sentences for which it isn't defined---namely, any sentence where we "cross" intensions of the terms.

Thony

"Curious green ideas sleep furiously."
So here's the sentence:

($) The water in The River Thames is H2O.

What I want to know is whether this is necessary or not where we are interested in is how "water" is evaluated in worlds considered as actual, but where "The River Thames" is given the semantic value when considered counterfactually. That is, in computing the semantic value of ($) we want the referent given by the PI of "water" but the SI of "The River Thames". If I'm right, this isn't possible on the 2D account. So there is a space of sentences for which it isn't defined---namely, any sentence where we "cross" intensions of the terms.

Hmm, I'm not quite sure what the counterexample sentence is supposed to be. If the sentence is just ($), then it isn't a counterexample, as this has a perfectly straightforward PI and SI. Rather, I take it your counterexample is some modification or "interpretation" of ($), on which we "give the terms semantic values" according to their PI and SI respectively in different cases. It's not clear to me in what sense the result is a "sentence".

Maybe given a sentence with a well-defined PI and SI, one can define some abstract object which gets evaluated in possible worlds according to some combination of the PIs and the SIs in the original sentence. But this doesn't seem to correspond naturally to anything we find in language. It doesn't seem to be meaningful to talk about the PI or SI of such an abstract object; but that alone isn't obviously a problem for two-dimensional semantics. 2-D semantics is meant to apply to sentences in natural languages, not to arbitrary abstract objects.

It seems to me that on any natural reading of ($), it gets evaluated in worlds considered as actual according to the PI of both "water" and "River Thames" -- one can't just stipulate that it will be evaluated according to the SI of "River Thames". At least, if one did, one would have a very different sentence where the word "River Thames" means something different to what it means in ordinary English (a new word whose PI happens to be the same as the SI of our word "River Thames"). Even if one did this, one could now naturally evaluate the PI and the SI of the new sentence in a pretty straightforward way; it would have a PI that differs from that of the original sentence, but that's only to be expected.

I may be missing the way you intend the example to be understood, in which case I'd be interested to hear it articulated.

For next week we are focusing on issues re the contents of thought. In particular, we will be focusing on issues about internalism, externalism, and "narrow content", and the application of the 2-D framework to these issues.

The central reading is my paper "The Components of Content". You've read this already earlier in the term for the general issues re 2-D semantics; it might be worth reading it again for the more specific issues concerning the narrow content, the explanation of behavior, belief ascription, and so on.

There are also a number of background readings that Jodie will photocopy and put in the folder, hopefully tomorrow. These are:

- Putnam, "The Meaning of `Meaning'"
- Burge, Excerpt from "Individualism and the Mental"
- White, "Partial Character and the Language of Thought"
- Stalnaker, "Narrow Content"
- Schiffer, "The Mode-of-Presentation Problem".

The Putnam and the Burge are the classic sources re externalism. Many or most of you will have read them before. If you haven't, I certainly recommend reading them; if you have, you might look over them again. The White and Stalnaker are two papers on whether we can make sense of a notion of "narrow content" (a sort of content that is "in the head") in response to the externalist arguments. White ends up arguing for a picture that has some similarities to the 2-D framework, while Stalnaker argues against narrow content and on the way argues against the use of the 2-D framework. Both also have some good general discussion. Finally, the Schiffer has good coverage on some of the issues re the semantics of belief ascription that come up in my content paper.

The Stalnaker will be more central next week (when we will discuss objections to and problems for the 2-D framework), but you might find it useful to look over this week for its general way of framing the issues. I'm not sure whether we will discuss the White in detail (it was a special request from Brad), but again it is useful and interesting background material. The same goes for Schiffer. Hopefully these papers will help make some of the background to "The Components of Content" fall into place.

Finally, the folder will also have a copy of John Burgess's article "Quinus ..." (I've forgotten the full Latin title, but it translates as "Quine Freed of Every Flaw"). That's the article I was discussing today re the debate over quantified modal logic, with some reference to subjunctive and indicative conditionals. This isn't an official reading, but it's a very interesting and enlightening discussion of the issues re quantified modal logic (it should also work well as background for those who don't know much about the debate), and I recommend it to everyone.

A reminder that I am going to England tomorrow, and will be arriving back in town next Tuesday at 4pm, so next week's meeting is scheduled for 5:20pm Tuesday. I'll get in touch by e-mail or phone if it looks like I'll be late.
Also, as I said in class today, anyone who wants to give me a draft of their term paper by next Friday (April 30) is welcome to do so, and I'll give them comments back.

Subject: Re: truth conditions and conceivable worlds
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: R

Regarding Dave's response to Thony's "River Thames" sentence, it strikes me that the 2D framework is immune to the possibility that a space of sentence may have uncomputable truth values (due to mixing intensions), but for a reason that may itself raise a red flag. It's just been *stipulated* that statements get evaluated according to primary or secondary intensions, uniformly for all terms. That keeps Thony's example from gaining any ground, I suppose, but given that certain statements are most naturally interpreted by assigning different intensions (take Thony's example, for one), the stipulation cries out for justification, at least as a general theory of semantics. I suppose the justification is practical, or *methodological*, in that we can apparently put the 2D semantics to good use (eg, in evaluating Kripkean cases). But given that we can't make sense of "The water in the River Thames is H20" by taking the natural intensions of the composite terms, it seems somehow ad hoc. Part of my frustration here stems from my own attempt to formulate statements whose natural interpretation mixes intensions, until I realized (from reading Dave's message) that it's just been *stipulated* that you can't do that. (Trivially, I managed to come up with statements that always end up false when evaluated according to the PI, even when the composite clauses of the sentences get different truth values when evaluated in different worlds considered as actual. Consider "Water is actually H20, but not here." This is equivalent to the conjunction "Water is actually H2O and Water is not H20 here.", where the first conjunct is false and the second true in Twin Earth, and vice versa for Earth. (Since conjunction are false when at least one conjunct is false, the statement is always false no matter in what world considered as actual it is evaluated).) This I say is trivial, because who cares if we can construct sentences contradictory or otherwise according to an intension, as long as our semantics always *gives* us a truth value one way or the other. Thony's example was meant to challenge the latter, but it evidently can't be done, in the same sense that you won't likely find any round squares laying around either. Questions: How seriously do we take the 2D framework as a theory of semantics? Should we be bothered by its inflexibility with respect to Thony's example? To be really speculative, might *adding* the sort of flexibility of evaluation that can produce compositional semantics using different intensions from the terms on up possibly *undermine* the motivation for the anti-materialist argument, but give us new methodological justification for its acceptance nonetheless (because it is a more flexible semantics)?

On Tue, 20 Apr 1999, David Chalmers wrote:

I would like to resolve my intuitions with the 2-Framework and I'm not quite sure how to do it. I've listed my intuitions on each of the 6 cases:

1) The twins relation to their environment is identical.

2) There is a difference between saying "Hesperus is Hesperus", and "Hesperus is Phosphorus". The first is just a figurative way of saying "a thing is itself", which HAS meaning, just not a very important one because it's so trivial and obvious. The second, on the other hand, is more like saying "two things are the same when you think about it". Content doesn't just denote something's physical embodiment but it's entire meaning. "the former is trivial and the latter is not"

3) Kripke's puzzle happens in real life. And the language issue doesn't do anything but explicate that Pierre doesn't see that THAT'S the "London" (however you wanna say it) that he's been told is pretty. Consider this real life scenario: I was told in phone conversations and e-mails "Mike is a cool guy." Then one night I was at a party and I met a guy, his name was mike. Later, my friend asked if I had met Mike at the party, and being the flaky guy I am, said, "Well yes, I met a guy named Mike, why?" and she responded "THAT'S MIKE!" (meaning, that's THE Mike she had been speaking of in correspondence). At which time I "linked/combined" these two, otherwise separated references. Now there doesn't seem to be anything confusing about this, and yet it is similar, in the relevant way, to the Londres case. If I had thought Mike was a jerk when I met him, this contradiction would be resolved in the "linking/combining" stage--analyzing my reasons for thinking he's a jerk with her reasons for thinking he's cool and weighing everything in the mix. I might even keep BOTH contents because they differ in their relation to Mike. To make the analogy hold, we could say that at the party he introduced himself as "Michel" or something stupid like that but this doesn't do any work.

4) My favorite video game is a car race (I forget what it's called) that is at the Flying J truckstop halfway to Phoenix (that's relevant). When I play it and I believe that "I'm" going to crash into a guardrail, I take evasive action. After I'm done playing, I get into the real car and I get yelled at by my girlfriend because I'm apparently driving like I'm still in the video game. The distinction is made in the differing degrees of indistructability. There is no difference IN KIND between the case where I am indestructible and the case where I might actually get hurt, just a severe difference in degree of personal meaning they have. The same concept holds for the difference in degrees of recklessness in driving a car -vs- a motorcycle.

5) "Clark Kent" and "Superman" have two totally different meanings, the only similarity is that they occupy the same body.

6) This one has me stumped.

-erik h.
(1) First, a point about Thony's and Erik L's comments on why mixed intension sentences are naughty. If we take *concepts* as primary, then the strictures against mixed intension sentences would seem to be ad hoc. If, on the other hand, we take *thoughts* as primary, then it might be reasonable to hold that mixed intension thoughts are a no-no, b/c they're not really thoughts. Problem is, most semantics are compositional: take concepts as primary, and build up thoughts out of them. Reply: sure semantics is compositional, but even so, <Green ideas sleep furiously> doesn't make any sense (or, doesn't give one a coherent thought), as Thony would no doubt be the first to agree. In the same way, <The water [1-intension] in the Thames [2-intension] is H2O [1-intension]> or what-have-you, is also nonsensical. So, we're going to have to give some account of why <Green ideas sleep furiously> is not a legitimate thought, why can't we just plug in this account to rule out mixed intension sentences?

(2) I'm losing sleep over the issue of whether content is effable. (There are two ways in which one might cash effability out: thinkability, communicability/sayability. I'm going to stick with the latter.) Fodor says that his notion of narrow content is ineffable. I'm worried that *both* of Chalmers's notions of content are ineffable. There are different ways to put my worry and I'm not sure which is best, but here's a stab. Sometimes the account of notional/relations content sounds as if there are actually two distinct concepts per 'folk' concept or word. Or, to put it at the level of thoughts, if thoughts are individuated by their truth conditions, and if 'a' thought interpreted via 1-intension has one truth-condition and 'the same' thought interpreted via 2-intention has different truth-conditions, then there are different thoughts. Thus, it would be possible to have a language in which 1- and 2-intensions are explicitly distinguished at a syntactic level. In the same way that some languages build temporal discriminations into verb endings, our hypothetical language builds intensional discriminations into its words. *Indeed, I take it that this is just what we've done in this seminar when we write "water 1-intension".* Further, I take it that Chalmers sees cognitive psychology as moving towards a more purely notional/1-intensional language. (p. 12)

BUT on the other hand, there is evidence that one can not, even in principle, prise the notional apart from the relational in this way. The problem is that if we split folk concepts into two concepts, the notional and the relational, then *THERE IS NO END TO THIS PROCESS, FOR EVERY CONCEPT HAS A PRIMARY INTENSION AND A SECONDARY INTENSION.* In other words, it looks like you're going to get something like a 'what-Achilles-said-to-the Tortoise' kind of problem. Tortoise: "What is the 1-intension of X?" Achilles: "X, Y and Z". T: "Do you mean X, Y and Z in the 1-intension sense, or the 2-intensions sense?" A: "The 1-intension sense". T: "Ah, and that would be?" T: "F, G and H". T: "Ah, do you mean F, G and H in the 1-intension sense, or the 2-intension sense?". and so on.

Chalmers says that 'we should not mistake the linguistic expression [of 1-intensions] for the real thing' (p. 13) Fair enough, but if there is a real thing here, should we be able to *unambiguously* refer to it. And it looks like we can't, for every attempt that one makes to refer to notional or relational content *via words* (and what else can one use?) can be interpreted in one of two ways, either 1-intensionally or 2-intensionally.
(Actually, I think that there's more than one problem contained in the above, but it's lunchtime and I'm not going to rewrite it.)

(3) I'm worried about the implications Kripke's rule-following has for the accessibility of notional content. Chalmers says that notional content is always (in principle, at least) accessible. It is internal to the thinker. But consider Kripke's plus/quus concerns. It's not exactly clear what these are, but here's a stab: Do I know what I mean by 'plus' merely by introspecting? No. In fact, I only mean something by plus by 'how I go on', that is, by the rule I follow *over time*. So how can I know what I mean by 'plus' *now* if what I do in fact mean is in part fixed by the rule that I follow? In a nutshell, the worry is that (certain) notional contents are fixed by rules that I follow over time, and these may be cognitively inaccessible to me *at a time*.

Here are some comments on just some of Tim's message:

> Chalmers says that 'we should not mistake the linguistic expression [of >1-intensions] for the real thing' (p. 13) Fair enough, but if there is a >real thing here, should we be able to *unambiguously* refer to it.

We do unambiguously *refer* to primary intensions, simply by saying "the primary intension of x". What seems less clear is whether we can *specify* the primary intension, that is, give a conceptual analyses.

And it

> looks like we can't, for every attempt that one makes to refer to notional >or relational content *via words* (and what else can one use?) can be >interpreted in one of two ways, either 1-intensionally or 2-intensionally.

I can't think of two intensions for "the primary intension of 'water'". There can be cases where the primary and the secondary intension coincide, and maybe *complete* conceptual analyses of primary intensions will consist in only these unambiguous statements. If not, can't we just stipulate the intended interpretation like above, by prefacing the statement with "the primary intension of..." or "the secondary intension of..."?

>(3) I'm worried about the implications Kripke's rule-following has for the >accessability of notional content. Chalmers says that notional content is
But consider Kripke's plus/quus concerns. It's not exactly clear what these are, but here's a stab: Do I know what I mean by 'plus' merely by introspecting? No. In fact, I only mean something by plus by 'how I go on', that is, by the rule I follow *over time*. So how can I know what I mean by 'plus' *now* if what I do in fact mean is in part fixed by the rule that I follow? In a nutshell, the worry is that (certain) notional contents are fixed by rules that I follow over time, and these may be cognitively inaccessible to me *at a time*.

I do think that you know merely by introspecting what you mean by "plus". I'm not prepared to give a full-scale argument against Kripke though. Would Kripke really say that the meaning of "plus" is fixed by the rule that you follow? This leaves meaning forever indeterminate, since at the time of your death we will still be left with an infinitude of possible rules that you *were* following. It has been awhile since I read it, but I thought that Kripke's resolution of the problem was to go social with meaning. If so, then this can easily be accommodated within the 2d framework. The primary intension of "plus" is [the rule that I am following as specified by my linguistic community] or something like that. This is no different in kind, and no more problematic, than the primary intension of water.

Brad
> in kind, and no more problematic, than the primary intension of water.

I think Brad is probably right in thinking that Kripke wants to locate the rules in social practices, but this cannot be accommodated with the framework as presented in "The Components of Content", b/c *I* don't have direct access to the rules of my community. The problem now isn't one of my having access to a diachronic fact at this moment, but *my* having access to a fact that is fixed by social practices. How do I know what rule the rest of the folks in my community are now following? Wouldn't that be like saying that I have direct introspective access to the fact that my community thinks that it is rude to burp at the table? If what I now mean is fixed by socially constituted facts, how do I know what I mean?

Re effability of notional content, and re Kripke on rule-following.

Tim writes:

>(2) I'm losing sleep over the issue of whether content is effable. (There are two ways in which one might cash effability out: thinkability, communicability/sayability. I'm going to stick with the latter.) Fodor says that his notion of narrow content is ineffable. I'm worried that *both* of Chalmers's notions of content are ineffable. There are different ways to put my worry and I'm not sure which is best, but here's a stab.

>Sometimes the account of notional/relations content sounds as if there are actually two distinct concepts per 'folk' concept or word. Or, to put it at the level of thoughts, if thoughts are individuated by their truth conditions, and if 'a' thought interpreted via 1-intension has one truth-condition and 'the same' thought interpreted via 2-intention has different truth-conditions, then there are different thoughts. Thus, it would be possible to have a language in which 1- and 2-intensions are explicitly distinguished at a syntactic level. In the same way that some languages build temporal discriminations into verb endings, our hypothetical language builds intensional discriminations into its words.

>*Indeed, I take it that this is just what we've done in this seminar when we write "water 1-intension".* Further, I take it that Chalmers sees cognitive psychology as moving towards a more purely notional/1-intensional language. (p. 12)
BUT on the other hand, there is evidence that one can not, even in principle, prise the notional apart from the relational in this way. The problem is that if we split folk concepts into two concepts, the notional and the relational, then *THERE IS NO END TO THIS PROCESS, FOR EVERY CONCEPT HAS A PRIMARY INTENSION AND A SECONDARY INTENSION.* In other words, it looks like you're going to get something like a 'what-Achilles-said-to-the Tortoise' kind of problem. Tortoise: *What is the 1-intension of X?* Achilles: "X, Y and Z". T: "Do you mean X, Y and Z in the 1-intension sense, or the 2-intensions sense?" A: "The 1-intension sense". T: "Ah, that would be?" T: "F, G and H". T: "Ah, do you mean F >, G and H in the 1-intension sense, or the 2-intension sense?". and so on.

OK, here's what I think. First, I do want to say that it is *one* concept that has both a primary intension and a secondary intension. E.g. a being might have just the concept of "water" and not the concept of "H2O". So they'll have just one concept in the vicinity, with both a primary intension and secondary intension. The primary intension will pick out watery stuff in all worlds, and the secondary intension will pick out H2O in all worlds, but that is not to say the being has separate concepts of "watery stuff" and of "H2O". There is just the one "water" concept, with a complex structure of semantic evaluation.

Of course it will often happen that when a being has a concept with a primary intension and a secondary intension, that being will have two concepts in the vicinity which come close to mirroring each of these. For example, as a matter of fact, in addition to my concept of "water" I have a concept of "watery stuff" and "H2O". It isn't required that I have these distinct concepts to have the concept of "water", though.

In effect, what is going on in those cases is that one has an initial concept C1 (e.g. "water") with PI(C1) = P and SI(C1) = S. Then one finds a further concept C2 (e.g. "watery stuff") such that PI(C2) = P and SI(C2) = P. That is, C2 is a concept such that *both* its PI and its SI mirror the PI of C1 -- so we can see C2 as in some sense "isolating" the PI of C1 more purely.

And then one finds a still further concept C3 (e.g. "H2O") such that PI(C3) = S and SI(C3) = S. That is, C3 is a concept such that *both* its PI and its SI mirror the SI of C1 -- so we can see C2 as in some sense "isolating" the SI of C1 more purely.

All this is nice to "articulate" the 2-D structure of the initial concept C1. But it certainly isn't required just to have the initial concept C1. To do that, one needs just one concept. It's the articulation that requires further concepts.

Note that when we "articulate" a concept in this way, your Achilles/Tortoise problem doesn't quite come up, as the further concepts we've introduced have more or less the same PI and SI. Or at least, they are closer to doing so than the original concept.

Still, it's not obvious to me to what extent we can really expect the PI and SI of our concepts to be "articulated". As far as I can tell, that more or less requires a reductive definition of either of these intensions in terms that don't involve the original concept. E.g., we want to define the PI and SI of "water" without appealing to water. Now that is sometimes possible and sometimes isn't, as philosophers well know from experience. But it's not clear to what extent such definability is really required to say that content is "effable". Take the concept of "knowledge" -- maybe not definable, but do we want to say it is ineffable? I don't think the PI and SI of our concepts...
in general will be any worse than this.

Why do people sometimes say that the wide content of a concept such as "water" is effable? Perhaps because one can say something like: the SI of "water" picks out the water in all worlds. But that obviously isn't all that helpful -- one is just implicitly appealing to the SI to characterize the SI. And one could do something similar to characterize the PI.

Alternatively, maybe they think the content here is effable because one can say the SI of "water" picks out H2O in all worlds. Here we have something like a reductive definition. But (a) it's not clear this is possible for all concepts (it's not obvious that it really even works for "water"), and (b) something similar can work for primary intensions, via e.g. "watery stuff". Of course what goes on is, in effect, that we find another concept ("H2O") which has the same SI as "water", and whose PI is a lot closer to that SI too. So similarly, with the PI, we find another concept ("watery stuff") which has the same PI as "water", and whose SI is a lot closer to that PI too. That seems a legitimate thing to do.

Whether this sort of reductive definability is possible for all concepts, who knows? My own view is that it probably isn't possible for some central concepts, such as e.g. concepts of experience, cause, space, and time (cf. discussions of global Ramsification in Jenann's seminar). For other concepts (e.g. knowledge), approximations at reductive definitions may be possible, but not perfect definitions. And for others (e.g. bachelor), there may be near-perfect definitions.

It seems to me that this was the position that we knew we were in before thinking about these things in terms of the 2-D framework. The 2-D framework doesn't seem to change things too much. We can try to characterize a concept's PI in terms of the PI or the SI of others' concepts, and we can try to characterize a concept's SI in terms of the PI or the SI of others' concepts, and we'll succeed to differing extents in different cases.

>Chalmers says that 'we should not mistake the linguistic expression [of 1-intensions] for the real thing' (p. 13) Fair enough, but if there is a real thing here, should we be able to *unambiguously* refer to it. And it looks like we can't, for every attempt that one makes to refer to notional or relational content *via words* (and what else can one use?) can be interpreted in one of two ways, either 1-intensionally or 2-intensionally. (Actually, I think that there's more than one problem contained in the above, but it's luncheon and I'm not going to rewrite it.)

Two things to say here. (1) If we characterize a PI or SI in terms of an expression E such that E's PI and SI are more or less the same, this problem won't really come up. (2) It seems to me that we can avoid ambiguity in any case simply by saying that we are talking about the PI or E, or the SI of E. So we can say: the PI of concept C corresponds more or less to the PI of E, where hopefully E has a more transparent structure. And same for the SI. So hopefully this gives us some sort of effability. Here I am just repeating what Brad said, I think.

Sometimes people say narrow content is ineffable basically because it is hard to characterize the PI of a concept C in terms of the *SI* of another concept E. (E.g., the narrow content of "water" is the function that picks out such-and-such in all counterfactual worlds.) But as I say in the paper, that seems to be something of an unfair requirement. Just as we can characterize the SI of one concept in
terms of the SI of others, we can characterize the PI of one concept in terms of the PI of others.

Re Kripke on rule-following, Tim wrote:

>(3) I'm worried about the implications Kripke's rule-following has for the accessibility of notional content. Chalmers says that notional content is always (in principle, at least) accessible. It is internal to the thinker. But consider Kripke's plus/quus concerns. It's not exactly clear what these are, but here's a stab: Do I know what I mean by 'plus' merely by introspecting? No. In fact, I only mean something by plus by 'how I go on', that is, by the rule I follow *over time*. So how can I know what I mean by 'plus' *now* if what I do in fact mean is in part fixed by the rule that I follow? In a nutshell, the worry is that (certain) notional contents are fixed by rules that I follow over time, and these may be cognitively inaccessible to me *at a time*.

Hmm, interesting. I certainly don't claim to have a full answer to the Kripke/Wittgenstein problem. But the sense in which I have access to a PI is not (or at least not obviously) the sense in which I can specify a PI all at once, or grasp it all at one time, or some such. Think again of the case of "knowledge". The sense in which we have access to a PI is the sense in which, *given* a description of a scenario (or ultimately a world), we can say how and whether the PI applies to it.

It's best ultimately to do this with thoughts rather than concepts (because of problems with inscrutability of reference). The PI of a thought is a function from worlds to truth-values; we have access to the PI because given a qualitative description of a world, we can determine whether the PI of the thought is true. That's to say, we can evaluate the function in question at any world, and we can do this a priori.

It seems to me that we have something like this in the "plus" case. For any given statement involving plus -- "56 + 65 = 121", for example -- we're in a position to know whether it is true or false (of course if it is true in one world it is true in any world). So we have access to the PI of these statements.

It's true that in evaluating these statements, one is doing something new. And there is a deep philosophical puzzle about just what in my prior state determines that my answer to this question is "true" rather than "false". But I don't think we need to solve this puzzle here. We can just taken it as an intuitive datum there *is* a correct answer to give to these questions, upon rational reflection, and define the PI in terms of that.

The philosophical problem of just how this determinate intensionality is grounded remains, as it does for any semantic theory, but we don't need to solve all our problems at once! For my part, I think this is part of the project of "naturalizing intentionality", one that I haven't talked much about in this seminar. Specifically, what "natural" facts makes it the case that a thinker has a concept with one PI rather than another? Personally I think this will be grounded in a combination of functioning and phenomenology, by virtue of certain idealization principles which are built into our intentional concepts, but that's a long story.

I suppose another way the K/W problem comes up is in yielding a determinate PI for "plus" thoughts involving billion-digit numbers,
say, such that I will never in fact be able to give a determinate judgment. Here I need again to appeal to an idealization, going with what a less limited reasoner would say, or what would be the rationally correct thing to say. Again, the question of just what grounds that is tricky, but here I am simply appealing to the very strong intuition that there is indeed a rationally correct answer to these questions. If that intuition turned out to be wrong (perish the thought!), it might then turn out that the PIs of our concepts are less determinate than we think they are.

<MODALITY@LISTSERV.ARIZONA.EDU>
From: Erik A Herman <erikh@U.ARIZONA.EDU>
Subject:      Intuitions on Components of Content
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: R

I would like to resolve my intuitions with the 2-Framework and I'm not quite sure how to do it. I've listed my intuitions on each of the 6 cases:

1) The twins relation to their environment is identical.

2) There is a difference between saying "Hesperus is Hesperus", and "Hesperus is Phosphorus". The first is just a figurative way of saying "a thing is itself", which HAS meaning, just not a very important one because it's so trivial and obvious. The second, on the other hand, is more like saying "two things are the same when you think about it". Content doesn't just denote something's physical embodiment but it's entire meaning. "the former is trivial and the latter is not"

3) Kripke's puzzle happens in real life. And the language issue doesn't do anything but explicate that Pierre doesn't see that THAT'S the "London" (however you wanna say it) that he's been told is pretty. Consider this real life scenario: I was told in phone conversations and e-mails "Mike is a cool guy." Then one night I was at a party and I met a guy, his name was Mike. Later, my friend asked if I had met Mike at the party, and being the flaky guy I am, said, "Well yes, I met a guy named Mike, why?" and she responded "THAT'S MIKE!" (meaning, that's THE Mike she had been speaking of in our correspondence). At which time I "linked/combined" these two, otherwise separated references. Now there doesn't seem to be anything confusing about this, and yet it is similar, in the relevant way, to the London case. If I had thought Mike was a jerk when I met him, this contradiction would be resolved in the "linking/combining" stage--analyzing my reasons for thinking he's a jerk with her reasons for thinking he's cool and weighing everything in the mix. I might even keep BOTH contents because they differ in their relation to Mike. To make the analogy hold, we could say that at the party he introduced himself as "Michel" or something stupid like that but this doesn't do any work.

4) My favorite video game is a car race (I forget what it's called) that is at the Flying J truckstop halfway to Phoenix (that's relevant). When I play it and I believe that "I'm" going to crash into a guardrail, I take evasive action. After I'm done playing, I get into the real car and I get yelled at by my girlfriend because I'm apparently driving like I'm still in the video game. The distinction is made in the differing degrees of indistructability. There is no difference IN KIND between the case where I am indestructible and the case where I might actually get hurt, just a
severe difference in degree of personal meaning they have. The same concept holds for the difference in degrees of recklessness in driving a car -vs- a motorcycle.

5) "Clark Kent" and "Superman" have two totally different meanings, the only similarity is that they occupy the same body.

6) This one has me stumped.

-erik h.

<MODALITY@LISTSERV.ARIZONA.EDU>
From: Josh Cowley <josh@MATH.ARIZONA.EDU>
Subject:      PIs as narrow content
To: MODALITY@LISTSERV.ARIZONA.EDU
Status: R

I'm having a worry about PIs being something that is entirely in the head (i.e.. internal). In particular I'm not sure if they can do the work we want them to if they are restricted to the head. Here is a sketch of the argument.

PIs are supposed to be functions from worlds to referents. Dave suggested that PIs might supervene on the physical/phenominal state of the individual. The problem is combining 2D semantics with a reductive theory semantics. A reductive theory of semantics is one which does not use any semantic terms in its terminology. Some of what people have been worried about in cashing out narrow content is how something that is *just* internal is going to pick out referents in the world. For example, if you are not allowed to use semantic terms it is hard to see how my concept "water" picks out water in the actual world. Since we are not allowed to use any sort of physical or causal chain to connect "water" to water, one wonders why it doesn't pick out toothpicks.

People have attempted to give reductive semantic theories which are in the head. I want to get on to why this is a problem for 2D semantics so I'll just give a quick example to motivate the problem. Conceptual role semantics (CR) claims that a concept gets its meaning by the role that it plays in a persons conceptual structure. For example, the role it plays in inferences, belief generation etc. Now this is clearly all in the head, but the question is whether it is enough to get reference. There are two ways we can go about getting the referent of "water." The first is to show the relationship between water and other concepts. For instance, "water" is a clear liquid which quenches thirst. It isn't an animal. It makes up the bulk of the lakes and rivers etc. This fits well with 2D semantics, but it defines "water" by other terms whose meaning is fixed. So this isn't really a reductive theory. The second way is to look at all the relations between all concepts, then find a set of objects and relations in the world which has a 1to1 correspondence to the relations of the concepts. The problem with this method is that you can always find some set of relations holding between objects which will be in 1to1 correspondence with the conceptual role relations.

That was a little sloppy, but others have argued for it more carefully and similar arguments have been raised against other internal
semantic theories. So suppose it is true that no strictly internal
theory can determine a referent. Why does this cause problems for
saying that PIs supervene on the physical state of the brain. Well, a
PI is a function from worlds to referents. In order to be a function
it has to pick out only one referent per world. But internal theories
don't seem able to do this.

I may be missing Josh's point here, but I gather that he thinks that PI's
are problematic because they are functions, and functions have to pick out
unique referents, but PI's are committed to internal semantic theories,
and these don't seem capable of pin-pointing unique referents.

I have a couple of comments, although I'm not entirely sure they are on
track with what Josh is getting at. First, on the 2D view, both primary
and secondary intensions are functions, and hence both are committed to
returning unique referents as outputs. The problem, I suppose, is that
only primary intensions are supposed to be confined to the head, and so
are vulnerable to problems with internal theory semantics. It seems like
one could argue that there isn't much of a distinction here however, and
that primary and secondary intensions are functions that are either both
both vulnerable to problems with internal semantics, or both okay, for
roughly the same reasons. However we pick out water, as the clear
drinkable liquid of a PI, or the H2O or XYZ of a SI, it seems that the
story of how we manage to refer to what we do is going to pretty similar
in both cases. So, we might have a problem with our semantics getting the
unique referent of a function, but it will apply equally to watery stuff
or H2O.

More generally, I think that worrying about reference re functions is an
interesting problem, but it probably applies to some pretty standard
thought (eg arithmetic). I take it this is Kripke's point in his
"Kripenstein" argument. So, I suppose this means we up against a
puzzling situation, but it's no problem for PI's alone, as Josh seems to
suggest.

in the world. For example, if you are not allowed to use semantic terms it is hard to see how my concept "water" picks out water in the actual world. Since we are not allowed to use any sort of physical or causal chain to connect "water" to water, one wonders why it doesn't pick out toothpicks.

People have attempted to give reductive semantic theories which are in the head. I want to get on to why this is a problem for 2D semantics so I'll just give a quick example to motivate the problem. Conceptual role semantics (CR) claims that a concept gets its meaning by the role that it plays in a person's conceptual structure. For example, the role it plays in inferences, belief generation etc. Now this is clearly all in the head, but the question is whether it is enough to get reference. There are two ways we can go about getting the referent of "water." The first is to show the relationship between water and other concepts. For instance, "water" is a clear liquid which quenches thirst. It isn't an animal. It makes up the bulk of the lakes and rivers etc. This fits well with 2D semantics, but it defines "water" by other terms whose meaning is fixed. So this isn't really a reductive theory. The second way is to look at all the relations between all concepts, then find a set of objects and relations in the world which has a 1to1 correspondence to the relations of the concepts. The problem with this method is that you can always find some set of relations holding between objects which will be in 1to1 correspondence with the conceptual role relations.

That was a little sloppy, but others have argued for it more carefully and similar arguments have been raised against other internal semantic theories. So suppose it is true that no strictly internal theory can determine a referent. Why does this cause problems for saying that PIs supervene on the physical state of the brain. Well, a PI is a function from worlds to referents. In order to be a function it has to pick out only one referent per world. But internal theories don't seem able to do this.

Some advice for drivers on the University of Arizona campus:

"When passenger of foot heave in sight, tootle the horn. Trumpet him melodiously at first, but if he still obstacles your passage then tootle him with vigor."

I think that only wide content exists. The subject's relation to a concept is what the concept consists in. For instance, there is nothing internal to Bert that distinguishes the two worlds. There is no "hard content" where there is a one to one correspondence between the content...
across worlds and the object itself. The mind just aims, shoots, and hopefully hits. It seems odd for me to be able to vary worlds and keep contents constant. Every subject is centered on their respective world—I don't get how the content could possibly hold across worlds or what such a concept could possibly mean. Where this is particularly clear to me is the case where Bert might say: "that is pretty" (and points). So I would guess that I agree with Loar if I understand his realization conditions correctly. In my view, contents are definitely context dependent and loose their meaning when extrapolated from their respective world.

Thony makes the case for the importance of narrow content and draws the following conclusion:

> I'm being unreasonable in the first case, and reasonable in the second.
> In an important sense, by belief that the thing is red is unjustified in
> the first case. If all that matters in beliefs is their wide content, we
> shouldn't have conflicting intuitions in these cases: there is no water
> that my beliefs are about. We clearly have conflicting intuitions about
> the cases, so there is some other kind of content that matters in
> justification.
>
> I guess I have some sense of conflicting intuitions in this case, but it
seems that the sense of conflict goes away if one considers exactly what
question one is asking. If we ask whether the envatted individuals in
1 and 2 are justified in the beliefs they form, then clearly it seems that
1's belief is not justified and 2's is. But it seems to be a different
question when we look at them from an external perspective and pronounce
that, in both cases, their beliefs are unjustified.

It seems that the conflicting intuitions one has in this case just
corresponds to which the different answers to the two questions.
Ultimately, the two questions seems to corresponf to PIs and SIs, and,
once again, the disagreement arises from our different inclinations as to
which is more essential.

Another reason why we need narrow content: although it looks like wide
content underwrites belief ascription, narrow content is what underwrites ascription of justification w.r.t. beliefs. Here's a sketch of how.

Consider the brain in a vat case. There is nothing in the world (outside the head) which justifies any of my beliefs, since my beliefs are about what I take to be the physical world made up of tables, chairs, water, books, cookies, and so on. But, by hypothesis, there are no such things outside my head; in reality it's just a big vat, with some liquid and electrodes. That's it. So my beliefs are not about (wide) e.g. water. But, borrowing a nice argument of Stew Cohen's, we still want to distinguish two different possible scenarios in the vat.

1. In the first scenario, suppose I have lots of beliefs about how water can refract light and how this influences the way things appear to me. So, I believe that I can't trust the shape of how things look to me when I believe they are partially immersed in water. Say I think that I see a bent stick, and draw the conclusion that it is bent. (Of course, the conclusion is false b/c I'm really just a brain in a vat.) Then suppose I also form the belief that the thing is partially immersed in water. Nevertheless (and without any other relevant beliefs) I continue to hold on to my belief that the thing is bent.

2. Now suppose everything is as in 1, except that upon forming the belief that thing is partially immersed in water, I withdraw my belief that the thing is bent.

I'm being unreasonable in the first case, and reasonable in the second. In an important sense, by belief that the thing is red is unjustified in the first case. If all that matters in beliefs is their wide content, we shouldn't have conflicting intuitions in these cases: there is no water that my beliefs are about. We clearly have conflicting intuitions about the cases, so there is some other kind of content that matters in justification.

Some thoughts on yesterdays discussion. The PI of a concept is a function from worlds to referents. In order to give a reductive analysis of PIs we are going to have to find something internal that can act as a function from worlds to referents. It seems to me that nothing internal is going to really be a function from *worlds* to referents. Worlds are not psychological entities. Instead we are going to need some psychological entities which represent or perhaps are just in a 1to1 correspondence with worlds (for ease I'm going to suppose they represent worlds). So a reductive analysis of PIs is going to consist in finding a function from psychological representations to referents.

Now my worry is what the referents are going to be in this case. The referent either has to be something in the representation or something
in the world the representation is of. For example, consider the reductive primary intention of water given a representation of Twin Earth as its input. Either it has to pick out the representation of XYZ in my Twin Earth representation or it needs to pick XYZ in the Twin Earth world.

At the moment I don't have any argument that it is going to have to be one or the other. But I do have some general concerns. In order to make reference in the actual world work out, the range of the function better be things in worlds and not representations of them. If the range of the function is representations then in the actual world my term "Dave Chalmers" refers to that part of my actual world representation which represents Dave Chalmers. But we want "Dave Chalmers" to refer to Dave Chalmers himself, not a representation of him.

Now you might suggest that if you found a function from "Dave Chalmers" to the part of my world representation which represented Dave Chalmers, then you could simply extend the function by saying "Dave Chalmers" refers to whatever is represented by the part of my world representation which is picked out. But this ceases to be a reductive definition. Now we need to know what the Dave Chalmers part of the world representation represents. And that is just more semantics.

One last point; I think there are two assumptions underlying this worry. 1) PIs are internal (or supervene on what is in the head). 2) You (or your thought) doesn't have to be in a world in order to refer to something in the world. If you ditch both of these then you can use worlds themselves as the input to even a reductive function. Of course, this raises other problems.

Josh

To: MODALITY@LISTSERV.ARIZONA.EDU
Status: R

In looking over the Block & Stalnaker and Stalnaker pieces again, I'm getting a bit puzzled why people are so certain that there ain't any such beast as narrow content. This dovetails a bit with what I wrote last time on justification, so I'll expand on that as well.

Anthony responded to my call for narrow content this way:

> I guess I have some sense of conflicting intuitions in this case, but it > seems that the sense of conflict goes away if one considers exactly what > question one is asking. If we ask whether the envatted individuals in > 1 > and 2 are justified in the beliefs they form, then clearly it seems that > 1's belief is not justified and 2's is. But it seems to be a different > question when we look at them from an external perspective and pronounce > that, in both cases, their beliefs are unjustified. >

I think that there is probably an ambiguity on 'justification' lurking around here. In one sense, S's belief in P is justified if S's belief in
P correlates or tracks truth to some specified degree. And whether a belief tracks truth is, presumably, a fact external to the believer. This, of course, is the sort of justification that Alvin wants to talk about. Anthony is right that in this sense of 'justification' the envatted believer has unjustified beliefs in both cases.

But Cohen's argument is that this is an uncomfortable consequence for externalists about justification. We have clear intuitions that go different ways in the two cases. And this is taken to suggest that there is another---perfectly respectable---notion of 'justification' which is essentially procedural in nature. Theories of justification are theories for rational belief acquisition, retention, and revision. And these are notions that can be explicated by appeal to stuff in the head (and nothing else). So there is an equally well-defined sense of 'justification' which relies on the mental states of the cognizer. And wide content cannot make sense out of this sort of justification. And that, in turn, suggests that there is another sort of content that must do the job.

It's been a long time coming, but I think people in epistemology are starting to come around to recognizing that there are at least these two different senses of 'justification', and that one need not be taken as more basic than the other. (Historical note: arguably, the internal sense of 'justification' is the sense we find in Descartes and Hume.) If that's right, then if it's also right that narrow content is needed for internalist epistemology, then we need not think that wide content is basic and narrow content derived, or vice-versa.

So, when Block&Stalnaker, and Stalnaker complain that narrow content can't be cleanly derived from wide content, an answer (probably an answer that Dave wants to give anyway) is basically a "So what?" reply: So narrow can't be derived from wide. Big deal. Internalist justification can't be derived from externalist justification, direct realism can't be derived from reliabilism. That just points to there being *two* phenomena in need of explanation. There is a clear sense of narrow content, and everybody knows it: it's that content that is needed (whatever the theory turns out to look like) that undergirds procedural justification. So there.

Cheers,
Thony

are just in a 1to1 correspondence with worlds (for ease I'm going to suppose they represent worlds). So a reductive analysis of PIs is going to consist in finding a function from psychological representations to referents.

My post starts here:

Some thoughts on primary intensions and reductive analysis. We want a reductive analysis of a primary intension that satisfies the following constraints. One, it is, as Josh says, "in the head" or psychological and two, it is a reduction of the primary intension as a function from centered worlds to referents. So, what is a psychological reduction of a function from centered worlds to referents? That's an interesting question. As Josh notes, "worlds" are not the sorts of objects that we can leave alone in a psychological reduction, because of course the brute notion of a possible world is not something that is likely to be have a psychological realization simpliciter. So we need something more psychologically plausible, perhaps symbols in a LOT or at least something broadly representational. Now, I don't have any idea how this would work, and there is of course all the standard objections to reductive semantics of this sort. But it occurs to me that the characterization of a primary intension as a function is not problematic for psychological explanation per se, or if it is, it isn't any more puzzling than other functions that we employ in cognition. A rational agent can do arithmetic. That's in the head. It takes as input a specified domain--natural numbers, not worlds--and produces a unique output, the set of which constitute the range (a bunch more natural numbers in this case). But it seems that this is all in the head too. And so we have this miracle, internalist function--arithmetic! And it needs some psychological reduction, but we can't just take the NATURAL NUMBERS as psychologically brute, because those things are not psychological entities. And you can see the rest.

So, my point is just this. With Josh, I agree that there is a deep puzzle about how we could get an internal, psychological reduction of something like a primary intension, but unlike Josh (perhaps) I don't see this as a problem for a primary intension alone, especially when considered as a function whose domain and range are not prima facie psychological entities. This is just what we expect from the functions we commonly employ in cognition, whether balancing our check book or considering what the referent of a term in some world considered as actual is. Of course, there is a lot of ambiguity here about just what we mean by a reductive explanation in these cases, and just how far down it has to go. On a broad scale this sort of concern reflects the confusion over what to do with "rationality" and conditions of normativity generally in psychological reductions of "thinking".

So, consider:
1) we have the ability to use functions with potentially infinite domains and ranges in cognition and 2) by virtue of rational reflection, we have the ability to see whether the output of our functions is correct.

It seems to me that there is some puzzle about 1) (eg to what extent do we have to represent all this stuff cognitively, and how exactly is it represented?) but that 2) is the crux of the puzzle about giving a reductive analysis of a primary intension. I can return a referent from a centered world. How is this referent the right one? Well, what is the intuitive, rational thing to say about cases where primary intensions are evaluated? That question is just the question of how we can get a psychological account of rationality, and that is a tricky one indeed. How do we get it from causal or functional processes, or even more puzzling, from a bunch of grey stuff in our skulls? So perhaps the
analysis of a primary intension is going to have to wait until we understand better how we do a priori reasoning, eg how we manage to be rational at all.

> ps Hey Rachael, did you get that paper turned in for Goldmann?

Erik L.

> Now my worry is what the referents are going to be in this case. The referent either has to be something in the representation or something in the world the representation is of. For example, consider the reductive primary intension of water given a representation of Twin Earth as its input. Either it has to pick out the representation of XYZ in my Twin Earth representation or it needs to pick XYZ in the Twin Earth world.

> At the moment I don't have any argument that it is going to have to be one or the other. But I do have some general concerns. In order to make reference in the actual world work out, the range of the function better be things in worlds and not representations of them. If the range of the function is representations then in the actual world my term "Dave Chalmers" refers to that part of my actual world representation which represents Dave Chalmers. But we want "Dave Chalmers" to refer to Dave Chalmers himself, not a representation of him.

> Now you might suggest that if you found a function from "Dave Chalmers" to the part of my world representation which represented Dave Chalmers, then you could simply extend the function by saying "Dave Chalmers" refers to whatever is represented by the part of my world representation which is picked out. 2.8 Mental Content, Misc [43]
2.1a

The Language of Thought (Fodor)

Argues that thought involves computation upon representations, and that these are structured as sentences in a mental language. With linguistic and psychological evidence, and arguments that the mental language is innate.

Because it fits explanatory methodology, it coheres with the usual ontology of psychological processes, and it explains systematicity.

About what PA's are, and why they're at the foundations of thought.

Argues that symbol processing can't account for the intrinsically contentful nature of thought: using a symbol doesn't give understanding of its content. With defense against arguments from twin earth and conceptual-role semantics.

No need to postulate LOT: diachronic explanation is as good as synchronic, and high-level laws can exist without high-level causal connections.

Review of Fodor's LOT. Fodor's view is too strong: function, not structure, is criterial for content. The structure of a predictive theory need not be directly reflected in inner processing.

On the explicit representation of belief: criteria, plausibility, and relationship to verbal reports and conscious judgments.

A general treatment of Fodor, identifying him as arch-conservative mentalist.

Relates Schank's conceptual dependency to Fodor's LOT.

Contra two of Fodor's arguments for LOT. Complex causes need not have LOT constituency structure; and evidence from psychological theory falls short.

Analyzes belief into a relation between a person and an internal sentence, along with a semantic relation between that sentence and e.g. a proposition. With arguments against functionalist analyses, and against propositions.

There are no good arguments for LOT of the form "The brain needs to do X, and X entails LOT". Considers X = concatenation, logical form, tracking, combinatorial encoding. Either LOT is weakened deeply or is unnecessary.

Argues that the primary role of language is in thought rather than in communication, and the language of thought incorporates natural language.

LOT confuses processes with descriptions of processes. Also, symbols cannot denote solely in virtue of structure, so must rely on human interpretation.

Defends sententialism of the homuncular variety: little modules all the way in. Lots of pro-belief arguments.

Distinguishes varieties of Sententialism, reasonable vs. mad-dog.
Part 2: Mental Content

Argues from the unboundedness of thinking and the need for a finite stock of elements to something like a language of thought. With remarks on connectionism and instrumentalism, and a reply by Stalnaker.

Arguments that contrary to some claims, cognitive psychology does not provide much support for a computational/representational theory of propositional attitudes. Specifically considers research in psycholinguistics and vision.

Fodor's theory can't deal with inexplicit attitudes: the core/derivative distinction is untenable. But we can make sense of intentional causation and psychological explanation without explicit representation.

On some problems typing tokens in the language of thought. There's no principled distinction between type-identical tokens and type-distinct tokens with an identity judgment. With interesting remarks on co-identification.

Arguments that there is no good way to individuate syntactic types in Mentalese. Neural typing, causal typing, and semantic typing all fail.

Argues that the language of thought need not have a compositional semantics; productivity and systematicity can be explained without it.

On Danto's suggestion that beliefs are like sentences. Conventionality poses problems, as does differentiating between different sorts of attitudes.

Motivates LOT and defends it against various objections: e.g. tacit belief, identity conditions, infinite regress, and semantic nativism.

Tienson, J. 1990. Is this any way to be a realist? Philosophical Psychology.

2.1b The Intentional Stance (Dennett)

Can view systems from physical stance, design stance, or intentional stance. Beliefs/wishes are attributed under the intentional stance, with help from certain idealized norms of rationality and accuracy licensed by

Reply to Stich 1981. Irrationality is misdesign (take design stance). Etc.

Beliefs/desires are useful predictive attributions. This isn't inconsistent with a certain degree of realism (abstracta/illata distinction).

TIS, with commentaries and replies.

Mental states are underdetermined: like interpreting a text, or finding an object's function. Even adaptationist teleology gives no fact of the matter.

Proposition attitudes have the ontological status of a noisy pattern that helps make sense of behavior. This degree of realism falls on a scale: Fodor > Davidson > Dennett > Rorty > Churchland.

Dennett vacillates between stance-dependence, -independence; e.g. on rationality, design features. Instrumentalism can't be rescued.

Dennett should be a realist, of the relative-to-environment variety.

Argues contra Dennett and Smolensky that language is fundamental, not just an add-on.

Questioning Dennett on the bridge between intentional characterization and functional characterization. Arguing for the importance of context.

Dennett's rationality/intentional idealization assumptions should not be viewed as Platonic but epistemic. PA's are real and play real roles.

Against "interpretivism" about intentionality: projectivism is hopeless, and Dennett's arguments for normativism (via charity and evolution) go wrong or beg the question.

McLaughlin, B. & O'Leary-Hawthorne, J. 1995. Dennett's logical behaviorism. Philosophical Topics

Dennett must be one of: realist, eliminativist, instrumentalist.

Dennett's instrumentalism can't explain the acquisition of intentional concepts. Proposition attitudes are directly introspectible entities, although still theoretical and still patterns.

Slors, M. 1996. Why Dennett cannot explain what it is to adopt the intentional stance. Philosophical Quarterly 46:93-98.

Critical review of *Brainstorms*, with response.

Dennett has problems with rationality, realism, etc. Hard line/soft line: either intentional stance is too close to FP or too far away.

Very thorough account of the evolution of Dennett's views. Elucidates abstracta/illata, criticizes intentional subpersonal psychology.

2.1c Eliminativism (Churchlands) [see also 4.3c]

Sentential processing is out. Against Harman's mental English and Fodor's Mentalese. Arguments from learning, evolution, neuroscience, mental images.

Eliminate beliefs/desires, remnants of a stagnant folk theory.

How to dethrone language and still handle content.

Reply to Foss 1985: EM is plausible, though certainly not applicable everywhere -- e.g. sensations will be reduced, not eliminated.

14 glimpses of the neurophilosophical golden age.

Reply to Haldane 1988. Even observations can be reconceived. With remarks perceptual plasticity and propositions, and a rejoinder by Haldane.

It's "bad faith" to accept modern epistemology but to deny the possibility of eliminativism. On various objections: "functional kinds", "self-defeating", "what could falsify it?", "different purposes", "no alternatives".

Elaborating the paradoxes of disbelieving in belief. Rational acceptability, assertion, and truth are all at risk.

Eliminativism is pragmatically incoherent, as it implies that language isn't meaningful and that the thesis isn't formulable. Folk psychology needn't be scientifically reduced to be true. With comments by Chastain, and reply.

Against Baker's cognitive-suicide arguments against eliminativism. We don't know what a replacement theory will look like, but that doesn't show that none is forthcoming.

Argues for a revisionary reduction of the propositional attitudes, rather than elimination or smooth reduction. Sentential aspects will go, but coarse-grained functional profiles and content will remain.

Irrealism about mental content (and therefore truth-conditions) can't be made sense of. An error thesis presupposes factual truth-conditions, and a non-factualist thesis presupposes a non-deflationary theory of truth.

Reply to Devitt 1990.

Unbelief in belief is not incoherent. Argues with Baker.

Cognitive states like belief are necessary to explain the dependence of behavior on perceptual features of the environment. Informational states alone are not enough, as they can't explain selective response to features.

Against Boghossian's critique: the eliminativism will express her claim in a new framework, so appeals to truth beg the question. With a response.

Rejoinder to Boghossian 1990.

EM needs much more evidence before being so gung ho.

Argues that folk psychological states exist, even if they aren't useful as causal explanation. We have independent reason to believe in them, e.g. from self-knowledge. They're useful in social psychology, too.

Argues that folk psychology is not a theory, and that psychological knowledge is a pre-theoretical given.
Part 2: Mental Content

With remarks on laws, the prediction of behavior, and neuroscience.

A bundle of arguments against eliminativism, e.g. from incoherence, the lack of alternatives, and against the folk-theory-theory. With commentary.

Defending folk psychology against the arguments of Churchland and Stich: e.g. incompleteness, stagnation, irreducibility, dual-control, modularity, and unfalsifiability. Even with no neat reduction, folk psychology may be OK.

FP is almost certainly true, irrespective of scientific absorbability or the language of thought. FP's commitments are austere, and mostly behavioral. Arguments from semantic competence and conceptual conservatism.

Argues that FP is not committed to much. The austere conception is supported by intuitions, conservatism, and the inconceivability of dropping it. Responds to phlogiston objections: they are not analogous.

Clarifies different senses of "theoretical" and "belief". Some beliefs are relevantly theoretical (dispositional, infra-conscious, unconscious ones), but conscious occurrent beliefs are not, and so can't be eliminated.

FP holds that beliefs-desires play a certain functional role, and it's almost certain that objects playing that role exist, so FP is fine, whether or not propositional attitudes are good scientific entities.

Even if nothing satisfies all or most common-sense properties of mental terms, reference can still be fixed
under a Putnam style theory of meaning. (More about qualia than about intentional states.)

The Churchlands underestimate the resources of intentional psychology.

Uses empirical evidence to argue that there is prelinguistic awareness, so nominalistic arguments for eliminativism fail. And some awareness is innate, so we can't reconceive things in less than evolutionary time.

The self-refutation objection reduces to other standard objections: counterexample, promissory note or reductio.

If connectionism is true, then eliminativism is true, as you can't isolate the causal role of individual beliefs in a connectionist system.

Response to Ramsey 1990: If there are no beliefs and so no assertions, there is no identifiable propositional content, and truth and knowledge are out. Eliminativism is pragmatically self-refuting.

A careful analysis of whether self-refutation arguments against eliminativism beg the question by supposing that assertion requires belief. An account of what it is to beg the question, and a comparison to arguments about vitalism.

There's no reason to abandon FP, even if it doesn't reduce.

Explaining how singular causal claims based on FP may be true even if FP is false; by analogy with phlogiston, and also because of near-vacuousness. EM isn't incoherent, as we can use a non-intentional replacement for belief.

Folk psychology is compatible with neuroscientific models, but it need not smoothly reduce to neuroscience to have an important role.

Eliminativism may have no determinate truth-conditions: if folk psychology is a poor theory, the question of whether or not "belief" refers may be empty.

Philosophical analysis isn't sufficient to understand intentional concepts; real cognitive science is required, with conceptual revision. The truth of eliminativism will be relative to the theory of reference that we choose.

Against transcendental arguments against eliminativism. These fail on their own terms, and even if successful they would not establish causal/explanatory relevance for the attitudes, which is the real key for folk psychology.

**2.1d Propositional Attitudes, General**

Beliefs are OK, despite no physicalist reduction of content.

Against beliefs construed as physically realized internal causes of behavior: syntax of these states can't be determinate, and their explanatory role wrt causation leads to a circle. Belief is irreducible.

Remarks on the conceptual analysis of belief/desire attribution. On the roles of causation, inner-route explanations, belief-desire-action triangles, teleology, unity, the presumption of simplicity, and evolution.

On requirements for belief/desire explanations: input/output patterns, the unity condition (i.e. no single
Part 2: Mental Content

associated mechanism), and teleological bases for generalizations, e.g. through evolution or educability.

Argues that desire will smoothly reduce to a neurophysiological kind.

The conditions on being a believer are mostly behavioral; to claim otherwise is to fall into a "modularity trap". A counterfactual account of mental causation is enough. With a defense of mentality for giant look-up tables.

Stich is confused about type-token, syntax/content, etc.

A taxonomy of positions on the representation of propositional attitudes: dividing up via questions about realism, functionalism, monadicity, and truth-conditions. With arguments for structured representations.

Things are only syntactic (in SS's sense) in virtue of intentionality. True.

Argues that there are no tacit beliefs: dispositions to believe can do all the explanatory work at lower cost. With some remarks on subdoxastic states, and the difference between belief and opinion.

A theory of propositional attitude ascription as like numerical measurement.

Folk psychology isn't a theory about laws, but about proper functions. desires are identified by proper functions; beliefs by Normal explanations.

Instrumentalism about belief can't be right, because of Martian marionettes, but the language of thought is too strong a requirement. A state's structured content may reside in its pattern of relations to other states.

Stich is wrong, circular, and representational anyway.

Must individuate mental states by semantics, not just by function.

Beliefs/desires are out, new Syntactic Theory is in.

2.1e

**The Nature of Folk Psychology**

Folk psychology is a theory: defense against objections from logicality, softness of laws, practical function, behavior, and simulation. It needn't be a deductive-nomological theory: e.g. it might be based on prototypes.

Folk psychology isn't all that bad. It survived evolution after all.

FP is craft, not theory. Opinions rather than beliefs are interesting.

On the psychology of self-ascription of mental states. Functionalism has serious problems, as we don't have direct access to causal roles. Defends a qualia-based account, even for propositional attitudes.

On the development of folk-psychological concepts in children. First the appearance/reality distinction, then more complex theories of perception, representation, and belief. Implications for the status of folk psychology.

Cambridge University Press.

Defending the claim that folk psychology is an empirical pre-scientific theory, with its own laws. In a particular, a detailed reply to the criticisms in Wilkes 1984.

Distinguishes internal and external accounts of folk psychology (mechanisms vs systematizations), and various versions of each of these. Only some are compatible with eliminativist arguments.

Common-sense psychology is no theory at all, and not in competition with scientific psychology. CSP is particular, rich, vague; SP is general, austere, precise. CSP will be neither subsumed nor eliminated by SP.

Argues that commonsense and scientific psychology are quite distinct in their aims, scope, framework, and nature, but have been confused by philosophy. With support from historical considerations.

2.1f

The Simulation Theory

FP is a strategy for prediction via simulation; an ability, not a theory.

Heal, J. 1996. Simulation, theory, and content. In (P. Carruthers & P. Smith, eds) Theories of Theories of
Mind. Cambridge University Press.

2.2

Internalism and Externalism [see also 1.5d]

2.2a Is Content in the Head? (Putnam, Burge)

Developing an externalist account consistent with psychological explanation. Contra Burge, social links aren't constitutive of content. Causal links are indirectly constitutive of content, via our conceptions.

Belief contents are not fully determined by internal state, as the linguistic community plays an important role: arthritis, brisket, contract, sofa, etc. So mental states are not individuated individualistically.

On Putnam's Twin Earth. Natural kind terms are not indexical. Even de dicto attitudes are not in the head; they presuppose the existence of other things.

On non-individualist elements due to by intellectual norms in the community, to which meanings are answerable. Even meaning-giving truths can be doubted. With remarks on sofas/safos, and on linguistic meaning vs. cognitive value.

Challenges Burge's interpretations of the thought-experiments: e.g. twins have the same concept, neither of which is the public concept of arthritis. With remarks on computationalism and Marr's theory.

Argues that natural kind terms are token-reflexive, with reference ultimately fixed to the underlying explanatory properties of the surface qualities of local matter.

Twins share the same concepts. Contra Putnam: essentialism is fallacious; contra Burge: speakers share beliefs, but one has false belief about meaning.

We shouldn't rely on intuitions about thought-experiments; we need an empirical theory about belief. Belief contents are distinct from sentence contents; we have to distinguish linguistic from psychological semantics.

Against Searle's theory of internal intentionality. Searle's theory requires magic to grasp external contents internally.

Argues that thought is extrinsic, but it is not essentially social. A system without a linguistic community could have thoughts, if it had an appropriate learning history.

Contra Burge on sofas: oblique that-clauses can't identify the (wide) way that the subject thinks of sofas, which is idiosyncratic and inexpressible.

Gives a Fregean account of belief semantics to handle the Burge cases, and argues that the *type* of a proposition may be internal even if the token itself is not. With remarks on the relevance to Grice's program.

Argues for a moderate externalism by synthesizing Putnam and Searle: internal intension leaves extension indeterminate, but it specifies the facts relevant to filling in the indeterminacy.

Argues that conscious experience is required for intentional states, and that any external relations could be satisfied without this experience, so external relations cannot suffice for intentional content.

Various arguments against Crane 1991 on externalism.

McGilvray, J. 1998. Meanings are syntactically individuated and found in the head. Mind and Language

Argues that meaning is determined by a certain kind of internal state, involving de se cognitive attitudes. These states aren't shared by twins, but are still narrow in a strong sense.

Functional organization doesn't determine attitude content, even if we include inputs and outputs.

Indexicals are essential to some beliefs, so belief cannot just be a relation to a proposition. Belief contents must be at least in part construed relative to a subject. Separate belief object and belief state.

What is in the head doesn't determine the reference of our thoughts: my twin on Twin Earth refers to XYZ where I refer to H2O. Content is determined by environment and linguistic community as well as by internal stereotypes.

Meanings *still* aren't in the head.

Sure, meanings are in the head -- e.g. the content of a given visual experience is "the thing that is causing this experience".

On concepts as abilities, and on construals of abilities that lead to internalism and externalism. Maybe the relevant abilities are characterized externally but determined internally. Remarks on Putnam, Davidson,

Making sense of twin earth intuitions with an information-theoretic account of content: information depends on relations in normal conditions, which are extrinsic. With remarks on the context-sensitivity of content-attribution.

Burge's arguments show only that context-ascription is pragmatically sensitive to context, depending on the epistemic predicament of the ascriber. Content itself is still internal.

Argues that the extension of `water' is the same on earth and twin earth, using arguments from isotopes and scientific development. Molar properties determine classification. Remarks on historicism and the division of labor.

2.2b Externalism and Psychological Explanation (Burge, Fodor)

Buller, D. J. 1997. Individualism and evolutionary psychology (or: In defense of "narrow" functions). Philosophy of Science 64:74-95.

Reply to Fodor 1982, clarification of position.

Psychology should be and is done non-individualistically, i.e. with reference to environment. Examples from vision, e.g. Marr.

Advocates a different sort of "active externalism", based on the role of the environment in actively driving cognition. Beliefs can extend into an agent's immediate environment (e.g. a notebook) in this way.

Argues that extrinsic properties can play a respectable role in scientific explanation; e.g. the histories of plants, animals, and devices are relevant in explaining their current behavior.

Maybe, maybe not. Contra Fodor: science can be non-individualistic. Contra Burge re oblique ascriptions and Marr.

Should do psychology without reference to the external world. What counts for psychology is in the head; who cares about truth, reference, and the rest?

Twin Earth isn't a problem for cognitive science. Intents of utterances, de re/de dicto, etc. Truth conditions aren't in the head, but that's no problem.

Methodological solipsism implies epistemological solipsism.

Argues against Stich, Fodor, Block: use different taxonomies (narrow/wide) for different purposes. Both
are OK, functionalism *and* content survive.

Relates the individualism debate to Roschian prototype research.

MS doesn't rule out all use of content, just of wide content. Narrow content is OK. With remarks on folk psychology and computation.

Various problems for computational psychology handling content. It shares the problems of a naturalistic psychology.

Object-dependent thoughts are redundant in psychological explanation, as an explanation applying to a hallucinator will work as well. But this needn't defeat externalism in general. With remarks on self-knowledge.

Uses examples to argue that in explaining behavior we often ascribe beliefs in an individualistic way, even in cases where individual and community use diverge. These contents are at least sometimes expressible.

Developmental psychologists attribute concepts individualistically.

Externalist states are required for the explanation of relational properties. Counters objections from conceptual connections and dormitive-virtue worries, and applies to teleology, self-knowledge, etc.

Argues that behavior is often individuated widely for explanatory purposes, so that wide content is relevant, and that there is more to causation than local causation, so Stich's autonomy principle fails.

Beliefs are not in the head, so aren't good for psychological explanation. Interesting, but confuses the role of truth-values with truth-conditions.

Philosophy of Science 61:55-75.

### 2.2c Externalism and Mental Causation

> Argues contra Fodor that broad contents can be explanatory -- if they can't, no relational properties can. Fodor's "no-conceptual-connection" and "cross-context" tests for causal powers fail to do the job.

> Arguments for the causal significance of broad content. Physical twins can differ in causal powers; broad content figures in (ceteris paribus) causal generalizations; can make twin arguments against narrow content too. Hmm.

> Contra Fodor: psychological processes can play differing causal roles, despite being physically identical.

> Fodor's modal argument for narrow content rests on a false analogy between cases concerning thoughts and those concerning planets.

On when a difference in effects amounts to a difference in causal powers: when the effects are connected contingently, not conceptually, to the causes. Differences in wide content don't satisfy this, so aren't causal powers.

Mental content can be extrinsic and efficacious. Narrow content strategies don't work, as observation concepts are still extrinsic. One can't screen of the intrinsic part from the rest. Thought-experiments are inconclusive.

Reconciling Twin Earth with the causal relevance of content. Historical factors can be causally relevant.

Argues that externalist content is not causally efficacious, but is relevant to causal explanations of behavior indirectly, via the cognitive activities of others external to the system.

Epistemology requires the causal relevance of content, and the relevant content is narrow. On how various architectures might support this causal relevance, by being realized by more specific intrinsic features.

Against some arguments for internalism: local causation doesn't imply local type-individuation, as distal relations affect distal causes and effects; and processes can have access to semantic properties via formal properties.

Science frequently appeals to relational and historical taxonomies, so either causal powers can be non-intrinsic or science needn't taxonomize by causal powers. With remarks on causal properties and conceptual connections.

Arguments from causal powers beg the question, either on whether relational properties can have causal powers or on whether science taxonomizes by causal powers, as relational properties are common in scientific explanation.

2.2d

Externalism and the Theory of Vision

Psychology should be and is done non-individualistically, i.e. with reference to environment. Examples from vision, e.g. Marr.

Contra Burge, Marr's theory is individualistic. Intentional contents therein are neutral between twins' environments; nothing grounds a more specific attribution.

Contra Segal, Marr's theory is non-individualistic even though it may classify twins together. Computational-level task descriptions rather than behavior guide content ascription, so the environment plays a crucial role.

2.2e

Externalism and Computation

Winograd's SHRDLU doesn't support individualism: its concepts are anchored (to a fictional world) via its programmer, and it could have made errors.

Syntax is extrinsically determined, as well as semantics. So if broad content is irrelevant to psychology, syntax is too.

2.2f

Externalism and Self-Knowledge

We can't know our thought-contents by inference (circular), by introspection (because they're relational), or directly, so we can't know them at all.

Contra McKinsey 1991, anti-individualism doesn't lead to a priori knowledge. The belief that water is wet doesn't conceptually entail facts about the external world (e.g. H2O), although it may metaphysically necessitate them.

Knowledge of our thoughts is compatible with externalism: its content is self-referential and self-verifying. We needn't be able to explicate the content or its enabling conditions, or rule out twin possibilities.

Externalist anti-skeptical arguments fail as they require us to know a priori that our terms designate natural kinds, and also because they require us to know a priori that externalism is true. A thorough analysis.

Subjectivism and environmentalism seem to clash on knowledge of content, but it's OK: under environmentalism we still know our contents w/o evidence.

Argues that cases of switching between language communities are quite common, so that Warfield's case for externalist self-knowledge doesn't work.

   On reconciling externalism with the non-evidential character of first-person knowledge.

   Argues that we can know the meaning of our words a priori. Analyzes twin earth cases by separating propositional meaning from linguistic meaning, which is indexical, fixes reference, and is knowable a priori.

   Contra Burge: if there are conceptual connections between wide contents and and the external world, then we can't know wide contents a priori, as otherwise we could know a priori that the world exists.

   Reply to Brueckner 1992: The claim that belief metaphysically necessitate external facts is trivial. Almost all states do that, for Kripkean reason.

2.2g

**The Status of Narrow Content**

Traces and criticizes Fodor's position on narrow content. Argues that narrow content isn't content, and doesn't explain behavior. Fun but arguable.

Part 2: Mental Content

Argues that problems with names don't require an appeal to narrow content in explanation. Broad content plus associated descriptions will do the job.

Representational cognitive science has no need for narrow content -- wide contents and formal properties can do all the work. Argues that the semantics of mental expressions needn't mirror the semantics of language.

Argues that type-identical functional states can differ in narrow content, so methodological solipsism fails. Uses the example of identical programs for playing chess and arms negotiations.

Some implausible twin cases trying to show that mental life can vary wildly while preserving physical/computational state. Bizarre.

Lots of arguments against narrow content. Very stimulating, though wrong.

Contra Loar 1988, the contents of "that"-clauses often reflects psychological content, even if it sometimes does not. We don't need narrow content.

There are big problems specifying the "mapping" and the relevant contexts for Fodor's theory noncircularly. Narrow content either collapses into syntax or is too coarse-grained. Nontrivial narrow content must be holistic.

Criticizes the "bracketing" strategy of Stich and Walker, and argues that intrinsic belief state should be individuated according to how it embeds in different environments. With a comparison with Fodor's related theory.

Argues for a two-dimensional intensional theory, with different kinds of intensions constituting notional and relational content. Notional content governs the dynamics of thought and behavior, and is primary in explanation.

Comments on Fodor 1987. Fodor doesn't make a conclusive case against externalism; but narrow content may be promising, and inexpressibility doesn't pose any real problems. With comparisons to neo-Fregean theories.

What matters are not propositional attitudes but notional attitudes; but it's hard to calibrate notional worlds. Very nice.

Not syntactic psychology nor wide psychology, but narrow psychology.

Science taxonomizes by causal powers, which are locally supervenient, so psychology needs a narrow notion of content. Proposes that a relativized notion -- a function from context to extension -- can do the job. Nice.

Argues that folk psychology needs a notion of narrow content to provide robust predictive behavioral generalizations that covers doppelgangers. If not, then some behavioral patterns would be flukey.

There's no good way to construe narrow content. Phenomenologist strategy is intrinsically wide, and indexicalist strategy can't specify content.

Uses examples to argue that psychological content is not fixed by the content of "that"-clauses in belief ascription, and vice versa. We require a subtler kind of narrow content to capture what's going on.

Contests the "provoked/aggravated assault" example of Baker 1986. If they're doppelgangers, then their narrow content can't differ.

Narrow beliefs are de re beliefs about our inputs and outputs.

Against perceptual-prototype and conceptual-role accounts of narrow content.

Can't get a `mode of presentation' account of narrow content to work, either through description theory or prototypes. Psych should be non-individualist.

There are levels of narrowness, varying by whether independence is of actual or normal environment. Argues that this can be consistent with externalism.

On some problems with narrow content, contra Loar 1987. Narrow content is hard to spell out with "diagonal" propositions. Loar doesn't show that psychological content is narrow. With some remarks on privileged access.

Argues that narrow content is still too coarse-grained for explanation, classifying psychologically distinct states together. Use syntax instead.

Argues that the partial character construal of narrow content is not interestingly semantic. It collapses into syntax or phenomenology.

Uses a "fraternal twin earth" thought experiment to show that even de dicto attributions don't supervene on narrow role, and that narrow content can't be explicated descriptively unless it collapses into phenomenalism.

Replies to Burge/Stich arguments by introducing partial character -- a function from context to content, analogous to Kaplan's character -- as the semantic property determined by functional state and relevant to explanation.

Argues for an account of narrow content in terms of notional worlds, by considering "objective optimality" across worlds. This allows for a sort of narrow radical interpretation. With arguments against Stalnaker.

Narrow content theories can't handle the normativity of content. In-depth treatment of Burge cases and of the failures of causal and conceptual-role accounts. Normativity is fundamentally social. A long, interesting paper.

2.2h

Miscellaneous

An entertaining fable about a swampthing doppelganger of a murder witness. Does he have content? With plot twists about personal identity.

Argues that a swampthing isn't intelligent or intentional, with different physiological processes and no sensations, as these are functional kinds.

   Should construe functionalism broadly rather than narrowly; then can handle the problem of broad content.

   Anti-intensional arguments are not independent but a series of dominos.
   Quine/Quine/Davidson/Putnam/Burge rise and fall together.

   Belief content has two distinct elements, one causal-explanatory, the other truth-related.

   Supplements externalist "locking" theories of content with an account of internal "conceptions" by which thoughts lock onto environmental kinds, with that aid of dthat operators, thus solving various philosophical problems.

Contra Owens 1987: wide intentional descriptions and molar bodily descriptions don't exhaust the options. A bracketing strategy gives a narrow intentional taxonomy of mental states.

2.3

Causal Theories of Content

2.3a

Information-Based Accounts (Dretske, etc)

Defending information against Fodor 1986. Information is objective but relational, and depends on the relevant constraints between representation and environment. Circumstances play a vital role.

From material (formal) info to semantic info via teleology; from semantic information to representation via internal structure. Cute. With a good reply by Israel, and a terse reply by Dretske.

Uses information theory to analyze misrepresentation. A signal represents what it carries most information about, not what it correlates best with. Treating some signals as noise can increase information content.

Defines knowledge content is in terms of information-flow from events, and applies to various aspects of psychology.

A summary of the book, with commentary and replies.

On the causal role of information (as opposed to meaning). Information is causally efficacious if considered with respect to learning. With commentary by Brian Smith.

Transmission of information is no good without the encoding of information. With criticisms of associative networks, which transmit without encoding, and criticism of Barwise & Perry's account of attunement to a relation.

Shannon's notion of information is more useful for naturalized epistemology than Dretske's.

We need to analyze indication in terms of "close enough" worlds; the relevant conditionals are "might"-conditionals.

Argues that a representationalist theory of semantics beats a realist one.

Dretske has problems with ruling out alternative possibilities; and there is a gap between information-caused belief and knowledge.

Makes a distinction between absolute information and information that's relative to other knowledge.

On problems with a computational approach to content: computers process info(t), the non-semantic content of communication theory, not info(s), or semantic content. Get info(s) from efficient processing of mutual info(t).

2.3b Asymmetric Dependence (Fodor)

Defends and refines a causal theory, using the notion of asymmetric dependence of a token upon the world.

Defending the asymmetric dependence theory against various objections.

Argues that Fodor's theory is a type-1 theory, requiring naturalistically specifiable circumstances in which a symbol is only caused by its referent; and that these theories fail for various reasons, e.g. verificationism.

Fodor's theory has counterexamples and can't explain its counterfactuals; but we can save it by borrowing from Dretske's account of misrepresentation.

### 2.3c Causal Accounts, General

A somewhat sympathetic commentary on the Dretske/Stampe causal theories, but raising the problem of misrepresentation.

On various attempts to solve the error problem and why they don't work.

World-head reliability is just as important as head-world reliability. With arguments and examples from signal detection theory.

2.3d

Teleological Approaches (Millikan, etc)

Argues that a teleological account can resolve content indeterminacies, by an appeal to counterfactuals in examining what properties were selected for.

Defends evolutionary theories of content against Fodor.

Attacks original intentionality (Fodor/Burge/Dretske/Searle/Kripke) -- our intentionality, if anything, is derived through evolution, and so is as indeterminate as that of an artifact.

Tries to deal with misrepresentation by appealing to function.

Truth conditions are "entry conditions" for belief under "normal function". Later repudiated.

Teleological solutions can't work, because of underdetermination and so on.

An evolutionary account of thought, content, and various intentional phenomena, appealing to proper functions and adaptational role to individuate contents.

The content of a desire is its adaptational Proper Function; the content of a belief is its Normal Condition for success.

Representation content is determined by the consumption of a representation, not its production. The representation-world correspondence is best taken as a normal condition for the consumer's function.

Contrasting positions on the role of representation production and consumption; also on the role of reliability, articulateness, and learning.

A reply to some of Fodor's criticisms of teleological theories in *Psychosemantics_ and elsewhere. With some remarks on Fodor's asymmetric dependence theory.

A collection of papers on teleological semantics and other issues about psychology and mental content.

It's not unreasonable to deny a swampthing beliefs: swampcows aren't cows and swamphearts aren't hearts. Semantic norms are plausibly grounded in biological norms and so in history.

Contra Dennett 1988, designed creatures can have intrinsic (if not original) intentionality. Overall purpose is dependent on designer's goals, but specific contents need not be.

A teleological theory of belief/desire contents: the satisfaction conditions for a desire are those effects for which it was selected; truth conditions for a belief are circumstances resulting in satisfaction of desires.

Best theory is combination of a success-guaranteeing account of truth-conditions with a teleological account of desire.

Combining the analysis-relative and historical accounts of function, and using these to give an account of intentionality: representation are produced by conditional productive functions. Argues against Fodor on indeterminacy.

Millikan's theory has an implausible consequence: creatures' belief contents can involve properties which they cannot discriminate. With examples.

Teleosemantics has big problems with indeterminacy, holism, false belief, and "psychophysical normalcy" in causation. So do all naturalistic stories.

2.3e Conceptual Role Approaches

An in-depth program for conceptual-role semantics, and its role in a two-factor account of meaning. Also a defense of narrow content.

A defense of functional role semantics, and an account of its relation to truth-conditional factors. A two-factor theory will handle wide content.

No matter how we understand the denial of the analytic/synthetic distinction, the falsity of inferential-role semantics does not follow. The meaning-constitutive inferences needn't be the analytic inferences.

CRS conflates representation content and attitude content (which depends on a representation's "target"), so can't handle representation content; it makes all content-based explanations vacuous; and it can't handle error properly.

Explicates conceptual role in terms of conditional probability, and analyzes meaning as conceptual role plus reference. With remarks on truth, descriptions, and synonymy.

Conceptual role semantics isn't compatible with compositional semantics and the denial of an analytic/synthetic distinction, as full conceptual roles aren't compositional, and there's no way to specify a relevant subset.

Meaning and content is determined by the role of symbols in thought (e.g. inference and perception). With remarks on indeterminacy, context-dependence, the linguistic division of labor, qualia, speech acts, and more.

On the relation between conceptual role and truth-conditions. Contra Harman, truth-conditions are to an extent independent of conceptual role.

Contra Harman 1982, truth-conditions are central to a semantic theory.

Argues against Putnam 1987 that conceptual role plays an important role in determining meaning. Appeals to the induction theory of Holland et al.

Contra Fodor and Lepore, meanings can be compositional even if inferential roles are not, as long as meanings only supervene on inferential role.

2.3f

Theories of Content, Misc

On "translational" (conceptual) and "calibrational" (referential) content. Relation of content issues to computational issues.

Critiques other views, offers interpretational semantics.

On the reference and content of representations. Reference is determined by causation; content, i.e. representation "as", is determined by functional role, when functioning normally in natural habitat.

On some tensions in Fodor's view of content: e.g. narrow content must be dependent on functional role, which seems to lead to holism. The role of denotational semantics as a defense is unclear.

2.4

**Representation (General) [see also 4.2]**

Because paramecia can't respond to non-nomic properties of the stimulus. Perceptual categories vs. sensory manifolds.

On the philosophical (inward-out) vs. psychological (outward-in) approaches to the mind-world relation; the psychological approach is more useful in understanding representation. Internal reality is an imperfect construction.

On different senses of "representation" -- external, experiential, mental locus, substrate of meaning, mediating functions, technicalpsychological.

On the distinction between representation and representation-use.

2.5 The Explanatory Role of Content (Dretske, etc)

On Dretske's account of the causal role of content. Addresses some objections: Dennett's worries about intrinsic intentionality, Fodor's about external causal powers, and some worries about syntax.

A critique of Fodor. Semantics per se doesn't cause. Also, Fodor's is an account of the what, not the how, of semantics. Somewhat bizarre.

Criticizes Dretske's account of the role of content, especially because of its dependence on an organism's history; also, it may not cohere with work in cognitive science. Argues for an interpretational, not a causal account.

Content must explain why (not how) an internal state caused a certain output. The explanation is given in terms of what a state has historically indicated. With thermostats and sea-snails as examples. Comments by Cummins, and reply.

Distinguishes three problems of mental causation (extrinsic factors, exclusion of the nonphysical, anomalism). Criticizes Dretske's theory (can't handle unlearnt or here-and-now reasons), offers a counterfactual account.

We must individuate mental states by semantics, not just by function, as we need representation to capture generalizations about behavior; particularly due to the information-sensitivity and stimulus-independence of behavior.

2.6 Concepts

Connectionism builds up concepts from the nonconceptual level. From nonconceptual content (e.g. perceptual experiences) to the emergence of objectivity.

A symposium on the book, with comments by Heal, Rey, Papineau.

On the significance of psychological work on concepts for philosophical conceptual analysis -- simple, precise analyses do not exist in general.

On concepts as abilities, and on construals of abilities that lead to internalism and externalism. Maybe the relevant abilities are characterized externally but determined internally. Remarks on Putnam, Davidson, Burge.

2.7

Meaning Holism

Uses Putnam's "Ruritania" example to argue that narrow content, if it exists, is holistic. Twins in different
Part 2: Mental Content

Communities start with same narrow content, diverge by acquiring new beliefs; so belief change affects narrow content.

Rebutting arguments for meaning holism: those based on confirmation holism (Quine), normativity of interpretation (Davidson, Dennett, Lewis), and functional-role semantics (Block, Field, Churchland).

A discussion of Holism with comments by Devitt, Rey, McLaughlin, Brandom, and Churchland, and a reply by Fodor and Lepore.

A critique of Fodor and Lepore. Distinguishes versions of holism, and argues for a weak version. Real thinkers are subjects, which imposes constraints on the interrelations of thoughts. Science fiction is irrelevant here.

Contra Fodor, meaning holism is compatible with intentional psychology. Most psychological generalizations quantify over contents, rather than appealing to specific contents.

http://www.u.arizona.edu/~chalmers/biblio/2.html (70 of 74) [4/7/2002 1:49:27 PM]

A nice criticism of Fodor and Lepore's arguments that holism implies (a) the nonexistence of intentional laws and (b) the nonlearnability of language.

The argument from anatomism and the failure of the analytic/synthetic distinction to holism fails. On the many different interpretations of holism and anatomism: there is a reasonable molecularist position.

2.8

Mental Content, Misc

   Morris 1991 is wrong: formal individuation is easy, and objectively determinate content isn't needed. External grounding is also irrelevant.

There can be no non-stipulative content to non-semantically individuated tokens. Mostly a critique of Cummins; also Fodor and Dennett.

Remarks on a number of aspects of mental content -- narrow, propositional, qualitative -- with respect to functionalism and the language of thought. With comments by Baker.

On the tacit theories underlying the folk psychology of belief: beliefs are states associated with typical causal patterns. With remarks on ambiguity, content identity and similarity, and environmental dependence.

Argues that a failure to "naturalize" intentionality won't lead to disasters such as irreality, irrelevance, or non-science, whether naturalization is understood as analysis, property identity, supervenience, or whatever.

There's no deep problem of naturalism about intentionality, as we know it's true already. The real puzzle is that of finding a mechanism to close the gap, e.g. via analysis or essentialism. But naturalism doesn't require that.

3.1 Supervenience

3.1a

Psychophysical Supervenience (Kim, etc)

Contra Papineau 1989: the assumption of completeness is false or trivial. Maybe the mental is part of a complete physics. With response by Papineau.

Various objections to Kim's arguments for supervenience. Not all internal states relevant to I/O relations are psychological states. Strange.

Supervenience of the mental on the physical is what is required to make mental causation possible. Very nice.

Internal mental states (i.e. ones that are not rooted outside) supervene on synchronous internal physical states, and internal states are all that is relevant in the explanation of behavior.

Distinguishes weak (within-world) vs strong (across-worlds) supervenience. Relates to reduction, internal/external mental states, and various theories.

Lewis, H. 1985. Is the mental supervenient on the physical? In (B. Vermazen & M. Hintikka, eds) Essays
On some problems with supervenience, the relation between supervenience and reduction, and on reasons for accepting psychophysical supervenience. Loose.

If mental properties are supervenient but irreducible to physical/functional properties, we can't confirm them. Confirmation requires an indispensable explanatory role, which irreducibility precludes. With comments by Schiffer.

Psychophysical supervenience follows from completeness of physical laws.

### 3.1b Supervenience and Physicalism [see also 3.3a]

Argues that everything is logically supervenient on the physical. Considers classes, possibilities, numbers, universals, and objects of thought.

Supervenience is all we need for materialism. Various materialist arguments (unity, "nothing but", history, fear of darkness, simplicity, law) don't support physical exhaustion & token identity, over and above supervenience.

Some applications of the earlier treatment: examples of determination without reduction; the statuf of properties and universals; the mental; the life sciences; modalities and essentialism; theoretical equivalence.

Some remarks on determination, physicalism, model theory, and logical truth.

Argues that the generality of physics should be a supervenience thesis, not token physicalism. Fodor's token physicalism is untenable but might be saved with an appropriate view of events.

An account of how all facts supervene on microphysical facts, and how all intrinsic facts supervene on intrinsic microphysical facts.

Laplacean demon's job: number crunching, plus cosmic hermeneutics to explain high-level truths. All high-level truths follow from low-level by meaning constraints. Application to theoretical/mentalistic/everyday terms. Nice.

Supervenience is neither necessary nor sufficient for materialism. With various (contentious) counterexamples. So we need a different formulation.

Argues for strict implication rather than supervenience as a formulation of "minimal physicalism" (unless supervenience is formulated just right).

Formulates a definition of materialism: among worlds where no natural properties alien to our worlds are instantiated, no two differ without differing physically. With a lot of other material on universals.

How can supervenience, as a relationship between ontologically distinct properties, be explained? Modal realism and grand-properties don't work. Eliminativism about supervenient properties is the only possibility.

Defines physicalism in terms of claims that microphysical entities constitute everything and that microphysical laws govern everything. With a reply by Crane.

Weak supervenience provides a more tenable form of materialism than strong supervenience, because of inverted spectrum possibilities, etc.

A construal of materialism in terms of constitution, not identity. Discusses the entailment between physical properties and mental properties; considers a nonreductive physicalism and a primitive dualism.

3.1c Technical Issues in Supervenience

A modal-logic analysis of the relations between various notions of supervenience. Most concepts of supervenience entail necessary co-extension, under certain closure assumptions for properties.

A model-theoretic treatment of supervenience, in terms of relations between theories. Supervenience turns out to be equivalent to reduction.

A nonreductive supervenience hypothesis: supervenient properties are properties of properties, e.g intrinsic goodness is a property of an object's nature.

On dependency supervenience (B properties determine A properties) versus determination supervenience (A properties need B properties).

Distinguishes weak and strong supervenience. A mistaken proof that strong and global supervenience are equivalent. Strong supervenience implies a kind of reduction, but not an explanatorily useful reduction.

Reasons why global supervenience doesn't entail strong supervenience, and trying to rescue global supervenience as a useful notion. Suggests a similarity-based notion of global supervenience.

How properties in one domain can supervene on properties in another, with or without co-ordination between domains. Relation to global supervenience.

Supervenience doesn't entail reducibility, as necessary coextension doesn't suffice, and is incompatible with reducibility, due to ontological asymmetry.

Distinguishes modal-operator and possible-worlds versions of supervenience, and explicates global supervenience and its relation to weak and strong. With remarks on multiple-domain supervenience and the relation to reduction.

Argues that global supervenience has epistemological problems -- how could we ever know that it holds, and that certain worlds are impossible?

Closure under resplicing makes supervenience both too narrow and too wide. Weak supervenience is generally too weak to capture the dependence relation.

Gives a proof of the distinction between strong and global supervenience that improves on Petrie's, and argues contra Kim that global supervenience is a perfectly reasonable dependence relation for physicalism.

Defending global supervenience: it's weaker than strong supervenience, as base properties of other individuals are relevant. It doesn't entail type or token reducibility. On the relation to implicit definability and reduction.

Properties in supervenience relations shouldn't be closed under negation or resplicing, due to bad consequences. With reply by Bacon on resplicing.

3.1d

Supervenience, General

On the incompatibility of weak supervenience without strong supervenience and realism. With discussion of various strengths of necessity involved in supervenience claims, and application to moral realism and anomalous monism.

How social facts supervene on the totality of individual facts. Application to belief, etc.

Supervenience is too weak to function as a dependency relation, as e.g. it can hold in two directions at once.

Reply to Miller 1990. Miller underestimates the modal force of supervenience and invokes irrelevant dispositional properties.

An overview of supervenience, with focus on the problem of explaining supervenience relations. With remarks on mental causation, emergence, physicalism, and reduction.

Developing and motivating the notion of supervenience. Investigating the relationship to reducibility and definability (equivalence, under certain conditions), and to microphysical determination.

On weak/strong supervenience, and high-level causation via supervenience.

A nice overview of supervenience and covariance.

A collection of articles on supervenience and causation in metaphysics and the philosophy of mind, with some added postscripts.

Supervenience doesn't entail reducibility, which is epistemological. The problem's not just huge disjuncts, but also the sharing of bases, no local correlations, and base-properties presupposing supervenient properties.

Argues that lower-level theories can explain supervenient but irreducible higher-level theories, but only under certain conditions, as low-level accounts don't have the relevant kind terms.

On supervenience as an ontological relation (via metaphysical necessity) or as an ascriptive relation (via conceptual necessity). The first doesn't preclude the second. Moral realism and mental realism are in the same boat.

New Essays.

On a number of issues: possible worlds vs modal notions, explicating global supervenience, the relation between weak/strong/global supervenience, multiple-domain supervenience, and implications for reduction.

If supervening properties can make arbitrarily fine distinctions, then physical properties supervene on moral/aesthetic/mental properties.

Contra Blackburn 1984 on the possibility of weak supervenience without strong supervenience, even with metaphysical necessity; using Nozick's concept structures, or indexical definitions. With application to moral realism.

Distinguishes "reductionist" and "metaphysical" conceptions of supervenience. Also discusses the relation between strong and global supervenience, degrees of necessity, and the explanatory role of supervenience.

Compares the Hellman/Thompson notion of determination with Kim's development of supervenience. Uses these to investigate the concept of materialism, and argues that materialism isn't contingent.

3.2

Reduction

3.2a

Reduction and Multiple Realizability

On species-specific reductions. These can't reduce standard psychological properties, and problems with intra-species multiple realizability can't be circumvented without giving up property reduction for token event identity.

The anti-reductionist argument assumes that functional properties aren't physical properties (not even extrinsic physical properties). This, not multiple realizability, does the work.

Multiple realization is compatible with reductionism. Jade (= jadeite or nephrite) isn't a scientific kind, and neither are multiply realizable mental properties. So there's no global psychology, just lots of local reductions.

Some comments on Wilson 1985: some special-science properties may be relevantly different in kind from his expanded physical properties.

Argues contra Fodor and Block that neurological equipotentiality doesn't refute type materialism. Mental states may not be anatomically defined neural states, but they may be more abstract neural holograms.

Argues for type-type identities and for an expanded view of the physical, as properties from physics exhibit
the same sort of multiple realizability as functional properties. Sophisticated, with many interesting
examples.

3.2b

Nonreductive Materialism [see also 3.5d]

Beckermann, A. 1992. Reductive and nonreductive physicalism. In (A. Beckermann, H. Flohr, & J. Kim,

On varieties of physicalism with respect to reduction: semantic physicalism, identity theory,
supervenience, and the denial of emergence. Advocates a version on which physical states realize mental
states.

Physicalism. De Gruyter.

Arguing for a pluralistic conception. With criticism of Churchland's reductionism, Davidson's token
identity, and more generally reverential "scientism". Reductionist explanation is not the general rule.

Philosophy of Psychology (MIT Press, 1980).

Psychological kinds can't be reduced to physical kinds, due to cross-classification, although token
physicalism still holds. How to maintain the generality of physics without a reductionist unity of science.

Francescotti, R. M. 1998. The nonreductionist's troubles with supervenience. Philosophical Studies
89:105-24.

Gives four constraints on interlevel connections, and some arguments against reductionism and for the autonomy of psychology. Argues that supervenience fact are themselves in need of explanation.

Classifying psychophysical theories by the status (necessary, lawful, anomalous, false) of psychophysical/psychological generalizations. Defending autonomous monism: nonreductive materialism with psychological laws.

Somewhat loose arguments that non-reductive physicalist realism is untenable. Anomalous monism makes the mental irrelevant, functionalism is compatible with species-specific reduction, and supervenience is weak or reductive.

Argues that nonreductive materialism implies downward causation (as the mental has more causal powers than the physical alone), and that downward causation violates the causal closure of the physical.

Argues that nonreductive materialism is just like 1930s emergentism, with the the mental contributing new causal powers, and so implies downward causation.

Contra Kim, physicalists can avoid reduction by embracing strict implication.

Non-reductive physicalism is a mystery unless we invoke teleology.

Explicating anti-reductionism: mental causal powers are constituted of physical causal powers, but aren't type- or token-identical to them. Against arguments from local reduction, neuroscience, explanatory exclusion, etc.

A careful discussion of how to characterize physicalism, in terms of identity or supervenience, and argues that physicalism must reduce (bowdlerize) qualia to something they are not, as physicalism requires topic-neutral analyses.

On how a nonreductive materialism can handle problems about mental causation, psychophysical dependencies, and qualia. A teleofunctionalist view with different conceptual frameworks, but mental
properties physically realized.

### 3.2c Reduction in Psychology

Argues that cognitive theories have already been reduced to neurobiology in some domains, such as associative learning.

Psychology shouldn't be autonomous from natural science. By analogy with biology, nature provides (a) conceptual insight, and (b) real constraints, e.g. thermodynamic ones. Biology and psychology are continuous.

The relationship between psychology and neuroscience is best characterized not by reduction but by explanatory extension, where each field is enriched by the other. With a number of examples from recent empirical work.

Anti-reductionism needn't be ad hoc (contra Churchland). Although evolution provides some pressure for 1-1 psychophysical mappings, there are significant countervailing forces, e.g. in vision, memory, learning, and language use.

3.2d

Reduction, Misc

Reduction comes to supervenience plus explicability. Thus biconditionals, multiple realizability, etc, are irrelevant. Biology is already reduced (mostly via functional explanation), and psychology looks promising. Nice.

On the links between supervenience, reduction, and explanation. Supervenience is compatible with reductive explanation of a localized variety. We don't need laws, but explanatory links.

Contra Richardson 1979, a purely functional psychology is irreducible. The genetics analogy is misleading; multiple realizations can't explain high-level laws.

Mind is not reducible to body, but societies reduce to individuals. Multiple realization is in tension with predictability. Natural selection resolves the tension for the mental, but cannot for the social.

Argues that functionalism is compatible with reductionism, by analogies. Genetics has multiple realization and multiple function; reduction doesn't require biconditionals. With remarks on the de facto autonomy of psychology.

Response to Kitcher 1980. Reductions are usually domain-specific, and high-level regularities are indeed explained.

Excellent coverage of the notion of level and its applicability to mind.

3.3

Other Psychophysical Relations

3.3a

Physicalism [see also 1.3, 1.7b, 3.1b, 3.2b, 3.5]

If there are no contingent psychophysical laws, then there are no mental properties. So physicalism/supervenience is false; God had extra work to do.

Physical sciences have no ontological authority over the mental. Considers and dismisses arguments from laws, causation, reduction, supervenience.

On why materialism requires conceptual analysis to locate mental properties in the natural world. Even a posteriori necessary connections have to be backed by a priori links. With remarks on supervenience. A nice paper.

If every physical events has a physical explanation, and the mental is causally efficacious, then mental facts are strictly implied by physical facts. A nice argument.

Materialism doesn't need a identity thesis. The requirement that mental facts are entailed by physical facts plays the role played by Kripke's requirement of necessary identity, and is more reasonable.

Nothing in the arguments of Crane and Mellor 1990 count against a physicalism based on strict implication.

On the problems posed for materialism by intentionality, autonomy, awareness, and indexicality.
Part 3: Metaphysics of Mind

Tentatively advocates a Cartesian position.

Advocates "realization physicalism": all properties are either physical or functional properties realized by physical ones. This achieves unity between sciences better than alternatives, and avoids overdetermination.

Discusses two formulations of physicalism: requiring high-level properties to be disjunctions of physical states, or to be functional properties realized physically. Tentatively endorses the latter.

Physicalism is the claim that (1) There are microphysical entities, (2) Microphysical entities constitute everything, (3) There are microphysical regularities, (4) Microphysical regularities govern everything.

3.3b Token Identity [see also 3.5b, 3.5d]

We individuate mental events by their causal role, but we can't individuate causes uniquely. So each mental event has multiple physical correlates, and token identity doesn't hold.

Supervenience doesn't imply token identity, and Davidson's argument for token identity equivocates on "event". But weak supervenience (mentally discernible worlds are physically discernible) is all we need. With nice examples.

Physical/psychological token identity is no good: you can't individuate physical events without psychological predicates.

Can't isolate the physical token of a belief, say, as it's always accompanied by other beliefs. Meaning doesn't come in discrete tokens.

3.3c Emergence

On varieties of supervenience and of emergence, and of what is required for reduction. Argues that reduction involves general explanatory connections, whereas emergence involves unique and ultimate bridge laws.

A defence of radical emergence against Spencer-Smith 1995.

Argues against Alexander's and van Cleve's accounts of emergence, instead suggesting an account in terms of supervenience, non-structurality, and downward causation.

An in-depth analysis of Sperry's views on consciousness. Sperry is not a dualist; he believes in "structural causation" based on emergent properties.

Distinguishes radical, epistemic, and interactional emergence, favoring the latter. With consideration of qualia as a radical emergent.

Consciousness is an emergent property of brain dynamics that itself governs low-level flow of excitation. Midway between mentalism and materialism.

On different ways of understanding emergence: as nonadditivity, novelty, nonpredictability, nondeducibility; and on problems about qualia and downward causation.

An attempt to explicate "emergent" properties in terms of relational properties. Argues that even problem cases, e.g. space-time separation and phenomenal properties, might be treated this way.

On Nagel 1979: emergence is more plausible than panpsychism. A construal of emergence as nomological supervenience without logical supervenience.

Dualism [see also 1.3f, 1.4e, 1.4f]

Interactionism is compatible with conservation of energy and momentum: the mind exerts a non-physical force on the brain.

Various arguments about interactionism based on conservation of energy. C of E only applies to causally isolated systems, so objections beg the question.

Argues that there can be interaction without breaking physical laws: e.g. by basic psychic forces, or by varying physical constants, or especially by arranging fractal trees of physical causation leading to behavior.

Argues that interactionist dualism is compatible with the causal closure of the physical, if we allow causal overdetermination; and there is a strong case for the latter.

Dualism is an empty hypothesis. Everything must be matter, though we may have to expand the notion of matter.

3.3e Psychophysical Relations, Misc

Defending lawlike connections between physical states & conscious occurrents. Contra anomalous monism
and identity theory for occurrents. But occurrents may not be causally efficacious. Comments by Wilson/Sprigge/Mackie/Stich.

Argues that mental kinds are not natural kinds, and don't have real essences but nominal essences. For this reason, there are no psychophysical laws. With remarks on psychological laws, and the role of behavior.

Physical completeness, mental causation, non-reductionism are inconsistent. Ryle and Putnam are closet dualists, and Davidson's an epiphenomenalist.

3.4

Functionalism [see also 1.8, 4.6]

3.4a Causal Role Functionalism (Armstrong/Lewis)

Mental states should be analyzed as states that are apt to bring about certain kinds of behavior. Analysis of all kinds of mental states as such. With comments on dualism, behaviorism, identity theory, and consciousness.

Mental states are internal states that are apt to cause certain behaviors. A synthesis between the "thesis" of idealism and the "antithesis" of behaviorism. With defense against objections from consciousness.

Psychofunctionalism can evade chauvinism by specifying different functional identifications within each species. Applying same mental terms to each is justified by theory similarity; but it still isn't analytic functionalism.

Against functionalism: experiences have intrinsic introspectible acausal properties, such as duration, felt location, and unpleasantness. Both analytic and empirical functionalism fail.

Formalizing versions of functionalism, and seeing which entail token physicalism and/or type physicalism. On the most plausible versions, we have token physicalism without type physicalism.

Functionalism is compatible with type identity, as e.g. "pain" designates the state-type that fills the right functional role in an organism at a given time, i.e. a brain state. Contra Kripke, pain is not a rigid designator.

Argues that Lewis's functionalism founders on the specification of behavior. Described intentionally => non-materialist; physically => chauvinist.

Causal roles are definitive of mental states. Since physical states fill these causal roles (by the explanatory adequacy of physics), mental states are physical states.

Mental states can be defined, via a Ramsey-sentence analysis of the platitude of folk psychology, as entities that fill causal roles specified by the analysis. These fillers turn out to be physical.

Accounting for both pains that don't play the usual causal role and for pains that are realized in different substances, by a mixed theory: pain is the physical state that typically occupies a certain causal role in a population.

Functionalism (reducing the mental to its effects on the physical) is no more plausible than phenomenalism (reducing the physical to its effects on the mental).

Lewis's original theory leads to Kripkean reference-fixing, so chauvinism. Token functionalism can't deal with paralytics. Species-relative functionalism fails as pain is intrinsic, not extrinsic.

Fleshing out Ramsey-sentence functionalism; against Lewis's "mad pain" mixed theory; relating functionalism to the causal theory of properties. Empirical functionalism is chauvinistic so probably false. A terrific, in-depth paper.

Contra Lewis: Functionalism isn't compatible with type physicalism. There are intra-population difficulties with species-relative construals, and individual-relative construals can still have multiple fillers.

### 3.4b Machine Functionalism (Putnam) [see also 4.8]

The relationship between mental and physical states is just like that between logical and structural states of Turing Machines, so no great mystery. With comments on privacy and semantic analysis.

Why mental states are more likely to be functional states (in probabilistic automata) than brain states or behavioral dispositions.

On explaining behavior via TM states, e.g. explaining preference via utility functions. Logical behaviorism assumes rational preference functions. Functional organization is what matters, not physical make-up.

Psychological states aren't TM states after all: we have lots of psych states at once; they depend on learning/memory; disjunctions of TM states are no good. But functional organization rather than physics is still what counts.

Type functionalism isn't any better than type physicalism, as mental states can be multiply realized as functional states. With what in common?

On abstract vs. physical TMs: Putnam should say that mental states are physical TM states. But then functionalism is compatible with physicalism. On the relation between Putnam's and Armstrong's functionalism.

If machine functionalism were true, a homunculus-head would have all the mental states of its homunculus (by the definition of "realization"), which is absurd.

Reply to Elugardo 1983: so how do you specify what count as inputs/outputs?

Criticism of Lycan 1979, and a re-making of the argument.

Lycan's New Lilliputian argument fails as inputs/outputs for the homunculus are not the same as inputs/outputs for the full system.

Kane, R. H. 1966. Turing machines and mental objects

Argues for mechanism rather than functionalism. Criticizes Putnam for hypostasizing mental states, which are disanalogous to mental states. Defending mechanism against Kalke's & Rorty's objections.

Logical states don't give us any understanding of mind over and above what the function/structure distinction gives us. In particular, it doesn't help with the understanding of privacy and incorrigibility.

Contra Putnam: logical states are not physical states, and utterances about them are not about physical states.

Contra Lycan: machine functionalism can handle Bolivia and CRT cases by a causal/counterfactual account, and Lilliputian case by assigning mental states to minds, not bodies.

3.4c Functionalism, Miscellaneous

A formal argument showing that functional definitions are equivalent to behavioral definitions.

Bechtel, W. 1984. Autonomous psychology: What it should and should not entail. Philosophy of Science
Part 3: Metaphysics of Mind [1026]

Association 1984, 1:43-55.

The functional level is the appropriate level for psychology, but neurophysiological facts constrain this level and are thus relevant.

Ten papers on functionalism. Originally was Philosophical Topics, volume 12.

Distinguishes varieties of functionalism, e.g. machine and Ramsey-sentence functionalism; and compares to behaviorism. With a historical overview, and arguments for why functionalism is incompatible with physicalism.

Distinguishes analytic and empirical functionalism. Both have problems with absent qualia, and inputs/outputs. Analytic functionalism has problems with paralytics, etc; empirical functionalism has problems with Martians.

Mental states are not physical or behavioral states; could they be functional states? With various arguments against type identity, and against machine-table functionalism.

On the role of functional explanation versus other kinds of explanation. Functionalism applies an analytic, not subsumptive strategy.

On mental state as inferred theoretical entities, individuated according to their function (cf. valve-lifters). Psychology and neuroscience will mutually constrain each other, giving a relation more complex than reduction.

Argues that functional explanation are reducible to structural explanations.

There's no absolute functional/structural distinction, as it depends on how you choose boundaries and levels of abstraction.

Pursue a multi-leveled homuncular functionalism, with mental states characterized as states of teleologically identified subsystems. Even the identity theorist is a functionalist at a low level.

Scientific realism requires dispositions of kinds be explained by intrinsic properties. Neural/functional properties won't work, because of reductionism and circularity. Use intrinsic psychological properties instead.

Argues that functionalism is compatible with reductionism, by analogies. Genetics has multiple realization and multiple function; reduction doesn't require biconditionals. With remarks on the de facto autonomy of psychology.

Against functionalism for beliefs. Both common-sense functionalism and psychofunctionalism have problems with finding the right functional theory, distinguishing beliefs, perceptual input conditions, Twin

Need teleological functionalism, not Turing Machine functionalism.

The structure/function distinction is level-relative, so physiology might be relevant even under functionalism. Problems with automata, and with causal connections to nonintentionally characterized behavior.

Functionalism may be appropriate for cognitive psychology but not for folk psychology, due to differing goals. Neuroscience will play an important role in developing functional theories.

Argues that the possibility of multiple realization has not been established, whether by arguments from imagination, concepts, or empirical facts.

### 3.5

**Other Psychophysical Theories**

### 3.5a
Logical Behaviorism (Ryle, etc)

The ancestor of most contemporary philosophy of mind. Among other things, argues that the "ghost in the machine" view of mind is a category mistake, and presents dispositional analyses of many mental concepts.

Defends behaviorism as a scientific hypothesis, so that conceivability arguments aren't relevant, and advocates "penetrability" behaviorism which can appeal to internal physical states.

**3.5b Identity Theory (Smart, etc) [see also 1.3c, 1.4g, 3.3b]**

The idea that consciousness is a brain process is logically coherent. It's a scientific hypothesis, not a necessary truth. On the "is" of composition vs the "is" of definition, and the fallacy of the internal phenomenal field.

Defending the thesis that sensations are contingently identical to brain processes against various objections. Topic-neutral analysis of sensation reports. Materialism beats epiphenomenalism on grounds of simplicity.

The number of possible mental states is infinite (think of any number), whereas there are only finitely many brain states, so they're not identical.

Likens the anti-materialist position to the "headless woman" fallacy: "I'm not aware the mental states are physical", so "I'm aware that mental states are non-physical".

A prima facie case for materialism based on grounds of rational consensus, arising especially from common-sense and scientific evidence. Mental states exist (common-sense) but should be analyzed causally (evidence from science).

Mental states are necessarily private, and so cannot be physical states, which are public. We have epistemological authority about our mental states.

Argues that phenomenal properties aren't needed to identify sensations with brain-states, and nor are topic-neutral analyses.

An anthology of central articles on the identity theory.

Arguing for an event-identity construal of the identity theory. Comparing the identity theory to the weaker "principle of simultaneous isomorphism". The only reason to accept the identity theory is ontological simplicity.

Argues that the identity theory is compatible with linguistic dualism, as the mental and the physical may differ in intensional properties only.

On problems with theories that leave the nature of mind open a priori: how can we even understand the possibilities?

Location of mental states by convention (Shaffer 1961) won't work, as it (a) makes mental states public, and (b) conflicts with connections to behavior.

On topic-neutral reports, after-images, and after-radishes. Such a report requires epistemic access to physical resemblance, which we don't have.

There's no empirical support for identity, over and above that for correlation; and unity of science gives no reason to accept identity. The only reason might be that of ontological simplicity.

Deal with phenomenal properties by allowing only mental events, and eliminating mental objects. Identity theories needn't suppose psychophysical laws. With defense against multiple realizability arguments.

Recasting the identity theory and functionalism, using Kripkean theories of reference, so mental states can refer to physiological or psychological states that we don't yet understand; and qualia problems are handled better.

Mental states are defined by their causal roles. So, by the completeness of physics, they must be physical states.

On how materialism, as opposed to a double aspect view, can handle mental features -- by moving them into the world via a realist theory of perception. Remarks on identification of states. After-images, etc, cause problems.

Using the special theory of relativity to show that if mental events have a temporal location, then they must have a spatial location.

The identity theory is meaningless, if identity is analyzed as spatiotemporal coincidence, as thoughts don't have location. Thoughts also require context. Even if identity holds, explaining brain doesn't imply explaining mind.

Sensations and processes have different logical type, so it is a priori impossible that they should be identical.

Identity requires explanation to be accepted, but Smart doesn't provide this. But one can deny identity without claiming dualism -- e.g. a "duck-rabbit" theory of mind/brain. With remarks on the completeness of descriptions.

Contra Smart 1959: Materialism is a scientific hypothesis, if we accept certain logical criteria for what a sensation is; otherwise it's just false.

Comparing contemporary materialism to Pace's 1956 variety. With remarks on whether the thesis is empirical or a priori, and on deciding the issue between materialism and epiphenomenalism.

Discusses a paper of Martin's and the genesis of the identity theory, with a focus on `public' and 'private logic' and topic-neutral descriptions.

The identity theory must be false, as pain centers in vitro will not be pains. With a reply by G. Pearce and a rejoinder.

On the identity theory as a linguistic proposal, compatible with dualism; epiphenomenalism and parallelism must be false, leaving interactionism.

Mental states don't have a location, and brain processes do; but we could stipulate a location for mental states. With remarks on possible relations between mental and physical features, states, and concepts.

We identify mental events by noticing mental features that must be nonphysical, but still might be empirically reducible. Against topic-neutral definitions, and with response to Coburn 1963 on location.

Reply to Stevenson 1960: There are no irreducible mental properties; they reduce to physical properties via topic-neutral definitions.

Reply to Baier 1962: epistemological authority is compatible with materialism. Mental state reports are not completely incorrigible, though.

Defending topic-neutral analyses of mental reports, and arguing against Wittgensteinian behaviorism via brain-in-vat examples. With remarks on the appeal of materialism and on compatibility with ordinary language.

On some problems for the identity theory arising from the intensionality of mental states and from the appeal to properties, and on how to modify the translation form of the theory without embracing the disappearance version.

Identity theory implies nomological danglers, due to the irreducibility of defining mental properties.

The identity thesis isn't ontologically simpler than dualism: we still need a dualism of properties, and explanatory danglers. Not much turns on the issue, except in teleological explanation.

Contra Malcolm 1965: explaining brain will explain mind, if the explanation is conjoined with the identity statement. With rejoinder from Malcolm.

Property identity theses fail due to meaning differences, and event identity these fail due to a lack of entailment relations. Rebuts objections from weaker identity criteria and analogies with scientific identification.

Suggests a theory in which neural states are components of, but not identical to, overall psychological
states. This can accommodate raw feels if necessary as a further component, but is mostly materialistic.

3.5c Eliminative Materialism (Rorty, Feyerabend) [see also 1.4d, 1.7c, 2.1c]

Doppelt, G. 1977. Incorrigibility, the mental, and materialism. Philosophy Research Archives.

Identity theory implies dualism, though its acceptance of mental properties. Instead we should eliminate talk of mental processes altogether, or redefine them in physiological terms.

3.5d Anomalous Monism (Davidson)

Arguing for anomalous monism: no strict psychophysical laws, no strict psychological laws, and token identity without type identity. Mental events can still cause, via subsumption under physical laws.

The psychological supervenes on the physical but is not reducible to it, because of the holistic nature of intentional attribution. So building a perfect physical model may not explain psychology.

On the differing constitutive standards of mental and physical concepts. Attribution of mental concepts is holistic, and presupposes a background of rationality, etc. With examples from decision theory.

A collection of papers on action, causation and the philosophy of psychology.

Remarks on how mental properties can explain action without strict laws. The mental is a conceptual, not an ontological category, governed by normative standards, and not reducible to the non-normative.

Criticism of Davidson's argument for rational causation. Reasons must cause in virtue of their rational properties. Token identities can't exist, due to normativity. Quinean psychology can't yield rational explanations.

Anomalism is compatible with supervenience, if it is construed as denying psychophysical laws useful for explaining behavior. It is incompatible with token identity, though. With much on the uncodifiability of rationality.

Davidson's argument equivocates on the term "physical": the physical events that mental events cause might not be subsumed under laws.

Anomalous monism implies that mental properties don't cause anything.

If anomalous monism is true, mental events may cause, but their mental properties aren't causally relevant.

Anomalous monism loses out to Australian materialism. It can't be a priori, it leads to exhaustive monism, it doesn't support a new view of free action, and it implies the causal irrelevance of the mental.

Davidson's view leads to epiphenomenalism about content, as it can't support the appropriate counterfactuals. Strong supervenience might be a way out, but that is inconsistent with anomalism.

How there can be psychophysical generalizations but no laws -- they might lack modal force. On the relation between psychophysical anomalism and psychological anomalism. Casting Davidson as a Kantian dualist.

Anomalous supervenience is consistent, at the cost of anti-realism about the mental. Supervenience is a constraint on interpretation, but needn't support counterfactuals as different interpretation schemes are possible.

Problems with holism and ceteris paribus laws aren't unique to psychology. One finds the same thing in the physical sciences. So rationality plays no special role, and psychological laws are as reasonable as physical laws.

Anomalous monism is not committed to epiphenomenalism, as even non-strict laws can ground counterfactuals and so support the causal relevance of mental properties.

A functionalist defense against anomalous monism. Psychofunctional laws and psychological laws, though not psychophysical laws, may exist. Rebutting arguments from rationality, indeterminism, intensionality, etc.

Against Loar's functionalist reductionism: it doesn't begin to capture the normative role of rationality or the subjectivity of the mental.

A very thorough summary of Davidson's views. Highly recommended.

30 essays on Davidson.

Comments on Davidson 1992. Davidson can respond to critics accepting causal relevance of mental properties and still denying strict laws. Davidson misconstrues his critics' positions on supervenience.

Davidson is concerned with intentional, not phenomenal states; and his characterization of these is just as physical states under a certain description. So he avoids epiphenomenalism (contra e.g. Honderich 1982).

Kim's version of Davidson's argument against psychophysical laws cannot work. Elucidating the notion of a constitutive principle.

Anomalous monism implies that there aren't even heteronomic psychological generalizations, as variables can't be independently measured.

Supervenience is compatible with anomalism: biconditional laws are ruled out by the disjunctive base, and the wideness of mental states rules out one-way psychophysical laws, as there's no single property in the base.

Elucidating Davidson's argument, focusing on the argument against strict psychophysical laws. Generalizations involve disjunctive kinds and so are heteronomic and not law-like.

Argues contra Kim that supervenience is compatible with anomalous monism: the disjunctive generalizations aren't lawlike, as they aren't confirmed by their instances.

Some comments on holism, indeterminacy, anomalism, and materialism.

Response to Honderich 1982: physical events are individuated as mental states by virtue of their causal role, so the mental is causally relevant.

Supervenience entails psychophysical principles, but this is compatible with anomalous monism. On what constitutes a strict psychophysical law.

Various: physics is indeterministic and intensional, animals have beliefs, psychology has derived laws, and decision-theory doesn't need speech.

Rationality constraints don't introduce an irreducibly normative element into intentional attributions. Rationality serves as a condition of adequacy for psychophysical theories, but it doesn't rule them out.

12 essays on Davidson, with replies.

3.6 Mental Causation [see also 2.2c]

Mental causation is incompatible with strong supervenience and causal closure of physics, as we can't distinguish high-level causes from non-causes. So reject the metaphysics and make explanation prior to causation.

Arguing for the causal efficacy and scientific respectability of higher-order states, such as functional-role states. To require appeal to particular physical states is to succumb to a "Tractarian" view of physical primacy.

Rescuing content from epiphenomenalism via functional role argument; but then functional roles aren't really causally efficacious (cf. dormitive virtue), so epi all over again? Roles vs fillers, causation vs explanation.

Mental causation is not a real worry, but the to-do shows that materialist metaphysics has shed little light on it. It needs to be understood at the mental level. With remarks on exclusion arguments and token identity.

How can a relation to a proposition (an abstract object) be causally efficacious? Analogy with numbers doesn't work: weight properties are only pseudo-relational, depending on units, but propositions are absolute.

Argues that anomalism and causal closure don't pose problems for mental causation as they are false, and that functional properties can efficacious. States with content may be efficacious, although content itself may not be.

Argues that mental causation is a deep problem for constitutive (but not identity) forms of physicalism. The only way out is to argue that it is a different variety of causation. But then what motivates physicalism?

Mental events are structuring causes of behavior; biological events are triggering causes, dependent on previous mental structuring. This allows extrinsic properties to play a causal role.

On various problems with mental causation, and the relationship between psychology ans philosophy.

The identity theory and psychoneural correlation can't handle mental causation; only the union theory can. Anti-individualism causes problems, but should be rejected in any case.

How mental events are causally relevant qua mental: via an account of "qua" causation in general, using counterfactuals on "pertinently similar worlds".

A defense of functional role as a causally efficacious property of physical states. With application to connectionism & eliminativism.

How can content properties be causes, given that content is a matter of functional role and that functional properties are not causes? Defends a type-identity answer against various objections.

A "state of the art" review paper, concentrating on problems posed by autonomy, functionalism, and externalism, and advocating a sort of identity theory. With discussion of a "map-system" view vs. a language of thought.

Psychological causation, like all macrocausation, is supervenient epiphenomenal causation.

Argues that nonreductive materialism implies downward causation (as the mental has more causal powers than the physical alone), and that downward causation violates the causal closure of the physical.

Argues that nonreductive materialism is just like 1930s emergentism, with the mental contributing new causal powers, and so implies downward causation.

Argues that the arguments of Fodor and LePore & Loewer don't succeed in defeating the threat of epiphenomenalism.

On the problems that irreducibility -- multiple realizability, normativity, and non-supervenience -- poses for mental causation. Criticizes Kim's supervenient causation and Fodor's causal powers, and looks to "quasation".

Physical comprehensiveness and mental/physical non-reductionism don't imply mental inefficacy; nor does anomalous monism. Non-physical types can still can be causal, though they must be accompanied by physical causation.

On making sense of the causal efficacy of higher-level properties under naturalism. They're relevant at the program level, not quite in the way that basic properties are. With remarks on Macdonald's objections.

On Goldman's (1969) argument that dualism and causal closure are compatible with mental causation.

Goldman establishes only hypothetical necessity, not causal necessity

Intentionality is caused by the physical, and causes. More a 1P emphasis.

Interactionist dualism is out, supervenient causation is in. But there are problems with mental events' causal relevance qua mental, especially for anomalous monism. Cf: a loud shot causes death, but loudness

On three arguments against mental causation, from strict laws, non-local supervenience, and especially exclusion. Mental properties are stable, recurring high-level patterns with their own causal relevance.

Argues that mental events/properties stand to physical events/properties as determinable to determinates, solving the exclusion problem. Some mental events are *better* candidates for the cause of action than physical events.

Argues that anomalous monism is compatible with mental causation: supervenience is necessary and sufficient for causal efficacy.

4.1 Can Machines Think?
4.1a

The Turing Test

Proposes the Imitation game (Turing test) as a test for intelligence: If a machine can't be told apart from a human in a conversation over a teletype, then that's good enough. With responses to various objections.

A look-up table could pass the Turing test, and surely isn't intelligent. The TT errs in testing behavior and not mechanisms. A nice, thorough paper.

Defending the Turing test as a good test for intelligence.

The Turing Test is too hard, as it requires not intelligence but human intelligence. Any machine could be unmasked through careful questioning, but this wouldn't mean that the machine was unintelligent.

Response to Jacquette 1993.

The Turing test is not broad enough: there's much more to thought than the ability to play the imitation game.

On the Total Turing Test (full behavioral equivalence) as a test for mind.

A dialogue on the Turing test.

Defending the Turing test against French 1990. Turing did not intend the test to provide a *necessary* condition for intelligence.

Turing's test is neutral about the structure of the machine that passes it, but it must be practical and reliable (thus excluding Searle's and Block's counterexamples).

The basis of the Turing test is not an operational definition of thinking, but rather an inference to the best explanation.

Reply to Stalker 1978: Mechanistic and mentalistic explanations are no more incompatible than program-based and physical explanations.

Some obscure remarks on lying, imitation, and the Turing test.

A weak argument against Block: input/output function doesn't guarantee a capacity to respond sensibly.

The Turing test presupposes a representational/computational framework for cognition. Not all phenomena can be captured in teletype communication.

Contra Moor 1976: The best explanation of computer behavior is mechanistic, not mentalistic.

4.1b

Godelian arguments (Lucas, Penrose)

Discusses and sharpens Lucas's arguments. Argues that the real consequence is that if we are Turing machines, we can't know which.

Lucas's very Godelization procedure makes him inconsistent, unless he has an independent way to see if any TM is consistent, which he doesn't.

Remarks on the various ways in which Lucas and a machine might be said to "prove" anything, and the ways in which a machine might simulate Lucas. The argument has all sorts of level confusions, and a bit of circularity.

Can't reduce the lawless creative process to computation.

An analysis of the Lucas/Benacerraf argument. On various senses in which a machine might come to know its own program.

Only mathematicians understand Godel, so Lucas's argument isn't general; and Turing machines can go wrong. Weak.

There is no unique TM which we are -- there could be many.

   Lucas's argument applies only to deductive machines, not inductive ones.

   Even humans can't Godelize forever. On ordinals and transfinite counting.

   Rejoinder to Lucas 1967: the role of consistency; non-constructible ordinals.

   An analysis of Benacerraf 1967. Benacerraf's "paradox" is illusory; there are no strong consequences of Godel's theorem for mechanism.

   Contra Lucas: we can't Godelize forever; and we're not formal on top level.

Hutton, A. 1976. This Godel is killing me. Philosophia 3:135-44.

   Gives a statistical argument to the effect that we cannot know that we are consistent; so the Lucas argument cannot go through.

   Contra Lewis 1979, Lucas can derive the consistency of M even without the premise that he is M. Hmm.

A nice analysis of Lucas's argument and the circumstances under which a machine might prove another's Godel sentences. There's no reason to believe that machines and humans are different here.

A machine will fail a Turing test if it's asked about Godel sentences.

Lucas's argument fails, as theorems by humans don't correspond to outputs of their formal systems.

Lucas needs a rule of inference from sentences to their consistency, yielding Lucas arithmetic. No machine can prove all of Lucas arithmetic, but there's no reason to suppose humans can either, as the rule is infinitary.

Reply to Lucas 1970: the dialectical argument fails, as the human's output depends on the premise that it is the machine (to derive M's consistency). With a similar premise, the machine itself can do equally well.

Humans can Godelize any given machine, so we're not a machine.

Reply to Good 1967: a human can trump any given machine, so the human is not the machine, whether or not the human is superior across the board.

Benacerraf 1967 is empty and omega-inconsistent. Reply to arguments based on difficulty of seeing consistency (e.g. Putnam). Fallacious but engaging.

Response to Lewis 1969 and Coder 1969. Lewis misses the dialectical nature of the argument.

Contra Hutton, we know -- even if fallibly -- that we are consistent.

Reply to Lewis 1979.

Addresses all the counterarguments. Fun.

Martin, J. & Engleman, K. 1990. The mind's I has two eyes. Philosophy 510-16.

Contra Hofstadter: Lucas can believe his Whitely sentence.

Maudlin, T. 1996. Between the motion and the act... Psyche 2:40-51.

We are non-algorithmic as we can see Godel sentences of any algorithm.

Much debate over the "non-algorithmic insight" in seeing Godel sentences.

An argument from the halting problem to the nonalgorithmicity of mathematical thought. Addresses objections: that the algorithm is unknowable, unsound, everchanging, environmental, or random. New physical laws may be involved.

A reply to Chalmers, Feferman, Maudlin, McDermott, etc.

A generalized Godelian argument: if our prescriptive inductive competence is formalizable, then we could not know that such a formalization is correct.

Penrose's argument depends on our knowledge of the validity of the algorithm we use, and here he equivocates between conscious and unconscious algorithms.

General analysis; Lucas commits type/token error; self-ref paradoxes.

Cogito was a diagonal argument; connection to Godel, Lucas, Minsky, Nagel.

A machine could escape the Godelian argument by inductively ascertaining its own syntax. With comments on the relevance of ingenuity.

Weak defense of Lucas; response to Putnam, Bowie, Dennett.

Humans get trapped too: "Lucas cannot consistently assert this formula".

### 4.1c The Chinese Room (Searle)

Implementing a program is not sufficient for mentality, as someone could e.g. implement a "Chinese-speaking" program without understanding Chinese. So strong AI is false, and no program is sufficient for consciousness.

Axiomatizes the argument: Syntax isn't sufficient for semantics, programs are syntactic, minds are semantic, so no program is sufficient for mind.

More on the arguments against AI, e.g. the Chinese room and considerations about syntax and semantics.

Mind is a high-level physical property of brain.

On the status of the Chinese Room argument, ten years on.

Press.

A procedural account of how computers might have understanding and semantics.

A fully functional Chinese room is impossible, as it (for instance) could not say what the time is.

A chess-playing machine embodied as a robot could have intentional states. Reference requires input/output, computation, and context.

Criticizes Searle's "conclusion" that brains are needed for intentionality, notes that even a homunculus has intentional states. A misinterpretation.

Arguing against Searle on a number of fronts, somewhat unconvincingly.

Gives an account of symbolic vs. subsymbolic computation, and argues that the latter is less vulnerable to the Chinese-room intuition, as representations there are not computational tokens.

Artificial mentality is possible, not through classical AI but through brain-like AI. Argues the syntax/semantics point using an analogy with electromagnetism and luminance.

Lots of thought experiments like Searle's, against Searle. Searle's argument is like Leibniz's "mill" argument, with similar level confusions. Nice but patchy.

In the Chinese room, neither the person nor the system understands: a virtual person does. This person isn't the system, just as a normal person isn't a body. Follows from the "Kornese" room, which has two distinct understanders.

Advocates the systems reply, and criticizes Searle's "Chinese Gym" response to connectionism: Searle (like those he accuses) confuses a simulation with the thing being simulated. Nice.

Arguments with Searle on many points. A little weak.

The homunculus doesn't have access to the system's intentionality. The syntax/semantics relation is like the neurophysiology/mind relation.

Reply to Searle/Harnad: systems reply, level confusions, etc.

Reply to Harnad 1990: symbols, other minds, physically embodied algorithms.

Double's argument implies that the brain isn't the basis of intentionality.

The Chinese room isn't even implementing a Turing machine, because it doesn't use proximal causation. With a reply by Searle.

Argues that Searle is confused, and underestimates computers. Weak.

Non-symbolic function is necessary for mentality. Trying hard to work out a theory of why the Chinese Room shows what it does. Nice but wrong.

Reply to Dyer 1990: on the differences between real and as-if intentionality.

A discussion about the Chinese room, symbol grounding, and so on.

Searle is committing a level confusion, and understates the complexity of the case. We can move from the CR to a brain (with a demon) by twiddling knobs, and the systems reply should work equally well in both cases.

Searle's view implies that intentional causation is not efficient causation.

If we had microfunctional correspondence, the CR argument would fail. With points about the status of abstract/biological intentionality. A bit weak.

Jacquette misses the point of the argument. Also, biological and abstract intentionality are quite compatible.

Reply to Searle on CR, central control, biological intentionality & dualism.

Against Rapaport's Korean Room argument -- syntax isn't enough.

The Chinese room doesn't succeed as an argument about semantics. At best it might succeed as an argument about consciousness.

Defends Searle against all kinds of objections.

Computational systems must also meet performance criteria.

A program can possess intentionality, even if not consciousness.

Comments on Cole, and some general material on syntax and semantics.

Recommends the systems reply, and a causal account of semantics. Discusses the relevance of wide and narrow notions of content, and the tension between Searle's positive and negative proposals.

In arguing against the relevance of the serial/parallel distinction to mental states, Searle becomes a formalist. A nice point.

Searle's presence in the room destroys the integrity of the system, so that it is no longer a proper implementation of the program.

A person running the program, with interpretations at hand, would understand. Point-missing.

Argues against Searle, but misses the point for the most part.

Story about homunculi within homunculi. Fun.

Get semantics computationally via induction and functional roles.

Searle-in-the-room isn't in a position to know about the system's first-person states. Intrinsic intentionality is an incoherent notion.

Defending Searle's position, with remarks on the "causal powers" argument.

4.1d Machine Consciousness, Misc [see also 1.8b]

Response to Maudlin 1989. True computation needs active, not passive causation, so Maudlin's machine isn't really computing.

One could model brain states with monadic states and appropriate connections. But surely that's not intelligent -- the causation has the wrong form. Nice.

Computational state is not sufficient for consciousness, as it can be instantiated by a mostly inert object. A nice thought-experiment, raising questions about the relevance of counterfactuals to consciousness.

Of course, as we are machines. But what *sort* of machines are conscious, and in virtue of what properties? Remarks on artefacts, life, functionalism, and computationalism. So far, we don't know what makes the brain conscious.

Machines can think but can't feel, so aren't persons.

Various arguments and counter-arguments re machine consciousness and civil liberties. Problems of machine consciousness are analogous to problems of human consciousness. The structural basis of the two may well be the same.

More on TMs: explaining their psychology via preference functions.

To speak of a conscious machine is to commit a semantic mistake. Consciousness presupposes life and non-mechanism. Later retracted.

Argues that AI systems like Pollock's Oscar needn't be conscious. Blindsight tells us that complex perceptual processing can go on unconsciously.

Accepting machine consciousness would have few philosophical consequences, whereas rejecting it would tend to commit one to epiphenomenalism.

Of course robots can't think: they're not alive, so this gives us good reason not to rely on behavior. With replies by J.J.C. Smart, N. Smart.

4.1e Machine Thought, Misc

Arguing that a finite deterministic automaton can perform all natural human functions. With remarks on the logical organization of computers.

Subservience to known or knowable rules is incompatible with mentality.

Dennett, D. C. 1985. Can machines think? In How We Know (Shafto).

Defends the Turing Test, among other things.

Intelligence requires not just action or thought, but the governance of action by thought, which requires a history. "Wired-up" systems lack the explanatory connection between thought and action, so are not intelligent.

Computers follow rules, people don't.

On the philosophical importance of criteria for intelligence. With remarks on Searle, the Turing test, attitudes to AI, and ethical considerations.

An expert system would lack Holmes' ability to raise the right questions, sort out relevant data, and determine what data are in need of explanation.

Lucas, Searle, and Penrose all fall prey to "dual-description" fallacies.

A machine could possess every characteristic of human thought: e.g. freedom, creativity, learning,

4.2

Computation and Representation

4.2a

Symbols and Symbol Systems [see also 2.1a, 4.3e]

AI symbols are empty and meaningless. They need to be "grounded" in something, e.g. sensory projection. Maybe connectionism can do the trick?

On the limitations of symbol systems, and the potential for grounding symbols in sensory icons and categorical perception, e.g. with neural networks.

On computer science, AI, & the Physical Symbol System Hypothesis.

4.2b Computational Semantics

Against procedural semantics; it's a rerun of verificationism.

On the virtues of denotational semantics for AI. Notation without denotation, as found in many AI systems, leads to castles in the air.

Criticism of McDermott's views on semantics, logic and natural language.

   With commentaries by Haugeland, J. D. Fodor.

4.2c

**Implicit/Explicit Rules and Representations**

   Argues that we need explicit rules for flexibility, adaptibility, and representational redescription. With remarks on eliminativism.

   On various kinds of representation of knowledge or belief without explicit tokens: control-implicit, domain-implicit, and procedural information. The key distinction is representation vs. execution of a rule.

Hadley, R. F. 1990. Connectionism, rule-following, and symbolic manipulation. Proc AAAI.

   Some rules are learnt so quickly that representation must be explicit.

Kirsh, D. 1990. When is information explicitly represented? In (P. Hanson, ed) *Information, Language and Cognition*. University of British Columbia Press.

Cummins' account of inexplicit information fails, as even "executed" rules must be represented in the system. With remarks on the Chinese room.

4.2d

**AI without Representation?**

We don't need explicit representation; the world can do the job instead. Use embodied, complete systems, starting simple and working incrementally.

A discussion of anti-representationalism in situated robotics and the dynamic systems movement (Brooks, Beer, van Gelder). These arguments appeal to overly simple domains, and a modest notion of representation survives.

Argues for a dynamic-systems conception of the mind that is non-computational and non-representational. Uses an analogy with the Watt steam governor to argue for a new kind of dynamic explanation.

4.2e

**Miscellaneous**

On the problems with context-free symbolic representation.

On Searle's critique of computational explanation, contrasted with Gallistel's use thereof. The real issue is computation on indirect vs. direct representations; direct computationalism is an attractive view.

4.3

**Philosophy of Connectionism**

4.3a

**Connectionism and Compositionality (Fodor/Pylyshyn)**

Connectionist models can't explain cognitive systematicity and productivity, as their representations lack compositional structure. The allures of connectionism are illusory; it's best used as an implementation strategy.

Fodor and Pylyshyn's argument is an invalid instance of inference to the best explanation, as there is much
to explain than systematicity. Connectionism and classicism may be compatible even without implementation, in any case.

Connectionism can make do with unstructured representations, as long have they have the right causal relations between them.

Contra Chalmers 1993, F&P's argument doesn't apply at the implementational level. Contra Chater and Oaksford 1990, connectionism can't be purely implementational, but some implementational details can be relevant.

Argues against Clark on holism and the conceptual truth of systematicity.

An experimental demonstration that connectionist models can handle structure-sensitive operations in a non-classical way, transforming structured representations of active sentences to passive sentences.

Points out a structural flaw in F&P's argument, and traces the problem to a lack of appreciation of distributed representation. With some empirical results on structure sensitive processing, and some remarks on explanation.

Implementation can make a difference at the algorithmic level.

Christiansen, M. H. & Chater, N. 1994. Generalization and connectionist language learning. Mind and

Smolensky's weak compositionality is useless; and tensor product architecture can't support systematicity, as nonexistent tokens can't play a causal role.

Argues that existing connectionist models do not achieve an adequate systematicity in learning; they fail to generalize to handle structures with novel constituents.

Localist connectionist models may not be able to handle structured presentation, but appropriate distributed models can.

A discussion of how connectionism might achieve "effective syntax" without implementing a classical system.

F&P deal a sucker bet: on their terms, connectionism could never give a non-implementational explanation of systematicity, as the notions are construed in a manner specific to classical architectures.

Against responses to Fodor and Pylyshyn claiming that cognitive theories needn't explain systematicity. Contra Clark, the conceptual truth of systematicity won't help. Contra others, nor will evolution.

Argues that no connectionist model so far has come close to explaining systematicity. Considers the models of Elman, Chalmers, and Smolensky.

Develops a connectionist architecture -- recursive auto-associative memory -- that can recursively represent compositional structures in distributed form.

F&P's argument confuses constituent structure with logical/sentential structure. Connectionism is a psychotechtonic project, whereas propositional description is a psychosemantic project.
Part 4: Philosophy of Artificial Intelligence [565]

---

F&P ignore distributed representation and interaction effects.

Develops a connectionist architecture that represents compositional structures as tensor products of distributed representations.

Connectionism can do compositionality its own way, including both weak compositionality (with context effects) or strong compositionality (via tensor products).

Connectionism can do compositionality functionally. All one needs is the right functional relation between representations; physical concatenation is not necessary.

On connectionism as a Kuhnian paradigm shift in cognitive science, with emphasis on the implications of functional compositionality and distributed representations.

---

### 4.3b Representation in Connectionism

On some troubles connectionism has with higher-order knowledge. Contrasts Cussins, Karmiloff-Smith on development. Subsymbols without symbols are blind.

On the importance of representational redescription, and on the limits of connectionist networks in cross-domain knowledge transfer. What does a true believer need, above behavior: conceptual combination, real-world fluency?

Connectionism isn't really radical. There's no new concept of representation or of learning, and cognition can still be the manipulation of semantically structured representations.

Connectionism builds up concepts from the nonconceptual level. From nonconceptual content (e.g. perceptual experiences) to the emergence of objectivity.

On correlational semantics and context-dependent representations.

Some remarks on psychology & physiology. Even connectionism uses psychological concepts.

Argues that talk of representations has no explanatory role in connectionist theory, and can be discarded. It can't be understood along the lines of the teleo-informational or classical frameworks.

Pictorialism isn't compatible with language of thought, but connectionism might be.

Argues that distributed representation is best analyzed in terms of superposition of representation, not in terms of extendedness.

4.3c

Connectionism and Eliminativism

Connectionism implies eliminativism, as connectionist systems do not have functionally discrete contentful states, and folk psychology is committed to functional discreteness of propositional attitudes.

Outlines the semantic view of scientific theories, and applies it to the connectionism/eliminativism debate. There's no reason why folk psychology shouldn't be reducible, in a homogeneous or heterogeneous way.

Distinguishes active from dispositional beliefs: the former are realized discretely in activation patterns, the latter nondiscretely in weights, which is all that folk psychology needs.

Commentary on Ramsey/Stich/Garon. Connectionism has symbols that interact, and has propositional modularity in processing if not in storage.

Connectionism needn't imply eliminativism, as higher levels may have a causal role, if not causal completeness. Also, it may not tell the whole story.

Responding to eliminativist challenge via cluster analysis and recurrence.

Argues that our conception of thought requires causal systematicity, which requires a language of thought. Connectionist systems are not causally systematic, so connectionism leads to eliminativism.

Contra Ramsey, Stich, and Garon, connectionist representations can be seen to be functionally discrete on an appropriate analysis of causal relevance.

A dispositional construal of beliefs and desires can distinguish the relevant active states (via counterfactuals) and is compatible with FP, so internals can't threaten FP. With remarks on Davidson, overdetermination, etc.

Upon examination, the model of Forster and Sadel 1994 does not exhibit features that are both distributed and causally discrete.

4.3d

The Connectionist/Classical Debate

The distinction between programming languages and networks is neutral on rule-following, etc, so there's nothing really new about connectionism.

A detailed analysis purporting to show that connectionism and "logicism" are compatible, as Turing machines can do everything a neural network can. Entertaining, but misunderstands subsymbolic processing.

Distributed models are at the implementational, not computational, level.

Connectionism won't affect AI too much, as AI is concerned with the information-processing (task) level. With greater modularity, connectionism will look more like traditional AI.

Drawing the battle-lines: High Church Computationalism at the "East Pole", New Connectionism, Zen Holism, etc, at various locations on the "West Coast". With remarks on connectionism, and on AI as thought-experimentation.

Reiterating the value of connectionism, especially biological plausibility.

Connectionism and classicism aren't necessarily incompatible on symbolic discreteness, causal role, functional discreteness, constituency, representation of rules.

On connectionism, basketball, and representation without rules. Responses to the "syntactic" and "semantic" arguments against connectionism. Nice.

Cognition uses structured representations without high-level rules, and connectionism is better at accounting for this. With remarks on exceptions to psychological laws, and the crisis in traditional AI.

Response to Broadbent 1985: Distributed models are at the algorithmic level. Elucidating the low-level/high-level relation via various analogies.

Argues that symbolic systems such as decision trees are as good at learning and pattern recognition as connectionist networks, and it is just as plausible that they are implemented in the brain.

Challenges connectionism to explain things that the classical approach seems to handle better: the structure, systematicity, causal role, and grain of propositional attitudes, their rational relations, and conceptual stability.

4.3e

Subsymbolic Computation (Smolensky)

Connectionism offers a complete account at the subsymbolic level, rather than an approximate account at the symbolic level.

Explicates the distinction between symbolic and subsymbolic computation, and argues that connectionism can better handle the emergence of semantics from syntax, due to the non-atomic nature of its representations.

AI needs statistical emergence. For real semantics, symbols must be decomposable, complex, autonomous - i.e. active.

Argues with Smolensky: symbolic systems such as decision trees have all the positive features of neural networks (flexibility, lack of brittleness), and can represent concepts as sets of subconcepts. With a reply by Clark.

Rejects Smolensky's PTC, as the proper interaction of the microscopic and macroscopic levels would take a "miracle".

On connectionist networks as subsymbolic dynamic systems.

**4.3f Philosophy of Connectionism, Misc.**

On the relationship between connectionism, symbol processing, psychology and neuroscience.

Lots of questions about connectionism.

There's room for both styles within a single mind. The rule-based level needn't be autonomous; the connectionist level plays a role in pattern recognition, concepts, and so on.

An account of the shift from propositions to pattern recognition in the study of cognition: knowing-how, imagery, categorization, connectionism.

Argues that connectionism allows for a more plausible epistemology of perception, compatible with direct realism rather than representationalism. With remarks on Fodor and Pylyshyn's argument against Gibson.

Connectionism will revolutionize our review of scientific theories: From the deductive-nomological view to descent in weight-space. Some cute analogies.

We achieve explanatory understanding not through the manipulation of propositions but through the activation of prototypes.

Implications of connectionism and neuroscience for our concept of mind.

All kinds of stuff on connectionism and philosophy.

Connectionism separates processing from competence. Instead of hopping down Marr's levels (theory->process), connectionism goes (1) task (2) low-level performance (3) extract theory from process. Cute.

On computation and representation in AI and connectionism, and on problems for radical connectionism in reconciling these without denying representation or embracing mystery.

Explicates computationalism, and discusses ways in which connectionism might end up non-computational: if causal states cross-classify representational states, or if transitions between representations aren't computable.

Argues that connectionist networks don't have tacit knowledge of modular theories (as representations lack the appropriate structure, etc.).

Gibson is compatible with connectionism. In both, we can have rule-instantiation without rule-following.

An overview: local/distributed/featural representations; explanation in connectionism (how to avoid big mush); relation to neuroscience; explicit representations of rules vs weight matrices.

On various ways in which connectionism relates to representational homuncular functionalism, e.g. on implementation, eliminativism, and explanation.

How connectionism bears on the nativism debate. Conclusion: not too much.

Criticism of Churchland's connectionist epistemology.

In some senses of "cognitive", yes; in other senses, no. Phenomenological, theoretical, and sociological perspectives. Toward meaning-laden models.

4.3g

Foundational Empirical Issues

On how to get connectionist networks to learn about structured task domains. Concentrates on incremental learning, and other developmental/scaffolding strategies. With remarks on systematicity.

Criticizes connectionism for not being sufficiently rooted in neuroscience, and for not being grounded in the world.

What's new to connectionism is not learning or representation but the way that learning and representation interact.

Kaplan, S., Weaver, M. & French, R. M. 1990. Active symbols and internal models: Towards a cognitive
connectionism. AI and Society.

Addresses behaviorist/associationist charges. Connectionism needs recurrent circuits to support active symbols.

On the importance of variable binding, and why it's hard with connectionism.

Criticism of connectionist language models. They build in too much.

On the relationship between ND, PDP and AI. All are computational.

Connectionism is better at explaining empirical findings about mind.

Extremely thorough criticism of the R&M past-tense-learning model, with arguments on why connectionism can't handle linguistic rules.

4.4

Dynamical Systems

Part 4: Philosophy of Artificial Intelligence [565]

Philosophical Psychology 9:441-63.

On the brain as a vector-processing system, and the problems raised by indeterminacy, chaos, and so on. With morals for cognitive science.

Sloman, A. 1993. The mind as a control system. In (C. Hookway & D. Peterson, eds) *Philosophy and

Argues for a dynamic-systems conception of the mind that is non-computational and non-representational. Uses an analogy with the Watt steam governor to argue for a new kind of dynamic explanation.

4.5

**Foundational Questions in AI**

4.5a

**The Nature of AI**

AI as detailed armchair psychology and as thought-experimental epistemology. Implications for mind: e.g. a solution to the problem of homuncular regress.

No, AI is an a priori science that uses empirical methods; its status is similar to that of mathematics.

On the status of "medium AI", the study of intelligence in computational systems (not just humans). Contra to many, this is not an empirical science, but a combination of (experimental) mathematics and engineering.

4.5b

Levels of Analysis (Marr, etc)

Outlines a theory of the equivalence of algorithms.

Generalizes Marr's levels to: cognitive state-transitions, mathematical state-transitions, implementation. Discusses these with respect to connectionism, dynamical systems, and computation below the cognitive level.

On levels of organization vs. levels of analysis.

Defines computational, algorithmic and implementational levels.

On different kinds of level-shifts: organizational and contextual changes. There are more than three levels available.

With commentaries by Smith, Dennett.

Psychological explanation is typically somewhere *between* the computational and algorithmic levels.

### 4.5c The Frame Problem

General overview.

FP is an artifact of computational explicitness. Contrast human commonsense know-how, with relevance built in. Comparison to expert/novice distinction.

FP is Hamlet's problem: when to stop thinking. It's equivalent to the general problem of non-demonstrative inference.

The FP may be a consequence of the explicit/implicit rep distinction. Use "complicit" reps instead, and changes will be carried along intrinsically.

FP is a relatively narrow problem, Some, e.g. Fodor, wrongly equate FP with the "Generalized AI Problem".

Criticizes Dennett's, Haugeland's and Fodor's construals of the FP.

Solve frame problem by using the sleeping-dog strategy -- keeping things fixed unless there's a reason to suppose otherwise.

Lots of papers on the frame problem.

### 4.5d

**AI Methodology**

AI must integrate perception and cognition in the interest of flexible representation. Current models ignore
perception and the development of representation, but this cannot be separated from later cognitive processes.

AI should look at biology.

Micro-worlds don't test true understanding, and frames and scripts are doomed to leave out too much. Explicit representation can't capture intelligence.

History of AI (boo) and connectionism (qualified hooray). And Husserl/Heidegger/Wittgenstein. Quite nice.

Various AI approaches to belief: syntactic, propositional/meaning-based, information, tractability, discoverability, and degree of confidence.

AI will need holism: interpretational, common-sense, situational, existential.

Identifying the dividing lines: pre-eminence of knowledge, embodiment, language-like kinematics, role of learning, uniformity of architecture.

AI usually comes up with Type 2 (algorithmic) theories, when Type 1 (info processing) theories might be more useful -- at least if they exist.

Problems in AI methodology: wishful mnemonics, oversimplifying natural language concepts, and never implementing programs. Entertaining.

Criticism of logicism (i.e. reliance on deduction) in AI.

Lots of papers on various aspects of AI methodology. Quite thorough.

On the non-represented background to everyday activity, and environmental interaction in cognition. Criticizes cognitivism, connectionism, looks at Agre/Chapman/Brooks, ethology, anthropology for support.

10 papers on philosophy of AI, psychology and knowledge representation.

Defending limited rationalism: i.e. a theory of intelligence below the conceptual level but above the neuronal level.

4.6

**Computationalism in Cognitive Science [see also 2.2e]**

Overview of computationalism. Relationship to intentionality, LOT, etc.

Argues for theses of computational sufficiency and computational explanation, resting on the fact that computation provides an abstract specification of causal organization. With replies to many anti-computationalist worries.

On analog/digital, representational/nonrepresentational, direct/indirect.

What computationalism is, as opposed to computerism & cognitivism. Implies: intentionality isn't special, and we don't make decisions. With commentary.

Argues that computational explanation requires the attribution of semantic content. Addresses Stich's
arguments against content, and argues that computers are not formal symbol manipulators.

Machines can’t even add, let alone think, as the symbols they use aren’t meaningful to them. They would need real information based on perceptual embodiment, and conceptual capacities, for meaning to play a real role.

Computationalism is false, as it can’t distinguish the ability to solve a maze for the ability to solve its mirror image. An embodied computational taxonomy is needed, rather than software alone.

Only belief is computational: rest of mind is not.
Part 4: Philosophy of Artificial Intelligence

Argues contra Pylyshyn 1984 that finite state automata are good models for cognitive science: they are semantically interpretable and process symbols.

A thorough account of the symbolic/computational view of cognition.

An overview of the computational view of mind. On symbols, levels, control structures, levels of correspondence for computational models, and empirical methods for determining degrees of equivalence.

Various points on pros and cons of computational psychology.

4.7 Computation and Physical Systems

Gives an account of what it is for a physical system to implement a computation: the causal structure of the system must mirror the formal structure of the computation. Answers objections by Searle and others.

Argues that Putnam's "proof" that every ordinary open system implements every finite automaton is fallacious. It can be patched up, but an appropriate account of implementation resists these difficulties.

Many physically realized functions can't be computed by Turing machines: e.g. "mundane procedures" and continuous functions. So the C-T thesis is false of these, and maybe even of number-theoretic functions.

Adapts Goodman's notational systems to explicate computational information processing. What is/isn't a physical notational system (e.g. LOT, symbol systems, connectionism) and why. How to reconcile notational/mental content?

Pragmatic factors are vital in connecting the theory of computation with empirical theory, and particularly in determining whether a given system counts as performing a given computation.

Syntax isn't intrinsic to physics, so computational ascriptions are assigned by observer. Syntax has no
causal powers. Brain doesn't process information.

Disputes Kripke's argument that there is no objective way of determining when a system computes a given function, due to infinite domains and unreliability. Stipulating normal background conditions is sufficient.

4.8

Philosophy of AI, Misc

12 papers on the foundations of AI and cognitive science.

Thagard 1986 is wrong; speed and the like make no fundamental difference. With Thagard's reply: it makes a difference in practice, if not in principle.

A nice paper on the relationship between techniques of theory formation from machine learning and philosophical problems of induction and knowledge.

All about how the computer should change the way we think about the mind.

Parallelism does make a difference. Some somewhat anti-functionalist points.

A comparison of philosophical and AI approaches to explanation: deductive, statistical, schematic, analogical, causal, and linguistic.

5.1 Issues in Cognitive Science

5.1a Nativism (Chomsky, etc)

   Reply to Putnam 1967: Putnam underestimates complexity of grammar, etc.

   Concepts are undefinable, so primitive, so innate (plus gloss).

Part 5: Philosophy of Psychology

Overview; poverty of stimulus, unobservable features => rationalism.

An excellent collection of papers & responses by Piaget, Chomsky and others.

Why learning is selective and not instructive. Biological analogies, linguistic evidence. Dispense with "learning" as a scientific term.

Contra nativism: disputes (1) surprising universals (2) explanation of universals (3) ease of learning (4) relevance of IQ-independence.

Identifies minimal nativism vs anti-empiricism vs rationalism. Considers the relevance of connectionist
networks. Some nativist arguments may survive.

Concepts can be acquired without being learned by symbol-manipulation.

Explain universals via Popper/Simon empirical model.

Can take middle ground. Anti-empiricism doesn't imply rationalism.

**5.1b Modularity (Fodor, etc)**

Against Fodor: modules are smaller, interact strongly, not domain-specific.

Remarks on Shanon and Fodor.

Overview of the original studies on top-down effects in perception.

Our perception is deeply theory-laden, and potentially very plastic.

Contra Fodor 1984: observation is theory-laden (built-in or not); supported by neurophysiological evidence; perceptual systems have long-term plasticity.

Perception happens in informationally encapsulated, domain-specific modules. Central systems aren't encapsulated, and so may be impossible to understand.

Summary of MOM (with commentary and reply in the BBS printing).

Informal discussion of modularity. With commentaries by Fahlman, Caplan.

Part 5: Philosophy of Psychology [561]

Argues for an observation/theory distinction, and against belief affecting perception.

Churchland is up the creek without a paddle.

A collection of papers on modularity in language and vision.

Fodor's arguments for unencapsulated central systems are no good; AI is possible after all.

Criticism of Fodor. Modularity is dynamic, and can be central.

'Direct perception' can't correspond to anything. Perception is inferential.

5.1c Mental Imagery [see also 6.2j]

Schwartz, R. 1980. Imagery: There is more to it than meets the eye. Philosophy of Science Association 1980.

Tye, M. 1991. The Imagery Debate. MIT Press,

5.1d Rationality

5.1e

**Embodiment [see also 2.2]**

On the importance of embodiment of systems in cognition.

Advocates a sort of "active externalism", based on the role of the environment in actively driving cognition. Beliefs can extend into an agent's immediate environment (e.g. a notebook) in this way.

Argues that the mind is not just embedded but intimately intermingled with the world. With some systems-
theoretic arguments arguing against a determinate interface. Mind is not an inner realm.

Argues against the contemporary "Cartesian" view of mind as an ontologically homogeneous inner representational realm that causes behavior, arguing for a holistic embodied view instead. Mind is therefore safe from elimination.

Wilkerson, W. S. 1999. From bodily motions to bodily intentions: the perception of bodily activity. Philosophical Psychology 12:61-77.

5.1f Animal Cognition [see also 6.4c, 6.4d]

### 5.2 Aspects of Mind

#### 5.2a Pain and Pleasure

Goldstein, I. 1999. Intersubjective properties by which we specify pain, pleasure, and other kinds of mental states. Philosophy.

**5.2b**

*Emotions*

**5.2c**

**Dreams [see also 6.2l]**

5.2d Memory [see also 2.2f, 3.7]

5.2e Color [see also 1.3a, 1.7a, 1.7d]

Philosophical Studies 93:21-44.

Watkins, M. 1999. Do animals see colors? An anthropocentrist's guide to animals, the color blind, and far away places. Philosophical Studies 94:189-209.

### 5.3 Philosophy of Psychology, General

#### 5.3a

**Psychological Laws [see also 3.5d]**

Fodor, J. A. 1991. You can fool some of the people all of the time, everything else being equal: Hedged laws and psychological explanation. Mind 100:19-34.
Ceteris paribus means that every realizing state has completing conditions. Even absolute exceptions are OK, as long as they're not across-the-board.

Non-strict psychological laws are compatible with the (nomologically sufficient) causal responsibility of mental properties. So there's no need for epiphobia. With comments on the relation between laws and mechanisms.

Argues that any laws in intentional psychology have ineliminable same-level exceptions; the Kuhnian crisis in cognitive science gives evidence for this. But ceteris paribus laws provide perfectly good theoretical explanation.

A functionalist defense against anomalous monism. Psychofunctional laws and psychological laws, though not psychophysical laws, may exist. Rebutting arguments from rationality, indeterminism, intensionality, etc.

There are no ceteris paribus laws, as there's no satisfactory way to cash the "unless" cause. But psychology doesn't need laws, anyway.

5.3b Psychology and Neuroscience [see also 6.1i]

Arguing for the notion of functional architecture as a bridge whereby neural components can be components of cognitive processes.

Argues that we can understand the brain under the hypothesis that it is optimized to "save wire", due to bounded resources: organization predicts placement. With remarks on the relation between cognitive and neural levels.

Some cute examples of neurophysiological reductions using state-spaces.

Churchland, P. M. 1995. The Engine of Reason, the Seat of the Soul: A Philosophical Journey into the Brain. MIT Press.

The brain can tell us a lot about the mind. With examples.

All about neuroscience, philosophy and prospects for their interaction.

About how neuroscience and connectionism affect our conception of mind.

On paradigm shifts, biology, evolution, connectionism, etc.

The relationship between psychology and neuroscience is best characterized not by reduction but by explanatory extension, where each field is enriched by the other. With a number of examples from recent empirical work.

Wittgenstein wouldn't have liked the Churchlands, as neuro might be chaos, and too much neuro might undermine our self-conception nihilistically.

Incommensurable theories don't necessarily require elimination, if their relationship is synchronic/interlevel, rather than diachronic/intralevel.

Argues contra Fodor and Block that neurological equipotentiality doesn't refute type materialism. Mental states may not be anatomically defined neural states, but they may be more abstract neural holograms.

Argues that the mind is not identical with the brain -- at the very least, it's the central nervous system, and perhaps more. "Brain" does not denote a natural kind in neurophysiology.

Cognitive psychology can transmogrify itself, who needs neuroscience?

5.3c Explanation in Cognitive Science

Psychological explanation is typically via functional analysis, not causal subsumption. On interpretation, computation, and an analysis of cognition and intentionality. With remarks on Dretske, Searle, Titchener, Hull, Freud.

Contra Kitcher 1988, much of Marr's theory doesn't depend on optimization; in any case, optimization isn't so bad. With remarks on interdisciplinarity.

On the tension between formal explanation and representational explanation.

Discusses the principle: there cannot be two independent explanations of the same phenomena. With application to purposive explanation of behavior, theory reduction, and eliminativism, and a discussion of explanatory realism.

On the problems posed by explanatory exclusion, and possible solutions. With focus on the problems as they arise for Dretske's and Davidson's theories.

5.3d

Philosophy of Cognitive Science, Misc

Philosophy is autonomous: empirical considerations can't affect it.

On the role of non-empirical advances in psychology: e.g. in theory construction, coherence analysis,
conceptual innovation, with the aid of logically necessary truths and the contingent/pragmatic a priori.

5.4

**Philosophy of Mind, General**

A general overview.

An overview of the last 40 years of the philosophy of language and the philosophy of mind, covering many issues and trends.

   An overview of everything, circa 1978: logical behaviorism, functionalism, the identity theory, qualia, meaning, and so on, with bibliography.

In praise of the "Ryle-Dennett" tradition, and the elimination of dualism from the philosophy of mind.

A pragmatist perspective on the recent history of the philosophy of mind, focusing on consciousness, intentionality, and mental representation, and on debates between Fodor, Dennett, Searle, Putnam, and Davidson.

Part 6: Consciousness in Science [1599]

1.1 Consciousness
-----------------

1.1a  Consciousness -- General
-----------------------------

An anthology of central philosophical papers on consciousness.

Exploring the link between consciousness and judgments about consciousness.
Coherence between these => consciousness depends on the functional but isn't reducible. Toward a dual-aspect theory based on pattern and information.

Argues against the reductive explanation of consciousness, and for a kind of naturalistic dualism. Moves toward a "fundamental theory" to bridge the gap, and draws out some consequences.

A collection of 5 psychological and 8 philosophical essays on consciousness.

Argues that consciousness can be accounted for in a naturalistic framework.
With arguments against eliminativism and epiphenomenalism, evidence from neuroscience and psychology, and discussions of the stream and the self.

A history of the study of consciousness, especially in psychology.

A summary of recent philosophical debates over consciousness, focusing on the "what/where/who/why/how" questions, the explanatory gap, and the stalemate between "essentialist" and "causal" intuitions.

Separates computational mind from phenomenological mind, and studies the former, a third-person approach. The residue is the "Mind-Mind" problem. Consciousness supervenes on an intermediate level of representation. Elegant.

Physicalism can explain consciousness in all its glory. Argues against zombies and inverted-spectrum scenarios, and suggests that the explanatory gap can be bridged by an account of directly-active information-processing.

An excellent collection of 20 philosophical papers on consciousness.

Argues that the first-person view has been ignored too much in the philosophy of mind. Even unconscious states are only mental by virtue of their potential consciousness.

On the centrality of consciousness to the mind. Consciousness is irreducible but biological. On the history of the field, the structure of consciousness, its role in constituting intentionality, and problems with computation.

On the notion of consciousness, its relation to the brain, and some features that need to be explained: its subjectivity, unity, intentionality, center and periphery, Gestalt structure, aspect of familiarity, and so on.

Value is only found within streams of consciousness. Three ways of studying it: phenomenology, anthropology, and by relation to the physical. With an analysis of the "self-transcending" nature of conscious intentionality.

A collection of philosophical articles on consciousness.

1.1b The Concept of Consciousness
---------------------------------

On minimal consciousness, perceptual consciousness, and introspective consciousness. Introspective consciousness seems so special because it gives inner awareness of self, and memory of other mental events.

Distinguishes C1 (phenomenal experience) from C2 (access of parts of a system to other parts). C2 is can be scientifically studied, and has a graspable, if fragmented, causal role. C1 is mysterious and perhaps beyond science.

Reportability is not phenomenology, as blindsight has reportability but no phenomenology.
  Argues that the cognitive correlate of consciousness is direct availability for global control.

  Analyzes consciousness in terms of the "presence" of information to the main decision-making processes of a system. No great conceptual capacities required, no higher-order thoughts. With application to blindsight.

  Separates consciousness from the mental -- functionalist accounts work for the latter but not the former. With remarks on Zen "pure consciousness".

  On the role of consciousness in psychology, and distinguishing various notions of consciousness: mutual knowledge, internal knowledge, awareness, direct awareness, personal unity, wakefulness, and double consciousness.

  Ideas about consciousness from Locke, Brentano, Hebb, Dennett, Skinner, Sellars, Aristotle, Gibson. Theories: inner eye vs. verbal vs. outer eye.

Nelkin, N. 1993. What is consciousness? Philosophy of Science 60:419-34. On three senses of consciousness: phenomenality, intentionality, and introspectibility. Argues from empirical evidence (especially blindsight cases) that these three are all dissociable.

1.2 Explaining Consciousness?

1.2a Subjectivity and Objectivity (Nagel) [see also 1.3a]

Nagel, T. 1974. What is it like to be a bat? Philosophical Review 4:435-50. Reprinted in _Mortal Questions_ (Cambridge University Press, 1979). Physicalist explanations leave out consciousness, i.e. what it is like to be an organism. Objective accounts omit points of view (could there be an objective phenomenology?). Physicalism may be true, but we can't see how.

Subjective and objective views clash e.g. on meaning of life, free will, personal identity, mind-body problem, ethics. How to reconcile: reduction, elimination, annexation? Maybe just let multiple viewpoints coexist.

Nagel, T. 1986. _The View From Nowhere_. Oxford University Press.

Seeing philosophy as a clash between the subjective and objective views of various phenomena (mental states, self, knowledge, freedom, value, ethics). Eliminating the subjective is impossible.

Akins, K. 1993. What is it like to be boring and myopic? In (B. Dahlbom, ed) _Dennett and his Critics_. Blackwell.

Gives a detailed account of perceptual processing in bats, and suggests that we can know what bat-experience is like: it's like nerd experience. But then is there an unexplained residue?

On what science tells us about the experience of bats, birds, and others. Why a movie of bat-experience isn't good enough -- because of the inseparability of intentionality and experience. Science can do OK.

No real problems are posed by subjectivity and points of view, no matter how they are construed (fixed, portable, tokens, types). It's either a confusion or a triviality about the logic of indexicality.

On what is required for consciousness of agency (rather than qualia): belief, intention, and most importantly desire, enabling a capacity to care. A robot could have all this, and it would be like something to be it.

Naturalism can do autophenomenology just fine.

A Super Neuroscientist will know how we describe and think about experience, so will know as much as a Super Sympathist. One doesn't have to imagine to know what it's like. With remarks on bat experience.

Nagel conflates metaphysical and epistemological versions of the subjective/objective distinction. Consciousness is metaphysically subjective, and science is epistemically objective, so there is incompatibility.

Being graspable from only one point of view does not define the class of experience.
factuals about conscious experience. Various ways of cashing this out fail.

The objective and subjective don't conflict, but complement each other.

Nagel conflates questions about sensory qualities with those about a unique point of view. The truth of physicalism is irrelevant to uniqueness.

The subjective/objective distinction is ill-drawn. Objective descriptions aren't species-independent, but in terms of the space-time causal network. Science can explain the experience this way, but not provide the experience.

Knowing what it's like consists in an ability, not possession of information.

Various anti-Nagel points.

Lycan, W.G. 1990. What is the "subjectivity" of the mental? Philosophical Perspectives.
The subjectivity of the mental is no more special than usual propositional subjectivity. It can be handled by a self-scanner model of introspection.

A critique of Nagel's idea of a "point of view" that is occupied by a "subject". There aren't any peculiar facts about given viewpoints.

There are no fact about what an experience is like. Knowing what it's like is an ability to imagine, recognize, and recall; this explains ineffability, etc. With remarks on the experience of imagining an experience.

Phenomenological properties cannot be picked out in physical or computational terms; argues against Lycan's criticism of Nagel. But all this is compatible with materialism. With comments on the phenomenological tradition.

Criticizes absent/inverted qualia arguments for a special "what it is like", but argues that the possibility of "what it is like" differences relative to semantic states shows that something's not conveyed by functional accounts.

The Nagel/Jackson argument is analogous to the Perry indexical argument, and can be treated the same way.

Nagel's dilemma: separating feeling from process. Moral consequences?

Nagel-consciousness exists, but isn't so important. It's essential for sensations, but not for thoughts. Beings without it could still be persons.

Understanding does not consist only in facts; we can understand via sympathy.

Knowing what it's like is really knowing how to imagine. We should reduce Nagel's question to a question about possession of a certain ability.

Subjectivity is not something we have knowledge of, as we lack comparisons.

On the Nagel/Dennett debate: Nagel holds out for unexplained intrinsic properties once the relational is all accounted for; Dennett can renounce the transcendental ambition. Remarks on realism, holism, and metaphilosophy.

Divides Nagel's problem: qualitative differences, special access, mineness.

Nagel's 'View from Nowhere' doesn't take subjectivity seriously enough.

Rebutting various intuitions for the non-physical nature of experience. The Nagel/Jackson argument commits an intensional fallacy; experiences are physical states known from a different perspective.

A Wittgensteinian critique of Nagel. Nagel's question is confused: "what it's like" is a matter of behavior, sociality, etc, not inner experience.

Reducing doesn't imply understanding. Two different kinds of reduction.
Nagel is an epistemological solipsist, whether he likes it or not.

1.2b The Explanatory Gap (Levine)
------------------------

   Reflections on the explanatory gap between physical processes and conscious experience. With remarks on different sorts of consciousness, and on why we need an intelligible necessary connection.

   On the physiological bases of phenomenal states, particularly color.
   Inverted spectrum isn't really coherent, as coolness/warmth would have to be inverted too. So the contingency of qualia is diminished.

   Argues in detail that psychophysics can provide a structural map to close the explanatory gap. If there is an explanatory residue, perhaps panpsychism can help.

   Argues for a distinction between reduction and reductive explanation, and argues that reductive explanations generally involves conceptual connections via "functionalization". With comments on Block and Stalnaker.

   Contra Kripkean arguments, a good enough functional theory may help close the conceivability/explanatory gap between the physical and qualia. Contra Nagel/Jackson, such a theory could provide us with recognitional abilities.

   How do we explain the apparent contingency of the qualia-matter reduction?
   Even if it's not metaphysically contingent, it's conceptually contingent, so there's a gap in any physical explanation of qualia. Excellent.

Physical accounts leave out qualia epistemologically but not metaphysically. So physicalism holds, but there is an explanatory gap. Discusses Kripke's and Jackson's arguments in detail; also explanation and content.

Argues that the explanatory gap between brain and consciousness is just the same as that found with causal relations everywhere; it's just that we usually overlook it in the latter case.

Qualia can't be explained in more basic terms, as that sort of explanation works by accounting for a property's canonical evidence, but the canonical evidence for qualia are qualia themselves. But they still may be physical.

1.2c 'Hard' and 'Easy' Problems (Chalmers) [see also 3.1]

-----------------------------

Divides the problems of consciousness into easy and hard problems; the hard problem eludes reductive explanation as it isn't about explaining functions. Argues instead for a nonreductionist theory with psychophysical laws.

Like the JCS article, but shorter, more accessible, and with pretty pictures.

There is no a priori entailment from the physical to phenomenal facts (arguments from conceivability, epistemology, analysis), so reductive explanation fails. With a critique of existing empirical proposals.

A reply to the 25 "hard problem" articles in JCS.

Argues that the "hard problem" in effect invokes an argument from ignorance, and that there's no deep difference between consciousness and other domains.

Argues contra Chalmers that experience is identical to certain functions, rather than emerging from them.

Divides the hard problem into three parts, and argues that neuroscience can make progress on at least one part (incommunicability); and maybe "meaning" holds the key to the rest.

Argues contra Chalmers 1995 that functions are all we need to explain.

Argues that consciousness plays a vital role in performing mental functions, so the easy problems won't be solved until the hard problem is solved.

Endorses the idea of consciousness as fundamental, but criticizes Chalmers' psychophysical laws. Advocates a theory with a "conscious mental field".

Argues that the "easy problems" -- reportability, attention, etc -- all involve concepts and therefore experience itself, for Kantian reasons, and therefore are not mechanistically explainable.

Argues that the truly hard problem is that of giving a constitutive account of consciousness, and Chalmers doesn't solve that (laws aren't good enough); in fact it's unsolvable.

Argue that we should work on the easy problems for now, as nobody has any good ideas about the hard problem; maybe it will gradually fade away.

On the epistemology of the hard problem. Argues that a scientific study of phenomenology is possible, drawing on work in developmental psychology and Eastern thought. "Pure consciousness" may be relevant to a resolution.
A collection of essays consisting of Chalmers' keynote paper, 26 replies from many perspectives, and Chalmers' response to the replies.

Advocates a careful phenomenological study of consciousness in its own right, systematically linked with a neurophysiological investigation.

Agrees with Chalmers on nonreductionism, but disagrees on "awareness", organizational invariance, and thermostats. Advocates a kind of dual-aspect theory, where the physical world is present within consciousness,

1.2d Cognitive Closure (McGinn)
----------------------

McGinn asks too much of a solution to the M-B problem. We might understand consciousness without understanding specific experiences; we could get at it by studying brain and consciousness not separately but simultaneously.

Argues that the mind-body problem might be solvable in principle, but beyond human capacities. Neither perception of the brain nor introspection of consciousness can uncover the property by which consciousness arises.

A collection of articles on the problem of consciousness, advocating a view on which the phenomenon is natural but permanently mysterious to us.

Argues that a naturalistic account of the intentionality of conscious states requires an account of their embodiment; and that embodiment may depend on the hidden structure of conscious states, not accessible to introspection.

Suggests that consciousness may have a hidden structure, analogous to the deep structure of language, that relates its surface properties to physical
properties. We may not be able to understand this hidden structure, however.

1.2e Miscellaneous

------------------

Parodies arguments by Searle, Jackson, and Chalmers for the irreducibility of consciousness with analogous arguments for the irreducibility of "luminescence". The consciousness arguments are no better.

Argues that consciousness can be handled within a scientific framework. We can translate first-person accounts into third-person accounts. Replies to skeptical objections using analogies from elsewhere in science.

A "committed materialist" will not see any explanatory gap, or any "brute fact". The entrenched differences lie in one's choice of initial framework.

Qualia pose no insurmountable problems for materialism: knowledge argument can be answered, explanatory gap can be closed, and absent qualia arguments beg the question. With speculations on their functional role.

Distinguishes six explananda, four explanatory restrictions, and four sorts of relations between them, making 96 possible problems. With a discussion of whether and how the central problems might be answered.

1.3 Materialism and Dualism
---------------------------

1.3a The Knowledge Argument (Jackson) [see also 1.2a]
-------------------------------------

Knowing a completed neuroscience does not imply knowing about qualia. Mary, the colorblind neuroscientist, gains color vision and learns about red. So physicalism is false, as there are facts over and above the physical facts.

Reply to Churchland 1985: Mary *learns*, Churchland misstates the argument.

Contra Pereboom 1994: The way a color sensation appears is a fact about it.

Argues that Churchland's neuroscientific descriptions must leave at least some qualia behind: they might account for what we know (e.g. brain states) in qualia-knowledge, but can't handle distinctions in how we know.

Mary gains knowledge of old facts, in a new way: she gains a new mode of acquaintance with those facts. Analogies with indexical knowledge: her new knowledge eliminates no possible worlds.

Qualia can undergo a normal reduction to the neurophysiological. Jackson commits an intensional fallacy; in any case, perhaps Mary can understand red. When we apprehend qualia, we are directly introspecting our brain state.

Rejoinder to Jackson 1986. The key lies in knowing-how vs. knowing-that.

Contra Lewis, Nemirow, and Horgan on the knowledge argument. But qualia may still be physical (though outside vocab of science) due to their causal role.

Mary knew all the facts about qualia beforehand, she just wasn't acquainted with them. Knowledge by acquaintance isn't factual knowledge.
Speculation on how consciousness might be left out by a physical account.

Argues that most people don't really imagine Mary's situation. In fact, Mary would be able to identify blue objects from the way they make her react.

Defends Jackson's argument against criticisms by Nemirow, Smith & Jones, Warner, Horgan, & Conee. The argument forces physicalism into a quandary: either deny qualia, or make the confused claim that qualia are physical.

On Dilthey's "Verstehen", or "understanding from within". Mostly about meaning, but with application to the knowledge Mary gains.

Mary didn't know all the physical facts: she knew all the explicitly physical information, but not all the ontologically physical information.

A new version of the knowledge argument: given all the physical facts, one can't know when two experiences are indistinguishable. This avoids various objections to the standard version.

Contra Nagel/Jackson: Understand qualia through relational properties, and separate the mental concept from the recognitional capacity.

Against the hypothesis that phenomenology carries information. If it does, then qualia are epiphenomenal. Better to analyze the "new information" as acquiring an ability instead. In-depth and entertaining.

Phenomenal and functional concepts are distinct, but the relevant properties may be identical. We directly refer to phenomenal properties by recognition. Remarks on other minds, transparency, incorrigibility & more. A meaty paper.

Gives nine arguments against the Lewis/Nemirow ability analysis, and proposes instead that the same fact is learned a new way, like water and H2O facts. This sort of phenomenal information is no danger to materialism.

Defends against objections from Dennett, Churchland, etc. Horgan's objection (same fact different ways) has a certain force, but the argument can be reformulated to avoid them and imply property dualism. With remarks on Loar.

Contra Churchland 1985: we couldn't introspect sensations as brain states, although we could interpret them as such.

Reconstructing the Mary case as a Marianna case, and introducing a distinction between phenomenal and nonphenomenal beliefs, to support the knowledge argument. A very nice and sophisticated paper.

Mary goes from a third-person concept of experience to a first-person concept, but they co-refer; we can refer to an experience without having the experience. Physical and phenomenal properties are brutely identical.

Mary learns an old fact under a new mode of presentation, and doesn't even learn a new fact about a mode of presentation. Her access to internal states is always mediated by representation, so we can always ascend to a new mode.

A thorough discussion of Lewis 1990. Phenomenal information implies epiphenomenalism, even at the intra-psychic level. Remarks on ineffability, and on whether properties should be individuated by nomic role or by essence.

Contra Dennett, Mary can't tell an object's color unless she already knows
about experience. The knowledge argument bears on thought, not just qualia.

Introspection reveals functional properties, not physical, so qualia should be reduced to the functional, not to the physical.

Physicalism explains all the relevant evidence, hence all facts, and needn't admit mental entities; belief in mental entities is based on physical facts.

Interesting remarks on what it would be for someone to see colors that we cannot, combining philosophical considerations with empirical findings about color space. Argues that science could tell us what such colors are like.

A Jackson-like argument that physical knowledge can't give you the knowledge of what pain feels like. With detailed consideration of objections and replies. Argues from limited incorrigibility to factualism about pains.

Epiphenomenalism => qualia don't cause beliefs => we don't know about qualia.

1.3b Zombies & Modal Arguments [see also 1.2c, 1.3a, 1.3c, 1.3d, 1.7e]

-----------------------------

Argues from the lack of logical supervenience to the falsity of physicalism.

A two-dimensional analysis shows that objections from a posteriori necessity fail. Argues for a naturalistic variety of property dualism.

Argues that the conceivability of zombies and the like can be explained away, in terms of the cognitive separability of perceptual imagination and sympathetic imagination of the same states.

Describing a situation where we would be justified in believing in zombies. Argues that zombies are logically possible, which seems incompatible with most or all varieties of materialism.

Materialism requires that physical states logically entail all non-relational states; but zombies are logically possible, so materialism fails. With a description of a zombie, and replies to a verificationist. All very true.

Reply to Locke 1976: materialism needs zombies to be logically impossible.

If Campbell's imitation man is possible, then the causal relation between the physical and phenomenal is unreliable.

Contra Kirk: the logical possibility of zombies is compatible with empirical materialism. With some comments on Kirk's thought-experiment.

Argues that behavioral differences in zombies would show up, in their discourse about consciousness.

   On the possibility of an Insentient Perceiver, who perceives the world without sensation. Sensation is inessential to perception and understanding, except understanding in the "whatlike" manner.

   Argues for the conceivability of insentient perception of colors (in "Insent", a kind of blindsighter or zombie), in order to argue for a realistic account of colors.

   A discussion of materialism and its difficulties. The conceivability of zombies poses special problems. Criticism of Smart's & Armstrong's analyses.

1.3c Essentialist Arguments (Kripke) [see also 1.3b, 1.3d]
-----------------------------------------------

Kripke, S.A. 1971. Identity and necessity. In (M. Munitz, ed) _Identity and Individuation_.
   An identity between mental and physical states can't be contingent, as it relates rigid designators. But nevertheless the co-occurrence of certain mental and physical states is contingent, so the identity theory is false.

   Both "pain" and "C-fibres firing" are rigid designators, so if they are identical, this must be necessary. But their co-occurrence is contingent, and this can't be explained away epistemically, so the identity theory fails.
Argues that pain and the associated epistemic situation are inequivalent. Beliefs about pain are simply produced by mechanisms, and could come about without any sensation.

Trying to turn Kripke's argument against him: it's possible that pains and C-fibre stimulations are identical, so it's necessary that they're identical.

On four arguments against the identity theory: multiple-realizability, modal, knowledge, and certainty arguments. All face difficulties due to scientific essentialism, but the latter two can be reformulated to avoid them.

Kripke's argument doesn't refute token identity. Pains can have other essential properties besides painfulness, so psychophysical token identities can be necessary.

Materialism doesn't need rigid identities, due to the compositional plasticity of mental states. So the possibility of disembodiment is compatible with materialism. The possibility of zombies is illusory.

Comments on Feldman 1974: Feldman's view requires rejection of Kripke's views on necessity, or a problematic mixed view on rigid designators.

A materialist must deny essentialism to meet Kripke's argument.

Kripke's premise that pains are essentially mental either begs the question (by assuming pains don't have physical properties) or weakens the premise that physical events aren't essentially mental.

Painfulness need not be an essential feature of pains.

Kripke's arguments against person-body and mind-brain identity rely on the essentialness of aliveness to persons and painfulness to pains. There's no reason to grant this. If we do, rigidity is irrelevant to the argument.

Defending a contingent event identity thesis against Kripke. Mental properties (which are distinct from physical properties) may not be essential properties of an event.

Uses Kripke's 1979 direct-reference theory against him. When rigid
designators don't have associated reference-fixing descriptions, we can't
expect the "explaining away" strategy to work.

Hill, C.S. 1981. Why Cartesian intuitions are compatible with the identity
The apparent contingency of identity is due to the fact that one can be aware
of pain without being aware of C-fibers and vice versa, as well as to the
fact that "C-fibers" may be picked out by a contingent description.

Holman, E. 1988. Qualia, Kripkean arguments, and subjectivity. Philosophy
Defending Kripkean arguments against various objections. Analysis in terms
of manifest properties and their role in fixing reference to the subjective
and objective.

Philosophy 58:26-34.
A Kripkean argument against non-analytic physicalism. Even if pain rigidly
designates a brain state, the physicalist still has problems explaining the
property of "pain-presents".

Kripke's argument doesn't refute contingent identity between minds and
nonrigidly designated bodies, which is all materialism needs.

Philosophia 8:673-88.
Some theoretical identification are analogous to mental-physical
identifications -- entities are introduced by properties considered
essential within a theory, but this doesn't preclude identification.

The reference of "pain" is fixed not by essential features but by contingent
topic-neutral descriptions; this is the real moral of Wittgenstein's private
language argument. So Kripke's apparent contingency can be explained away?

Reply to Bealer 1994. Tries to clarify the dialectic, and argues that the
materialist can explain "possibility" of straw thought as thought conjoined
with mere appearance of straw.

71:677-89.
Kripke equivocates on "pain-sensation": pains aren't the same as impressions
of pain. Argues that imaginability arguments aren't decisive, and that
functionalism may be less vulnerable than the identity theory.

Painfulness needn't be essential to pains: pains are events, not objects,
and events don't have essences; and the reference of "pain" is fixed by
topic-neutral descriptions. With remarks on pains vs. pain-sensations.

Studies in the Philosophy of Science 9.
"Brain state" reference is fixed by topic-neutral description; picks out pain
but mightn't have, explaining the illusion of contingency. "Nonphysicalist
materialism" results, with mind the essence of matter. An important paper.

2:78-80. Reprinted in (N. Block, ed) _Readings in the Philosophy of
Psychology_ (MIT Press, 1980).

Token identity theories aren't vulnerable to Kripke's argument: it may be essential to this pain that it is a C-fibre firing, although not to pain as a type.

We can explain away the apparent contingency of identity in terms of possible differences in *evidence* for the physical state. With a discussion on identities between something perceived and something described.

"Pain" need not be a rigid designator, but instead may pick out a state by its causal role. If it is a rigid designator, then the apparent contingency of identity comes from imagining something else filling the causal role.

The reference of "C-fibre stimulation" might be fixed contingently, allowing the intuitive contingency of identity to be explained away.

Contra McGinn 1977, the counterpart strategy fails as any pain that occurred here now would have been this pain. A counterpart strategy on brain states may work. With a reply by McGinn and a later rejoinder by Woodfield.

1.3d Arguments from Disembodiment [see also 1.3b, 1.3c]

Argues that materialism is only contingently true, as it's conceptually possible that we could become immaterial by gradual replacement.

Physicalism is compatible with the possibility of disembodiment: one can hold that mind and body are identical, that the body is physical, but that it is not essentially physical.

There's no reason to believe that disembodied existence is possible: lack of logical contradiction doesn't imply possibility, conceivability is too weak a criterion, and it's not obvious that the situation is imaginable.

1.3e Consciousness and Physicalism, Misc [see also 1.2, 1.3, 1.7b, 3.5b]

Defending type materialism, by way of criticism of dualism and functionalism. With treatments of introspection, sensory concepts, and other minds.

On why materialism requires conceptual analysis to locate mental properties in the natural world. Even a posteriori necessary connections have to be backed by a priori links. With remarks on supervenience. A nice paper.

If every physical events has a physical explanation, and the mental is causally efficacious, then mental facts are strictly implied by physical facts. A nice argument.

Physicalism requires that all mental facts be strictly implied by the physical facts. Once this is recognized, questions about necessary or contingent identity are beside the point, and indeed identity is irrelevant.

On the problems posed for materialism by intentionality, autonomy, awareness, and indexicality. Tentatively advocates a Cartesian position.

Seager, W.E. 1992. _Metaphysics of Consciousness_. Routledge and Kegan Paul. Consciousness could be physical even if not explicable; but supervenience worries make it hard to see how it *could* be physical, though causal role suggests that it must be. We need a new conception. A stimulating book.

On the place of "occurrent pink" and the "sensorium" in the physical world. It may turn out that the physics of the brain differs from other physics, in order to accommodate the causal role of sensations.

Smith, A.D. 1993. Non-reductive physicalism? In (H. Robinson, ed) _Objections to Physicalism_. Oxford University Press. A careful discussion of how to characterize physicalism, in terms of identity or supervenience, and argues that physicalism must reduce (bowdlerize) qualia to something they are not, as physicalism requires topic-neutral analyses.

1.3f Consciousness and Dualism [see also 1.2c, 1.3, 3.4d]

Latham, N. 2000. Chalmers on the addition of consciousness to the physical

A dialogue with a "hyperdualist". On the pros and cons of materialist vs. dualist ontology and cosmology. Dualism avoids the "magic" of emergence at the cost of an inflated and bizarre ontology.

On the non-physical nature of consciousness, and the threat of a merely contingent connection to behavior; suggests a denial of "Hume's principle". Perhaps consciousness is the noumenal essence of the physical. A nice paper.

1.3g Mind-Body Problem, General

An overview: behaviorism, identity theory, functionalism, etc.
Yes it is. Empirical evidence bears on materialism, property dualism, emergentism, functionalism, interactive dualism, idealism, etc.

The core of the mind-body problem is the first/third-person asymmetry. It's like a periscope trying to place itself between its crosshairs. But this doesn't imply any strong ontological consequences.

Against "neural functionalism", and on how Searle's view reduces to either neural functionalism or property dualism.

On the mind-body problem and physical theory. Against reductive physicalism; instead, experience is the intrinsic nature of the physical. Discusses the interpretation of quantum mechanics and much else. A very enjoyable book.

On ways in which we might locate consciousness within the natural world via
scientific study. Perhaps we need a wider conception of objective reality.

A collection of 27 (mostly original) papers on the mind-body problem.

1.4 Specific Views on Consciousness [see also 1.2, 1.3, 1.5c]

1.4a Higher-Order Thought Approaches (Rosenthal, etc) [see also 6.2i]

Higher-order thought theories have two unacceptable consequences: one can notice one's hearing a sound without noticing one's consciousness of the sound; and one can unconsciously perceive one's surroundings as gloomy.

Argues for a distinction between conscious and non-conscious experiences, depending on whether one is conscious of the experience. Animal experiences are of the second kind, and therefore are not morally significant.

Advocates the "reflexive thinking" account of consciousness over Kirk's "presence" account. Availability for reflexive thinking is naturally necessary and sufficient for qualia. Interesting paper.

Against higher-order thought accounts: one can have a conscious experience without being aware that one is having it. With remarks on thing-awareness vs. fact-awareness and on "inner-sense" accounts.

We're not conscious *of* our experience in general, but conscious *with* it.
Criticizes HOP theories (not conceptualized enough) and HOT theories (rules out animals; there's more in experience than thought).

Argues that a higher-order thought is insufficient for consciousness, even with Rosenthal's constraint. A causal constraint is required, but the only strong enough such constraint doesn't work.

Carruthers 1989 misanalyzes higher-order thought theory. There's no need for conscious HOTs, and not too much conceptual sophistication is required, so animals might have HOTs and therefore conscious pains.

A critique of higher-order-perception theories of consciousness. They're either committed to a "representational divide" fallacy or collapse into higher-order-thought or first-order theories.

Various points against Carruthers 1989. His examples of nonconscious experience are likely conscious, and the higher-order account is circular.

Argues for a Lockean quasi-perceptual view of consciousness as internal monitoring via second-order states. Contra objections, e.g. Rey's point that it makes consciousness too prevalent -- consciousness isn't an on-off affair.

Conscious belief (or assent) is believing that one believes. Addresses various objections, from self-deception and from consciousness of assent. Communication needs conscious belief, not just belief.

On various pros and cons of HOT theories, to do with reflexivity, objects of HOTs, introspection, and so on. With comparisons to "intrinsic" theories.

On three theories of our direct awareness of conscious states: mental-eye theories, self-intimational theories, and appendage theory (i.e. HOT theory) is promising, but how does an HOT determine its object?

On the differences between first-order and second-order consciousness. Second-order consciousness is essential for communication and locomotion. With remarks on "nonconscious consciousness".

Separates CN (phenomenological) from C1 (info-processing) and C2 (higher order beliefs). CN is a subset of CS (image-representation state). We are always C2 of CN states, but not of other CS states: unconscious sensations!

Argues that we need not be apperceptively aware of phenomenal states. Introspection leaves the matter open, but some empirical results (e.g. hue blindsight) and theoretical arguments support dissociability.

Consciousness should be construed neither as sensation nor intentionality, but as the existence of higher-order thoughts.

A conscious mental state is a state that is the subject of a higher-order thought. Consciousness is not essential to mentality, should be separated from sensory quality, and is not an intrinsic property of conscious states.

Because verbally expressing and reporting are easily and immediately connected for 1st-order thoughts. But not for 2nd-order thoughts. Hmmm.

Conscious states are states that are the contents of higher-order thoughts. Express/report distinction: we report them, and express the HOT (which may be unconscious). Defense against dispositional and collapsing objections.

Distinguishes the sense in which we are aware of conscious states; argues for the separation of consciousness and sensation; and outlines how higher-order thoughts might explain the what-it's-like of conscious states.

In response to Natsoulas, HOT theory needn't answer the general question of how intentional states determine their objects. With remarks on the
other alternatives and the dangers of self-intimation.

1.4b Dennett on Consciousness [see also 1.7c]

Criticizing Dennett's accounts of pains, dreams, and images: in no case do his arguments earn their eliminative conclusions.

Reportability is no good for capturing consciousness: it completely leaves out the qualitative content of conscious states.

Argues that Dennett's account of the blindspot and scotomas are wrong. Neurophysiological data suggests that blind areas are represented explicitly; psychological data shows that it's not just "more of the same".

On various notions of awareness: contents of the speech center, contents directing behavior, and contents of attention. We have privileged access to one sort, but it is a different sort that plays the main role in control.

Conscious contents are contents of a buffer memory to which a public report module has access. We only have conscious access to propositional judgments, not to underlying processes. With a cute functional diagram.

There is no real phenomenology. There are only *judgments* about phenomenology, and nothing more is going on. We don't have privileged access to anything, except perhaps certain propositional episodes.

We can study consciousness by the method of heterophenomenology: studying the things we say about conscious states, which we can interpret as we interpret texts. Autophenomenology gives nothing extra. With comments by Rorty.

Consciousness is a virtual machine which evolved.

Arguments against the "Cartesian Theatre", advocating a "multiple drafts" model of consciousness. Presents a detailed model of processes underlying verbal report, and argues that there is nothing else (e.g. qualia) to explain.

Using temporal anomalies in consciousness to support a "Multiple Drafts" theory of consciousness rather than a "Cartesian Theater". Contents of consciousness are wholly determined by effects on action/memory.

A discussion of _Consciousness Explained_, with comments by Tye, Jackson, Shoemaker, and Rosenthal, and a reply by Dennett.

A reply to Clark, Fellows & O'Hear, Foster, Lockwood, Seager, Siewert, and Sprigge.

A reply to Baars & McGovern, Mangan, Toribio.

Dennett, D.C. 1995. Is perception the "leading edge" of memory. In (A.
There is no "leading edge" of consciousness, separating perception and memory. With an analysis of metacontrast cases, etc.

Criticizes Dennett's first-person operationalism as Cartesian. There can be awareness without judgment -- e.g. non-epistemic perception. This comes from information or "micro-judgments", and is not conceptual.

Presses Dennett on the "truth-maker" question for materialists: what sort of physical fact makes it true that people are conscious?

Joycean machines and multiple drafts turn out to shed no light on the question of what features make a conscious system conscious.

Argues for a suitably sophisticated Cartesian Theatre, and against the identification of phenomenology with judgments.

Brings empirical evidence to bear against Dennett's "filling-in" account of the blindspot, and argues that blindsight and the blindspot aren't analogous.

Argues that Dennett's verificationism begs the question, and that "seeming" cannot be identified with believing or judging.

1.4c Functionalism [see also 1.4a, 1.4b, 1.5c, 1.8, 3.4]

Contra Kripkean arguments, a good enough functional theory may help close the conceivability/explanatory gap between the physical and qualia. Contra Nagel/Jackson, such a theory could provide us with recognition abilities.

Arguments that introspective access is essential to many sorts of mental state, due to constitutive rationality requirements. Against a perceptual model of introspection; introspecting and introspected states are closer than that.

How functionalism can handle consciousness: Self-consciousness is the possession of reflexive metapsychological information. This helps understand learning, representation, and belief. Phenomenal experience is still tricky.

1.4d Eliminativism [see also 1.7c, 2.1c, 3.5c]

Experimental evidence against consciousness/introspection/transparency.

Argues that dreams might not be experienced, but rather be stored directly into memory (the "cassette-tape" theory of dreaming).

Consciousness is an indispensable concept in anesthesiology, and therefore (contra Churchland and Wilkes) is a scientifically legitimate kind. With empirical details and anesthesiological theory on levels of consciousness.

One could make a machine, duplicating the usual abilities that go along with consciousness, but surely it wouldn't be conscious. So what are the conditions for consciousness? Maybe there are none.

A rerun of Rey 1982: An unconscious machine could duplicate all the obvious criteria for consciousness, so maybe even we aren't conscious. With remarks on the relation between our belief in consciousness and consciousness itself.

We "project" consciousness into ourselves and others. There are no explanation-transcendent phenomena for which there is non-question-begging evidence. With remarks on self-attribution and Wittgenstein.

Commentary on Rey 1986: we are directly aware of our consciousness. It's not a theoretical entity, but rather something to be explained.

A skeptical argument: single neurons are not conscious, and adding a neuron won't produce consciousness, so finite brains are not conscious.

No, and it's not very coherent either. It divides into awakeness, sensation, sensory experience, and propositional attitudes. Also a history of the term.

Consciousness is not a tenable notion in either commonsense or scientific psychology; we should return instead to the "psuche".

1.4e Epiphenomenalism [see also 1.3a, 1.3f, 1.6e, 3.6]

Considers major arguments against the causal or explanatory irrelevance of consciousness -- arguments from self-knowledge, memory, reference, etc -- and argues that none pose fatal flaws.

Discusses two senses of "epiphenomenalism" -- "Huxley's" and "philosophical" varieties -- and argues that the philosophical sort is crazy. (N.B. Huxley actually subscribed to the "philosophical" variety.)

Uses the Mary thought-experiment to argue that qualia are epiphenomenal, and argues that epiphenomenalism is a tenable doctrine.

If Campbell's imitation man is possible, then the causal relation between the physical and phenomenal is unreliable.

Argues that phenomenal information implies epiphenomenalism, even at the intra-psychic level. With remarks on ineffability and on whether properties should be individuated by nomic role or by essence.

World_. Oxford University Press.

Argues with Elitzur on quantum mechanics and consciousness. With response.

1.4g Panpsychism [see also 1.4h]

----------------

There are no strong arguments against panpsychism, and good reason to take it seriously. Extrapolating the processing properties crucial for standard complex experience suggests that simple process may yield simple experience.

An analysis of a debate between Griffin and McGinn on panexperientialism, arguing for new forms of understanding.

An excellent review article on panpsychism; highly recommended.

An interesting paper arguing for an experiential aspect in all matter,

   Argues for a new fundamental feature ("X") which stands to consciousness as time stands to motion, thus making consciousness possible and ubiquitous.

   Material composition, nonreductionism, realism, non-emergence => panpsychism.

   On why consciousness extends beyond the cognitive.  Argues that fundamental laws for consciousness must connect at a basic level, and argues that panpsychism is not as implausible as often thought.

   Examines a position on which experience is fundamental to the world, and suggests that this ought to lead to panpsychism.  With some connections to information and quantum mechanics.

   On Nagel 1979: emergence is more plausible than panpsychism.  A construal of emergence as nomological supervenience without logical supervenience.

1.4h Intrinsic Monism (Russell, etc) [see also 1.4h]

http://www.u.arizona.edu/~chalmers/biblio/1.ascii (41 of 70) [4/7/2002 1:50:18 PM]
Physics is dispositional, but if there are only bare dispositions, then the world has no nature of its own. And if there are categorical grounds, we have no idea what they could be, except maybe subjective qualia.

An "it from bit" view fits the Russellian metaphysics (described earlier): physics is info from the outside, (proto)experience is info from the inside. The problem is constituting macrophenomenal from microphenomenal; some ideas.

A nice account of Russell's (and Schlick's and Carnap's) structuralism and Newman's objection, with analysis. (N.B. no philosophy of mind.)

A long and very interesting essay on the mind-body problem. Ultimately advocates a "structural" view of the physical and identifies experience with the underlying reality, at least for some neurophysiological states.

Argues that Russell's and Schlick's views on the structural nature of physics and the possible identification of the "content" with experience are quite close to each other. With interesting historical remarks.

Argues that the Russellian view is implausible, as the structure of the underlying physical processes does not correspond to the structure and quality of consciousness.

On the mind-body problem and physical theory. Against reductive physicalism; instead, experience is the intrinsic nature of the physical. Explores some potential links with quantum mechanics.

On the "grain problem" for the intrinsic-nature view: how do lots of microphysical qualities add up into a smooth experience? Appeals to quantum mechanics and a preferred set of observables.

Newman, M.H.A. 1928. Mr. Russell's causal theory of perception. Mind. Argues against Russell's structuralism: any collection can be arranged to have a given structure, under some relation, so if physics tells us only about structure, it tells us at most the cardinality of the world.

Russell, B. 1927. _The Analysis of Matter_. London: Kegan Paul. Argues that physics characterizes the external world only structurally, and leaves intrinsic qualities unspecified. Only experience acquaints us with anything intrinsic. Perhaps the intrinsic nature of physics is experiential?

Schlick, M. 1925. _General Theory of Knowledge_.

1.5 Consciousness and Content
-----------------------------

1.5a Consciousness and Intentionality (Searle, etc)
-----------------------------------------------

Crane, T. 1998. Intentionality as the mark of the mental. Philosophy.

Searle's formulation of the connection principle is unclear, and there is no formulation is both plausible and interesting.

About conscious beliefs. We are not "conscious of" beliefs, merely "conscious that" -- i.e. belief is not phenomenological.

Against Searle: some intentional states aren't even potentially conscious (blindsight, etc) and intentional content doesn't require a particular phenomenal feel. So there's no essential link. With remarks on McGinn.

Searle, J.R. 1984. Intentionality and its place in nature. Synthese. (Subjective) intentionality sure is real. It causes and is caused.

Advocates a "connection principle": intentional states must be potentially conscious. If not, they're brutely neurophysiological. So cog-sci talk of "intentional" cognitive mechanisms below the conscious level isn't justified.

Clarifying the connection principle -- it's necessary in order to see how certain nonconscious neural states qualify as unconscious mental states.

Worley, S. 1997. Belief and consciousness. Philosophical Psychology 10:41-55. Argues that belief requires consciousness, as we can't make sense of the personal/subpersonal content distinction without appealing to consciousness.

1.5b The Content of Experience
-------------------------------

Davies, W.M. 1996. _Experience and Content: Consequences of a Continuum Theory_. Avebury.

DeBellis, M. 1991. The representational content of musical experience. Philosophy and Phenomenological Research 51:303-24. Contra Peacocke, we don't need sensational properties to understand the content of musical experience. Fine-grained representational properties can do the job, with the help of some Schenkerian analysis.

Peacocke, C. 2001. Phenomenology and nonconceptual content. Philosophy and
Phenomenological Research 62:609-615.

Lots of reasons why experiences have propositional content (i.e., their content is truth-evaluable, etc). A nice paper.

1.5c Representationalism
------------------------

Uses Inverted Earth case, colors and lenses inverted, to argue vs Harman that qualitative states aren't intentional states. Also, less convincingly, to argue that qualitative states aren't functional states.

There are no real qualia problems, just Intentional confusions.

Suggests that conscious states are identical to representational states, and that unconscious representation is impossible; transition between conscious states is non-representational. Appeals to connectionist models in support.

Argues that consciousness and representation are distinct, as e.g. the latter depends on context but the former does not.

The phenomenological can be reduced to the intentional. Intentional states have a what-it-is-like, and there is no special phenomenal object of introspection.

Qualia can't be reduced to standard intentional properties (due to certain inversion cases). Projectivist and sense-reference accounts don't work either. Perhaps qualia are necessarily-illusory intentional properties.

On the relationship between phenomenal and intentional aspects of qualia, and in particular on the accessibility of qualia to conscious awareness. Phenomenal & intentional similarity are connected but must be distinguished.

Tye, M. 1994. Do pains have representational content? In (R. Casati, B.
Smith, & S. White, eds) _Philosophy and the Cognitive Sciences_.
Holder-Pichler-Tempsky.

Argues that pain is representational, and that its phenomenal character is narrow nonconceptual content. They have a complex representational structure, with map-like arrays of sentential contents.

Tye, M. 1995. What "what it is like" is like. Analysis.
Argues that "what it is like to be X" is an intentional context, which solves some of the associated problems.

1.5d Internalism and Externalism about Experience [see also 2.2]

Argues that perceptual content does not supervene on internal state, even though it is non-conceptual. Constructs an Twin scenario to that effect. With remarks on the relation between perceptual content and phenomenology.

Distinguishes modal and constitutive externalism, characterizes perceptual content and its relation to sensational content, and argues for externalism about perceptual content by examples.

Argues that a swampthing isn't intelligent or intentional, with different physiological processes and no sensations, as these are functional kinds.

Dretske, F. 1996. Phenomenal externalism, or if meanings ain't in the head, where are qualia? In (E. Villanueva, ed) _Perception_. Ridgeview.
We only have access to qualia through our concepts, which are external; so internal qualia would be inaccessible. So if qualia are knowable, they're external; and if not, why posit them? With comments by Kim, Horwich, Biro.

1.5e Miscellaneous

1.6 Aspects of Consciousness
1.6a Self-Consciousness [see also 6.2o]

James, W. 1890. The consciousness of self. In _The Principles of Psychology_.

How functionalism can handle consciousness: Self-consciousness is the possession of reflexive metapsychological information. This helps understand learning, representation, and belief. Phenomenal experience is still tricky.

Weird examples of homunculi that are conscious but not self-conscious. Self-consciousness, not consciousness, is what really counts.

1.6b The Unity of Consciousness [see also 5.12d, 6.1e, 6.1g]

1.6c Homogeneity of Consciousness (Sellars, etc)

Explains homogeneity in terms of nontransitive matching among pixelized parts
of vision. Experience of continuity, not continuous experience. Experiences may have subphenomenal parts (e.g. invisible pixels).

1.6d Knowledge of Consciousness [see also 1.3a, 1.8a, 5.13, 6.2i]

Qualitative beliefs can supervene on behavioral dispositions even if absent/inverted qualia are possible. We just individuate belief contents and behavior widely, with wide content fixed to the qualia.

A discussion of in what sense we are aware of qualia, and how we can have beliefs about them, with reference to Sellars. Ends up reducing qualia to phenomenal beliefs in a language of thought. A rich and subtle paper.

Reconstructing the Mary case as a Marianna case, and introducing a distinction between phenomenal and nonphenomenal beliefs, to support the knowledge argument. A very nice and sophisticated paper.

Robinson, W.S. 1982. Causation, sensation, and knowledge. Mind 91:524-40. Argues that we can have non-inferential knowledge of sensations even if they don't make a causal difference to our beliefs, so epiphenomenalism is OK. All theories have a similar problem.

We have a limited special authority about the contents of our mental states. This follows from the link between a state and beliefs about it in the functional definition of that kind of state.

von Eckardt, B. 1975. Some consequences of knowing everything (essential) there is to know about one's mental states. Review of Metaphysics 29:3-18.

1.6e The Function of Consciousness [see also 1.4e, 6.4a]

------------------

Argues for nine major functions of consciousness: in defining inputs, adaptation, debugging, recruiting & control, prioritizing, decision-making, analogy-forming, self-monitoring, and self-maintenance.

Contra Popper, evolution doesn't provide an argument against physicalism or epiphenomenalism. Speculation on what the function of consciousness might be, and how it might be realized: e.g. selecting information.

Separates phenomenal consciousness from access consciousness, and argues that cases like blindsight only suggest a function for access consciousness, not phenomenal consciousness. The latter remains a mystery. With commentaries.

Argues for the possibility of zombies (contra Moody), then notes that any function could be performed by an unconscious zombie, it seems, so there's no function of consciousness in sight.

Suggests that qualia serve to distinguish hypotheses about present from past.

Contra Mott 1982: Function needn't be exclusive, and brain processes and consciousness may share a function, due to their close relationship.

Function always underdetermines intrinsic nature, so absent/inverted qualia cases aren't incompatible with consciousness having a function.

Consciousness doesn't have a function, as any function it might have is a function of brain processes.

Argues that the function of consciousness is not obvious, but that once one accepts a representational view of consciousness, it becomes obvious.

Trying to counter absent qualia arguments by finding a role for consciousness e.g. in metacognition, or as as a way to achieve semantic transparency. But consciousness doesn't seem necessary for these, so it's still a mystery.

Velmans, M. 1992. Is human information-processing conscious? Behavioral and Brain Sciences 14:651-69. Uses experimental evidence to argue that consciousness is functionally inessential: the tasks associated with consciousness can be performed without consciousness. Only focal-attentive processing is required.

1.7 Qualia
------------

1.7a General
------------

Clark, A. 1985. Qualia and the psychophysical explanation of color perception. Synthese 65:377-405. One can give an information-theoretic explanation of color perception, which leaves nothing out. Rebut various qualia objections, e.g. from the possibility of inversion. Qualia are codes for external properties.

Clark, A. 1992. _Sensory Qualities_. Clarendon. Argues that psychology is in the business of explaining sensory qualities, and does a perfectly good job using discriminability as a basis. With detailed argument and many interesting examples.

Searching for a theory of qualia: rejects epiphenomenalism, separation of the form and quality of experience, and immediate perception of phenomenal objects. Experience consists in represented (inexistent) objects of thought.

Against an account of phenomenal content as given by inner discrimination. Argues that the character of experience consists in its reason-giving role.

Qualia problems stem from assuming direct awareness of perceptual states. Instead, we should acknowledge only an ability to detect and label these states. Also argues for the possibility of unconscious and illusory pains.

A discussion of in what sense we are aware of qualia, and how we can have beliefs about them, with reference to Sellars. Ends up reducing qualia to phenomenal beliefs in a language of thought. A rich and subtle paper.

Lormand, E. 1995. Qualia! (Now showing at a theater near you.) Philosophical Topics 22:127-156.

Sensations are an inessential element of experiences. Experiences are typed by their cognitive component, and the naming of sensations is derivative on this. With examples and empirical evidence about pain, color, perception.

Considers qualia, inverted and absent, and various other stuff. Wishy-washy.

Explicating sensory experience in terms of an appropriate computational relation to a sentence in the language of thought. Argues that this handles
many features of qualia (privacy, ineffability, grainlessness, unity, etc).

1.7b Qualia and Materialism [see also 1.2, 1.3]

are problematic for materialism. Considers the case for phenomenal individuals, and argues that they are intentional inexistents.

Qualia aren't reducible to physical properties, but they are supervenient (and ontologically dependent) on microfunctional properties. With remarks on the knowledge argument, Kripke, absent qualia, epiphenomenalism, etc.

Argues that our inability to reidentify qualia is a problem for materialism. How are they represented? Empty demonstrative would be vacuous, predicate would be reidentified, so maybe a plain presentation? Very interesting.

Absent/inverted qualia aren't really imaginable. The Knowledge Argument fails, as discovering new experiences doesn't imply learning new facts, but only coming to know old facts in a new way.

1.7c Eliminativism about Qualia [see also 1.4d]
-------------------------------

The concept of pain is incoherent, as it's asked to do too many things at once. With a discussion of drugs, flowcharts, reportability, etc.

A response to Sellars. All there is to seeing occurrent yellow is the judgment that one is seeing occurrent yellow.

Argues against the existence of ineffable, intrinsic, private, directly accessible properties. With lots of meaty-thought experiments, and arguments that there is no fact of the matter about inversion cases.

There are no qualia: qualia would have to be vague (for Sorites reasons), but there can be no vague properties in nature. The usual Sorites defenses don't work here, as there's no appearance/reality distinction for qualia.

Arguing against eliminativism for qualia. Even if nothing satisfies all the common-sense properties of qualia, reference of qualia terms is still fixed under a Putnam-style theory of meaning. Argues for scientific functionalism.

There are no irreducible phenomenal properties. Materialism can handle our direct awareness of inner states by the right sort of causal connection. Gives a materialism account of discrimination and learning mental concepts.

On bold vs. modest qualophilia, and against various qualophobic strategies. With remarks on scientific objectivity, qualia as an explanandum, and on how our knowledge of qualia is consistent with the conceivability of zombies.

Dennett's 1988 argument against ineffability, etc., doesn't nearly make the case against qualia, and largely relies on verificationist assumptions.

1.7d The Inverted Spectrum
--------------------------

Uses Inverted Earth case, colors and lenses inverted, to argue vs Harman that qualitative states aren't intentional states. Also, less convincingly, to argue that qualitative states aren't functional states.

Functional role counts more than qualitative content in determining what e.g. "redness" is.

Argues that there could be inverted spectra even without a symmetrical color space. Qualia must be distinguished from their place in color space.

Acquired spectrum inversions do not refute functionalism, if qualia revert after behavioral adaptation (as they do with inverting lenses).

Describes some "inverted spectrum" scenario in computer registers, and argues that in the absence of a "central clearing house", the inversion of qualia is indeterminate. There's no reason to believe in non-dispositional qualia.

Inverted spectra with constant behavior is a meaningful hypothesis even under verificationism. Switching nerve endings, tinting contact lenses, etc.

On the physiological bases of phenomenal states, particularly color. Inverted spectrum isn't really coherent, as coolness/warmth would have to be inverted too. So the contingency of qualia is diminished.

Distinguishes various functionally distinct inverted spectrum cases.

Reply to Levine 1991. "Green residue" and "red residue" may be identical. Physiology might put more constraints on qualia, eventually ruling out all
other possibilities. But there may still be absent/alien qualia problems.

The inverted spectrum is impossible, due to asymmetries in color space.

The inverted spectrum can be detected, if a single person experiences both.

Against Shoemaker: physical realizations do not give empirical conditions for qualia inversion. Nice.

The possibility of an inverted spectrum w.r.t. dispositions implies the falsity of physicalism. But this rests on an implausible "slide-viewer" model of seeing, and is incoherent otherwise.

Inverted qualia, with respect to a functional account, are no more plausible than absent qualia (by analysis of thought experiments). Both lead to first-person skepticism about qualia.

Contra Hardin 1988: there's a "green residue" after coolness is subtracted, so inverted spectrum could still be possible. In any case, the impossibility of IS doesn't affect the explanatory gap for qualia, which is epistemic.

Inverted spectrum holding behavior constant is at least a coherent idea. Hook up brain in different ways, etc.

Argues that qualia are intentional properties, and that inverted spectra, though conceivable, are metaphysically impossible, due to considerations about society and normality. Argues against Block's "inverted earth".

A fascinating note on the possibility of people with doubled colorblindness genes, thus inverting color processing; such people may actually exist.

Argues for a computational/sentential theory under which qualia are fixed by
functional organization. Argues against Block's 1990 inversion: qualia might slowly change back as associations fade. Memory isn't 100% reliable.

    Maybe IS is ongoing, with memory changes. What is the logic of "appears"?

    All about the coherence and otherwise thereof. Uses switch in state for IS wrt behavior. Also claims that IS wrt function is possible as qualia are fixed by realizing state, not functional state. Bad assumption.

    Inverted spectra thought-experiments show that experiential content is incommunicable. Accounts for the fact that attempts to describe such cases lead to contradiction (I'm seeing green & not seeing green).

    Argues that qualia are intentional properties, along the lines of "looks F to P". Handles inverted earth and related cases by taking the narrow intentional content. With remarks on the semantics of color terms.

1.7e Absent Qualia (Block, etc) [see also 1.3b]
-------------------------------
    As a criticism of functionalism. raises the possibility that realizations of any given functional account of mental states may lack qualia.

    All kinds of absent qualia cases: homunculi-headed robots, the population of China, and so on. There is a prima facie doubt that such cases lack qualia, so there is a prima facie case against functionalism.

    It's OK for bizarre realizations to lack pain, as functionalism requires teleology as well as organization. With remarks on the relation between pain and "introspectible noxiousness".

    Taking the personal stance, we should regard the Chinese nation as having qualia. A lack of qualia would make a functional difference.

    Absent qualia are impossible. Also, qualia aren't essential to mental state, functional role is.

    Replace neurons one by one with homunculi: what happens? Beliefs don't change, does consciousness fade? Very nice.

    If absent qualia are possible, then either qualia are inexplicable or species
chauvinism is true. Homunculi-heads could make similar arguments about us.

Conceivability arguments are only a problem for empirical functionalism insofar as they are a problem for materialism in general. Very true.

Argues that metaphysical conclusions can be drawn from conceivability arguments, but that absent qualia cases have not been clearly and distinctly conceived. The functionalist is better off than the identity theorist here.

IQ are no more plausible than AQ (by analysis of thought experiments and skepticism). So there's no reason to choose physicalist-functionalism over pure functionalism, as Shoemaker does. Nice.

The Chinese Nation would require less people than Churchland & Churchland 1981 suggest, as we'd only need to handle a subset of all possible inputs.

Gives a thorough neurophysiological analysis of blindsight and related pathologies, and argues that these cannot be used to support the possibility of absent qualia. With remarks on the mystery of consciousness.

1.7f Introspection and Absent Qualia (Shoemaker) [see also 1.6d]

Absent qualia possible => qualia make no causal difference => no knowledge of qualia, therefore absent qualia are impossible. If qualia are introspectively accessible, they must be functional. An important argument.

Reply to Block 1980. Distinguishes two AQ theses, and argues that if AQ are possible, then the problem for functionalism isn't due solely to qualia.

Defending Shoemaker's argument against Conee: immediate awareness and qualitative beliefs are the same. But maybe people *can't* tell whether they're having genuine or ersatz pain. Eliminativism is the best option.

Reply to Shoemaker 1975. The possibility of absent qualia is compatible with a functional role for qualia, as qualia can make a causal difference that is independent of a given functional account.

Contra Shoemaker: qualia cause qualitative beliefs, which are affected by the absence of qualia, so we know about qualia even if AQ are possible.

Elucidating Shoemaker's argument: if absent qualia are possible, then the difference between real and ersatz pain makes no difference to belief, so qualia aren't introspectively accessible. A nice analysis.

Qualia and qualitative beliefs are the same, so Shoemaker's argument fails. A numbness/pain inversion argument shows that pain isn't a functional state; it yields an introspectible difference without a functional difference.

Qualitative beliefs can supervene on behavioral dispositions even if absent/inverted qualia are possible. We just individuate belief contents and behavior widely, with wide content fixed to the qualia.

Argues that the possibility of absent qualia is compatible with introspective knowledge. The fact that we have evidence of qualia isn't altered by the fact that we'd still think we had that evidence if we didn't have qualia.

Shoemaker's account leaves out experienced relations, such as experienced similarity. Experienced similarity is not the same as similarity between experiences. Being experienced is not an experienced feature.

1.7g Functionalism and Qualia, General
--------------------------------------

Various comments on functionalism's troubles with qualia, including absent and inverted qualia. Analogis with biology and information theory.

Press.
Argues that absent qualia and inverted qualia are empirically impossible (though logically possible), using neural-replacement thought-experiments. So functional organization fully determines conscious experience.

Acquired spectrum inversion doesn't refute functionalism, if qualia revert after behavioral adaptation. With empirical evidence.

Pain-qualia are in the body, not the mind, and so aren't part of psychology.

Gives a number of arguments against both analytic functionalism and psychofunctionalism: arguments from absent qualia, absent functional role, epistemology, semantics, and heterogeneity of functional roles.

Argues that non-phenomenal mental events are functional, while qualia are low-level physiological.

Accuses Block of a perspective error. Functionalism can handle a lot, if it's multi-levelled.

Various stuff, mostly against absent qualia arguments.

Behavioral evidence for qualia is always indirect. And you can't check by replacing own neurons by chips, as you'll still believe you have qualia if you're functionally identical. Posit robot qualia as explanatory construct?

Computational functionalism about qualia is compatible with Wittgenstein's views. It makes sense of the points about "dividing through" my private objects, for example. With remarks on spectrum inversions.

Functionalism can't explain the causal role of qualia by identifying them with functional states (circularity) or physical realizations (chauvinism). Which leaves property dualism, epiphenomenalism, or eliminativism for qualia.

Against drawing strong conclusions from first-person imaginings. Considers Searle's silicon-replacement scenario: we might infer that perception isn't veridical, that there's another mind about, or even another body.

Commentary on Moor 1988. Systems that differ in qualitative properties will...
likely differ in functional organization.

Criticism of "physicalist-functionalism", where functional organization doesn't completely determine qualia (e.g. Shoemaker/Block). The only tenable options are pure functionalism or transcendental dualism. Nice.

Taking transcendental dualism seriously. Privileged access provides strong arguments against objective theories, but it turns out that transcendentalism can't explain it any better, so maybe embrace objective theories after all.

Replacing a brain chunk while preserving causal role must preserve experience;

2.1 The Status of Propositional Psychology

2.1a The Language of Thought (Fodor)

Argues that thought involves computation upon representations, and that these
are structured as sentences in a mental language. With linguistic and
psychological evidence, and arguments that the mental language is innate.

Fodor, J.A. 1987. Why there still has to be a language of thought. In
_Psychosemantics_. MIT Press.
Because it fits explanatory methodology, it coheres with the usual
ontology of psychological processes, and it explains systematicity.

_RePresentations_ (MIT Press, 1980).
About what PA's are, and why they're at the foundations of thought.

and Philosophy 23:49-55.

Argues that symbol processing can't account for the intrinsically contentful
nature of thought: using a symbol doesn't give understanding of its content.
With defense against arguments from twin earth and conceptual-role semantics.
No need to postulate LOT: diachronic explanation is as good as synchronic, and high-level laws can exist without high-level causal connections.

Review of Fodor's LOT. Fodor's view is too strong: function, not structure, is criterial for content. The structure of a predictive theory need not be directly reflected in inner processing.

On the explicit representation of belief: criteria, plausibility, and relationship to verbal reports and conscious judgments.

A general treatment of Fodor, identifying him as arch-conservative mentalist.

Relates Schank's conceptual dependency to Fodor's LOT.

Contra two of Fodor's arguments for LOT. Complex causes need not have LOT constituency structure; and evidence from psychological theory falls short.

Analyzes belief into a relation between a person and an internal sentence, along with a semantic relation between that sentence and e.g. a proposition. With arguments against functionalist analyses, and against propositions.

There are no good arguments for LOT of the form "The brain needs to do X, and X entails LOT". Considers X = concatenation, logical form, tracking, combinatorial encoding. Either LOT is weakened deeply or is unnecessary.

Argues that the primary role of language is in thought rather than in communication, and the language of thought incorporates natural language.

LOT confuses processes with descriptions of processes. Also, symbols cannot denote solely in virtue of structure, so must rely on human interpretation.

Defends sententialism of the homuncular variety: little modules all the way in. Lots of pro-belief arguments.

Distinguishes varieties of Sententialism, reasonable vs. mad-dog.

Argues from the unboundedness of thinking and the need for a finite stock of elements to something like a language of thought. With remarks on connectionism and instrumentalism, and a reply by Stalnaker.

Argues that contrary to some claims, cognitive psychology does not provide much support for a computational/representational theory of propositional attitudes. Specifically considers research in psycholinguistics and vision.

Fodor's theory can't deal with inexplicit attitudes: the core/derivative distinction is untenable. But we can make sense of intentional causation and psychological explanation without explicit representation.

On some problems typing tokens in the language of thought. There's no principled distinction between type-identical tokens and type-distinct tokens.
with an identity judgment. With interesting remarks on co-identification.

Arguments that there is no good way to individuate syntactic types in Mentalese. Neural typing, causal typing, and semantic typing all fail.

Arguments that the language of thought need not have a compositional semantics; productivity and systematicity can be explained without it.

On Danto's suggestion that beliefs are like sentences. Conventionality poses problems, as does differentiating between different sorts of attitudes.

Motivates LOT and defends it against various objections: e.g. tacit belief, identity conditions, infinite regress, and semantic nativism.

Tienson, J. 1990. Is this any way to be a realist? Philosophical Psychology.

2.1b The Intentional Stance (Dennett)

Can view systems from physical stance, design stance, or intentional stance.
Beliefs/wishes are attributed under the intentional stance, with help from certain idealized norms of rationality and accuracy licensed by evolution.

Reply to Stich 1981. Irrationality is misdesign (take design stance). Etc.

Beliefs/desires are useful predictive attributions. This isn't inconsistent with a certain degree of realism (abstracta/illata distinction).

TIS, with commentaries and replies.

Mental states are underdetermined: like interpreting a text, or finding an object's function. Even adaptationist teleology gives no fact of the matter.

Proposition attitudes have the ontological status of a noisy pattern that helps make sense of behavior. This degree of realism falls on a scale: Fodor > Davidson > Dennett > Rorty > Churchland.

Dennett vacillates between stance-dependence, -independence; e.g. on rationality, design features. Instrumentalism can't be rescued.

Dennett should be a realist, of the relative-to-environment variety.

Argues contra Dennett and Smolensky that language is fundamental, not just an add-on.

Questioning Dennett on the bridge between intentional characterization and functional characterization. Arguing for the importance of context.

Dennett's rationality/intentional idealization assumptions should not be viewed as Platonic but epistemic. PA's are real and play real roles.

Against "interpretivism" about intentionality: projectivism is hopeless, and Dennett's arguments for normativism (via charity and evolution) go wrong or beg the question.

   Dennett must be one of: realist, eliminativist, instrumentalist.

   Dennett's instrumentalism can't explain the acquisition of intentional concepts. Proposition attitudes are directly introspectible entities, although still theoretical and still patterns.

Slors, M. 1996. Why Dennett cannot explain what it is to adopt the intentional stance. Philosophical Quarterly 46:93-98.

   Critical review of _Brainstorms_, with response.

   Dennett has problems with rationality, realism, etc. Hard line/soft line:
either intentional stance is too close to FP or too far away.

2.1c Eliminativism (Churchlands) [see also 4.3c]

Churchland, P.M. 1985. On the speculative nature of our self-conception. Canadian Journal of Philosophy Supplement 11:157-173. Reply to Foss 1985: EM is plausible, though certainly not applicable everywhere -- e.g. sensations will be reduced, not eliminated.

Baker, L.R. 1988. Cognitive suicide. In (R. Grimm & D. Merrill, eds) _Contents of Thought_. University of Arizona Press. Eliminativism is pragmatically incoherent, as it implies that language isn't meaningful and that the thesis isn't formulable. Folk psychology needn't be scientifically reduced to be true. With comments by Chastain, and reply.

Bertolet, R. 1994. Saving eliminativism. Philosophical Psychology 7:87-100. Against Baker's cognitive-suicide arguments against eliminativism. We don't know what a replacement theory will look like, but that doesn't show that none is forthcoming.
   Argues for a revisionary reduction of the propositional attitudes, rather than
   elimination or smooth reduction. Sentential aspects will go, but coarse-grained
   functional profiles and content will remain.

   Quarterly 32:487-98.

   Irrealism about mental content (and therefore truth-conditions) can't be
   made sense of. An error thesis presupposes factual truth-conditions, and
   a non-factualist thesis presupposes a non-deflationary theory of truth.

   Quarterly 71:264-78.
   Reply to Devitt 1990.

Chater, N. & Oaksford, M. 1996. The falsity of folk theories: Implications for
   psychology and philosophy. In (W. O'Donahue & R. Kitchener, eds) _The
   Philosophy of Psychology_. Sage Publications.

Clark, A. 1996. Dealing in futures: Folk psychology and the role of
   representations in cognitive science. In (R. McCauley, ed) _The Churchlands
   and their Critics_. Blackwell.

   Philosophical Studies 56:53-75.
   Unbelief in belief is not incoherent. Argues with Baker.

Cling, A. 1991. The empirical virtues of belief. Philosophical Psychology
   4:303-23.
   Cognitive states like belief are necessary to explain the dependence of
   behavior on perceptual features of the environment. Informational states
   alone are not enough, as they can't explain selective response to features.

Devitt, M. 1990. Transcendentalism about content. Pacific Philosophical
   Quarterly 71:247-63.
   Against Boghossian's critique: the eliminativism will express her claim in a
   new framework, so appeals to truth beg the question. With a response.

   Philosophical Quarterly 72:87-100.
   Rejoinder to Boghossian 1990.

   EM needs much more evidence before being so gung ho.

Graham, G. & Horgan, T. 1992. Southern fundamentalism and the end of

   of Folk Psychology_. Cambridge University Press.
   Argues that folk psychological states exist, even if they aren't useful as
   causal explanation. We have independent reason to believe in them, e.g.
   from self-knowledge. They're useful in social psychology, too.

Greenwood, J.D. 1992. Against eliminative materialism: from folk psychology to
   Volkerpsychologie. Philosophical Psychology 5:349-68.
Argues that folk psychology is not a theory, and that psychological knowledge is a pre-theoretical given. With remarks on laws, the prediction of behavior, and neuroscience.

A bundle of arguments against eliminativism, e.g. from incoherence, the lack of alternatives, and against the folk-theory-theory. With commentary.

Defending folk psychology against the arguments of Churchland and Stich: e.g. incompleteness, stagnation, irreducibility, dual-control, modularity, and unfalsifiability. Even with no neat reduction, folk psychology may be OK.

FP is almost certainly true, irrespective of scientific absorbability or the language of thought. FP's commitments are austere, and mostly behavioral. Arguments from semantic competence and conceptual conservatism.

Argues that FP is not committed to much. The austere conception is supported by intuitions, conservatism, and the inconceivability of dropping it. Responds to phlogiston objections: they are not analogous.

Clarifies different senses of "theoretical" and "belief". Some beliefs are relevantly theoretical (dispositional, infra-conscious, unconscious ones), but conscious occurrent beliefs are not, and so can't be eliminated.

FP holds that beliefs/desires play a certain functional role, and it's almost certain that objects playing that role exist, so FP is fine, whether or not propositional attitudes are good scientific entities.

Even if nothing satisfies all or most common-sense properties of mental terms, reference can still be fixed under a Putnam style theory of meaning. (More about qualia than about intentional states.)

The Churchlands underestimate the resources of intentional psychology.

Uses empirical evidence to argue that there is prelinguistic awareness, so
nominalistic arguments for eliminativism fail. And some awareness is innate, so we can't reconceive things in less than evolutionary time.

The self-refutation objection reduces to other standard objections: counterexample, promissory note or reductio.

If connectionism is true, then eliminativism is true, as you can't isolate the causal role of individual beliefs in a connectionist system.

Response to Ramsey 1990: If there are no beliefs and so no assertions, there is no identifiable propositional content, and truth and knowledge are out. Eliminativism is pragmatically self-refuting.

A careful analysis of whether self-refutation arguments against eliminativism beg the question by supposing that assertion requires belief. An account of what it is to beg the question, and a comparison to arguments about vitalism.

There's no reason to abandon FP, even if it doesn't reduce.

Explaining how singular causal claims based on FP may be true even if FP is false; by analogy with phlogiston, and also because of near-vacuousness. EM isn't incoherent, as we can use a non-intentional replacement for belief.

Folk psychology is compatible with neuroscientific models, but it need not smoothly reduce to neuroscience to have an important role.

Eliminativism may have no determinate truth-conditions: if folk psychology is a poor theory, the question of whether or not "belief" refers may be empty.

Philosophical analysis isn't sufficient to understand intentional concepts; real cognitive science is required, with conceptual revision. The truth of eliminativism will be relative to the theory of reference that we choose.

Against transcendental arguments against eliminativism. These fail on their own terms, and even if successful they would not establish causal/explanatory relevance for the attitudes, which is the real key for folk psychology.

Wright, C. 1996. Can there be a rationally compelling argument for anti-realism about ordinary ("folk") psychology? In (E. Villanueva, ed) _Content_. Ridgeview.

2.1d Propositional Attitudes, General

-------------------------------------

Beliefs are OK, despite no physicalist reduction of content.

Against beliefs construed as physically realized internal causes of behavior: syntax of these states can't be determinate, and their explanatory role wrt causation leads to a circle. Belief is irreducible.

Remarks on the conceptual analysis of belief/desire attribution. On the roles of causation, inner-route explanations, belief-desire-action triangles, teleology, unity, the presumption of simplicity, and evolution.

On requirements for belief/desire explanations: input/output patterns, the unity condition (i.e. no single associated mechanism), and teleological bases for generalizations, e.g. through evolution or educability.

Argues that desire will smoothly reduce to a neurophysiological kind.

The conditions on being a believer are mostly behavioral; to claim otherwise is to fall into a "modularity trap". A counterfactual account of mental causation is enough. With a defense of mentality for giant look-up tables.

Stich is confused about type-token, syntax/content, etc.

A taxonomy of positions on the representation of propositional attitudes: dividing up via questions about realism, functionalism, monadicity, and truth-conditions. With arguments for structured representations.

Things are only syntactic (in SS's sense) in virtue of intentionality. True.

Manfredi, P.A. 1993. Tacit beliefs and other doxastic attitudes. Philosophy. Argues that there are no tacit beliefs: dispositions to believe can do all the explanatory work at lower cost. With some remarks on subdoxastic states, and the difference between belief and opinion.

A theory of propositional attitude ascription as like numerical measurement.

Folk psychology isn't a theory about laws, but about proper functions. desires are identified by proper functions; beliefs by Normal explanations.

Instrumentalism about belief can't be right, because of Martian marionettes, but the language of thought is too strong a requirement. A state's structured content may reside in its pattern of relations to other states.

Stich is wrong, circular, and representational anyway.

Must individuate mental states by semantics, not just by function.

Beliefs/desires are out, new Syntactic Theory is in.

2.1e The Nature of Folk Psychology
----------------------------------

Folk psychology is a theory: defense against objections from logicality, softness of laws, practical function, behavior, and simulation. It needn't be a deductive-nomological theory; e.g. it might be based on prototypes.
Folk psychology isn't all that bad. It survived evolution after all.

FP is craft, not theory. Opinions rather than beliefs are interesting.

On the psychology of self-ascription of mental states. Functionalism has serious problems, as we don't have direct access to causal roles. Defends a qualia-based account, even for propositional attitudes.

On the development of folk-psychological concepts in children. First the appearance/reality distinction, then more complex theories of perception, representation, and belief. Implications for the status of folk psychology.

Defending the claim that folk psychology is an empirical pre-scientific theory, with its own laws. In a particular, a detailed reply to the criticisms in Wilkes 1984.

Distinguishes internal and external accounts of folk psychology (mechanisms vs systematizations), and various versions of each of these. Only some are compatible with eliminativist arguments.

Common-sense psychology is no theory at all, and not in competition with scientific psychology. CSP is particular, rich, vague; SP is general, austere, precise. CSP will be neither subsumed nor eliminated by SP.

Argues that commonsense and scientific psychology are quite distinct in their aims, scope, framework, and nature, but have been confused by philosophy. With support from historical considerations.

2.1f The Simulation Theory

FP is a strategy for prediction via simulation; an ability, not a theory.

Nichols, S., Stich, S., & Leslie, A. 1995. Choice effects and the

2.2 Internalism and Externalism [see also 1.5d]

2.2a Is Content in the Head? (Putnam, Burge)

Developing an externalist account consistent with psychological explanation. Contra Burge, social links aren't constitutive of content. Causal links are indirectly constitutive of content, via our conceptions.

Belief contents are not fully determined by internal state, as the linguistic community plays an important role: arthritis, brisket, contract, sofa, etc. So mental states are not individuated individualistically.

On Putnam's Twin Earth. Natural kind terms are not indexical. Even de dicto attitudes are not in the head; they presuppose the existence of other things.

On non-individualist elements due to by intellectual norms in the community, to which meanings are answerable. Even meaning-giving truths can be doubted. With remarks on sofas/safos, and on linguistic meaning vs. cognitive value.

Challenges Burge's interpretations of the thought-experiments: e.g. twins have the same concept, neither of which is the public concept of arthritis. With remarks on computationalism and Marr's theory.

Argues that natural kind terms are token-reflexive, with reference ultimately fixed to the underlying explanatory properties of the surface qualities of local matter.

Twins share the same concepts. Contra Putnam: essentialism is fallacious; contra Burge: speakers share beliefs, but one has false belief about meaning.

We shouldn't rely on intuitions about thought-experiments; we need an empirical theory about belief. Belief contents are distinct from sentence contents; we have to distinguish linguistic from psychological semantics.

Against Searle's theory of internal intentionality. Searle's theory requires magic to grasp external contents internally.

Argues that thought is extrinsic, but it is not essentially social. A system without a linguistic community could have thoughts, if it had an appropriate learning history.

Contra Burge on sofas: oblique that-clauses can't identify the (wide) way that the subject thinks of sofas, which is idiosyncratic and inexpressible.

Gives a Fregean account of belief semantics to handle the Burge cases, and argues that the *type* of a proposition may be internal even if the token itself is not. With remarks on the relevance to Grice's program.

Argues for a moderate externalism by synthesizing Putnam and Searle: internal intension leaves extension indeterminate, but it specifies the facts relevant to filling in the indeterminacy.

Argues that conscious experience is required for intentional states, and that any external relations could be satisfied without this experience, so external relations cannot suffice for intentional content.

Various arguments against Crane 1991 on externalism.

Argues that meaning is determined by a certain kind of internal state, involving de se cognitive attitudes. These states aren't shared by twins, but are still narrow in a strong sense.

Functional organization doesn't determine attitude content, even if we include inputs and outputs.

Indexicals are essential to some beliefs, so belief cannot just be a relation to a proposition. Belief contents must be at least in part construed relative to a subject. Separate belief object and belief state.

What is in the head doesn't determine the reference of our thoughts: my twin on Twin Earth refers to XYZ where I refer to H2O. Content is determined by environment and linguistic community as well as by internal stereotypes. 

Meanings *still* aren't in the head.

Sure, meanings *are* in the head -- e.g. the content of a given visual experience is "the thing that is causing this experience".

On concepts as abilities, and on construals of abilities that lead to internalism and externalism. Maybe the relevant abilities are characterized externally but determined internally. Remarks on Putnam, Davidson, Burge.

Making sense of twin earth intuitions with an information-theoretic account of content: information depends on relations in normal conditions, which are extrinsic. With remarks on the context-sensitivity of content-attribution.

Burge's arguments show only that context-ascription is pragmatically sensitive to context, depending on the epistemic predicament of the ascriber. Content itself is still internal.

Argues that the extension of 'water' is the same on earth and twin earth, using arguments from isotopes and scientific development. Molar properties determine classification. Remarks on historicism and the division of labor.

2.2b Externalism and Psychological Explanation (Burge, Fodor)

Buller, D.J. 1997. Individualism and evolutionary psychology (or: In defense of "narrow" functions). Philosophy of Science 64:74-95.

Reply to Fodor 1982, clarification of position.

Psychology should be and is done non-individualistically, i.e. with reference
to environment. Examples from vision, e.g. Marr.

Advocates a different sort of "active externalism", based on the role of the
environment in actively driving cognition. Beliefs can extend into an
agent's immediate environment (e.g. a notebook) in this way.

Argues that extrinsic properties can play a respectable role in scientific
explanation; e.g. the histories of plants, animals, and devices are relevant
in explaining their current behavior.

100:179-203.
Maybe, maybe not. Contra Fodor: science can be non-individualistic.
Contra Burge re oblique ascriptions and Marr.

Fodor, J.A. 1980. Methodological solipsism as a research strategy in cognitive
psychology. Behavioral and Brain Sciences 3:63-109. Reprinted in
_RePresentations_ (MIT Press, 1980).
Should do psychology without reference to the external world. What counts for
psychology is in the head; who cares about truth, reference, and the rest?

Twin Earth isn't a problem for cognitive science. Intents of utterances, de
re/de dicto, etc. Truth conditions aren't in the head, but that's no problem.

Globus, G. 1984. Can methodological solipsism be confined to psychology?
Cognition and Brain Theory 7:233-46.
Methodological solipsism implies epistemological solipsism.

Hardcastle, V.G. 1997. [Explanation] is explanation better. Philosophy of
Science 64:154-60.

Analysis 58:1-6.

Jacob, P. 1993. Externalism and the explanatory relevance of broad content.
Mind and Language 8:131.

Kitcher, P.S. 1984. Narrow taxonomy and wide functionalism. Philosophy of
Science 52:78-97.
Argues against Stich, Fodor, Block: use different taxonomies (narrow/wide)
for different purposes. Both are OK, functionalism *and* content survive.

Quarterly 70:1-18.
Relates the individualism debate to Roschian prototype research.

Losonsky, M. 1995. Embedded systems vs. individualism. Minds and Machines
5:357-71.

Macdonald, C. 1992. Weak externalism and psychological reduction. In (D
Charles & K. Lennon, eds) _Reduction, Explanation and Realism_. Oxford
University Press.

Marras, A. 1985. The Churchlands on methodological solipsism and computational
psychology. Philosophy of Science 52:295-309.
MS doesn't rule out all use of content, just of wide content. Narrow content
is OK. With remarks on folk psychology and computation.

Various problems for computational psychology handling content. It shares the problems of a naturalistic psychology.

Object-dependent thoughts are redundant in psychological explanation, as an explanation applying to a hallucinator will work as well. But this needn't defeat externalism in general. With remarks on self-knowledge.

Uses examples to argue that in explaining behavior we often ascribe beliefs in an individualistic way, even in cases where individual and community use diverge. These contents are at least sometimes expressible.

Developmental psychologists attribute concepts individualistically.

Externalist states are required for the explanation of relational properties. Counters objections from conceptual connections and dormitive-virtue worries, and applies to teleology, self-knowledge, etc.

Argues that behavior is often individuated widely for explanatory purposes, so that wide content is relevant, and that there is more to causation than local causation, so Stich's autonomy principle fails.

Beliefs are not in the head, so aren't good for psychological explanation. Interesting, but confuses the role of truth-values with truth-conditions.

2.2c Externalism and Mental Causation
-------------------------------------

Argues contra Fodor that broad contents can be explanatory -- if they can't, no relational properties can. Fodor's "no-conceptual-connection" and "cross-context" tests for causal powers fail to do the job.

Arguments for the causal significance of broad content. Physical twins can differ in causal powers; broad content figures in (ceteris paribus) causal generalizations; can make twin arguments against narrow content too. Hmm.

Contra Fodor: psychological processes can play differing causal roles, despite being physically identical.

Fodor's modal argument for narrow content rests on a false analogy between cases concerning thoughts and those concerning planets.

On when a difference in effects amounts to a difference in causal powers: when the effects are connected contingently, not conceptually, to the causes. Differences in wide content don't satisfy this, so aren't causal powers.

Mental content can be extrinsic and efficacious. Narrow content strategies
don't work, as observation concepts are still extrinsic. One can't screen
of the intrinsic part from the rest. Thought-experiments are inconclusive.

28:61-71.
Reconciling Twin Earth with the causal relevance of content. Historical
factors can be causally relevant.

Argues that externalist content is not causally efficacious, but is
relevant to causal explanations of behavior indirectly, via the cognitive
activities of others external to the system.

Klein, M. 1996. Externalism, content, and causation. Proceedings of the
Aristotelian Society 96:159-76.

Montgomery, R. 1995. Non-Cartesian explanations meet the problem of mental

Philosophy of Science 60:242-61.

Psychology 6:57-61.

Seymour, D. 1993. Some of the difference in the world: Crane on intentional

Sturgeon, S. 1994. Good reasoning and cognitive architecture. Mind and
Epistemology requires the causal relevance of content, and the relevant
content is narrow. On how various architectures might support this causal
relevance, by being realized by more specific intrinsic features.

van Gulick, R. 1989. Metaphysical arguments for internalism and why they don't
work. In (S. Silvers, ed) _ReRepresentation_. Kluwer.
Against some arguments for internalism: local causation doesn't imply local
type-individuation, as distal relations affect distal causes and effects; and
processes can have access to semantic properties via formal properties.

Science frequently appeals to relational and historical taxonomies, so either
causal powers can be non-intrinsic or science needn't taxonomize by causal
powers. With remarks on causal properties and conceptual connections.

Wilson, R.A. 1993. Against a priori arguments for individualism. Pacific
Arguments from causal powers beg the question, either on whether relational properties can have causal powers or on whether science taxonomizes by causal powers, as relational properties are common in scientific explanation.

2.2d Externalism and the Theory of Vision
------------------------------------------

Burge, T. 1986. Individualism and psychology. Philosophical Review 95:3-45. Psychology should be and is done non-individualistically, i.e. with reference to environment. Examples from vision, e.g. Marr.

2.2e Externalism and Computation
---------------------------------

Winograd's SHRDLU doesn't support individualism: its concepts are anchored (to a fictional world) via its programmer, and it could have made errors.

Syntax is extrinsically determined, as well as semantics. So if broad content is irrelevant to psychology, syntax is too.

2.2f Externalism and Self-Knowledge
-----------------------------------

We can't know our thought-contents by inference (circular), by introspection (because they're relational), or directly, so we can't know them at all.

Boghossian, P. 1997. What the externalist can know a priori. Proceedings of

Contra McKinsey 1991, anti-individualism doesn't lead to a priori knowledge. The belief that water is wet doesn't conceptually entail facts about the external world (e.g. H2O), although it may metaphysically necessitate them.

Knowledge of our thoughts is compatible with externalism: its content is self-referential and self-verifying. We needn't be able to explicate the content or its enabling conditions, or rule out twin possibilities.

Ebbs, G. 1996. Can we take our words at face value? Philosophy and

Subjectivism and environmentalism seem to clash on knowledge of content, but it's OK: under environmentalism we still know our contents w/o evidence.
Argues that cases of switching between language communities are quite common, so that Warfield's case for externalist self-knowledge doesn't work.

On reconciling externalism with the non-evidential character of first-person knowledge.

Argues that we can know the meaning of our words a priori. Analyzes twin earth cases by separating propositional meaning from linguistic meaning, which is indexical, fixes reference, and is knowable a priori.

Contra Burge: if there are conceptual connections between wide contents and the external world, then we can't know wide contents a priori, as otherwise we could know a priori that the world exists.

Reply to Brueckner 1992: The claim that belief metaphysically necessitate external facts is trivial. Almost all states do that, for Kripkean reason.

Boghossian's argument that externalism threatens self-knowledge fails: twin cases needn't be relevant alternatives (unless they are actual), so they don't threaten knowledge of content, by the usual standards of knowledge.

Argues that externalism and self-knowledge imply the falsity of skepticism (though externalism alone does not). And arguments against externalist self-knowledge are no better than standard skeptical arguments.

2.2g The Status of Narrow Content
-----------------------------------

Traces and criticizes Fodor's position on narrow content. Argues that narrow content isn't content, and doesn't explain behavior. Fun but arguable.

Argues that problems with names don't require an appeal to narrow content in explanation. Broad content plus associated descriptions will do the job.

Representational cognitive science has no need for narrow content -- wide contents and formal properties can do all the work. Argues that the semantics of mental expressions needn't mirror the semantics of language.

Argues that type-identical functional states can differ in narrow content, so methodological solipsism fails. Uses the example of identical programs for playing chess and arms negotiations.

Some implausible twin cases trying to show that mental life can vary wildly while preserving physical/computational state. Bizarre.

Lots of arguments against narrow content. Very stimulating, though wrong.

Contra Loar 1988, the contents of "that"-clauses often reflects psychological content, even if it sometimes does not. We don't need narrow content.

There are big problems specifying the "mapping" and the relevant contexts for Fodor's theory noncircularly. Narrow content either collapses into syntax or is too coarse-grained. Nontrivial narrow content must be holistic.

Criticizes the "bracketing" strategy of Stich and Walker, and argues that intrinsic belief state should be individuated according to how it embeds in different environments. With a comparison with Fodor's related theory.

Argues for a two-dimensional intensional theory, with different kinds of intensions constituting notional and relational content. Notional content governs the dynamics of thought and behavior, and is primary in explanation.

Comments on Fodor 1987. Fodor doesn't make a conclusive case against externalism; but narrow content may be promising, and inexpressibility doesn't pose any real problems. With comparisons to neo-Fregean theories.

What matters are not propositional attitudes but notional attitudes; but it's hard to calibrate notional worlds. Very nice.

Not syntactic psychology nor wide psychology, but narrow psychology.

Science taxonomizes by causal powers, which are locally supervenient, so psychology needs a narrow notion of content. Proposes that a relativized notion -- a function from context to extension -- can do the job. Nice.

Argues that folk psychology needs a notion of narrow content to provide robust predictive behavioral generalizations that covers doppelgangers. If not, then some behavioral patterns would be flukey.

There's no good way to construe narrow content. Phenomenologist strategy is intrinsically wide, and indexicalist strategy can't specify content.

Loar uses examples to argue that psychological content is not fixed by the content of "that"-clauses in belief ascription, and vice versa. We require a subtler kind of narrow content to capture what's going on.

Maloney contests the "provoked/aggravated assault" example of Baker 1986. If they're doppelgangers, then their narrow content can't differ.

McDermott argues that narrow beliefs are de re beliefs about our inputs and outputs.

Putnam argues against perceptual-prototype and conceptual-role accounts of narrow content.

Quillen can't get a 'mode of presentation' account of narrow content to work, either through description theory or prototypes. Psych should be non-individualist.

Recanati argues that this can be consistent with externalism.

Segal, G. 2000. _A Slim Book about Narrow Content_. MIT Press.

Stalnaker argues that psychological content is narrow. With some remarks on privileged access.

Stich argues that narrow content is still too coarse-grained for explanation, classifying psychologically distinct states together. Use syntax instead.

Argues that the partial character construal of narrow content is not interestingly semantic. It collapses into syntax or phenomenology.

Uses a "fraternal twin earth" thought experiment to show that even de dicto attributions don't supervene on narrow role, and that narrow content can't be explicated descriptively unless it collapses into phenomenalism.

Replies to Burge/Stich arguments by introducing partial character -- a function from context to content, analogous to Kaplan's character -- as the semantic property determined by functional state and relevant to explanation.

Argues for an account of narrow content in terms of notional worlds, by considering "objective optimality" across worlds. This allows for a sort of narrow radical interpretation. With arguments against Stalnaker.

Narrow content theories can't handle the normativity of content. In-depth treatment of Burge cases and of the failures of causal and conceptual-role accounts. Normativity is fundamentally social. A long, interesting paper.

2.2h Miscellaneous
------------------

An entertaining fable about a swampthing doppelganger of a murder witness. Does he have content? With plot twists about personal identity.

Argues that a swampthing isn't intelligent or intentional, with different physiological processes and no sensations, as these are functional kinds.

Gibbons, J. 1993. Identity without supervenience. Philosophical Studies

   Should construe functionalism broadly rather than narrowly; then can handle the problem of broad content.

   Anti-intensional arguments are not independent but a series of dominos. Quine/Quine/Davidson/Putnam/Burge rise and fall together.

   Belief content has two distinct elements, one causal-explanatory, the other truth-related.

   Supplements externalist "locking" theories of content with an account of internal "conceptions" by which thoughts lock onto environmental kinds, with that aid of dthat operators, thus solving various philosophical problems.

   Contra Owens 1987: wide intentional descriptions and molar bodily descriptions don't exhaust the options. A bracketing strategy gives a narrow intentional taxonomy of mental states.

Williams, M. 1990. Externalism and the philosophy of mind. Philosophical
Quarterly 40:352-80.

2.3 Causal Theories of Content
----------------------------------

2.3a Information-Based Accounts (Dretske, etc)
---------------------------------------------

Defending information against Fodor 1986. Information is objective but
relational, and depends on the relevant constraints between representation
and environment. Circumstances play a vital role.

Mind and Language.

From material (formal) info to semantic info via teleology; from semantic
information to representation via internal structure. Cute. With a good
reply by Israel, and a terse reply by Dretske.

90:290-310.

Uses information theory to analyze misrepresentation. A signal represents
what it carries most information about, not what it correlates best with.
Treating some signals as noise can increase information content.

Coulter, J. 1995. The informed neuron: Issues in the use of information theory
in the behavioral sciences. Minds and Machines 5:583-96.

Defines knowledge content is in terms of information-flow from events, and
applies to various aspects of psychology.

Behavioral and Brain Sciences 6:55-90.

A summary of the book, with commentary and replies.

Dretske, F. 1990. Putting information to work. In (P. Hanson, ed)
_Information, Language and Cognition_. University of British Columbia Press.

On the causal role of information (as opposed to meaning). Information is
causally efficacious if considered with respect to learning. With
commentary by Brian Smith.

Logic 27.

Transmission of information is no good without the encoding of information.
With criticisms of associative networks, which transmit without encoding,
and criticism of Barwise & Perry's account of attunement to a relation.

Synthese.

Shannon's notion of information is more useful for naturalized epistemology than Dretske's.

We need to analyze indication in terms of "close enough" worlds; the relevant conditionals are "might"-conditionals.

Israel, D. & Perry, J. 1990. What is information? In (P. Hanson, ed) _Information, Language and Cognition_. University of British Columbia Press.

Argues that a representationalist theory of semantics beats a realist one.

Dretske has problems with ruling out alternative possibilities; and there is a gap between information-caused belief and knowledge.

Makes a distinction between absolute information and information that's relative to other knowledge.

On problems with a computational approach to content: computers process info(t), the non-semantic content of communication theory, not info(s), or semantic content. Get info(s) from efficient processing of mutual info(t).

2.3b Asymmetric Dependence (Fodor)
----------------------------------------------

Defends and refines a causal theory, using the notion of asymmetric dependence of a token upon the world.

Defending the asymmetric dependence theory against various objections.

   A somewhat sympathetic commentary on the Dretske/Stampe causal theories, but raising the problem of misrepresentation.

Fodor, J.A. 1990. Information and representation. In (P. Hanson, ed) _Information, Language and Cognition_. University of British Columbia Press.

   On various attempts to solve the error problem and why they don't work.

   World-head reliability is just as important as head-world reliability.
   With arguments and examples from signal detection theory.

2.3d Teleological Approaches (Millikan, etc)

   Argues that a teleological account can resolve content indeterminacies, by an appeal to counterfactuals in examining what properties were selected for.

Dennett, D.C. 1988.  Evolution, error and intentionality.  In _The Intentional Stance_.  MIT Press.  Attacks original intentionality (Fodor/Burge/Dretske/Searle/Kripke) -- our intentionality, if anything, is derived through evolution, and so is as indeterminate as that of an artifact.

Fodor, J.A. 1990.  A theory of content I.  In _A Theory of Content_.  MIT Press.  Teleological solutions can't work, because of underdetermination and so on.

Millikan, R.G. 1984.  _Language, Thought and Other Biological Categories_.  MIT Press.  An evolutionary account of thought, content, and various intentional phenomena, appealing to proper functions and adaptational role to individuate contents.

not its production. The representation-world correspondence is best taken as a normal condition for the consumer's function.

Contrasting positions on the role of representation production and consumption; also on the role of reliability, articulateness, and learning.

A reply to some of Fodor's criticisms of teleological theories in _Psychosemantics_ and elsewhere. With some remarks on Fodor's asymmetric dependence theory.

Millikan, R.G. 1993. _White Queen Psychology and Other Essays for Alice_. MIT Press,
A collection of papers on teleological semantics and other issues about psychology and mental content.

It's not unreasonable to deny a swampthing beliefs: swampcows aren't cows and swamphearts aren't hearts. Semantic norms are plausibly grounded in biological norms and so in history.

Contra Dennett 1988, designed creatures can have intrinsic (if not original) intentionality. Overall purpose is dependent on designer's goals, but specific contents need not be.

A teleological theory of belief/desire contents: the satisfaction conditions for a desire are those effects for which it was selected; truth conditions for a belief are circumstances resulting in satisfaction of desires.

Best theory is combination of a success-guaranteeing account of truth-conditions with a teleological account of desire.

Papineau, D. 2001. The status of teleosemantics, or how to stop worrying about

Combining the analysis-relative and historical accounts of function, and using these to give an account of intentionality: representation are produced by conditional productive functions. Argues against Fodor on indeterminacy.

Millikan's theory has an implausible consequence: creatures' belief contents can involve properties which they cannot discriminate. With examples.

Teleosemantics has big problems with indeterminacy, holism, false belief, and "psychophysical normalcy" in causation. So do all naturalistic stories.

2.3e Conceptual Role Approaches

An in-depth program for conceptual-role semantics, and its role in a two-factor account of meaning. Also a defense of narrow content.

A defense of functional role semantics, and an account of its relation to truth-conditional factors. A two-factor theory will handle wide content.

No matter how we understand the denial of the analytic/synthetic distinction, the falsity of inferential-role semantics does not follow. The meaning-constitutive inferences needn't be the analytic inferences.

CMS conflates representation content and attitude content (which depends on a representation's "target"), so can't handle representation content; it makes all content-based explanations vacuous; and it can't handle error properly.

Explicates conceptual role in terms of conditional probability, and analyzes meaning as conceptual role plus reference. With remarks on truth, descriptions, and synonymy.

Conceptual role semantics isn't compatible with compositional semantics and the denial of an analytic/synthetic distinction, as full conceptual roles aren't compositional, and there's no way to specify a relevant subset.

Meaning and content is determined by the role of symbols in thought (e.g. inference and perception). With remarks on indeterminacy, context-dependence, the linguistic division of labor, qualia, speech acts, and more.

On the relation between conceptual role and truth-conditions. Contra Harman, truth-conditions are to an extent independent of conceptual role.

Contra Harman 1982, truth-conditions are central to a semantic theory.

Argues against Putnam 1987 that conceptual role plays an important role in determining meaning. Appeals to the induction theory of Holland et al.

Contra Fodor and Lepore, meanings can be compositional even if inferential
roles are not, as long as meanings only supervene on inferential role.

2.3f Theories of Content, Misc

On "translational" (conceptual) and "calibrational" (referential) content.

Relation of content issues to computational issues.

Critiques other views, offers interpretational semantics.

On the ways in which meanings can come to cohere with their causal roles: learning, natural selection, and design. Criticizes Dretske for undervaluing the latter two: all three are in the same boat.

On the reference and content of representations. Reference is determined by causation; content, i.e. representation "as", is determined by functional role, when functioning normally in natural habitat.

On some tensions in Fodor's view of content: e.g. narrow content must be dependent on functional role, which seems to lead to holism. The role of denotational semantics as a defense is unclear.

2.4 Representation (General) [see also 4.2]

Because paramecia can't respond to non-nomic properties of the stimulus. Perceptual categories vs. sensory manifolds.

On the philosophical (inward-out) vs. psychological (outward-in) approaches to the mind-world relation; the psychological approach is more useful in understanding representation. Internal reality is an imperfect construction.

On different senses of "representation" -- external, experiential, mental locus, substrate of meaning, mediating functions, technicalpsychological.

On the distinction between representation and representation-use.

2.5 The Explanatory Role of Content (Dretske, etc)
-----------------------------------

On Dretske's account of the causal role of content. Addresses some objections: Dennett's worries about intrinsic intentionality, Fodor's about external causal powers, and some worries about syntax.

A critique of Fodor. Semantics per se doesn't cause. Also, Fodor's is an account of the what, not the how, of semantics. Somewhat bizarre.

Criticizes Dretske's account of the role of content, especially because of its dependence on an organism's history; also, it may not cohere with work in cognitive science. Argues for an interpretational, not a causal account.

Devitt, M. 1991. Why Fodor can't have it both ways. In (B. Loewer & G. Rey, eds) _Meaning in Mind: Fodor and his Critics_. Blackwell.

Content must explain why (not how) an internal state caused a certain output. The explanation is given in terms of what a state has historically indicated. With thermostats and sea-snails as examples. Comments by Cummins, and reply.

Hassrick, B. 1995. Fred Dretske on the explanatory role of semantic content.

Distinguishes three problems of mental causation (extrinsic factors, exclusion of the nonphysical, anomalism). Criticizes Dretske's theory (can't handle unlearnt or here-and-now reasons), offers a counterfactual account.

We must individuate mental states by semantics, not just by function, as we need representation to capture generalizations about behavior; particularly due to the information-sensitivity and stimulus-independence of behavior.

2.6 Concepts

Connectionism builds up concepts from the nonconceptual level. From nonconceptual content (e.g. perceptual experiences) to the emergence of objectivity.

A symposium on the book, with comments by Heal, Rey, Papineau.

On the significance of psychological work on concepts for philosophical conceptual analysis -- simple, precise analyses do not exist in general.

On concepts as abilities, and on construals of abilities that lead to internalism and externalism. Maybe the relevant abilities are characterized externally but determined internally. Remarks on Putnam, Davidson, Burge.

2.7 Meaning Holism
-----------------

Uses Putnam's "Ruritania" example to argue that narrow content, if it exists, is holistic. Twins in different communities start with same narrow content, diverge by acquiring new beliefs; so belief change affects narrow content.

Miller, R.B. 1997. One bad and one not very good argument against holism. Australasian Journal of Philosophy 75:234-40. A nice criticism of Fodor and Lepore's arguments that holism implies (a) the nonexistence of intentional laws and (b) the nonlearnability of language.

2.8 Mental Content, Misc

Morris 1991 is wrong: formal individuation is easy, and objectively determinate content isn't needed. External grounding is also irrelevant.

Intentionality around the diamond: neoCartesianism, neobehaviorism, neopragmatism. 1B=Fodor/Pylshyn, 2B=Dennett/Quine, 3B=Heidegger/Sellars. SS=Wittgenstein. RF=Searle, CF=Skinner, LF=Rorty/Derrida. Lots of fun.

There can be no non-stipulative content to non-semantically individuated tokens. Mostly a critique of Cummins; also Fodor and Dennett.

Remarks on a number of aspects of mental content -- narrow, propositional, qualitative -- with respect to functionalism and the language of thought. With comments by Baker.

   On the tacit theories underlying the folk psychology of belief: beliefs are states associated with typical causal patterns. With remarks on ambiguity, content identity and similarity, and environmental dependence.

   Argues that a failure to "naturalize" intentionality won't lead to disasters such as irrealism, irrelevance, or non-science, whether naturalization is understood as analysis, property identity, supervenience, or whatever.

   There's no deep problem of naturalism about intentionality, as we know it's true already. The real puzzle is that of finding a mechanism to close the gap, e.g. via analysis or essentialism. But naturalism doesn't require that.

Compiled by David Chalmers, Department of Philosophy, University of Arizona.

3.1 Supervenience
-----------------
relevant in the explanation of behavior.

Distinguishes weak (within-world) vs strong (across-worlds) supervenience.
Relates to reduction, internal/external mental states, and various theories.

On some problems with supervenience, the relation between supervenience and reduction, and on reasons for accepting psychophysical supervenience. Loose.

If mental properties are supervenient but irreducible to physical-functional properties, we can't confirm them. Confirmation requires an indispensable explanatory role, which irreducibility precludes. With comments by Schiffer.

Psychophysical supervenience follows from completeness of physical laws.

3.1b Supervenience and Physicalism [see also 3.3a]
-----------------------------------------------

Argues that everything is logically supervenient on the physical. Considers classes, possibilities, numbers, universals, and objects of thought.

Supervenience is all we need for materialism. Various materialist arguments (unity, "nothing but", history, fear of darkness, simplicity, law) don't support physical exhaustion & token identity, over and above supervenience.

Some applications of the earlier treatment: examples of determination without reduction; the statuf of properties and universals; the mental; the life sciences; modalities and essentialism; theoretical equivalence.

Some remarks on determination, physicalism, model theory, and logical truth.

Argues that the generality of physics should be a supervenience thesis, not token physicalism. Fodor's token physicalism is untenable but might be saved with an appropriate view of events.

An account of how all facts supervene on microphysical facts, and how all intrinsic facts supervene on intrinsic microphysical facts.

Laplacean demon's job: number crunching, plus cosmic hermeneutics to explain high-level truths. All high-level truths follow from low-level by meaning constraints. Application to theoretical/mentalistic/everyday terms. Nice.

Supervenience is neither necessary nor sufficient for materialism. With various (contentious) counterexamples. So we need a different formulation.

Argues for strict implication rather than supervenience as a formulation of "minimal physicalism" (unless supervenience is formulated just right).

Formulates a definition of materialism: among worlds where no natural properties alien to our worlds are instantiated, no two differ without differing physically. With a lot of other material on universals.

How can supervenience, as a relationship between ontologically distinct properties, be explained? Modal realism and grand-properties don't work. Eliminativism about supervenient properties is the only possibility.

Defines physicalism in terms of claims that microphysical entities constitute everything and that microphysical laws govern everything. With a reply by Crane.

Weak supervenience provides a more tenable form of materialism than strong supervenience, because of inverted spectrum possibilities, etc.

A construal of materialism in terms of constitution, not identity. Discusses the entailment between physical properties and mental properties; considers a nonreductive physicalism and a primitive dualism.

3.1c Technical Issues in Supervenience

A modal-logic analysis of the relations between various notions of supervenience. Most concepts of supervenience entail necessary co-extension, under certain closure assumptions for properties.

A model-theoretic treatment of supervenience, in terms of relations between theories. Supervenience turns out to be equivalent to reduction.

A nonreductive supervenience hypothesis: supervenient properties are properties of properties, e.g. intrinsic goodness is a property of an object's nature.

On dependency supervenience (B properties determine A properties) versus
determination supervenience (A properties need B properties).

Distinguishes weak and strong supervenience. A mistaken proof that strong and global supervenience are equivalent. Strong supervenience implies a kind of reduction, but not an explanatorily useful reduction.

Reasons why global supervenience doesn't entail strong supervenience, and trying to rescue global supervenience as a useful notion. Suggests a similarity-based notion of global supervenience.

How properties in one domain can supervene on properties in another, with or without co-ordination between domains. Relation to global supervenience.

Supervenience doesn't entail reducibility, as necessary coextension doesn't suffice, and is incompatible with reducibility, due to ontological asymmetry.

Distinguishes modal-operator and possible-worlds versions of supervenience, and explicates global supervenience and its relation to weak and strong.
With remarks on multiple-domain supervenience and the relation to reduction.

Argues that global supervenience has epistemological problems -- how could we ever know that it holds, and that certain worlds are impossible?

Closure under resplicing makes supervenience both too narrow and too wide. Weak supervenience is generally too weak to capture the dependence relation.

Gives a proof of the distinction between strong and global supervenience that improves on Petrie's, and argues contra Kim that global supervenience is a perfectly reasonable dependence relation for physicalism.

Defending global supervenience: it's weaker than strong supervenience, as base properties of other individuals are relevant. It doesn't entail type or token reducibility. On the relation to implicit definability and reduction.

Properties in supervenience relations shouldn't be closed under negation or resplicing, due to bad consequences. With reply by Bacon on resplicing.

3.1d Supervenience, General
-----------------------------

On the incompatibility of weak supervenience without strong supervenience and realism. With discussion of various strengths of necessity involved in supervenience claims, and application to moral realism and anomalous monism.

How social facts supervene on the totality of individual facts. Application to belief, etc.

Supervenience is too weak to function as a dependency relation, as e.g. it can hold in two directions at once.

Reply to Miller 1990. Miller underestimates the modal force of supervenience and invokes irrelevant dispositional properties.

Horgan, T. 1993. From supervenience to superdupervenience: Meeting the demands of a material world. Mind 102:555-86.

An overview of supervenience, with focus on the problem of explaining...
supervenience relations. With remarks on mental causation, emergence, physicalism, and reduction.

Developing and motivating the notion of supervenience. Investigating the relationship to reducibility and definability (equivalence, under certain conditions), and to microphysical determination.

On weak/strong supervenience, and high-level causation via supervenience.

A nice overview of supervenience and covariance.

A collection of articles on supervenience and causation in metaphysics and the philosophy of mind, with some added postscripts.

Supervenience doesn't entail reducibility, which is epistemological. The problem's not just huge disjuncts, but also the sharing of bases, no local correlations, and base-properties presupposing supervenient properties.

Argues that lower-level theories can explain supervenient but irreducible higher-level theories, but only under certain conditions, as low-level accounts don't have the relevant kind terms.

On supervenience as an ontological relation (via metaphysical necessity) or as an ascriptive relation (via conceptual necessity). The first doesn't preclude the second. Moral realism and mental realism are in the same boat.

On a number of issues: possible worlds vs modal notions, explicating global supervenience, the relation between weak/strong/global supervenience, multiple-domain supervenience, and implications for reduction.

If supervening properties can make arbitrarily fine distinctions, then physical properties supervene on moral/aesthetic/mental properties.

Contra Blackburn 1984 on the possibility of weak supervenience without strong supervenience, even with metaphysical necessity; using Nozick's concept structures, or indexical definitions. With application to moral realism.

Distinguishes "reductionist" and "metaphysical" conceptions of supervenience. Also discusses the relation between strong and global supervenience, degrees of necessity, and the explanatory role of supervenience.

Compares the Hellman/Thompson notion of determination with Kim's development of supervenience. Uses these to investigate the concept of materialism, and argues that materialism isn't contingent.

3.2 Reduction
-------------

3.2a Reduction and Multiple Realizability
----------------------------------------

On species-specific reductions. These can't reduce standard psychological properties, and problems with intra-species multiple realization can't be circumvented without giving up property reduction for token event identity.
3.2b Nonreductive Materialism [see also 3.5d]

On varieties of physicalism with respect to reduction: semantic physicalism, identity theory, supervenience, and the denial of emergence. Advocates a version on which physical states realize mental states.

Arguing for a pluralistic conception. With criticism of Churchland's reductionism, Davidson's token identity, and more generally reverential "scientism". Reductionist explanation is not the general rule.

Psychological kinds can't be reduced to physical kinds, due to cross-classification, although token physicalism still holds. How to maintain the generality of physics without a reductionist unity of science.

Gives four constraints on interlevel connections, and some arguments against reductionism and for the autonomy of psychology. Argues that supervenience fact are themselves in need of explanation.

Classifying psychophysical theories by the status (necessary, lawful, anomalous, false) of psychophysical/psychological generalizations. Defending autonomous monism: nonreductive materialism with psychological laws.

Somewhat loose arguments that non-reductive physicalist realism is untenable. Anomalous monism makes the mental irrelevant, functionalism is compatible with species-specific reduction, and supervenience is weak or reductive.

Kim, J. 1992. The nonreductivist's trouble with mental causation. In (J. Heil & A. Mele, eds) _Mental Causation_. Oxford University Press. Reprinted in...
Supervenience and Mind (Cambridge University Press, 1993).

Argues that nonreductive materialism implies downward causation (as the mental has more causal powers than the physical alone), and that downward causation violates the causal closure of the physical.

Argues that nonreductive materialism is just like 1930s emergentism, with the mental contributing new causal powers, and so implies downward causation.

Contra Kim, physicalists can avoid reduction by embracing strict implication.

Non-reductive physicalism is a mystery unless we invoke teleology.

Explicating anti-reductionism: mental causal powers are constituted of physical causal powers, but aren't type- or token-identical to them. Against arguments from local reduction, neuroscience, explanatory exclusion, etc.

A careful discussion of how to characterize physicalism, in terms of identity or supervenience, and argues that physicalism must reduce (bowdlerize) qualia to something they are not, as physicalism requires topic-neutral analyses.

On how a nonreductive materialism can handle problems about mental causation, psychophysical dependencies, and qualia. A teleofunctionalist view with different conceptual frameworks, but mental properties physically realized.

3.2c Reduction in Psychology
Argues that cognitive theories have already been reduced to neurobiology in some domains, such as associative learning.

Psychology shouldn't be autonomous from natural science. By analogy with biology, nature provides (a) conceptual insight, and (b) real constraints, e.g. thermodynamic ones. Biology and psychology are continuous.

The relationship between psychology and neuroscience is best characterized not by reduction but by explanatory extension, where each field is enriched by the other. With a number of examples from recent empirical work.

Anti-reductionism needn't be ad hoc (contra Churchland). Although evolution provides some pressure for 1-1 psychophysical mappings, there are significant countervailing forces, e.g. in vision, memory, learning, and language use.

3.2d Reduction, Misc
-------------------

Reduction comes to supervenience plus expicability. Thus biconditionals, multiple realizability, etc, are irrelevant. Biology is already reduced (mostly via functional explanation), and psychology looks promising. Nice.

On the links between supervenience, reduction, and explanation. Supervenience is compatible with reductive explanation of a localized variety. We don't need laws, but explanatory links.

Contra Richardson 1979, a purely functional psychology is irreducible. The genetics analogy is misleading; multiple realizations can't explain high-level laws.

Mind is not reducible to body, but societies reduce to individuals. Multiple realization is in tension with predictability. Natural selection resolves the tension for the mental, but cannot for the social.

Argues that functionalism is compatible with reductionism, by analogies. Genetics has multiple realization and multiple function; reduction doesn't require biconditionals. With remarks on the de facto autonomy of psychology.

Response to Kitcher 1980. Reductions are usually domain-specific, and high-level regularities are indeed explained.

Excellent coverage of the notion of level and its applicability to mind.

3.3 Other Psychophysical Relations
----------------------------------

3.3a Physicalism [see also 1.3, 1.7b, 3.1b, 3.2b, 3.5]
--------------

If there are no contingent psychophysical laws, then there are no mental properties. So physicalism/supervenience is false; God had extra work to do.

Physical sciences have no ontological authority over the mental. Considers and dismisses arguments from laws, causation, reduction, supervenience.

If every physical events has a physical explanation, and the mental is causally efficacious, then mental facts are strictly implied by physical facts. A nice argument.

Materialism doesn't need a identity thesis. The requirement that mental facts are entailed by physical facts plays the role played by Kripke's requirement of necessary identity, and is more reasonable.

Nothing in the arguments of Crane and Mellor 1990 count against a physicalism based on strict implication.

On the problems posed for materialism by intentionality, autonomy, awareness, and indexicality. Tentatively advocates a Cartesian position.

Advocates "realization physicalism": all properties are either physical or functional properties realized by physical ones. This achieves unity between sciences better than alternatives, and avoids overdetermination.

Discusses two formulations of physicalism: requiring high-level properties to be disjunctions of physical states, or to be functional properties realized physically. Tentatively endorses the latter.

3.3b Token Identity [see also 3.5b, 3.5d]
-------------------

We individuate mental events by their causal role, but we can't individuate causes uniquely. So each mental event has multiple physical correlates, and token identity doesn't hold.

Supervenience doesn't imply token identity, and Davidson's argument for token identity equivocates on "event". But weak supervenience (mentally discernible worlds are physically discernible) is all we need. With nice examples.

Physical/psychological token identity is no good: you can't individuate physical events without psychological predicates.

Can't isolate the physical token of a belief, say, as it's always accompanied
by other beliefs. Meaning doesn't come in discrete tokens.

3.3c Emergence
-------------

On varieties of supervenience and of emergence, and of what is required for reduction. Argues that reduction involves general explanatory connections, whereas emergence involves unique and ultimate bridge laws.

A defence of radical emergence against Spencer-Smith 1995.

A careful account of British emergentism. Explicates their view of emergent causal powers and laws in terms of fundamental configurational forces, a coherent idea that turned out to be false. An excellent paper.

Morgan, C.L. 1923. _Emergent Evolution_. Williams and Norgate.

Argues against Alexander's and van Cleve's accounts of emergence, instead suggesting an account in terms of supervenience, non-structurality, and downward causation.

An in-depth analysis of Sperry's views on consciousness. Sperry is not a dualist; he believes in "structural causation" based on emergent properties.

vandervert, L.R. 1991. On the modeling of emergent interaction: Which will it be, the laws of thermodynamics or Sperry's "wheel" in the subcircuitry?
Interactionism is compatible with conservation of energy and momentum: the mind exerts a non-physical force on the brain.

Various arguments about interactionism based on conservation of energy. C of E only applies to causally isolated systems, so objections beg the question.

Argues that there can be interaction without breaking physical laws: e.g. by basic psychic forces, or by varying physical constants, or especially by arranging fractal trees of physical causation leading to behavior.

Argues that interactionist dualism is compatible with the causal closure of the physical, if we allow causal overdetermination; and there is a strong case for the latter.

Dualism is an empty hypothesis. Everything must be matter, though we may have to expand the notion of matter.

3.3e Psychophysical Relations, Misc

Argues that mental kinds are not natural kinds, and don't have real essences but nominal essences. For this reason, there are no psychophysical laws. With remarks on psychological laws, and the role of behavior.

Physical completeness, mental causation, non-reductionism are inconsistent. Ryle and Putnam are closet dualists, and Davidson's an epiphenomenalism.

3.4 Functionalism [see also 1.8, 4.6]

3.4a Causal Role Functionalism (Armstrong/Lewis)
Mental states should be analyzed as states that are apt to bring about certain kinds of behavior. Analysis of all kinds of mental states as such. With comments on dualism, behaviorism, identity theory, and consciousness.

Mental states are internal states that are apt to cause certain behaviors. A synthesis between the "thesis" of idealism and the "antithesis" of behaviorism. With defense against objections from consciousness.

Psychofunctionalism can evade chauvinism by specifying different functional identifications within each species. Applying same mental terms to each is justified by theory similarity; but it still isn't analytic functionalism.

Against functionalism: experiences have intrinsic introspectible acausal properties, such as duration, felt location, and unpleasantness. Both analytic and empirical functionalism fail.

Formalizing versions of functionalism, and seeing which entail token physicalism and/or type physicalism. On the most plausible versions, we have token physicalism without type physicalism.

Functionalism is compatible with type identity, as e.g. "pain" designates the state-type that fills the right functional role in an organism at a given time, i.e. a brain state. Contra Kripke, pain is not a rigid designator.

Argues that Lewis's functionalism founders on the specification of behavior. Described intentionally => non-materialist; physically => chauvinist.

Causal roles are definitive of mental states. Since physical states fill these causal roles (by the explanatory adequacy of physics), mental states are physical states.

Mental states can be defined, via a Ramsey-sentence analysis of the platitudes of folk psychology, as entities that fill causal roles specified by the analysis. These fillers turn out to be physical.

Accounting for both pains that don't play the usual causal role and for pains that are realized in different substances, by a mixed theory: pain is the physical state that typically occupies a certain causal role in a population.

Functionalist (reducing the mental to its effects on the physical) is no more plausible than phenomenalism (reducing the physical to its effects on the mental).

Lewis's original theory leads to Kripkean reference-fixing, so chauvinism. Token functionalism can't deal with paralytics. Species-relative functionalism fails as pain is intrinsic, not extrinsic.

Fleshing out Ramsey-sentence functionalism; against Lewis's "mad pain" mixed theory; relating functionalism to the causal theory of properties. Empirical functionalism is chauvinistic so probably false. A terrific, in-depth paper.

Contra Lewis: Functionalism isn't compatible with type physicalism. There are intra-population difficulties with species-relative construals, and individual-relative construals can still have multiple fillers.

3.4b Machine Functionalism (Putnam) [see also 4.8]

The relationship between mental and physical states is just like that between logical and structural states of Turing Machines, so no great mystery. With comments on privacy and semantic analysis.

Why mental states are more likely to be functional states (in probabilistic automata) than brain states or behavioral dispositions.

On explaining behavior via TM states, e.g. explaining preference via utility functions. Logical behaviorism assumes rational preference functions. Functional organization is what matters, not physical make-up.

Psychological states aren't TM states after all: we have lots of psych states at once; they depend on learning/memory; disjunctions of TM states are no
good. But functional organization rather than physics is still what counts.

Type functionalism isn't any better than type physicalism, as mental states can be multiply realized as functional states. What with in common?

On abstract vs. physical TMs: Putnam should say that mental states are physical TM states. But then functionalism is compatible with physicalism. On the relation between Putnam's and Armstrong's functionalism.

If machine functionalism were true, a homunculus-head would have all the mental states of its homunculus (by the definition of "realization"), which is absurd.

Reply to Elugardo 1983: so how do you specify what count as inputs/outputs?

Criticism of Lycan 1979, and a re-making of the argument.

Lycan's New Lilliputian argument fails as inputs/outputs for the homunculus are not the same as inputs/outputs for the full system.

Kane, R.H. 1966. Turing machines and mental objects

Argues for mechanism rather than functionalism. Criticizes Putnam for hypostasizing mental states, which are disanalogous to mental states. Defending mechanism against Kalke's & Rorty's objections.

Logical states don't give us any understanding of mind over and above what the function/structure distinction gives us. In particular, it doesn't help with the understanding of privacy and incorrigibility.

Contra Putnam: logical states are not physical states, and utterances about them are not about physical states.

Contra Lycan: machine functionalism can handle Bolivia and CRT cases by a causal/counterfactual account, and Lilliputian case by assigning mental states to minds, not bodies.

3.4c Functionalism, Miscellaneous
-------------------------------

A formal argument showing that functional definitions are equivalent to behavioral definitions.

The functional level is the appropriate level for psychology, but neurophysiological facts constrain this level and are thus relevant.

Ten papers on functionalism. Originally was Philosophical Topics, volume 12.

Distinguishes varieties of functionalism, e.g. machine and Ramsey-sentence functionalism; and compares to behaviorism. With a historical overview, and arguments for why functionalism is incompatible with physicalism.

Distinguishes analytic and empirical functionalism. Both have problems with absent qualia, and inputs/outputs. Analytic functionalism has problems with paralytics, etc; empirical functionalism has problems with Martians.

Mental states are not physical or behavioral states; could they be functional states? With various arguments against type identity, and against machine-table functionalism.

On the role of functional explanation versus other kinds of explanation. Functionalism applies an analytic, not subsumptive strategy.

On mental state as inferred theoretical entities, individuated according to their function (cf. valve-lifters). Psychology and neuroscience will mutually constrain each other, giving a relation more complex than reduction.

Argues that functional explanation are reducible to structural explanations.

There's no absolute functional/structural distinction, as it depends on how you choose boundaries and levels of abstraction.

Pursue a multi-leveled homuncular functionalism, with mental states characterized as states of teleologically identified subsystems. Even the identity theorist is a functionalist at a low level.

Scientific realism requires dispositions of kinds be explained by intrinsic properties. Neural/functional properties won't work, because of reductionism and circularity. Use intrinsic psychological properties instead.

Argues that functionalism is compatible with reductionism, by analogies. Genetics has multiple realization and multiple function; reduction doesn't require biconditionals. With remarks on the de facto autonomy of psychology.

Against functionalism for beliefs. Both common-sense functionalism and psychofunctionalism have problems with finding the right functional theory, distinguishing beliefs, perceptual input conditions, Twin Earth, etc.

Need teleological functionalism, not Turing Machine functionalism.

The structure/function distinction is level-relative, so physiology might be relevant even under functionalism. Problems with automata, and with causal connections to nonintentionally characterized behavior.

Functionalism may be appropriate for cognitive psychology but not for folk psychology, due to differing goals. Neuroscience will play an important role in developing functional theories.

Argues that the possibility of multiple realization has not been established, whether by arguments from imagination, concepts, or empirical facts.

3.5 Other Psychophysical Theories
---------------------------------

3.5a Logical Behaviorism (Ryle, etc)
------------------------------------

The ancestor of most contemporary philosophy of mind. Among other things, argues that the "ghost in the machine" view of mind is a category mistake, and presents dispositional analyses of many mental concepts.

Defends behaviorism as a scientific hypothesis, so that conceivability arguments aren't relevant, and advocates "penetrability" behaviorism which can appeal to internal physical states.

3.5b Identity Theory (Smart, etc) [see also 1.3c, 1.4g, 3.3b]

The idea that consciousness is a brain process is logically coherent. It's a scientific hypothesis, not a necessary truth. On the "is" of composition vs the "is" of definition, and the fallacy of the internal phenomenal field.

Defending the thesis that sensations are contingently identical to brain processes against various objections. Topic-neutral analysis of sensation reports. Materialism beats epiphenomenalism on grounds of simplicity.

The number of possible mental states is infinite (think of any number), whereas there are only finitely many brain states, so they're not identical.

Likens the anti-materialist position to the "headless woman" fallacy: "I'm not aware the mental states are physical", so "I'm aware that mental states are non-physical".

Armstrong, D.M. 1973. Epistemological foundations for a materialist theory of
mind. Philosophy of Science 40:178-93.

A prima facie case for materialism based on grounds of rational consensus, arising especially from common-sense and scientific evidence. Mental states exist (common-sense) but should be analyzed causally (evidence from science).

Mental states are necessarily private, and so cannot be physical states, which are public. We have epistemological authority about our mental states.

Argues that phenomenal properties aren’t needed to identify sensations with brain-states, and nor are topic-neutral analyses.

An anthology of central articles on the identity theory.

Arguing for an event-identity construal of the identity theory. Comparing the identity theory to the weaker "principle of simultaneous isomorphism". The only reason to accept the identity theory is ontological simplicity.

Carney, J. 1971. The compatibility of mind-body identity with dualism. Mind. Argues that the identity theory is compatible with linguistic dualism, as the mental and the physical may differ in intensional properties only.

On problems with theories that leave the nature of mind open a priori: how can we even understand the possibilities?

Location of mental states by convention (Shaffer 1961) won't work, as it (a)
makes mental states public, and (b) conflicts with connections to behavior.

2:251-70.

Philosophical Forum 7:139-58.

28:229-37.

80:279-98.

of Philosophy 43:77-81.

Studies 20:113-23.

Philosophical Quarterly 6:515-37.

45:221-6.

Hockutt, M. 1967. In defense of materialism. Philosophy and Phenomenological

Hoffman, R. 1967. Malcolm and Smart on brain-mind identity. Philosophy 42:
128-36.

On topic-neutral reports, after-images, and after-radishes. Such a report
requires epistemic access to physical resemblance, which we don't have.

Quarterly 3:227-35.

There's no empirical support for identity, over and above that for
correlation; and unity of science gives no reason to accept identity. The
only reason might be that of ontological simplicity.

Kim, J. 1972. Phenomenal properties, psychophysical laws and the identity

Deal with phenomenal properties by allowing only mental events, and
eliminating mental objects. Identity theories needn't suppose psychophysical
laws. With defense against multiple realizability arguments.

Kitcher, P.S. 1982. Two versions of the identity theory. Erkenntnis
Recasting the identity theory and functionalism, using Kripkean theories of reference, so mental states can refer to physiological or psychological states that we don't yet understand; and qualia problems are handled better.

Mental states are defined by their causal roles. So, by the completeness of physics, they must be physical states.

On how materialism, as opposed to a double aspect view, can handle mental features -- by moving them into the world via a realist theory of perception. Remarks on identification of states. After-images, etc, cause problems.

Using the special theory of relativity to show that if mental events have a temporal location, then they must have a spatial location.

The identity theory is meaningless, if identity is analyzed as spatiotemporal coincidence, as thoughts don't have location. Thoughts also require context. Even if identity holds, explaining brain doesn't imply explaining mind.

Sensations and processes have different logical type, so it is a priori impossible that they should be identical.

Identity requires explanation to be accepted, but Smart doesn't provide this. But one can deny identity without claiming dualism -- e.g. a "duck-rabbit" theory of mind/brain. With remarks on the completeness of descriptions.

Contra Smart 1959: Materialism is a scientific hypothesis, if we accept certain logical criteria for what a sensation is; otherwise it's just false.

Comparing contemporary materialism to Pace's 1956 variety. With remarks on whether the thesis is empirical or a priori, and on deciding the issue between materialism and epiphenomenalism.

Discusses a paper of Martin's and the genesis of the identity theory, with a focus on 'public' and 'private logic' and topic-neutral descriptions.

The identity theory must be false, as pain centers in vitro will not be pains. With a reply by G. Pearce and a rejoinder.

On the identity theory as a linguistic proposal, compatible with dualism; epiphenomenalism and parallelism must be false, leaving interactionism.

Mental states don't have a location, and brain processes do; but we could stipulate a location for mental states. With remarks on possible relations between mental and physical features, states, and concepts.

We identify mental events by noticing mental features that must be nonphysical, but still might be empirically reducible. Against topic-neutral definitions, and with response to Coburn 1963 on location.

Reply to Stevenson 1960: There are no irreducible mental properties; they reduce to physical properties via topic-neutral definitions.

Reply to Baier 1962: epistemological authority is compatible with materialism. Mental state reports are not completely incorrigible, though.

Defending topic-neutral analyses of mental reports, and arguing against Wittgensteinian behaviorism via brain-in-vat examples. With remarks on the appeal of materialism and on compatibility with ordinary language.

On some problems for the identity theory arising from the intensionality of mental states and from the appeal to properties, and on how to modify the translation form of the theory without embracing the disappearance version.

Identity theory implies nomological danglers, due to the irreducibility of defining mental properties.

The identity thesis isn't ontologically simpler than dualism: we still need a dualism of properties, and explanatory danglers. Not much turns on the issue, except in teleological explanation.

Contra Malcolm 1965: explaining brain will explain mind, if the explanation is conjoined with the identity statement. With rejoinder from Malcolm.

Property identity theses fail due to meaning differences, and event identity these fail due to a lack of entailment relations. Rebutts objections from
weaker identity criteria and analogies with scientific identification.

Suggests a theory in which neural states are components of, but not identical to, overall psychological states. This can accommodate raw feels if necessary as a further component, but is mostly materialistic.

3.5c Eliminative Materialism (Rorty, Feyerabend) [see also 1.4d, 1.7c, 2.1c]

Doppelt, G. 1977. Incorrigibility, the mental, and materialism. Philosophy Research Archives.

3.5d Anomalous Monism (Davidson)

Arguing for anomalous monism: no strict psychophysical laws, no strict psychological laws, and token identity without type identity. Mental events can still cause, via subsumption under physical laws.

The psychological supervenes on the physical but is not reducible to it, because of the holistic nature of intentional attribution. So building a perfect physical model may not explain psychology.

On the differing constitutive standards of mental and physical concepts. Attribution of mental concepts is holistic, and presupposes a background of rationality, etc. With examples from decision theory.

A collection of papers on action, causation and the philosophy of psychology.

Remarks on how mental properties can explain action without strict laws. The mental is a conceptual, not an ontological category, governed by normative standards, and not reducible to the non-normative.

Criticism of Davidson's argument for rational causation. Reasons must cause in virtue of their rational properties. Token identities can't exist, due to normativity. Quinean psychology can't yield rational explanations.

Anomalism is compatible with supervenience, if it is construed as denying psychophysical laws useful for explaining behavior. It is incompatible with token identity, though. With much on the uncodifiability of rationality.

   Davidson's argument equivocates on the term "physical": the physical events that mental events cause might not be subsumed under laws.

   Anomalous monism implies that mental properties don't cause anything.

   If anomalous monism is true, mental events may cause, but their mental properties aren't causally relevant.

   Anomalous monism loses out to Australian materialism. It can't be a priori, it leads to exhaustive monism, it doesn't support a new view of free action, and it implies the causal irrelevance of the mental.

   Davidson's view leads to epiphenomenalism about content, as it can't support the appropriate counterfactuals. Strong supervenience might be a way out, but that is inconsistent with anomalism.

   How there can be psychophysical generalizations but no laws -- they might lack modal force. On the relation between psychophysical anomalism and psychological anomalism. Casting Davidson as a Kantian dualist.

   Anomalous supervenience is consistent, at the cost of anti-realism about the mental. Supervenience is a constraint on interpretation, but needn't support counterfactuals as different interpretation schemes are possible.

   Problems with holism and ceteris paribus laws aren't unique to psychology. One finds the same thing in the physical sciences. So rationality plays no special role, and psychological laws are as reasonable as physical laws.

Anomalous monism is not committed to epiphenomenalism, as even non-strict laws can ground counterfactuals and so support the causal relevance of mental properties.

A functionalist defense against anomalous monism. Psychofunctional laws and psychological laws, though not psychophysical laws, may exist. Rebutting arguments from rationality, indeterminism, intensionality, etc.

Against Loar's functionalist reductionism: it doesn't begin to capture the normative role of rationality or the subjectivity of the mental.

A very thorough summary of Davidson's views. Highly recommended.

30 essays on Davidson.

Comments on Davidson 1992. Davidson can respond to critics accepting causal relevance of mental properties and still denying strict laws. Davidson misconstrues his critics' positions on supervenience.

Davidson is concerned with intentional, not phenomenal states; and his characterization of these is just as physical states under a certain description. So he avoids epiphenomenalism (contra e.g. Honderich 1982).

Kim's version of Davidson's argument against psychophysical laws cannot work. Elucidating the notion of a constitutive principle.

Anomalous monism implies that there aren't even heteronomic psychological generalizations, as variables can't be independently measured.

Supervenience is compatible with anomalism: biconditional laws are ruled out by the disjunctive base, and the wideness of mental states rules out one-way psychophysical laws, as there's no single property in the base.

Elucidating Davidson's argument, focusing on the argument against strict psychophysical laws. Generalizations involve disjunctive kinds
and so are heteronomic and not law-like.

Argues contra Kim that supervenience is compatible with anomalous monism: the
the disjunctive generalizations aren't lawlike, as they aren't confirmed by
their instances.

Smart, J.J.C. 1985. Davidson's minimal materialism. In (B. Vermazen &
M. Hintikka, eds) _Essays on Davidson_. Oxford University Press.
Some comments on holism, indeterminacy, anomalous, and materialism.

Response to Honderich 1982: physical events are individuated as mental states
by virtue of their causal role, so the mental is causally relevant.

_Mental Causation_. Oxford University Press.

Pacific Philosophical Quarterly 64:72-9.
Supervenience entails psychophysical principles, but this is compatible with
anomalous monism. On what constitutes a strict psychophysical law.

Suppes, P. 1985. Davidson's views on psychology as a science. In (B. Vermazen
& M. Hintikka, eds) _Essays on Davidson_. Oxford University Press.
Various: physics is indeterministic and intensional, animals have beliefs,
psychology has derived laws, and decision-theory doesn't need speech.

Tiffany, E.C. 2001. The rational character of belief and the argument for
mental anomalism. Philosophical Studies 103:258-314.

Philosophy Research Archives 7:1404.
Rationality constraints don't introduce an irreducibly normative element into
intentional attributions. Rationality serves as a condition of adequacy for
psychophysical theories, but it doesn't rule them out.

Philosophical Studies 71:59-79.

3.6 Mental Causation [see also 2.2c]
-----------------------

Antony, L. 1991. The causal relevance of the mental. Mind and Language
6:295-327.

Audi, R. 1993. Mental causation: Sustaining and dynamic. In (J. Heil &
A. Mele, eds) _Mental Causation_. Oxford University Press.
Mental causation is incompatible with strong supervenience and causal closure of physics, as we can't distinguish high-level causes from non-causes. So reject the metaphysics and make explanation prior to causation.

Arguing for the causal efficacy and scientific respectability of higher-order states, such as functional-role states. To require appeal to particular physical states is to succumb to a "Tractarian" view of physical primacy.

Rescuing content from epiphenomenalism via functional role argument; but then functional roles aren't really causally efficacious (cf. dormitive virtue), so epi all over again? Roles vs fillers, causation vs explanation.

Mental causation is not a real worry, but the to-do shows that materialist metaphysics has shed little light on it. It needs to be understood at the mental level. With remarks on exclusion arguments and token identity.

How can a relation to a proposition (an abstract object) be causally efficacious? Analogy with numbers doesn't work: weight properties are only pseudo-relational, depending on units, but propositions are absolute.

Argues that anomalism and causal closure don't pose problems for mental causation as they are false, and that functional properties can efficacious. States with content may be efficacious, although content itself may not be.

Argues that mental causation is a deep problem for constitutive (but not identity) forms of physicalism. The only way out is to argue that it is a different variety of causation. But then what motivates physicalism?

Mental events are structuring causes of behavior; biological events are triggering causes, dependent on previous mental structuring. This allows extrinsic properties to play a causal role.

On various problems with mental causation, and the relationship between psychology and philosophy.

The identity theory and psychoneural correlation can't handle mental causation; only the union theory can. Anti-individualism causes problems, but should be rejected in any case.

How mental events are causally relevant qua mental: via an account of "qua" causation in general, using counterfactuals on "pertinently similar worlds".

A defense of functional role as a causally efficacious property of physical states. With application to connectionism & eliminativism.

How can content properties be causes, given that content is a matter of functional role and that functional properties are not causes? Defends a type-identity answer against various objections.

A "state of the art" review paper, concentrating on problems posed by autonomy, functionalism, and externalism, and advocating a sort of identity theory. With discussion of a "map-system" view vs. a language of thought.

Psychological causation, like all macrocausation, is supervenient epiphenomenal causation.

Argues that nonreductive materialism implies downward causation (as the mental has more causal powers than the physical alone), and that downward causation violates the causal closure of the physical.

Kim, J. 1992. "Downward causation" in emergentism and nonreductive physicalism. In (A. Beckermann, H. Flohr, & J. Kim, eds) _Emergence or
Reduction?: Prospects for Nonreductive Physicalism_. De Gruyter.

http://www.u.arizona.edu/~chalmers/biblio/3.ascii (42 of 59) [4/7/2002 1:50:38 PM]
On making sense of the causal efficacy of higher-level properties under naturalism. They're relevant at the program level, not quite in the way that basic properties are. With remarks on Macdonald's objections.

On Goldman's (1969) argument that dualism and causal closure are compatible with mental causation. Goldman establishes only hypothetical necessity, not causal necessity.

Intentionality is caused by the physical, and causes. More a 1P emphasis.

Interactionist dualism is out, supervenient causation is in. But there are problems with mental events' causal relevance qua mental, especially for anomalous monism. Cf: a loud shot causes death, but loudness isn't relevant.

On three arguments against mental causation, from strict laws, non-local supervenience, and especially exclusion. Mental properties are stable, recurring high-level patterns with their own causal relevance.

Argues that mental events/properties stand to physical events/properties as determinable to determinates, solving the exclusion problem. Some mental events are *better* candidates for the cause of action than physical events.

Argues that anomalous monism is compatible with mental causation: supervenience is necessary and sufficient for causal efficacy.

4.1 Can Machines Think? [224]

4.1a The Turing Test [51]

Proposes the Imitation game (Turing test) as a test for intelligence: If a machine can't be told apart from a human in a conversation over a teletype, then that's good enough. With responses to various objections.

A look-up table could pass the Turing test, and surely isn't intelligent. The TT errs in testing behavior and not mechanisms. A nice, thorough paper.

Defending the Turing test as a good test for intelligence.

The Turing Test is too hard, as it requires not intelligence but human intelligence. Any machine could be unmasked through careful questioning, but this wouldn't mean that the machine was unintelligent.

Response to Jacquette 1993.

The Turing test is not broad enough: there's much more to thought than the ability to play the imitation game.

On the Total Turing Test (full behavioral equivalence) as a test for mind.

A dialogue on the Turing test.

Defending the Turing test against French 1990. Turing did not intend the test to provide a *necessary* condition for intelligence.

Turing's test is neutral about the structure of the machine that passes it, but it must be practical and reliable (thus excluding Searle's and Block's counterexamples).

The basis of the Turing test is not an operational definition of thinking, but rather an inference to the best explanation.

Reply to Stalker 1978: Mechanistic and mentalistic explanations are no more incompatible than program-based and physical explanations.

Some obscure remarks on lying, imitation, and the Turing test.

A weak argument against Block: input/output function doesn't guarantee a capacity to respond sensibly.

The Turing test presupposes a representational/computational framework for cognition. Not all phenomena can be captured in teletype communication.

the Association for Computing Machinery 37:70-82.

Contra Moor 1976: The best explanation of computer behavior is mechanistic, not mentalistic.

4.1b Godelian arguments (Lucas, Penrose)

Discusses and sharpens Lucas's arguments. Argues that the real consequence is that if we are Turing machines, we can't know which.

Lucas's very Godelization procedure makes him inconsistent, unless he has an independent way to see if any TM is consistent, which he doesn't.

Remarks on the various ways in which Lucas and a machine might be said to "prove" anything, and the ways in which a machine might simulate Lucas.

The argument has all sorts of level confusions, and a bit of circularity.

Can't reduce the lawless creative process to computation.

An analysis of the Lucas/Benacerraf argument. On various senses in which a machine might come to know its own program.

Only mathematicians understand Godel, so Lucas's argument isn't general; and Turing machines can go wrong. Weak.

There is no unique TM which we are -- there could be many.

Lucas's argument applies only to deductive machines, not inductive ones.

Even humans can't Godelize forever.  On ordinals and transfinite counting.

Rejoinder to Lucas 1967: the role of consistency; non-constructible ordinals.

An analysis of Benacerraf 1967.  Benacerraf's "paradox" is illusory; there are no strong consequences of Godel's theorem for mechanism.

Contra Lucas: we can't Godelize forever; and we're not formal on top level.

Hutton, A. 1976.  This Godel is killing me.  Philosophia 3:135-44.

Gives a statistical argument to the effect that we cannot know that we are consistent; so the Lucas argument cannot go through.

Contra Lewis 1979, Lucas can derive the consistency of M even without the premise that he is M.  Hmm.

A nice analysis of Lucas's argument and the circumstances under which a machine might prove another's Godel sentences.  There's no reason to believe that machines and humans are different here.

A machine will fail a Turing test if it's asked about Godel sentences.

Lucas's argument fails, as theorems by humans don't correspond to outputs of their formal systems.

Lucas needs a rule of inference from sentences to their consistency, yielding Lucas arithmetic.  No machine can prove all of Lucas arithmetic, but there's no reason to suppose humans can either, as the rule is infinitary.

Reply to Lucas 1970: the dialectical argument fails, as the human's output depends on the premise that it is the machine (to derive M's consistency). With a similar premise, the machine itself can do equally well.

Humans can Godelize any given machine, so we're not a machine.

Reply to Good 1967: a human can trump any given machine, so the human is not the machine, whether or not the human is superior across the board.

Benacerraf 1967 is empty and omega-inconsistent. Reply to arguments based on difficulty of seeing consistency (e.g. Putnam). Fallacious but engaging.

Response to Lewis 1969 and Coder 1969. Lewis misses the dialectical nature of the argument.

Contra Hutton, we know -- even if fallibly -- that we are consistent.

Reply to Lewis 1979.

Martin, J. & Engleman, K. 1990. The mind's I has two eyes. Philosophy 510-16.
Contra Hofstadter: Lucas can believe his Whitely sentence.

Maudlin, T. 1996. Between the motion and the act... Psyche 2:40-51.

We are non-algorithmic as we can see Godel sentences of any algorithm.

Much debate over the "non-algorithmic insight" in seeing Godel sentences.

An argument from the halting problem to the nonalgorithmicity of mathematical thought. Addresses objections: that the algorithm is unknowable, unsound, everchanging, environmental, or random. New physical laws may be involved.

A reply to Chalmers, Peferman, Maudlin, McDermott, etc.

A generalized Godelian argument: if our prescriptive inductive competence is formalizable, then we could not know that such a formalization is correct.

Penrose's argument depends on our knowledge of the validity of the algorithm we use, and here he equivocates between conscious and unconscious algorithms.

General analysis; Lucas commits type/token error; self-ref paradoxes.

Cogito was a diagonal argument; connection to Godel, Lucas, Minsky, Nagel.

A machine could escape the Godelian argument by inductively ascertaining its own syntax. With comments on the relevance of ingenuity.

Weak defense of Lucas; response to Putnam, Bowie, Dennett.

Humans get trapped too: "Lucas cannot consistently assert this formula".

4.1c The Chinese Room (Searle)

Implementing a program is not sufficient for mentality, as someone could e.g.
implement a "Chinese-speaking" program without understanding Chinese. So strong AI is false, and no program is sufficient for consciousness.

Axiomatizes the argument: Syntax isn't sufficient for semantics, programs are syntactic, minds are semantic, so no program is sufficient for mind.

More on the arguments against AI, e.g. the Chinese room and considerations about syntax and semantics. Mind is a high-level physical property of brain.

On the status of the Chinese Room argument, ten years on.

A procedural account of how computers might have understanding and semantics.

A fully functional Chinese room is impossible, as it (for instance) could not say what the time is.

A chess-playing machine embodied as a robot could have intentional states. Reference requires input/output, computation, and context.

Criticizes Searle's "conclusion" that brains are needed for intentionality, notes that even a homunculus has intentional states. A misinterpretation.

Arguing against Searle on a number of fronts, somewhat unconvincingly.

Gives an account of symbolic vs. subsymbolic computation, and argues that the latter is less vulnerable to the Chinese-room intuition, as representations there are not computational tokens.

Artificial mentality is possible, not through classical AI but through brain-like AI. Argues the syntax/semantics point using an analogy with electromagnetism and luminance.

Lots of thought experiments like Searle's, against Searle. Searle's argument is like Leibniz's "mill" argument, with similar level confusions. Nice but patchy.

In the Chinese room, neither the person nor the system understands: a virtual person does. This person isn't the system, just as a normal person isn't a body. Follows from the "Kornese" room, which has two distinct understanders.

A discussion about the Chinese room, symbol grounding, and so on.

Searle is committing a level confusion, and understates the complexity of the case. We can move from the CR to a brain (with a demon) by twiddling knobs, and the systems reply should work equally well in both cases.

Searle's view implies that intentional causation is not efficient causation.

If we had microfunctional correspondence, the CR argument would fail. With points about the status of abstract/biological intentionality. A bit weak.

Jacquette misses the point of the argument. Also, biological and abstract intentionality are quite compatible.

Reply to Searle on CR, central control, biological intentionality & dualism.

Against Rapaport's Korean Room argument -- syntax isn't enough.

The Chinese room doesn't succeed as an argument about semantics. At best it might succeed as an argument about consciousness.

Defends Searle against all kinds of objections.

Computational systems must also meet performance criteria.

A program can possess intentionality, even if not consciousness.

Comments on Cole, and some general material on syntax and semantics.

Recommends the systems reply, and a causal account of semantics. Discusses
the relevance of wide and narrow notions of content, and the tension
between Searle's positive and negative proposals.

Roberts, L. 1990. Searle's extension of the Chinese Room to connectionist
machines. Journal of Experimental and Theoretical Artificial Intelligence
  In arguing against the relevance of the serial/parallel distinction to mental
states, Searle becomes a formalist. A nice point.

  Searle's presence in the room destroys the integrity of the system, so that
it is no longer a proper implementation of the program.

20:167-73.
  A person running the program, with interpretations at hand, would understand.
  Point-missing.

Sharvy, R. 1985. Searle on programs and intentionality. Canadian Journal of
Philosophy Supplement 11:39-54.
  Argues against Searle, but misses the point for the most part.

Sloman, A. 1986. Did Searle attack Strong Strong AI or Weak Strong AI? In
(Cohn & Thomas, eds) _Artificial Intelligence and its Applications_.
  Chichester.

  Story about homunculi within homunculi. Fun.

Thagard, P. 1986. The emergence of meaning: An escape from Searle's Chinese
Room. Behaviorism 14:139-46.
  Get semantics computationally via induction and functional roles.

  Searle-in-the-room isn't in a position to know about the system's
  first-person states. Intrinsic intentionality is an incoherent notion.

Whitmer, J.M. 1983. Intentionality, artificial intelligence, and the causal
  Defending Searle's position, with remarks on the "causal powers" argument.

4.1d Machine Consciousness, Misc [see also 1.8b]

Angel, L. 1994. Am I a computer? In (E. Dietrich, ed) _Thinking Computers and
Virtual Persons_. Academic Press.

Barnes, E. 1991. The causal history of computational activity: Maudlin and
  Response to Maudlin 1989. True computation needs active, not passive
causation, so Maudlin's machine isn't really computing.

One could model brain states with monadic states and appropriate connections. But surely that's not intelligent -- the causation has the wrong form. Nice.

Computational state is not sufficient for consciousness, as it can be instantiated by a mostly inert object. A nice thought-experiment, raising questions about the relevance of counterfactuals to consciousness.

Of course, as we are machines. But what *sort* of machines are conscious, and in virtue of what properties? Remarks on artefacts, life, functionalism, and computationalism. So far, we don't know what makes the brain conscious.

Machines can think but can't feel, so aren't persons.

Various arguments and counter-arguments re machine consciousness and civil liberties. Problems of machine consciousness are analogous to problems of human consciousness. The structural basis of the two may well be the same.

More on TMs: explaining their psychology via preference functions.

To speak of a conscious machine is to commit a semantic mistake.
Consciousness presupposes life and non-mechanism. Later retracted.

Argues that AI systems like Pollock's Oscar needn't be conscious. Blindsight tells us that complex perceptual processing can go on unconsciously.

Accepting machine consciousness would have few philosophical consequences, whereas rejecting it would tend to commit one to epiphenomenalism.

Of course robots can't think: they're not alive, so this gives us good reason not to rely on behavior. With replies by J.J.C. Smart, N. Smart.

4.1e Machine Thought, Misc

Arguing that a finite deterministic automaton can perform all natural human functions. With remarks on the logical organization of computers.

Subservience to known or knowable rules is incompatible with mentality.

Defends the Turing Test, among other things.

Intelligence requires not just action or thought, but the governance of action by thought, which requires a history. "Wired-up" systems lack the explanatory connection between thought and action, so are not intelligent.

Computers follow rules, people don't.

On the philosophical importance of criteria for intelligence. With remarks on Searle, the Turing test, attitudes to AI, and ethical considerations.

An expert system would lack Holmes' ability to raise the right questions, sort out relevant data, and determine what data are in need of explanation.

Lucas, Searle, and Penrose all fall prey to "dual-description" fallacies.

A machine could possess every characteristic of human thought: e.g. freedom, creativity, learning, understanding, perceiving, feeling.

4.2 Computation and Representation
----------------------------------

4.2a Symbols and Symbol Systems [see also 2.1a, 4.3e]
-----------------------------------------------

AI symbols are empty and meaningless. They need to be "grounded" in something, e.g. sensory projection. Maybe connectionism can do the trick?

On the limitations of symbol systems, and the potential for grounding symbols in sensory icons and categorical perception, e.g. with neural networks.

On computer science, AI, & the Physical Symbol System Hypothesis.

4.2b Computational Semantics
----------------------------

Against procedural semantics; it's a rerun of verificationism.

On the virtues of denotational semantics for AI. Notation without denotation, as found in many AI systems, leads to castles in the air.

  Criticism of McDermott's views on semantics, logic and natural language.

  With commentaries by Haugeland, J.D. Fodor.

4.2c Implicit/Explicit Rules and Representations
-----------------------------------------------

  Argues that we need explicit rules for flexibility, adaptibility, and representational redescription. With remarks on eliminativism.

  On various kinds of representation of knowledge or belief without explicit tokens: control-implicit, domain-implicit, and procedural information.
  The key distinction is representation vs. execution of a rule.

Hadley, R.F. 1990. Connectionism, rule-following, and symbolic manipulation. Proc AAAI.
  Some rules are learnt so quickly that representation must be explicit.

Kirsh, D. 1990. When is information explicitly represented? In (P. Hanson, ed) _Information, Language and Cognition_.  University of British Columbia Press.

  Cummins' account of inexplicit information fails, as even "executed" rules
must be represented in the system. With remarks on the Chinese room.

4.2d AI without Representation?

We don't need explicit representation; the world can do the job instead.
Use embodied, complete systems, starting simple and working incrementally.

A discussion of anti-representationalism in situated robotics and the dynamic systems movement (Brooks, Beer, van Gelder). These arguments appeal to overly simple domains, and a modest notion of representation survives.

Args for a dynamic-systems conception of the mind that is non-computational and non-representational. Uses an analogy with the Watt steam governor to argue for a new kind of dynamic explanation.

4.2e Miscellaneous

On the problems with context-free symbolic representation.

On Searle's critique of computational explanation, contrasted with Gallistel's use thereof. The real issue is computation on indirect vs. direct representations; direct computationalism is an attractive view.

4.3 Philosophy of Connectionism

4.3a Connectionism and Compositionality (Fodor/Pylshyn)

http://www.u.arizona.edu/~chalmers/biblio/4.ascii
Connectionist models can't explain cognitive systematicity and productivity, as their representations lack compositional structure. The allures of connectionism are illusory; it's best used as an implementation strategy.

Fodor and Pylyshyn's argument is an invalid instance of inference to the best explanation, as there is much to explain than systematicity. Connectionism and classicism may be compatible even without implementation, in any case.

Connectionism can make do with unstructured representations, as long have they have the right causal relations between them.

Contra Chalmers 1993, F&P's argument doesn't apply at the implementational level. Contra Chater and Oaksford 1990, connectionism can't be purely implementational, but some implementational details can be relevant.

Argues against Clark on holism and the conceptual truth of systematicity.

An experimental demonstration that connectionist models can handle structure-sensitive operations in a non-classical way, transforming structured representations of active sentences to passive sentences.

Points out a structural flaw in F&P's argument, and traces the problem to a lack of appreciation of distributed representation. With some empirical results on structure sensitive processing, and some remarks on explanation.

Implementation can make a difference at the algorithmic level.

Smolensky's weak compositionality is useless; and tensor product architecture can't support systematicity, as nonexistent tokens can't play a causal role.

Argues that existing connectionist models do not achieve an adequate systematicity in learning; they fail to generalize to handle structures with novel constituents.

Localist connectionist models may not be able to handle structured presentation, but appropriate distributed models can.

A discussion of how connectionism might achieve "effective syntax" without implementing a classical system.

F&P deal a sucker bet: on their terms, connectionism could never give a non-implementational explanation of systematicity, as the notions are construed in a manner specific to classical architectures.

Against responses to Fodor and Pylyshyn claiming that cognitive theories needn't explain systematicity. Contra Clark, the conceptual truth of systematicity won't help. Contra others, nor will evolution.

Argues that no connectionist model so far has come close to explaining systematicity. Considers the models of Elman, Chalmers, and Smolensky.

Develops a connectionist architecture -- recursive auto-associative memory -- that can recursively represent compositional structures in distributed form.

F&P's argument confuses constituent structure with logical/sentential structure. Connectionism is a psychotechtonic project, whereas propositional description is a psychosemantic project.

F&P ignore distributed representation and interaction effects.

Develops a connectionist architecture that represents compositional structures as tensor products of distributed representations.

Connectionism can do compositionality its own way, including both weak compositionality (with context effects) or strong compositionality (via tensor products).

Connectionism can do compositionality functionally. All one needs is the right functional relation between representations; physical concatenation is not necessary.

On connectionism as a Kuhnian paradigm shift in cognitive science, with emphasis on the implications of functional compositionality and distributed representations.

4.3b Representation in Connectionism
-------------------------------------
Butler, K. 1995. Representation and computation in a deflationary assessment

On some troubles connectionism has with higher-order knowledge. Contrasts Cussins, Karmiloff-Smith on development. Subsymbols without symbols are blind.

On the importance of representational redescription, and on the limits of connectionist networks in cross-domain knowledge transfer. What does a true believer need, above behavior: conceptual combination, real-world fluency?

Connectionism isn't really radical. There's no new concept of representation or of learning, and cognition can still be the manipulation of semantically structured representations.

Connectionism builds up concepts from the nonconceptual level. From nonconceptual content (e.g. perceptual experiences) to the emergence of objectivity.

Some remarks on psychology & physiology. Even connectionism uses psychological concepts.

Place, U.T. 1989. Toward a connectionist version of the causal theory of

Argues that talk of representations has no explanatory role in connectionist theory, and can be discarded. It can't be understood along the lines of the teleo-informational or classical frameworks.

Pictorialism isn't compatible with language of thought, but connectionism might be.

Arguments that distributed representation is best analyzed in terms of superposition of representation, not in terms of extendedness.

4.3c Connectionism and Eliminativism
------------------------------------

Connectionism implies eliminativism, as connectionist systems do not have functionally discrete contentful states, and folk psychology is committed to functional discreteness of propositional attitudes.

Outlines the semantic view of scientific theories, and applies it to the connectionism/eliminativism debate. There's no reason why folk psychology shouldn't be reducible, in a homogeneous or heterogeneous way.

Distinguishes active from dispositional beliefs: the former are realized discretely in activation patterns, the latter nondiscretely in weights, which is all that folk psychology needs.

Commentary on Ramsey/Stich/Garon. Connectionism has symbols that interact, and has propositional modularity in processing if not in storage.

Connectionism needn't imply eliminativism, as higher levels may have a causal role, if not causal completeness. Also, it may not tell the whole story.

Responding to eliminativist challenge via cluster analysis and recurrence.

Argues that our conception of thought requires causal systematicity, which
requires a language of thought. Connectionist systems are not causally
systematic, so connectionism leads to eliminativism.

Egan, F. 1995. Folk psychology and cognitive architecture. Philosophy of

Philosophical Psychology 7:437-52.

Contra Ramsey, Stich, and Garon, connectionist representations can be seen
to be functionally discrete on an appropriate analysis of causal relevance.

Horgan, T., and Tienson, J. 1995. Connectionism and the commitments of folk
psychology. Philosophical Perspectives 9:127-52.

4:165-78.

Studies 74:325-46.

A dispositional construal of beliefs and desires can distinguish the relevant
active states (via counterfactuals) and is compatible with FP, so internals
can't threaten FP. With remarks on Davidson, overdetermination, etc.

to Forster and Saidel. Philosophical Psychology 7:453-61.

Upon examination, the model of Forster and Saidel 1994 does not exhibit
features that are both distributed and causally discrete.

Smolensky, P. 1995. On the projectable predicates of connectionist psychology:
A case for belief. In (C. Macdonald, ed) Connectionism: Debates on
Psychological Explanation_. Blackwell.

minds have beliefs? In (C. Macdonald, ed) Connectionism: Debates on
Psychological Explanation_. Blackwell.

4.3d The Connectionist/Classical Debate
-------------------------------

Adams, F., Aizawa, K. & Fuller, G. 1992. Rules in programming languages and
networks. In (J. Dinsmore, ed) The Symbolic and Connectionist Paradigms:
Closing the Gap_. Lawrence Erlbaum.

The distinction between programming languages and networks is neutral on
rule-following, etc, so there's nothing really new about connectionism.

Bringsjord, S. 1991. Is the connectionist-logicist debate one of AI's
wonderful red herrings? Journal of Theoretical and Experimental Artificial
Intelligence 3:319-49.

A detailed analysis purporting to show that connectionism and "logicism" are
compatible, as Turing machines can do everything a neural network can.
Entertaining, but misunderstands subsymbolic processing.

Distributed models are not at the implementational, not computational, level.

Chandrasekaran, B., Goel, A. & Allemang, D. 1988. Connectionism and
information-processing abstractions. AI Magazine 24-34.

Connectionism won't affect AI too much, as AI is concerned with the
information-processing (task) level. With greater modularity, connectionism
will look more like traditional AI.

Synthese 95:141-68.

provide models that are not mere implementations of classical theories.
Philosophical Psychology 10:25-40.

Dennett, D.C. 1986. The logical geography of computational approaches: A view
from the east pole. In (M. Brand & R. Harnish, eds) _The Representation of
Knowledge and Belief_. University of Arizona Press.

Drawing the battle-lines: High Church Computationalism at the "East Pole",
New Connectionism, Zen Holism, etc, at various locations on the "West Coast".
With remarks on connectionism, and on AI as thought-experimentation.

Dennett, D.C. 1991. Mother Nature versus the walking encyclopedia. In
(W. Ramsey, S. Stich, & D. Rumelhart, eds) _Philosophy and Connectionist
Theory_. Lawrence Erlbaum.

Reiterating the value of connectionism, especially biological plausibility.

Dinsmore, J. (ed) 1992. _The Symbolic and Connectionist Paradigms: Closing the
Gap_. Lawrence Erlbaum.

(T. Horgan & J. Tienson, eds) _Connectionism and the Philosophy of Mind_.
Kluwer.

In (T. Horgan & J. Tienson, eds) _Connectionism and the Philosophy of Mind_.
Kluwer.

Connectionism and classicism aren't necessarily incompatible on symbolic
discreteness, causal role, functional discreteness, constituency,
representation of rules.

100:291-306.

On connectionism, basketball, and representation without rules. Responses
to the "syntactic" and "semantic" arguments against connectionism. Nice.

Perspectives 17:147-74.

Cognition uses structured representations without high-level rules, and
connectionism is better at accounting for this. With remarks on exceptions
to psychological laws, and the crisis in traditional AI.

Horgan, T. & Tienson, J. 1994. Representations don't need rules: Reply to

Response to Broadbent 1985: Distributed models are at the algorithmic level.
Elucidating the low-level/high-level relation via various analogies.
Argues that symbolic systems such as decision trees are as good at learning and pattern recognition as connectionist networks, and it is just as plausible that they are implemented in the brain.

Challenges connectionism to explain things that the classical approach seems to handle better: the structure, systematicity, causal role, and grain of propositional attitudes, their rational relations, and conceptual stability.

4.3e Subsymbolic Computation (Smolensky)
----------------------------------------
Connectionism offers a complete account at the subsymbolic level, rather than an approximate account at the symbolic level.

Explicates the distinction between symbolic and subsymbolic computation, and argues that connectionism can better handle the emergence of semantics from syntax, due to the non-atomic nature of its representations.

AI needs statistical emergence. For real semantics, symbols must be decomposable, complex, autonomous -- i.e. active.

Argues with Smolensky: symbolic systems such as decision trees have all the positive features of neural networks (flexibility, lack of brittleness), and can represent concepts as sets of subconcepts. With a reply by Clark.

Rejects Smolensky's PTC, as the proper interaction of the microscopic and macroscopic levels would take a "miracle".

On connectionist networks as subsymbolic dynamic systems.

4.3f Philosophy of Connectionism, Misc.
---------------------------------------

Bechtel, W. 1986. What happens to accounts of mind-brain relations if we forgo an architecture of rules and representations? Philosophy of Science
Association 1986, 159-71.
On the relationship between connectionism, symbol processing, psychology and neuroscience.

Lots of questions about connectionism.

There's room for both styles within a single mind. The rule-based level needn't be autonomous; the connectionist level plays a role in pattern recognition, concepts, and so on.

An account of the shift from propositions to pattern recognition in the study of cognition: knowing-how, imagery, categorization, connectionism.

Argues that connectionism allows for a more plausible epistemology of perception, compatible with direct realism rather than representationalism.
With remarks on Fodor and Pylyshyn's argument against Gibson.

Connectionism will revolutionize our review of scientific theories: From the deductive-nomological view to descent in weight-space. Some cute analogies.

We achieve explanatory understanding not through the manipulation of propositions but through the activation of prototypes.

Implications of connectionism and neuroscience for our concept of mind.

All kinds of stuff on connectionism and philosophy.

Connectionism separates processing from competence. Instead of hopping down Marr's levels (theory->process), connectionism goes (1) task (2) low-level performance (3) extract theory from process. Cute.

On computation and representation in AI and connectionism, and on problems for radical connectionism in reconciling these without denying representation or embracing mystery.

Explicates computationalism, and discusses ways in which connectionism might end up non-computational: if causal states cross-classify representational states, or if transitions between representations aren't computable.

Argues that connectionist networks don’t have tacit knowledge of modular theories (as representations lack the appropriate structure, etc.).

Gibson is compatible with connectionism. In both, we can have rule-instantiation without rule-following.

An overview: local/distributed/featural representations; explanation in connectionism (how to avoid big mush); relation to neuroscience; explicit representations of rules vs weight matrices.

On various ways in which connectionism relates to representational homuncular functionalism, e.g. on implementation, eliminativism, and explanation.

How connectionism bears on the nativism debate. Conclusion: not too much.

Criticism of Churchland's connectionist epistemology.

In some senses of "cognitive", yes; in other senses, no. Phenomenological, theoretical, and sociological perspectives. Toward meaning-laden models.

4.3g Foundational Empirical Issues
----------------------------------

On how to get connectionist networks to learn about structured task domains.
Concentrates on incremental learning, and other developmental/scaffolding strategies. With remarks on systematicity.

Criticizes connectionism for not being sufficiently rooted in neuroscience, and for not being grounded in the world.

What's new to connectionism is not learning or representation but the way that learning and representation interact.

Addresses behaviorist/associationist charges. Connectionism needs recurrent circuits to support active symbols.

On the importance of variable binding, and why it's hard with connectionism.

Criticism of connectionist language models. They build in too much.

On the relationship between ND, PDP and AI. All are computational.

Connectionism is better at explaining empirical findings about mind.

Extremely thorough criticism of the R&M past-tense-learning model, with arguments on why connectionism can't handle linguistic rules.

4.4 Dynamical Systems
---------------------

On the brain as a vector-processing system, and the problems raised by indeterminacy, chaos, and so on. With morals for cognitive science.

4.5 Foundational Questions in AI

4.5a The Nature of AI

4.5b Levels of Analysis (Marr, etc)

Minds and Machines 4:1-25.

   Outlines a theory of the equivalence of algorithms.

   Generalizes Marr's levels to: cognitive state-transitions, mathematical state-transitions, implementation. Discusses these with respect to connectionism, dynamical systems, and computation below the cognitive level.

   On levels of organization vs. levels of analysis.

   Defines computational, algorithmic and implementational levels.

   On different kinds of level-shifts: organizational and contextual changes. There are more than three levels available.

   With commentaries by Smith, Dennett.

   Psychological explanation is typically somewhere *between* the computational and algorithmic levels.

4.5c The Frame Problem
-----------------------

   General overview.

   FP is an artifact of computational explicitness. Contrast human commonsense know-how, with relevance built in. Comparison to expert/novice distinction.

   FP is Hamlet's problem: when to stop thinking. It's equivalent to the general problem of non-demonstrative inference.
The FP may be a consequence of the explicit/implicit rep distinction. Use "complicit" reps instead, and changes will be carried along intrinsically.

FP is a relatively narrow problem, Some, e.g. Fodor, wrongly equate FP with the "Generalized AI Problem".

Criticizes Dennett's, Haugeland's and Fodor's construals of the FP.

McDermott, D. 1987. We've been framed: Or, Why AI is innocent of the frame problem. In (Z. Pylyshyn, ed) _The Robot's Dilemma_. Ablex.
Solve frame problem by using the sleeping-dog strategy -- keeping things fixed unless there's a reason to suppose otherwise.

Lots of papers on the frame problem.

4.5d AI Methodology
---------------------

AI must integrate perception and cognition in the interest of flexible representation. Current models ignore perception and the development of representation, but this cannot be separated from later cognitive processes.

AI should look at biology.

Micro-worlds don't test true understanding, and frames and scripts are doomed to leave out too much. Explicit representation can't capture intelligence.
  History of AI (boo) and connectionism (qualified hooray). And Husserl/Heidegger/Wittgenstein. Quite nice.

  Various AI approaches to belief: syntactic, propositional/meaning-based, information, tractability, discoverability, and degree of confidence.

  AI will need holism: interpretational, common-sense, situational, existential.

  Identifying the dividing lines: pre-eminence of knowledge, embodiment, language-like kinematics, role of learning, uniformity of architecture.

  AI usually comes up with Type 2 (algorithmic) theories, when Type 1 (info processing) theories might be more useful -- at least if they exist.

  Problems in AI methodology: wishful mnemonics, oversimplifying natural language concepts, and never implementing programs. Entertaining.

  Criticism of logicism (i.e. reliance on deduction) in AI.

  Lots of papers on various aspects of AI methodology. Quite thorough.

  On the non-represented background to everyday activity, and environmental interaction in cognition. Criticizes cognitivism, connectionism, looks at Agre/Chapman/Brooks, ethology, anthropology for support.

  10 papers on philosophy of AI, psychology and knowledge representation.

  Defending limited rationalism: i.e. a theory of intelligence below the conceptual level but above the neuronal level.

4.6 Computationalism in Cognitive Science [see also 2.2e]

-----------------------------------------

Computationalism is false, as it can't distinguish the ability to solve a maze for the ability to solve its mirror image. An embodied computational taxonomy is needed, rather than software alone.

Only belief is computational: rest of mind is not.

Nelson, R. 1987. Machine models for cognitive science. Philosophy of Science Argues contra Pylyshyn 1984 that finite state automata are good models for cognitive science: they are semantically interpretable and process symbols.

A thorough account of the symbolic/computational view of cognition.

An overview of the computational view of mind. On symbols, levels, control structures, levels of correspondence for computational models, and empirical methods for determining degrees of equivalence.

Various points on pros and cons of computational psychology.

4.7 Computation and Physical Systems

Gives an account of what it is for a physical system to implement a
computation: the causal structure of the system must mirror the formal structure of the computation. Answers objections by Searle and others.

Argues that Putnam's "proof" that every ordinary open system implements every finite automaton is fallacious. It can be patched up, but an appropriate account of implementation resists these difficulties.

Many physically realized functions can't be computed by Turing machines: e.g. "mundane procedures" and continuous functions. So the C-T thesis is false of these, and maybe even of number-theoretic functions.

Adapts Goodman's notational systems to explicate computational information processing. What is/isn't a physical notational system (e.g. LOT, symbol systems, connectionism) and why. How to reconcile notational/mental content?

Pragmatic factors are vital in connecting the theory of computation with empirical theory, and particularly in determining whether a given system counts as performing a given computation.

Syntax isn't intrinsic to physics, so computational ascriptions are assigned by observer. Syntax has no causal powers. Brain doesn't process information.

Disputes Kripke's argument that there is no objective way of determining when a system computes a given function, due to infinite domains and unreliability. Stipulating normal background conditions is sufficient.

4.8 Philosophy of AI, Misc
--------------------------

12 papers on the foundations of AI and cognitive science.

Thagard 1986 is wrong: speed and the like make no fundamental difference. With Thagard's reply: it makes a difference in practice, if not in principle.

A nice paper on the relationship between techniques of theory formation from machine learning and philosophical problems of induction and knowledge.

All about how the computer should change the way we think about the mind.

Parallelism does make a difference. Some somewhat anti-functionalist points.

A comparison of philosophical and AI approaches to explanation: deductive, statistical, schematic, analogical, causal, and linguistic.

5.4 Philosophy of Mind (General) [27]

5.1 Issues in Cognitive Science
-------------------------------
5.1a Nativism (Chomsky, etc)
----------------------------

   Reply to Putnam 1967: Putnam underestimates complexity of grammar, etc.

Concepts are undefinable, so primitive, so innate (plus gloss).

Overview; poverty of stimulus, unobservable features => rationalism.

An excellent collection of papers & responses by Piaget, Chomsky and others.

Why learning is selective and not instructive. Biological analogies, linguistic evidence. Dispense with "learning" as a scientific term.

Contra nativism: disputes (1) surprising universals (2) explanation of universals (3) ease of learning (4) relevance of IQ-independence.

Identifies minimal nativism vs anti-empiricism vs rationalism. Considers the relevance of connectionist networks. Some nativist arguments may survive.

Concepts can be acquired without being learned by symbol-manipulation.

Explain universals via Popper/Simon empirical model.

Can take middle ground. Anti-empiricism doesn't imply rationalism.

5.1b Modularity (Fodor, etc)
---------------

Against Fodor: modules are smaller, interact strongly, not domain-specific.

Remarks on Shannon and Fodor.

Overview of the original studies on top-down effects in perception.

Churchland, P.M. 1979. _Scientific Realism and the Plasticity of Mind_. Cambridge University Press.
Our perception is deeply theory-laden, and potentially very plastic.

Churchland, P.M. 1988. Perceptual plasticity and theoretical neutrality: A

Contra Fodor 1984: observation is theory-laden (built-in or not); supported by neurophysiological evidence; perceptual systems have long-term plasticity.

Perception happens in informationally encapsulated, domain-specific modules. Central systems aren't encapsulated, and so may be impossible to understand.

Summary of MOM (with commentary and reply in the BBS printing).

Informal discussion of modularity. With commentaries by Fahlman, Caplan.

Argues for an observation/theory distinction, and against belief affecting perception.

Churchland is up the creek without a paddle.

A collection of papers on modularity in language and vision.

Fodor's arguments for unencapsulated central systems are no good; AI is possible after all.

Criticism of Fodor. Modularity is dynamic, and can be central.

'Direct perception' can't correspond to anything. Perception is inferential.

5.1c Mental Imagery [see also 6.2j]

--

Fodor, J.A. 1975. Imagistic representation. In _The Language of Thought_.

Harvard University Press.

Schwartz, R. 1980. Imagery: There is more to it than meets the eye. Philosophy of Science Association 1980.

of Science 55:218-27.
Gardner, S. 1996. _Irrationality and the Philosophy of Psychoanalysis_.
Cambridge University Press.
Holt, L. 1999. Rationality is still hard work: Some further notes on the

5.1e Embodiment [see also 2.2]
------------

On the importance of embodiment of systems in cognition.

Advocates a sort of "active externalism", based on the role of the environment in actively driving cognition. Beliefs can extend into an agent's immediate environment (e.g. a notebook) in this way.

Argues that the mind is not just embedded but intimately intermingled with the world. With some systems-theoretic arguments arguing against a determinate interface. Mind is not an inner realm.

Argues against the contemporary "Cartesian" view of mind as an ontologically homogeneous inner representational realm that causes behavior, arguing for a holistic embodied view instead. Mind is therefore safe from elimination.

Wilkerson, W.S. 1999. From bodily motions to bodily intentions: the perception of bodily activity. Philosophical Psychology 12:61-77.

5.1f Animal Cognition [see also 6.4c, 6.4d]

5.2 Aspects of Mind
-------------------

5.2a Pain and Pleasure
----------------------

Goldstein, I. 1999. Intersubjective properties by which we specify pain, pleasure, and other kinds of mental states. Philosophy.

5.2b Emotions

--------

Furlong, E.J. 1951. _A Study in Memory: A Philosophical Essay_. Nelson.

5.2e Color [see also 1.3a, 1.7a, 1.7d]  
--------

Philosophical Review 100:67-106.

Philosophical Studies 93:21-44.

Watkins, M. 1999. Do animals see colors? An anthropocentrist's guide to animals, the color blind, and far away places. Philosophical Studies 94:189-209.

5.3 Philosophy of Psychology, General

5.3a Psychological Laws [see also 3.5d]

Fodor, J.A. 1991. You can fool some of the people all of the time, everything else being equal: Hedged laws and psychological explanation. Mind 100:19-34. Ceteris paribus means that every realizing state has completing conditions. Even absolute exceptions are OK, as long as they're not across-the-board.

arguments from rationality, indeterminism, intensionality, etc.

There are no ceteris paribus laws, as there's no satisfactory way to cash the "unless" cause. But psychology doesn't need laws, anyway.

5.3b Psychology and Neuroscience [see also 6.1i]
---------------------------------

Arguing for the notion of functional architecture as a bridge whereby neural components can be components of cognitive processes.

Argues that we can understand the brain under the hypothesis that it is optimized to "save wire", due to bounded resources: organization predicts placement. With remarks on the relation between cognitive and neural levels.

Some cute examples of neurophysiological reductions using state-spaces.

Churchland, P.M. 1995. _The Engine of Reason, the Seat of the Soul: A Philosophical Journey into the Brain_. MIT Press.

The brain can tell us a lot about the mind. With examples.

All about neuroscience, philosophy and prospects for their interaction.

About how neuroscience and connectionism affect our conception of mind.

On paradigm shifts, biology, evolution, connectionism, etc.

The relationship between psychology and neuroscience is best characterized not by reduction but by explanatory extension, where each field is enriched by the other. With a number of examples from recent empirical work.

Wittgenstein wouldn't have liked the Churchlands, as neuro might be chaos, and too much neuro might undermine our self-conception nihilistically.

Incommensurable theories don't necessarily require elimination, if their relationship is synchronic/interlevel, rather than diachronic/intralevel.

Argues contra Fodor and Block that neurological equipotentiality doesn't refute type materialism. Mental states may not be anatomically defined neural states, but they may be more abstract neural holograms.

Argues that the mind is not identical with the brain -- at the very least, it's the central nervous system, and perhaps more. "Brain" does not denote a natural kind in neurophysiology.

Cognitive psychology can transmogrify itself, who needs neuroscience?

5.3c Explanation in Cognitive Science

Psychological explanation is typically via functional analysis, not causal subsumption. On interpretation, computation, and an analysis of cognition and intentionality. With remarks on Dretske, Searle, Titchener, Hull, Freud.

Contra Kitcher 1988, much of Marr's theory doesn't depend on optimization; in any case, optimization isn't so bad. With remarks on interdisciplinarity.

On the tension between formal explanation and representational explanation.

Discusses the principle: there cannot be two independent explanations of the same phenomena. With application to purposive explanation of behavior, theory reduction, and eliminativism, and a discussion of explanatory realism.

Kim, J. 1990. Explanatory exclusion and the problem of mental causation. In
(E. Villanueva, ed) _Information, Semantics, and Epistemology_. Blackwell.
On the problems posed by explanatory exclusion, and possible solutions. With
focus on the problems as they arise for Dretske's and Davidson's theories.

28:63-80.

Millikan, R.G. 1993. Explanation in biopsychology. In (J. Heil & A. Mele,
ed) _Mental Causation_. Oxford University Press.

Philosophy of Science 62:261-82.

114:463-495.

Psychology 7:63-84.

115:143-169.

8:165-91.

5.3d Philosophy of Cognitive Science, Misc
------------------------------------------

Philosophy is autonomous: empirical considerations can't affect it.

Bogdan, R. 2000. _Minding Minds: Evolving a Reflexive Mind by Interpreting
Others_. MIT Press.

Hardcastle, V. 1996. _How to Build a Theory in Cognitive Science_. SUNY
Press.

science. In (T. Simon & R. Scholes, eds) _Language, Mind, and Brain_.
Lawrence Erlbaum.

Hooker, C.A. 1975. The information-processing approach to the brain-mind and
its philosophical ramifications. Philosophy and Phenomenological Research

Philosophy of Science 67:404-418.

44:485-94.
On the role of non-empirical advances in psychology: e.g. in theory
construction, coherence analysis, conceptual innovation, with the aid of
logically necessary truths and the contingent/pragmatic a priori.

5.4 Philosophy of Mind, General

A general overview.

An overview of the last 40 years of the philosophy of language and the philosophy of mind, covering many issues and trends.

An overview of everything, circa 1978: logical behaviorism, functionalism, the identity theory, qualia, meaning, and so on, with bibliography.

A pragmatist perspective on the recent history of the philosophy of mind, focusing on consciousness, intentionality, and mental representation, and on debates between Fodor, Dennett, Searle, Putnam, and Davidson.

Shaffer, J.A. 1964. _Philosophy of Mind_. Prentice-Hall.

--------------------------------

the Nature of Mind_.  Blackwell.

Block, N., Flanagan, O., & Guzeldere, G. (eds) 1997.  _The Nature of
Consciousness: Philosophical Debates_.  MIT Press.
An anthology of central philosophical papers on consciousness.

Coherence between these => consciousness depends on the functional but isn't reducible. Toward a dual-aspect theory based on pattern and information.

Argues against the reductive explanation of consciousness, and for a kind of naturalistic dualism. Moves toward a "fundamental theory" to bridge the gap, and draws out some consequences.

A collection of 5 psychological and 8 philosophical essays on consciousness.

Argues that consciousness can be accounted for in a naturalistic framework. With arguments against eliminativism and epiphenomenalism, evidence from neuroscience and psychology, and discussions of the stream and the self.

A history of the study of consciousness, especially in psychology.

A summary of recent philosophical debates over consciousness, focusing on the "what/where/who/why/how" questions, the explanatory gap, and the stalemate between "essentialist" and "causal" intuitions.

Separates computational mind from phenomenological mind, and studies the former, a third-person approach. The residue is the "Mind-Mind" problem. Consciousness supervenes on an intermediate level of representation. Elegant.

Physicalism can explain consciousness in all its glory. Argues against zombies and inverted-spectrum scenarios, and suggests that the explanatory gap can be bridged by an account of directly-active information-processing.

An excellent collection of 20 philosophical papers on consciousness.

Argues that the first-person view has been ignored too much in the philosophy of mind. Even unconscious states are only mental by virtue of their potential consciousness.

On the centrality of consciousness to the mind. Consciousness is irreducible but biological. On the history of the field, the structure of consciousness, its role in constituting intentionality, and problems with computation.

On the notion of consciousness, its relation to the brain, and some features that need to be explained: its subjectivity, unity, intentionality, center and periphery, Gestalt structure, aspect of familiarity, and so on.

Value is only found within streams of consciousness. Three ways of studying it: phenomenology, anthropology, and by relation to the physical. With an analysis of the "self-transcending" nature of conscious intentionality.

A collection of philosophical articles on consciousness.

1.1b The Concept of Consciousness
---------------------------------

On minimal consciousness, perceptual consciousness, and introspective consciousness. Introspective consciousness seems so special because it gives inner awareness of self, and memory of other mental events.

Distinguishes C1 (phenomenal experience) from C2 (access of parts of a system to other parts). C2 is can be scientifically studied, and has a graspable, if fragmented, causal role. C1 is mysterious and perhaps beyond science.

Reportability is not phenomenology, as blindsight has reportability but no phenomenology.

   Argues that the cognitive correlate of consciousness is direct availability for global control.

   Analyzes consciousness in terms of the "presence" of information to the main decision-making processes of a system. No great conceptual capacities required, no higher-order thoughts. With application to blindsight.

   Separates consciousness from the mental -- functionalist accounts work for the latter but not the former. With remarks on Zen "pure consciousness".

   On the role of consciousness in psychology, and distinguishing various notions of consciousness: mutual knowledge, internal knowledge, awareness, direct awareness, personal unity, wakefulness, and double consciousness.

   Ideas about consciousness from Locke, Brentano, Hebb, Dennett, Skinner, Sellars, Aristotle, Gibson. Theories: inner eye vs. verbal vs. outer eye.

Nelkin, N. 1993. What is consciousness? Philosophy of Science 60:419-34. On three senses of consciousness: phenomenality, intentionality, and introspectibility. Argues from empirical evidence (especially blindsight cases) that these three are all dissociable.

1.2 Explaining Consciousness?

1.2a Subjectivity and Objectivity (Nagel) [see also 1.3a]

Nagel, T. 1974. What is it like to be a bat? Philosophical Review 4:435-50. Reprinted in _Mortal Questions_ (Cambridge University Press, 1979). Physicalist explanations leave out consciousness, i.e. what it is like to be an organism. Objective accounts omit points of view (could there be an objective phenomenology?). Physicalism may be true, but we can't see how.
Subjective and objective views clash e.g. on meaning of life, free will, personal identity, mind-body problem, ethics. How to reconcile: reduction, elimination, annexation? Maybe just let multiple viewpoints coexist.

Nagel, T. 1986. _The View From Nowhere_. Oxford University Press.
Seeing philosophy as a clash between the subjective and objective views of various phenomena (mental states, self, knowledge, freedom, value, ethics). Eliminating the subjective is impossible.

Akins, K. 1993. What is it like to be boring and myopic? In (B. Dahlbom, ed) _Dennett and his Critics_. Blackwell.
Gives a detailed account of perceptual processing in bats, and suggests that we can know what bat-experience is like: it's like nerd experience. But then is there an unexplained residue?

On what science tells us about the experience of bats, birds, and others. Why a movie of bat-experience isn't good enough -- because of the inseparability of intentionality and experience. Science can do OK.

No real problems are posed by subjectivity and points of view, no matter how they are construed (fixed, portable, tokens, types). It's either a confusion or a triviality about the logic of indexicality.

On what is required for consciousness of agency (rather than qualia): belief, intention, and most importantly desire, enabling a capacity to care. A robot could have all this, and it would be like something to be it.

Naturalism can do autophenomenology just fine.

A Super Neuroscientist will know how we describe and think about experience, so will know as much as a Super Sympathist. One doesn't have to imagine to know what it's like. With remarks on bat experience.

Nagel conflates metaphysical and epistemological versions of the subjective/objective distinction. Consciousness is metaphysically subjective, and science is epistemically objective, so there is incompatibility.

Being graspable from only one point of view does not define the class of...
facts about conscious experience. Various ways of cashing this out fail.

The objective and subjective don't conflict, but complement each other.

Nagel conflates questions about sensory qualities with those about a unique point of view. The truth of physicalism is irrelevant to uniqueness.

The subjective/objective distinction is ill-drawn. Objective descriptions aren't species-independent, but in terms of the space-time causal network.
Science can explain the experience this way, but not provide the experience.

Knowing what it's like consists in an ability, not possession of information.

Various anti-Nagel points.

Lycan, W.G. 1990. What is the "subjectivity" of the mental? Philosophical Perspectives.
The subjectivity of the mental is no more special than usual propositional subjectivity. It can be handled by a self-scanner model of introspection.

A critique of Nagel's idea of a "point of view" that is occupied by a "subject". There aren't any peculiar facts about given viewpoints.

There are no fact about what an experience is like. Knowing what it's like is an ability to imagine, recognize, and recall; this explains ineffability, etc. With remarks on the experience of imagining an experience.

Phenomenological properties cannot be picked out in physical or computational terms; argues against Lycan's criticism of Nagel. But all this is compatible with materialism. With comments on the phenomenological tradition.

Criticizes absent/inverted qualia arguments for a special "what it is like", but argues that the possibility of "what it is like" differences relative to semantic states shows that something's not conveyed by functional accounts.

The Nagel/Jackson argument is analogous to the Perry indexical argument, and can be treated the same way.

   Nagel's dilemma: separating feeling from process. Moral consequences?

   Nagel-consciousness exists, but isn't so important. It's essential for sensations, but not for thoughts. Beings without it could still be persons.

   Understanding does not consist only in facts; we can understand via sympathy.

   Knowing what it's like is really knowing how to imagine. We should reduce Nagel's question to a question about possession of a certain ability.

   Subjectivity is not something we have knowledge of, as we lack comparisons.

   On the Nagel/Dennett debate: Nagel holds out for unexplained intrinsic properties once the relational is all accounted for; Dennett can renounce the transcendental ambition. Remarks on realism, holism, and metaphilosophy.

   Divides Nagel's problem: qualitative differences, special access, mineness.

   Nagel's 'View from Nowhere' doesn't take subjectivity seriously enough.

   Rebutting various intuitions for the non-physical nature of experience. The Nagel/Jackson argument commits an intensional fallacy; experiences are physical states known from a different perspective.

   A Wittgensteinian critique of Nagel. Nagel's question is confused: "what it's like" is a matter of behavior, sociality, etc, not inner experience.

   Reducing doesn't imply understanding. Two different kinds of reduction.
Nagel is an epistemological solipsist, whether he likes it or not.

1.2b The Explanatory Gap (Levine)
------------------------

Reflections on the explanatory gap between physical processes and conscious experience. With remarks on different sorts of consciousness, and on why we need an intelligible necessary connection.

On the physiological bases of phenomenal states, particularly color. Inverted spectrum isn't really coherent, as coolness/warmth would have to be inverted too. So the contingency of qualia is diminished.

Argues in detail that psychophysics can provide a structural map to close the explanatory gap. If there is an explanatory residue, perhaps panpsychism can help.

Argues for a distinction between reduction and reductive explanation, and argues that reductive explanations generally involve conceptual connections via "functionalization". With comments on Block and Stalnaker.

Contra Kripkean arguments, a good enough functional theory may help close the conceivability/explanatory gap between the physical and qualia. Contra Nagel/Jackson, such a theory could provide us with recognitional abilities.

How do we explain the apparent contingency of the qualia-matter reduction? Even if it's not metaphysically contingent, it's conceptually contingent, so there's a gap in any physical explanation of qualia. Excellent.

Physical accounts leave out qualia epistemologically but not metaphysically. So physicalism holds, but there is an explanatory gap. Discusses Kripke's and Jackson's arguments in detail; also explanation and content.

Argues that the explanatory gap between brain and consciousness is just the same as that found with causal relations everywhere; it's just that we usually overlook it in the latter case.

Qualia can't be explained in more basic terms, as that sort of explanation works by accounting for a property's canonical evidence, but the canonical evidence for qualia are qualia themselves. But they still may be physical.

1.2c 'Hard' and 'Easy' Problems (Chalmers) [see also 3.1]

-----------------------------------

Divides the problems of consciousness into easy and hard problems; the hard problem eludes reductive explanation as it isn't about explaining functions. Argues instead for a nonreductive theory with psychophysical laws.

Like the JCS article, but shorter, more accessible, and with pretty pictures.

There is no a priori entailment from the physical to phenomenal facts (arguments from conceivability, epistemology, analysis), so reductive explanation fails. With a critique of existing empirical proposals.

A reply to the 25 "hard problem" articles in JCS.

Argues that the "hard problem" in effect invokes an argument from ignorance, and that there's no deep difference between consciousness and other domains.

Argues contra Chalmers that experience is identical to certain functions, rather than emerging from them.
Divides the hard problem into three parts, and argues that neuroscience can make progress on at least one part (incommunicability); and maybe "meaning" holds the key to the rest.

Argues contra Chalmers 1995 that functions are all we need to explain.

Argues that consciousness plays a vital role in performing mental functions, so the easy problems won't be solved until the hard problem is solved.

Endorses the idea of consciousness as fundamental, but criticizes Chalmers' psychophysical laws. Advocates a theory with a "conscious mental field".

Argues that the "easy problems" -- reportability, attention, etc -- all involve concepts and therefore experience itself, for Kantian reasons, and therefore are not mechanistically explainable.

Argues that the truly hard problem is that of giving a constitutive account of consciousness, and Chalmers doesn't solve that (laws aren't good enough); in fact it's unsolvable.

Argue that we should work on the easy problems for now, as nobody has any good ideas about the hard problem; maybe it will gradually fade away.

On the epistemology of the hard problem. Argues that a scientific study of phenomenology is possible, drawing on work in developmental psychology and Eastern thought. "Pure consciousness" may be relevant to a resolution.
A collection of essays consisting of Chalmers' keynote paper, 26 replies from many perspectives, and Chalmers' response to the replies.

Advocates a careful phenomenological study of consciousness in its own right, systematically linked with a neurophysiological investigation.

Agrees with Chalmers on nonreductionism, but disagrees on "awareness", organizational invariance, and thermostats. Advocates a kind of dual-aspect theory, where the physical world is present within consciousness.

1.2d Cognitive Closure (McGinn)

McGinn asks too much of a solution to the M-B problem. We might understand consciousness without understanding specific experiences; we could get at it by studying brain and consciousness not separately but simultaneously.

Argues that the mind-body problem might be solvable in principle, but beyond human capacities. Neither perception of the brain nor introspection of consciousness can uncover the property by which consciousness arises.

A collection of articles on the problem of consciousness, advocating a view on which the phenomenon is natural but permanently mysterious to us.

Argues that a naturalistic account of the intentionality of conscious states requires an account of their embodiment; and that embodiment may depend on the hidden structure of conscious states, not accessible to introspection.

Suggests that consciousness may have a hidden structure, analogous to the deep structure of language, that relates its surface properties to physical
properties. We may not be able to understand this hidden structure, however.

1.2e Miscellaneous

-------------------

Parodies arguments by Searle, Jackson, and Chalmers for the irreducibility of consciousness with analogous arguments for the irreducibility of "luminescence". The consciousness arguments are no better.

Argues that consciousness can be handled within a scientific framework. We can translate first-person accounts into third-person accounts. Replies to skeptical objections using analogies from elsewhere in science.

Qualia pose no insurmountable problems for materialism: knowledge argument can be answered, explanatory gap can be closed, and absent qualia arguments beg the question. With speculations on their functional role.

1.3 Materialism and Dualism
---------------------------

1.3a The Knowledge Argument (Jackson) [see also 1.2a]
-------------------------------------

Bachrach, J.E. 1990. Qualia and theory reduction: A criticism of Paul Churchland. Iyyun 28:1-94. Argues that Churchland's neuroscientific descriptions must leave at least some qualia behind: they might account for what we know (e.g. brain states) in qualia-knowledge, but can't handle distinctions in how we know.

Churchland, P.M. 1985. Reduction, qualia and the direct introspection of brain states. Journal of Philosophy 82:8-28. Reprinted in A Neurocomputational Perspective (MIT Press, 1989). Qualia can undergo a normal reduction to the neurophysiological. Jackson commits an intensional fallacy; in any case, perhaps Mary can understand red. When we apprehend qualia, we are directly introspecting our brain state.

On Dilthey's "Verstehen", or "understanding from within". Mostly about meaning, but with application to the knowledge Mary gains.

Mary didn't know all the physical facts: she knew all the explicitly physical information, but not all the ontologically physical information.

A new version of the knowledge argument: given all the physical facts, one can't know when two experiences are indistinguishable. This avoids various objections to the standard version.

Contra Nagel/Jackson: Understand qualia through relational properties, and separate the mental concept from the recognitional capacity.

Against the hypothesis that phenomenology carries information. If it does, then qualia are epiphenomenal. Better to analyze the "new information" as acquiring an ability instead. In-depth and entertaining.

Phenomenal and functional concepts are distinct, but the relevant properties may be identical. We directly refer to phenomenal properties by recognition. Remarks on other minds, transparency, incorrigibility & more. A meaty paper.
Gives nine arguments against the Lewis/Nemirow ability analysis, and proposes instead that the same fact is learned a new way, like water and H2O facts. This sort of phenomenal information is no danger to materialism.

Defends against objections from Dennett, Churchland, etc. Horgan's objection (same fact different ways) has a certain force, but the argument can be reformulated to avoid them and imply property dualism. With remarks on Loar.

Contra Churchland 1985: we couldn't introspect sensations as brain states, although we could interpret them as such.

Reconstructing the Mary case as a Marianna case, and introducing a distinction between phenomenal and nonphenomenal beliefs, to support the knowledge argument. A very nice and sophisticated paper.

Mary goes from a third-person concept of experience to a first-person concept, but they co-refer; we can refer to an experience without having the experience. Physical and phenomenal properties are brutely identical.

Mary learns an old fact under a new mode of presentation, and doesn't even learn a new fact about a mode of presentation. Her access to internal states is always mediated by representation, so we can always ascend to a new mode.

A thorough discussion of Lewis 1990. Phenomenal information implies epiphenomenalism, even at the intra-psychic level. Remarks on ineffability, and on whether properties should be individuated by nomic role or by essence.

Contra Dennett, Mary can't tell an object's color unless she already knows
about experience. The knowledge argument bears on thought, not just qualia.

Introspection reveals functional properties, not physical, so qualia should be reduced to the functional, not to the physical.

Physicalism explains all the relevant evidence, hence all facts, and needn't admit mental entities; belief in mental entities is based on physical facts.

Interesting remarks on what it would be for someone to see colors that we cannot, combining philosophical considerations with empirical findings about color space. Argues that science could tell us what such colors are like.

A Jackson-like argument that physical knowledge can't give you the knowledge of what pain feels like. With detailed consideration of objections and replies. Argues from limited incorrigibility to factualism about pains.

Epiphenomenalism => qualia don't cause beliefs => we don't know about qualia.

1.3b Zombies & Modal Arguments [see also 1.2c, 1.3a, 1.3c, 1.3d, 1.7e]

------------------------

Argues that the conceivability of zombies and the like can be explained away, in terms of the cognitive separability of perceptual imagination and sympathetic imagination of the same states.

Describing a situation where we would be justified in believing in zombies.
Argues that zombies are logically possible, which seems incompatible with most or all varieties of materialism.

Materialism requires that physical states logically entail all non-relational states; but zombies are logically possible, so materialism fails. With a description of a zombie, and replies to a verificationist. All very true.

Reply to Locke 1976: materialism needs zombies to be logically impossible.

If Campbell's imitation man is possible, then the causal relation between the physical and phenomenal is unreliable.

Contra Kirk: the logical possibility of zombies is compatible with empirical materialism. With some comments on Kirk's thought-experiment.

Argues that behavioral differences in zombies would show up, in their discourse about consciousness.

On the possibility of an Insentient Perceiver, who perceives the world without sensation. Sensation is inessential to perception and understanding, except understanding in the "whatlike" manner.

Argues for the conceivability of insentient perception of colors (in "Insent", a kind of blindsighter or zombie), in order to argue for a realistic account of colors.

A discussion of materialism and its difficulties. The conceivability of zombies poses special problems. Criticism of Smart's & Armstrong's analyses.

1.3c Essentialist Arguments (Kripke) [see also 1.3b, 1.3d]
-----------------------------------------------

Kripke, S.A. 1971. Identity and necessity. In (M. Munitz, ed) _Identity and Individuation_.
An identity between mental and physical states can't be contingent, as it relates rigid designators. But nevertheless the co-occurrence of certain mental and physical states is contingent, so the identity theory is false.

Both "pain" and "C-fibres firing" are rigid designators, so if they are identical, this must be necessary. But their co-occurrence is contingent, and this can't be explained away epistemically, so the identity theory fails.

Bayne, S.R. 19xx. Kripke's Cartesian argument. Philosophia. Trying to turn Kripke's argument against him: it's possible that pains and C-fibre stimulations are identical, so it's necessary that they're identical.

Bealer, G. 1994. Mental properties. Journal of Philosophy 91:185-208. On four arguments against the identity theory: multiple-realizability, modal, knowledge, and certainty arguments. All face difficulties due to scientific essentialism, but the latter two can be reformulated to avoid them.

Della Rocca, M. 1993. Kripke's essentialist arguments against the identity theory. Philosophical Studies 69:101-112. Kripke's premise that pains are essentially mental either begs the question (by assuming pains don't have physical properties) or weakens the premise that physical events aren't essentially mental.

Uses Kripke's 1979 direct-reference theory against him. When rigid designators don't have associated reference-fixing descriptions, we can't expect the "explaining away" strategy to work.

The apparent contingency of identity is due to the fact that one can be aware of pain without being aware of C-fibers and vice versa, as well as to the fact that "C-fibers" may be picked out by a contingent description.

Defending Kripkean arguments against various objections. Analysis in terms of manifest properties and their role in fixing reference to the subjective and objective.

A Kripkean argument against non-analytic physicalism. Even if pain rigidly designates a brain state, the physicalist still has problems explaining the property of "pain-presents".

Kripke's argument doesn't refute contingent identity between minds and nonrigidly designated bodies, which is all materialism needs.

Some theoretical identification are analogous to mental-physical identifications -- entities are introduced by properties considered essential within a theory, but this doesn't preclude identification.

The reference of "pain" is fixed not by essential features but by contingent topic-neutral descriptions; this is the real moral of Wittgenstein's private language argument. So Kripke's apparent contingency can be explained away?

Reply to Bealer 1994. Tries to clarify the dialectic, and argues that the materialist can explain "possibility" of straw thought as thought conjoined with mere appearance of straw.

Kripke equivocates on "pain-sensation": pains aren't the same as impressions of pain. Argues that imaginability arguments aren't decisive, and that functionalism may be less vulnerable than the identity theory.

Painfulness needn't be essential to pains: pains are events, not objects, and events don't have essences; and the reference of "pain" is fixed by topic-neutral descriptions. With remarks on pains vs. pain-sensations.

"Brain state" reference is fixed by topic-neutral description; picks out pain but mightn't have, explaining the illusion of contingency. "Nonphysicalist materialism" results, with mind the essence of matter. An important paper.

Psychology_ (MIT Press, 1980).

Token identity theories aren't vulnerable to Kripke's argument: it may be essential to this pain that it is a C-fibre firing, although not to pain as a type.

We can explain away the apparent contingency of identity in terms of possible differences in *evidence* for the physical state. With a discussion on identities between something perceived and something described.

"Pain" need not be a rigid designator, but instead may pick out a state by its causal role. If it is a rigid designator, then the apparent contingency of identity comes from imagining something else filling the causal role.

The reference of "C-fibre stimulation" might be fixed contingently, allowing the intuitive contingency of identity to be explained away.

Contra McGinn 1977, the counterpart strategy fails as any pain that occurred here now would have been this pain. A counterpart strategy on brain states may work. With a reply by McGinn and a later rejoinder by Woodfield.

1.3d Arguments from Disembodiment [see also 1.3b, 1.3c]
---------------------------------

Argues that materialism is only contingently true, as it's conceptually possible that we could become immaterial by gradual replacement.

Physicalism is compatible with the possibility of disembodiment: one can hold that mind and body are identical, that the body is physical, but that it is not essentially physical.

1.3e Consciousness and Physicalism, Misc [see also 1.2, 1.3, 1.7b, 3.5b]

On the problems posed for materialism by intentionality, autonomy, awareness, and indexicality. Tentatively advocates a Cartesian position.

A collection of arguments against physicalism, mostly based on worries about consciousness and qualia.

Consciousness could be physical even if not explicable; but supervenience worries make it hard to see how it *could* be physical, though causal role suggests that it must be. We need a new conception. A stimulating book.

On the place of "occurrent pink" and the "sensorium" in the physical world. It may turn out that the physics of the brain differs from other physics, in order to accommodate the causal role of sensations.

A careful discussion of how to characterize physicalism, in terms of identity or supervenience, and argues that physicalism must reduce (bowdlerize) qualia to something they are not, as physicalism requires topic-neutral analyses.

1.3f Consciousness and Dualism [see also 1.2c, 1.3, 3.4d]
----------------------------------

Arguments that all forms of materialism fail, and that dualism is the only option. Defends dualism against objections, and argues for interactionism over epiphenomenalism. A very clear and interesting paper.

Arguments that the hypothesis of consciousness as an irreducible global property of the brain is compatible with what we know of both neuroscience and physics. With interesting remarks on quantum mechanics.

Latham, N. 2000. Chalmers on the addition of consciousness to the physical
A dialogue with a "hyperdualist". On the pros and cons of materialist vs. dualist ontology and cosmology. Dualism avoids the "magic" of emergence at the cost of an inflated and bizarre ontology.

On the non-physical nature of consciousness, and the threat of a merely contingent connection to behavior; suggests a denial of "Hume's principle".
Perhaps consciousness is the nomenal essence of the physical. A nice paper.

1.3g Mind-Body Problem, General
----------------------------------

 An overview: behaviorism, identity theory, functionalism, etc.
Yes it is. Empirical evidence bears on materialism, property dualism, emergentism, functionalism, interactive dualism, idealism, etc.

The core of the mind-body problem is the first/third-person asymmetry. It's like a periscope trying to place itself between its crosshairs. But this doesn't imply any strong ontological consequences.

Against "neural functionalism", and on how Searle's view reduces to either neural functionalism or property dualism.

On the mind-body problem and physical theory. Against reductive physicalism; instead, experience is the intrinsic nature of the physical. Discusses the interpretation of quantum mechanics and much else. A very enjoyable book.

On ways in which we might locate consciousness within the natural world via...
scientific study. Perhaps we need an wider conception of objective reality.

A collection of 27 (mostly original) papers on the mind-body problem.

1.4 Specific Views on Consciousness [see also 1.2, 1.3, 1.5c]

-----------------------------------

1.4a Higher-Order Thought Approaches (Rosenthal, etc) [see also 6.2i]

------------------------------------

Higher-order thought theories have two unacceptable consequences: one can notice one's hearing a sound without noticing one's consciousness of the sound; and one can unconsciously perceive one's surroundings as gloomy.

Argues for a distinction between conscious and non-conscious experiences, depending on whether one is conscious of the experience. Animal experiences are of the second kind, and therefore are not morally significant.

Advocates the "reflexive thinking" account of consciousness over Kirk's "presence" account. Availability for reflexive thinking is naturally necessary and sufficient for qualia. Interesting paper.

Against higher-order thought accounts: one can have a conscious experience without being aware that one is having it. With remarks on thing-awareness vs. fact-awareness and on "inner-sense" accounts.

We're not conscious *of* our experience in general, but conscious *with* it.
Criticizes HOP theories (not conceptualized enough) and HOT theories (rules out animals; there's more in experience than thought).

Argues that a higher-order thought is insufficient for consciousness, even with Rosenthal's constraint. A causal constraint is required, but the only strong enough such constraint doesn't work.

Carruthers 1989 misanalyzes higher-order thought theory. There's no need for conscious HOTs, and not too much conceptual sophistication is required, so animals might have HOTs and therefore conscious pains.

A critique of higher-order-perception theories of consciousness. They're either committed to a "representational divide" fallacy or collapse into higher-order-thought or first-order theories.

Various points against Carruthers 1989. His examples of nonconscious experience are likely conscious, and the higher-order account is circular.

Argues for a Lockean quasi-perceptual view of consciousness as internal monitoring via second-order states. Contra objections, e.g. Rey's point that it makes consciousness too prevalent -- consciousness isn't an on-off affair.

Conscious belief (or assent) is believing that one believes. Addresses various objections, from self-deception and from consciousness of assent. Communication needs conscious belief, not just belief.

On various pros and cons of HOT theories, to do with reflexivity, objects of HOTs, introspection, and so on. With comparisons to "intrinsic" theories.

On three theories of our direct awareness of conscious states: mental-eye theories, self-intimational theories, and appendage theory (i.e. HOT theory) is promising, but how does an HOT determine its object?

On the differences between first-order and second-order consciousness. Second-order consciousness is essential for communication and locomotion. With remarks on "nonconscious consciousness".

Nelkin, N. 1989. Unconscious sensations. Philosophical Psychology 2:129-41. Separates CN (phenomenological) from C1 (info-processing) and C2 (higher order beliefs). CN is a subset of CS (image-representation state). We are always C2 of CN states, but not of other CS states: unconscious sensations!

Argues that we need not be apperceptively aware of phenomenal states. Introspection leaves the matter open, but some empirical results (e.g. hue blindsight) and theoretical arguments support dissociability.

Consciousness should be construed neither as sensation nor intentionality, but as the existence of higher-order thoughts.

A conscious mental state is a state that is the subject of a higher-order thought. Consciousness is not essential to mentality, should be separated from sensory quality, and is not an intrinsic property of conscious states.

Because verbally expressing and reporting are easily and immediately connected for 1st-order thoughts. But not for 2nd-order thoughts. Hmmm.

Conscious states are states that are the contents of higher-order thoughts. Express/report distinction: we report them, and express the HOT (which may be unconscious). Defense against dispositional and collapsing objections.

Distinguishes the sense in which we are aware of conscious states; argues for the separation of consciousness and sensation; and outlines how higher-order thoughts might explain the what-it's-like of conscious states.

In response to Natsoulas, HOT theory needn't answer the general question of how intentional states determine their objects. With remarks on the
other alternatives and the dangers of self-intimation.

1.4b Dennett on Consciousness [see also 1.7c]

-----------------------------

Criticizing Dennett's accounts of pains, dreams, and images: in no case do his arguments earn their eliminative conclusions.

Reportability is no good for capturing consciousness: it completely leaves out the qualitative content of conscious states.
   Argues that Dennett's account of the blindspot and scotomas are wrong.
   Neurophysiological data suggests that blind areas are represented explicitly;
   psychological data shows that it's not just "more of the same".

   On various notions of awareness: contents of the speech center, contents directing behavior, and contents of attention.  We have privileged access to one sort, but it is a different sort that plays the main role in control.

   Conscious contents are contents of a buffer memory to which a public report module has access.  We only have conscious access to propositional judgments, not to underlying processes.  With a cute functional diagram.

   There is no real phenomenology.  There are only *judgments* about phenomenology, and nothing more is going on.  We don't have privileged access to anything, except perhaps certain propositional episodes.

   We can study consciousness by the method of heterophenomenology: studying the things we say about conscious states, which we can interpret as we interpret texts.  Autophenomenology gives nothing extra.  With comments by Rorty.

   Consciousness is a virtual machine which evolved.

   Argues against the "Cartesian Theatre", advocating a "multiple drafts" model of consciousness.  Presents a detailed model of processes underlying verbal report, and argues that there is nothing else (e.g. qualia) to explain.

   Using temporal anomalies in consciousness to support a "Multiple Drafts" theory of consciousness rather than a "Cartesian Theater".  Contents of consciousness are wholly determined by effects on action/memory.

   A discussion of _Consciousness Explained_, with comments by Tye, Jackson, Shoemaker, and Rosenthal, and a reply by Dennett.

   A reply to Clark, Fellows & O'Hear, Foster, Lockwood, Seager, Siewert, and Sprigge.

   A reply to Baars & McGovern, Mangan, Toribio.

Dennett, D.C. 1995.  Is perception the "leading edge" of memory.  In (A.
There is no "leading edge" of consciousness, separating perception and memory. With an analysis of metacognitive cases, etc.

Criticizes Dennett's first-person operationalism as Cartesian. There can be awareness without judgment -- e.g. non-epistemic perception. This comes from information or "micro-judgments", and is not conceptual.

Presses Dennett on the "truth-maker" question for materialists: what sort of physical fact makes it true that people are conscious?

Joycean machines and multiple drafts turn out to shed no light on the question of what features make a conscious system conscious.

Argues for a suitably sophisticated Cartesian Theatre, and against the identification of phenomenology with judgments.

Brings empirical evidence to bear against Dennett's "filling-in" account of the blindspot, and argues that blindsight and the blindspot aren't analogous.

Dennett's Orwell/Stalin argument doesn't establish its conclusion, as "brain smear" is quite compatible with determinate qualia.

We can subtract first-person operationalism from Dennett's multiple-drafts account, giving a higher-order thought theory.

Criticizes behavioral, localist, and "intransitive" approaches to consciousness, and recommends a "transitive" metacognitive approach. But criticizes Dennett for not explaining subjective experience.

Tye, M. 1993. Reflections on Dennett and consciousness. Philosophy and
Argues that Dennett's verificationism begs the question, and that "seeming" cannot be identified with believing or judging.

1.4c Functionalism [see also 1.4a, 1.4b, 1.5c, 1.8, 3.4]
------------------
Contra Kripkean arguments, a good enough functional theory may help close the conceivability/explanatory gap between the physical and qualia. Contra Nagel/Jackson, such a theory could provide us with recognitional abilities.

Argues that introspective access is essential to many sorts of mental state, due to constitutive rationality requirements. Against a perceptual model of introspection; introspecting and introspected states are closer than that.

How functionalism can handle consciousness: Self-consciousness is the possession of reflexive metapsychological information. This helps understand learning, representation, and belief. Phenomenal experience is still tricky.

1.4d Eliminativism [see also 1.7c, 2.1c, 3.5c]
------------------

Experimental evidence against consciousness/introspection/transparency.

Argues that dreams might not be experienced, but rather be stored directly into memory (the "cassette-tape" theory of dreaming).

Consciousness is an indispensable concept in anesthesiology, and therefore (contra Churchland and Wilkes) is a scientifically legitimate kind. With empirical details and anesthesiological theory on levels of consciousness.

One could make a machine, duplicating the usual abilities that go along with consciousness, but surely it wouldn't be conscious. So what are the conditions for consciousness? Maybe there are none.

A rerun of Rey 1982: An unconscious machine could duplicate all the obvious criteria for consciousness, so maybe even we aren't conscious. With remarks on the relation between our belief in consciousness and consciousness itself.

We "project" consciousness into ourselves and others. There are no explanation-transcendent phenomena for which there is non-question-begging evidence. With remarks on self-attribution and Wittgenstein.

Commentary on Rey 1986: we are directly aware of our consciousness. It's not a theoretical entity, but rather something to be explained.

A skeptical argument: single neurons are not conscious, and adding a neuron won't produce consciousness, so finite brains are not conscious.

No, and it's not very coherent either. It divides into awakeness, sensation, sensory experience, and propositional attitudes. Also a history of the term.

Consciousness is not a tenable notion in either commonsense or scientific psychology; we should return instead to the "psuche".

1.4e Epiphenomenalism [see also 1.3a, 1.3f, 1.6e, 3.6]

Considers major arguments against the causal or explanatory irrelevance of consciousness -- arguments from self-knowledge, memory, reference, etc -- and argues that none pose fatal flaws.

Discusses two senses of "epiphenomenalism" -- "Huxley's" and "philosophical" varieties -- and argues that the philosophical sort is crazy. (N.B. Huxley actually subscribed to the "philosophical" variety.)

Uses the Mary thought-experiment to argue that qualia are epiphenomenal, and argues that epiphenomenalism is a tenable doctrine.

If Campbell's imitation man is possible, then the causal relation between the physical and phenomenal is unreliable.

Argues that phenomenal information implies epiphenomenalism, even at the intra-psychic level. With remarks on ineffability and on whether properties should be individuated by nomic role or by essence.

Argues that we can have non-inferential knowledge of sensations even if they don't make a causal difference to our beliefs, so epiphenomenalism is OK. All theories have a similar problems.

Epiphenomenalism => qualia don't cause beliefs => we don't know about qualia.

1.4f Interactionism [see also 1.3f, 3.3d]
-------------------

Argues from the fact that we talk about consciousness to the conclusion that consciousness plays an active role, so physical laws must be incomplete.

Argues with Elitzur on quantum mechanics and consciousness. With response.

1.4g Panpsychism [see also 1.4h]

----------------

There are no strong arguments against panpsychism, and good reason to take it seriously. Extrapolating the processing properties crucial for standard complex experience suggests that simple process may yield simple experience.

An analysis of a debate between Griffin and McGinn on panexperientialism, arguing for new forms of understanding.

An excellent review article on panpsychism; highly recommended.

An interesting paper arguing for an experiential aspect in all matter,
explicating a Whiteheadian position.

Argues for a new fundamental feature ("X") which stands to consciousness as time stands to motion, thus making consciousness possible and ubiquitous.

Material composition, nonreductionism, realism, non-emergence => panpsychism.

On why consciousness extends beyond the cognitive. Argues that fundamental laws for consciousness must connect at a basic level, and argues that panpsychism is not as implausible as often thought.

Examines a position on which experience is fundamental to the world, and suggests that this ought to lead to panpsychism. With some connections to information and quantum mechanics.

On Nagel 1979: emergence is more plausible than panpsychism. A construal of emergence as nomological supervenience without logical supervenience.

1.4h Intrinsic Monism (Russell, etc) [see also 1.4h]

---------------------

Physics is dispositional, but if there are only bare dispositions, then the world has no nature of its own. And if there are categorical grounds, we have no idea what they could be, except maybe subjective qualia.

An "it from bit" view fits the Russellian metaphysics (described earlier): physics is info from the outside, (proto)experience is info from the inside. The problem is constituting macrophenomenal from microphenomenal; some ideas.

A nice account of Russell's (and Schlick's and Carnap's) structuralism and Newman's objection, with analysis. (N.B. no philosophy of mind.)

A long and very interesting essay on the mind-body problem. Ultimately advocates a "structural" view of the physical and identifies experience with the underlying reality, at least for some neurophysiological states.

Argues that Russell's and Schlick's views on the structural nature of physics and the possible identification of the "content" with experience are quite close to each other. With interesting historical remarks.

Argues that the Russellian view is implausible, as the structure of the underlying physical processes does not correspond to the structure and quality of consciousness.

On the mind-body problem and physical theory. Against reductive physicalism; instead, experience is the intrinsic nature of the physical. Explores some potential links with quantum mechanics.

On the "grain problem" for the intrinsic-nature view: how do lots of microphysical qualities add up into a smooth experience? Appeals to quantum mechanics and a preferred set of observables.

"Brain state" reference is fixed by topic-neutral description; picks out pain but mightn't have, explaining the illusion of contingency. "Nonphysicalist materialism" results, with mind the essence of matter. An important paper.

Newman, M.H.A. 1928. Mr. Russell's causal theory of perception. Mind. Argues against Russell's structuralism: any collection can be arranged to have a given structure, under some relation, so if physics tells us only about structure, it tells us at most the cardinality of the world.

Russell, B. 1927. _The Analysis of Matter_. London: Kegan Paul. Argues that physics characterizes the external world only structurally, and leaves intrinsic qualities unspecified. Only experience acquaints us with anything intrinsic. Perhaps the intrinsic nature of physics is experiential?

Schlick, M. 1925. _General Theory of Knowledge_.

1.5 Consciousness and Content
-------------------------------------

1.5a Consciousness and Intentionality (Searle, etc)
-------------------------------------

Crane, T. 1998. Intentionality as the mark of the mental. Philosophy.

Searle's formulation of the connection principle is unclear, and there is no formulation is both plausible and interesting.

About conscious beliefs. We are not "conscious of" beliefs, merely "conscious that" -- i.e. belief is not phenomenological.

Against Searle: some intentional states aren't even potentially conscious (blindsight, etc) and intentional content doesn't require a particular phenomenal feel. So there's no essential link. With remarks on McGinn.

Searle, J.R. 1984. Intentionality and its place in nature. Synthese. (Subjective) intentionality sure is real. It causes and is caused.

Advocates a "connection principle": intentional states must be potentially conscious. If not, they're brutally neurophysiological. So cog-sci talk of "intentional" cognitive mechanisms below the conscious level isn't justified.

Clarifying the connection principle -- it's necessary in order to see how certain nonconscious neural states qualify as unconscious mental states.

Worley, S. 1997. Belief and consciousness. Philosophical Psychology 10:41-55. Argues that belief requires consciousness, as we can't make sense of the personal/subpersonal content distinction without appealing to consciousness.

1.5b The Content of Experience
--------------------------------

Davies, W.M. 1996. _Experience and Content: Consequences of a Continuum Theory_. Avebury.

DeBellis, M. 1991. The representational content of musical experience. Philosophy and Phenomenological Research 51:303-24. Contra Peacocke, we don't need sensational properties to understand the content of musical experience. Fine-grained representational properties can do the job, with the help of some Schenkerian analysis.

Peacocke, C. 2001. Phenomenology and nonconceptual content. Philosophy and
Phenomenological Research 62:609-615.

Lots of reasons why experiences have propositional content (i.e., their content is truth-evaluable, etc). A nice paper.

1.5c Representationalism
------------------------

Uses Inverted Earth case, colors and lenses inverted, to argue vs Harman that qualitative states aren't intentional states. Also, less convincingly, to argue that qualitative states aren't functional states.

There are no real qualia problems, just Intentional confusions.

Suggests that conscious states are identical to representational states, and that unconscious representation is impossible; transition between conscious states is non-representational. Appeals to connectionist models in support.

Argues that consciousness and representation are distinct, as e.g. the latter depends on context but the former does not.

The phenomenological can be reduced to the intentional. Intentional states have a what-it-is-like, and there is no special phenomenal object of introspection.

Qualia can't be reduced to standard intentional properties (due to certain inversion cases). Projectivist and sense-reference accounts don't work either. Perhaps qualia are necessarily-illusory intentional properties.

On the relationship between phenomenal and intentional aspects of qualia, and in particular on the accessibility of qualia to conscious awareness. Phenomenal & intentional similarity are connected but must be distinguished.

Tye, M. 1994. Do pains have representational content? In (R. Casati, B.
Smith, & S. White, eds) _Philosophy and the Cognitive Sciences_.

Holder-Pichler-Tempsky.

Argues that pain is representational, and that its phenomenal character is narrow nonconceptual content. They have a complex representational structure, with map-like arrays of sentential contents.

Tye, M. 1995. What "what it is like" is like. Analysis.

Argues that "what it is like to be X" is an intentional context, which solves some of the associated problems.

1.5d Internalism and Externalism about Experience [see also 2.2]

Argues that perceptual content does not supervene on internal state, even though it is non-conceptual. Constructs an Twin scenario to that effect. With remarks on the relation between perceptual content and phenomenology.

Distinguishes modal and constitutive externalism, characterizes perceptual content and its relation to sensational content, and argues for externalism about perceptual content by examples.

Argues that a swampthing isn't intelligent or intentional, with different physiological processes and no sensations, as these are functional kinds.

Dretske, F. 1996. Phenomenal externalism, or if meanings ain't in the head, where are qualia? In (E. Villanueva, ed) _Perception_. Ridgeview.

We only have access to qualia through our concepts, which are external; so internal qualia would be inaccessible. So if qualia are knowable, they're external; and if not, why posit them? With comments by Kim, Horwich, Biro.

Argues against McGinn that one should embrace a form of "strong externalism" about experience. Experience can be laden with externally-grounded concepts.

There is no epistemically available aspect of experience that is determined internally; experiences are "fused" with the environment.

1.5e Miscellaneous

On conceptual influences on experience, and aspectual seeing, focusing on bodily and dynamic elements. Self-awareness is not of phenomenal states but *in* them. With commentary by S. Mulhall.

Sensations don't have intentional objects, they *are* intentional objects.

Comparing the problems of consciousness and content, and reconciling optimism on content with pessimism on consciousness. The phenomenological nature of content may be mysterious, but the individuation of contents is not.

Arguing against the view that phenomenal properties are "read off" in making perceptual judgments. Experiences do not literally have color or shape.

On a propositional conception of experience, and making sense of awareness of experience and various problems for sense-data monadicism.

1.6 Aspects of Consciousness
1.6a Self-Consciousness [see also 6.2o]

Argues that consciousness entails having episodic memory, which entails self-consciousness. So consciousness entails self-consciousness.

James, W. 1890. The consciousness of self. In The Principles of Psychology.

Self-consciousness is consciousness of agency. Castaneda/Nozick/Nagel.

Strawson, P.F. 1974. Self, mind, and body. In _Freedom and Resentment and Other Essays_.

How functionalism can handle consciousness: Self-consciousness is the possession of reflexive metapsychological information. This helps understand learning, representation, and belief. Phenomenal experience is still tricky.

Weird examples of homunculi that are conscious but not self-conscious. Self-consciousness, not consciousness, is what really counts.

1.6b The Unity of Consciousness [see also 5.12d, 6.1e, 6.1g]

-------------------------

1.6c Homogeneity of Consciousness (Sellars, etc)

Expects homogeneity in terms of nontransitive matching among pixelized parts
of vision. Experience of continuity, not continuous experience. Experiences may have subphenomenal parts (e.g. invisible pixels).

1.6d Knowledge of Consciousness [see also 1.3a, 1.8a, 5.13, 6.2i]

-----------------------------

Mary knew all the facts about qualia beforehand, she just wasn't acquainted with them. Knowledge by acquaintance isn't factual knowledge.

Qualitative beliefs can supervene on behavioral dispositions even if absent/inverted qualia are possible. We just individuate belief contents and behavior widely, with wide content fixed to the qualia.

A discussion of in what sense we are aware of qualia, and how we can have beliefs about them, with reference to Sellars. Ends up reducing qualia to phenomenal beliefs in a language of thought. A rich and subtle paper.

Reconstructing the Mary case as a Marianna case, and introducing a distinction between phenomenal and nonphenomenal beliefs, to support the knowledge argument. A very nice and sophisticated paper.

Robinson, W.S. 1982. Causation, sensation, and knowledge. Mind 91:524-40. Argues that we can have non-inferential knowledge of sensations even if they don't make a causal difference to our beliefs, so epiphenomenalism is OK. All theories have a similar problems.

Shoemaker, S. 1990. First-person access. Philosophical Perspectives 4:187-214. We have a limited special authority about the contents of our mental states. This follows from the link between a state and beliefs about it in the functional definition of that kind of state.

von Eckardt, B. 1975. Some consequences of knowing everything (essential) there is to know about one's mental states. Review of Metaphysics 29:3-18.

1.6e The Function of Consciousness [see also 1.4e, 6.4a]

Argues for nine major functions of consciousness: in defining inputs, adaptation, debugging, recruiting & control, prioritizing, decision-making, analogy-forming, self-monitoring, and self-maintenance.

Contra Popper, evolution doesn't provide an argument against physicalism or epiphenomenalism. Speculation on what the function of consciousness might be, and how it might be realized: e.g. selecting information.

Separates phenomenal consciousness from access consciousness, and argues that cases like blindsight only suggest a function for access consciousness, not phenomenal consciousness. The latter remains a mystery. With commentaries.

Argues for the possibility of zombies (contra Moody), then notes that any function could be performed by an unconscious zombie, it seems, so there's no function of consciousness in sight.

Suggests that qualia serve to distinguish hypotheses about present from past.

Contra Mott 1982: Function needn't be exclusive, and brain processes and consciousness may share a function, due to their close relationship.

Function always underdetermines intrinsic nature, so absent/inverted qualia cases aren't incompatible with consciousness having a function.

Consciousness doesn't have a function, as any function it might have is a function of brain processes.

1.7 Qualia
----------

Kitcher, P.S. 1979. Phenomenal qualities. American Philosophical Quarterly 16:123-9. Qualia problems stem from assuming direct awareness of perceptual states. Instead, we should acknowledge only an ability to detect and label these states. Also argues for the possibility of unconscious and illusory pains.

Leeds, S. 1993. Qualia, awareness, Sellars. Nous 27:303-330. A discussion of in what sense we are aware of qualia, and how we can have beliefs about them, with reference to Sellars. Ends up reducing qualia to phenomenal beliefs in a language of thought. A rich and subtle paper.

Lormand, E. 1995. Qualia! (Now showing at a theater near you.) Philosophical Topics 22:127-156.

many features of qualia (privacy, ineffability, grainlessness, unity, etc).

1.7b Qualia and Materialism [see also 1.2, 1.3]
---------------------------

are problematic for materialism. Considers the case for phenomenal individuals, and argues that they are intentional inexistents.

Qualia aren't reducible to physical properties, but they are supervenient (and ontologically dependent) on microfunctional properties. With remarks on the knowledge argument, Kripke, absent qualia, epiphenomenalism, etc.

Argues that our inability to reidentify qualia is a problem for materialism. How are they represented? Empty demonstrative would be vacuous, predicate would be reidentified, so maybe a plain presentation? Very interesting.

Absent/inverted qualia aren't really imaginable. The Knowledge Argument fails, as discovering new experiences doesn't imply learning new facts, but only coming to know old facts in a new way.

1.7c Eliminativism about Qualia [see also 1.4d]
------------------------------

The concept of pain is incoherent, as it's asked to do too many things at once. With a discussion of drugs, flowcharts, reportability, etc.

A response to Sellars. All there is to seeing occurrent yellow is the judgment that one is seeing occurrent yellow.

Argues against the existence of ineffable, intrinsic, private, directly accessible properties. With lots of meaty-thought experiments, and arguments that there is no fact of the matter about inversion cases.

There are no qualia: qualia would have to be vague (for Sorites reasons), but there can be no vague properties in nature. The usual Sorites defenses don't work here, as there's no appearance/reality distinction for qualia.

Arguing against eliminativism for qualia. Even if nothing satisfies all the common-sense properties of qualia, reference of qualia terms is still fixed under a Putnam-style theory of meaning. Argues for scientific functionalism.

There are no irreducible phenomenal properties. Materialism can handle our direct awareness of inner states by the right sort of causal connection. Gives a materialism account of discrimination and learning mental concepts.

On bold vs. modest qualophilia, and against various qualophobic strategies. With remarks on scientific objectivity, qualia as an explanandum, and on how our knowledge of qualia is consistent with the conceivability of zombies.

Dennett's 1988 argument against ineffability, etc., doesn't nearly make the case against qualia, and largely relies on verificationist assumptions.

1.7d The Inverted Spectrum
--------------------------

Uses Inverted Earth case, colors and lenses inverted, to argue vs Harman that qualitative states aren't intentional states. Also, less convincingly, to argue that qualitative states aren't functional states.

Functional role counts more than qualitative content in determining what e.g. "redness" is.

Argues that there could be inverted spectra even without a symmetrical color space. Qualia must be distinguished from their place in color space.

Acquired spectrum inversions do not refute functionalism, if qualia revert after behavioral adaptation (as they do with inverting lenses).

Describes some "inverted spectrum" scenario in computer registers, and argues that in the absence of a "central clearing house", the inversion of qualia is indeterminate. There's no reason to believe in non-dispositional qualia.

Inverted spectra with constant behavior is a meaningful hypothesis even under verificationism. Switching nerve endings, tinting contact lenses, etc.

On the physiological bases of phenomenal states, particularly color. Inverted spectrum isn't really coherent, as coolness/warmth would have to be inverted too. So the contingency of qualia is diminished.

Distinguishes various functionally distinct inverted spectrum cases.

Reply to Levine 1991. "Green residue" and "red residue" may be identical. Physiology might put more constraints on qualia, eventually ruling out all
other possibilities. But there may still be absent/alien qualia problems.

The inverted spectrum is impossible, due to asymmetries in color space.

The inverted spectrum can be detected, if a single person experiences both.

Against Shoemaker: physical realizations do not give empirical conditions for qualia inversion. Nice.

The possibility of an inverted spectrum w.r.t. dispositions implies the falsity of physicalism. But this rests on an implausible "slide-viewer" model of seeing, and is incoherent otherwise.

Inverted qualia, with respect to a functional account, are no more plausible than absent qualia (by analysis of thought experiments). Both lead to first-person skepticism about qualia.

Contra Hardin 1988: there's a "green residue" after coolness is subtracted, so inverted spectrum could still be possible. In any case, the impossibility of IS doesn't affect the explanatory gap for qualia, which is epistemic.

Inverted spectrum holding behavior constant is at least a coherent idea. Hook up brain in different ways, etc.

Argues that qualia are intentional properties, and that inverted spectra, though conceivable, are metaphysically impossible, due to considerations about society and normality. Argues against Block's "inverted earth".

A fascinating note on the possibility of people with doubled colorblindness genes, thus inverting color processing; such people may actually exist.

Argues for a computational/sentential theory under which qualia are fixed by
functional organization. Argues against Block's 1990 inversion: qualia might slowly change back as associations fade. Memory isn't 100% reliable.

Maybe IS is ongoing, with memory changes. What is the logic of "appears"?

All about the coherence and otherwise thereof. Uses switch in state for IS IS wrt behavior. Also claims that IS wrt function is possible as qualia are fixed by realizing state, not functional state. Bad assumption.

Inverted spectra thought-experiments show that experiential content is incommunicable. Accounts for the fact that attempts to describe such cases lead to contradiction (I'm seeing green & not seeing green).

Argues that qualia are intentional properties, along the lines of "looks F to P". Handles inverted earth and related cases by taking the narrow intentional content. With remarks on the semantics of color terms.

1.7e Absent Qualia (Block, etc) [see also 1.3b]

----------------------

As a criticism of functionalism. raises the possibility that realizations of any given functional account of mental states may lack qualia.

All kinds of absent qualia cases: homunculi-headed robots, the population of China, and so on. There is a prima facie doubt that such cases lack qualia, so there is a prima facie case against functionalism.

It's OK for bizarre realizations to lack pain, as functionalism requires teleology as well as organization. With remarks on the relation between pain and "introspectible noxiousness".

Taking the personal stance, we should regard the Chinese nation as having qualia. A lack of qualia would make a functional difference.

Absent qualia are impossible. Also, qualia aren't essential to mental state, functional role is.

Replace neurons one by one with homunculi: what happens? Beliefs don't change, does consciousness fade? Very nice.

If absent qualia are possible, then either qualia are inexplicable or species
chauvinism is true. Homunculi-heads could make similar arguments about us.

Conceivability arguments are only a problem for empirical functionalism insofar as they are a problem for materialism in general. Very true.

Arguments that metaphysical conclusions can be drawn from conceivability arguments, but that absent qualia cases have not been clearly and distinctly conceived. The functionalist is better off than the identity theorist here.

IQ are no more plausible than AQ (by analysis of thought experiments and skepticism). So there's no reason to choose physicalist-functionalism over pure functionalism, as Shoemaker does. Nice.

The Chinese Nation would require less people than Churchland & Churchland 1981 suggest, as we'd only need to handle a subset of all possible inputs.

Gives a thorough neurophysiological analysis of blindsight and related pathologies, and argues that these cannot be used to support the possibility of absent qualia. With remarks on the mystery of consciousness.

1.7f Introspection and Absent Qualia (Shoemaker) [see also 1.6d]

Absent qualia possible => qualia make no causal difference => no knowledge of qualia, therefore absent qualia are impossible. If qualia are introspectively accessible, they must be functional. An important argument.

Reply to Block 1980. Distinguishes two AQ theses, and argues that if AQ are possible, then the problem for functionalism isn't due solely to qualia.

Defending Shoemaker's argument against Conee: immediate awareness and qualitative beliefs are the same. But maybe people *can't* tell whether they're having genuine or ersatz pain. Eliminativism is the best option.

Reply to Shoemaker 1975. The possibility of absent qualia is compatible with a functional role for qualia, as qualia can make a causal difference that is independent of a given functional account.

Contra Shoemaker: qualia cause qualitative beliefs, which are affected by the absence of qualia, so we know about qualia even if AQ are possible.

Elucidating Shoemaker's argument: if absent qualia are possible, then the difference between real and ersatz pain makes no difference to belief, so qualia aren't introspectively accessible. A nice analysis.

Qualia and qualitative beliefs are the same, so Shoemaker's argument fails. A numbness/pain inversion argument shows that pain isn't a functional state; it yields an introspectible difference without a functional difference.

Qualitative beliefs can supervene on behavioral dispositions even if absent/inverted qualia are possible. We just individuate belief contents and behavior widely, with wide content fixed to the qualia.

Argues that the possibility of absent qualia is compatible with introspective knowledge. The fact that we have evidence of qualia isn't altered by the fact that we'd still think we had that evidence if we didn't have qualia.

Shoemaker's account leaves out experienced relations, such as experienced similarity. Experienced similarity is not the same as similarity between experiences. Being experienced is not an experienced feature.

Pain-qualia are in the body, not the mind, and so aren't part of psychology.

Commentary on Moor 1988. Systems that differ in qualitative properties will
likely differ in functional organization.

Criticism of "physicalist-functionalism", where functional organization doesn't completely determine qualia (e.g. Shoemaker/Block). The only tenable options are pure functionalism or transcendental dualism. Nice.

Taking transcendental dualism seriously. Privileged access provides strong arguments against objective theories, but it turns out that transcendentalism can't explain it any better, so maybe embrace objective theories after all.

Replacing a brain chunk while preserving causal role must preserve experience;

2.1 The Status of Propositional Psychology
------------------------------------------
2.1a The Language of Thought (Fodor)
------------------------------------

Arguments that thought involves computation upon representations, and that these
are structured as sentences in a mental language. With linguistic and
psychological evidence, and arguments that the mental language is innate.

Because it fits explanatory methodology, it coheres with the usual
ontology of psychological processes, and it explains systematicity.

About what PA's are, and why they're at the foundations of thought.

and Philosophy 23:49-55.

Arguments that symbol processing can't account for the intrinsically contentful
nature of thought: using a symbol doesn't give understanding of its content.
With defense against arguments from twin earth and conceptual-role semantics.

thought. Synthese 83:3-29.
No need to postulate LOT: diachronic explanation is as good as synchronic,
and high-level laws can exist without high-level causal connections.

Quarterly 78:261-??.

Clark, A. 1988. Thoughts, sentences and cognitive science. Philosophical
Psychology 1:263-78.

Crane, T. 1990. The language of thought: No syntax without semantics. Mind
and Language 5:187-213.

Review of Fodor's LOT. Fodor's view is too strong: function, not structure,
is criterial for content. The structure of a predictive theory need not be
directly reflected in inner processing.

On the explicit representation of belief: criteria, plausibility, and
relationship to verbal reports and conscious judgments.

Dennett, D.C. 1990. Granny's campaign for safe science. In (B. Loewer &
G. Rey, eds) _Meaning in Mind: Fodor and his Critics_. Blackwell.
A general treatment of Fodor, identifying him as arch-conservative mentalist.

Dunlop, G. 1990. Conceptual dependency as the language of thought. Synthese
Relates Schank's conceptual dependency to Fodor's LOT.

Contra two of Fodor's arguments for LOT. Complex causes need not have LOT
constituency structure; and evidence from psychological theory falls short.

(N. Block, ed) _Readings in the Philosophy of Psychology_ (MIT Press, 1980).
Analyzes belief into a relation between a person and an internal sentence,
along with a semantic relation between that sentence and e.g. a proposition.
With arguments against functionalist analyses, and against propositions.

There are no good arguments for LOT of the form "The brain needs to do X, and
X entails LOT". Considers X = concatenation, logical form, tracking,
combinatorial encoding. Either LOT is weakened deeply or is unnecessary.

and Language_. Princeton University Press.

the Philosophy of Science 7:270-298.

Argues that the primary role of language is in thought rather than in
communication, and the language of thought incorporates natural language.

Philosophy of Science 9.

Behavior and Philosophy 23:41-47.

LOT confuses processes with descriptions of processes. Also, symbols cannot
denote solely in virtue of structure, so must rely on human interpretation.

Knowles, J. 1998. The language of thought and natural language

Lycan, W.G. 1982. Toward a homuncular theory of believing. Cognition and
Brain Theory 4:139-59.
Defends sententialism of the homuncular variety: little modules all the
way in. Lots of pro-belief arguments.

Lycan, W.G. 1990. Mental content in linguistic form. Philosophical Studies
58:147-54.
Distinguishes varieties of Sententialism, reasonable vs. mad-dog.

Lycan, W.G. 1993. A deductive argument for the representational theory of
thinking. Mind and Language 8:404-22.
Argues from the unboundedness of thinking and the need for a finite stock of elements to something like a language of thought. With remarks on connectionism and instrumentalism, and a reply by Stalnaker.

Fodor's theory can't deal with inexplicit attitudes: the core/derivative distinction is untenable. But we can make sense of intentional causation and psychological explanation without explicit representation.

On some problems typing tokens in the language of thought. There's no principled distinction between type-identical tokens and type-distinct tokens with an identity judgment. With interesting remarks on co-identification.

Arguments that there is no good way to individuate syntactic types in Mentalese. Neural typing, causal typing, and semantic typing all fail.

Arguments that the language of thought need not have a compositional semantics; productivity and systematicity can be explained without it.

On Danto's suggestion that beliefs are like sentences. Conventionality poses problems, as does differentiating between different sorts of attitudes.

Motivates LOT and defends it against various objections: e.g. tacit belief, identity conditions, infinite regress, and semantic nativism.

Stich, S.P. 1978. Beliefs and subdoxastic states. Philosophy of Science

Tienson, J. 1990. Is this any way to be a realist? Philosophical Psychology.

2.1b The Intentional Stance (Dennett)
-------------------------------------

Can view systems from physical stance, design stance, or intentional stance.
Beliefs/desires are attributed under the intentional stance, with help from certain idealized norms of rationality and accuracy licensed by evolution.

Reply to Stich 1981. Irrationality is misdesign (take design stance). Etc.

Beliefs/desires are useful predictive attributions. This isn't inconsistent with a certain degree of realism (abstracta/illata distinction).

TIS, with commentaries and replies.

Mental states are underdetermined: like interpreting a text, or finding an object's function. Even adaptationist teleology gives no fact of the matter.

Proposition attitudes have the ontological status of a noisy pattern that helps make sense of behavior. This degree of realism falls on a scale: Fodor > Davidson > Dennett > Rorty > Churchland.

Dennett vacillates between stance-dependence, -independence; e.g. on rationality, design features. Instrumentalism can't be rescued.

Dennett should be a realist, of the relative-to-environment variety.

  Argues contra Dennett and Smolensky that language is fundamental, not just an
  add-on.

Cohen, B. 1995.  Patterns lost: Indeterminism and Dennett's realism about

Cummins, R. 1981.  What can be learned from _Brainstorms_?  Philosophical
  Topics 12:83-92.
  Questioning Dennett on the bridge between intentional characterization
  and functional characterization.  Arguing for the importance of context.

Davies, D. 1995.  Dennett's stance on intentional realism.  Southern Journal of
  Philosophy 33:299-312.

Fodor, J.A. 1981.  Three cheers for propositional attitudes.  In
  _Representations_.  MIT Press.
  Dennett's rationality/intentional idealization assumptions should not be
  viewed as Platonic but epistemic.  PA's are real and play real roles.

  normative?  In (B. Dahlbom, ed) _Dennett and His Critics_.  Blackwell.
  Against "interpretivism" about intentionality: projectivism is hopeless,
  and Dennett's arguments for normativism (via charity and evolution)
  go wrong or beg the question.

Foss, J. 1994.  On the evolution of intentionality as seen from the intentional

Haugeland, J. 1993.  Pattern and being.  In (B. Dahlbom, ed) _Dennett and His
  Critics_.  Blackwell.

Heitner, R. 2000.  Is design relative or real?  Dennett on intentional relativism
  and physical realism.  Minds and Machines 10:267-83.

  Charles & K. Lennon, eds) _Reduction, Explanation and Realism_.  Oxford
  University Press.

Kukla, R. 2000.  How to get an interpretivist committed.  Protosociology
  14:180-221.

Lyons, W. 1990.  Intentionality and modern philosophical psychology, I.  The

  Philosophical Topics 22:189-258.

McLaughlin, B. 2000.  Why intentional systems theory cannot reconcile

  40:1-12.
  Dennett must be one of: realist, eliminativist, instrumentalist.

Narayanan, A. 1996.  The intentional stance and the imitation game.  In (P.
  Millican & A. Clark, eds) _Machines and Thought_.  Oxford University Press.

Dennett's instrumentalism can't explain the acquisition of intentional concepts. Proposition attitudes are directly introspectible entities, although still theoretical and still patterns.

Slors, M. 1996. Why Dennett cannot explain what it is to adopt the intentional stance. Philosophical Quarterly 46:93-98.

2.1c Eliminativism (Churchlands) [see also 4.3c]

Sentential processing is out. Against Harman's mental English and Fodor's Mentalese. Arguments from learning, evolution, neuroscience, mental images.

Churchland, P.M. 1985. On the speculative nature of our self-conception. Canadian Journal of Philosophy Supplement 11:157-173. Reply to Foss 1985: EM is plausible, though certainly not applicable everywhere -- e.g. sensations will be reduced, not eliminated.

Reply to Haldane 1988. Even observations can be reconceived. With remarks perceptual plasticity and propositions, and a rejoinder by Haldane.

It's "bad faith" to accept modern epistemology but to deny the possibility of eliminativism. On various objections: "functional kinds", "self-defeating", "what could falsify it?", "different purposes", "no alternatives".

Elaborating the paradoxes of disbelieving in belief. Rational acceptability, assertion, and truth are all at risk.

Eliminativism is pragmatically incoherent, as it implies that language isn't meaningful and that the thesis isn't formulable. Folk psychology needn't be scientifically reduced to be true. With comments by Chastain, and reply.

Against Baker's cognitive-suicide arguments against eliminativism. We don't know what a replacement theory will look like, but that doesn't show that none is forthcoming.

Argues for a revisionary reduction of the propositional attitudes, rather than elimination or smooth reduction. Sentential aspects will go, but coarse-grained functional profiles and content will remain.

Irrationalism about mental content (and therefore truth-conditions) can't be made sense of. An error thesis presupposes factual truth-conditions, and a non-factualist thesis presupposes a non-deflationary theory of truth.

Reply to Devitt 1990.

Unbelief in belief is not incoherent. Argues with Baker.

Cognitive states like belief are necessary to explain the dependence of behavior on perceptual features of the environment. Informational states
alone are not enough, as they can't explain selective response to features.

Against Boghossian's critique: the eliminativism will express her claim in a new framework, so appeals to truth beg the question. With a response.

Rejoinder to Boghossian 1990.

EM needs much more evidence before being so gung ho.

Argues that folk psychological states exist, even if they aren't useful as causal explanation. We have independent reason to believe in them, e.g. from self-knowledge. They're useful in social psychology, too.

Argues that folk psychology is not a theory, and that psychological knowledge is a pre-theoretical given. With remarks on laws, the prediction of behavior, and neuroscience.

A bundle of arguments against eliminativism, e.g. from incoherence, the lack of alternatives, and against the folk-theory-theory. With commentary.

Defending folk psychology against the arguments of Churchland and Stich: e.g. incompleteness, stagnation, irreducibility, dual-control, modularity, and unfalsifiability. Even with no neat reduction, folk psychology may be OK.

FP is almost certainly true, irrespective of scientific absorbability or the language of thought. FP's commitments are austere, and mostly behavioral. Arguments from semantic competence and conceptual conservatism.

Argues that FP is not committed to much. The austere conception is supported by intuitions, conservatism, and the inconceivability of dropping it. Responds to phlogiston objections: they are not analogous.

Clarifies different senses of "theoretical" and "belief". Some beliefs are relevantly theoretical (dispositional, infra-conscious, unconscious
ones), but conscious occurrent beliefs are not, and so can't be eliminated.

FP holds that beliefs/desires play a certain functional role, and it's almost certain that objects playing that role exist, so FP is fine, whether or not propositional attitudes are good scientific entities.

Even if nothing satisfies all or most common-sense properties of mental terms, reference can still be fixed under a Putnam style theory of meaning. (More about qualia than about intentional states.)

The Churchlands underestimate the resources of intentional psychology.

Uses empirical evidence to argue that there is prelinguistic awareness, so nominalistic arguments for eliminativism fail. And some awareness is innate, so we can't reconceive things in less than evolutionary time.

The self-refutation objection reduces to other standard objections: counterexample, promissory note or reductio.

If connectionism is true, then eliminativism is true, as you can't isolate the causal role of individual beliefs in a connectionist system.

Response to Ramsey 1990: If there are no beliefs and so no assertions, there is no identifiable propositional content, and truth and knowledge are out. Eliminativism is pragmatically self-refuting.

A careful analysis of whether self-refutation arguments against eliminativism beg the question by supposing that assertion requires belief. An account of what it is to beg the question, and a comparison to arguments about vitalism.

There's no reason to abandon FP, even if it doesn't reduce.
Explaining how singular causal claims based on FP may be true even if FP is false; by analogy with phlogiston, and also because of near-vacuousness. EM isn't incoherent, as we can use a non-intentional replacement for belief.

Folk psychology is compatible with neuroscientific models, but it need not smoothly reduce to neuroscience to have an important role.

Eliminativism may have no determinate truth-conditions: if folk psychology is a poor theory, the question of whether or not "belief" refers may be empty.

Philosophical analysis isn't sufficient to understand intentional concepts; real cognitive science is required, with conceptual revision. The truth of eliminativism will be relative to the theory of reference that we choose.

Against transcendental arguments against eliminativism. These fail on their own terms, and even if successful they would not establish causal/explanatory relevance for the attitudes, which is the real key for folk psychology.

Wright, C. 1996. Can there be a rationally compelling argument for anti-realism about ordinary ("folk") psychology? In (E. Villanueva, ed) _Content_. Ridgeview.

2.1d Propositional Attitudes, General
-------------------------------------

Beliefs are OK, despite no physicalist reduction of content.

Against beliefs construed as physically realized internal causes of behavior: syntax of these states can't be determinate, and their explanatory role wrt
causation leads to a circle. Belief is irreducible.

Remarks on the conceptual analysis of belief/desire attribution. On the roles of causation, inner-route explanations, belief-desire-action triangles, teleology, unity, the presumption of simplicity, and evolution.

On requirements for belief/desire explanations: input/output patterns, the unity condition (i.e. no single associated mechanism), and teleological bases for generalizations, e.g. through evolution or educability.

Argues that desire will smoothly reduce to a neurophysiological kind.

The conditions on being a believer are mostly behavioral; to claim otherwise is to fall into a "modularity trap". A counterfactual account of mental causation is enough. With a defense of mentality for giant look-up tables.

Stich is confused about type-token, syntax/content, etc.

A taxonomy of positions on the representation of propositional attitudes: dividing up via questions about realism, functionalism, monadicity, and truth-conditions. With arguments for structured representations.

Things are only syntactic (in SS's sense) in virtue of intentionality. True.

Argues that there are no tacit beliefs: dispositions to believe can do all the explanatory work at lower cost. With some remarks on subdoxastic states, and the difference between belief and opinion.

A theory of propositional attitude ascription as like numerical measurement.

Folk psychology isn't a theory about laws, but about proper functions. desires are identified by proper functions; beliefs by Normal explanations.

Instrumentalism about belief can't be right, because of Martian marionettes, but the language of thought is too strong a requirement. A state's structured content may reside in its pattern of relations to other states.

Stich is wrong, circular, and representational anyway.

Must individuate mental states by semantics, not just by function.

Beliefs/desires are out, new Syntactic Theory is in.

2.1e The Nature of Folk Psychology
----------------------------------

Folk psychology is a theory: defense against objections from logicality, softness of laws, practical function, behavior, and simulation. It needn't be a deductive-nomological theory; e.g. it might be based on prototypes.

Folk psychology isn't all that bad. It survived evolution after all.

FP is craft, not theory. Opinions rather than beliefs are interesting.

On the psychology of self-ascription of mental states. Functionalism has serious problems, as we don't have direct access to causal roles. Defends a qualia-based account, even for propositional attitudes.

On the development of folk-psychological concepts in children. First the appearance/reality distinction, then more complex theories of perception, representation, and belief. Implications for the status of folk psychology.

Distinguishes internal and external accounts of folk psychology (mechanisms vs systematizations), and various versions of each of these. Only some are compatible with eliminativist arguments.

Common-sense psychology is no theory at all, and not in competition with scientific psychology. CSP is particular, rich, vague; SP is general, austere, precise. CSP will be neither subsumed nor eliminated by SP.

Argues that commonsense and scientific psychology are quite distinct in their aims, scope, framework, and nature, but have been confused by philosophy. With support from historical considerations.

2.1f The Simulation Theory
--------------------------

FP is a strategy for prediction via simulation; an ability, not a theory.

2.2 Internalism and Externalism [see also 1.5d]

2.2a Is Content in the Head? (Putnam, Burge)

Belief contents are not fully determined by internal state, as the linguistic community plays an important role: arthritis, brisket, contract, sofa, etc. So mental states are not individuated individualistically.

On Putnam's Twin Earth. Natural kind terms are not indexical. Even de dicto attitudes are not in the head; they presuppose the existence of other things.

On non-individualist elements due to by intellectual norms in the community, to which meanings are answerable. Even meaning-giving truths can be doubted. With remarks on sofas/safos, and on linguistic meaning vs. cognitive value.

Challenges Burge's interpretations of the thought-experiments: e.g. twins have the same concept, neither of which is the public concept of arthritis. With remarks on computationalism and Marr's theory.
Arguments that natural kind terms are token-reflexive, with reference ultimately fixed to the underlying explanatory properties of the surface qualities of local matter.

Twins share the same concepts. Contra Putnam: essentialism is fallacious; contra Burge: speakers share beliefs, but one has false belief about meaning.

We shouldn't rely on intuitions about thought-experiments; we need an empirical theory about belief. Belief contents are distinct from sentence contents; we have to distinguish linguistic from psychological semantics.

Against Searle's theory of internal intentionality. Searle's theory requires magic to grasp external contents internally.

Argues that thought is extrinsic, but it is not essentially social. A system without a linguistic community could have thoughts, if it had an appropriate learning history.

Contra Burge on sofas: oblique that-clauses can't identify the (wide) way that the subject thinks of sofas, which is idiosyncratic and inexpressible.

Gives a Fregean account of belief semantics to handle the Burge cases, and argues that the *type* of a proposition may be internal even if the token itself is not. With remarks on the relevance to Grice's program.

Arguments for a moderate externalism by synthesizing Putnam and Searle: internal intension leaves extension indeterminate, but it specifies the facts relevant to filling in the indeterminacy.

Arguments that conscious experience is required for intentional states, and that any external relations could be satisfied without this experience, so external relations cannot suffice for intentional content.

Various arguments against Crane 1991 on externalism.

Argues that meaning is determined by a certain kind of internal state, involving de se cognitive attitudes. These states aren't shared by twins, but are still narrow in a strong sense.

Functional organization doesn't determine attitude content, even if we include inputs and outputs.

Indexicals are essential to some beliefs, so belief cannot just be a relation to a proposition. Belief contents must be at least in part construed relative to a subject. Separate belief object and belief state.

What is in the head doesn't determine the reference of our thoughts: my twin on Twin Earth refers to XYZ where I refer to H2O. Content is determined by environment and linguistic community as well as by internal stereotypes.

Meanings *still* aren't in the head.

Sure, meanings *are* in the head -- e.g. the content of a given visual experience is "the thing that is causing this experience".

On concepts as abilities, and on construals of abilities that lead to internalism and externalism. Maybe the relevant abilities are characterized externally but determined internally. Remarks on Putnam, Davidson, Burge.

Making sense of twin earth intuitions with an information-theoretic account of content: information depends on relations in normal conditions, which are extrinsic. With remarks on the context-sensitivity of content-attribution.
